## Open Source Declarations

Some software files have been licensed under certain open source or third-party licenses. End-user license agreements and open source declarations can be found at: <https://www.extremenetworks.com/support/policies/open-source-declaration/>

# About this Document

---

**Purpose** on page 3

**Conventions** on page 3

**Documentation and Training** on page 5

**Help and Support** on page 6

**Send Feedback** on page 7

This section discusses the purpose of this document, ways to provide feedback, additional help, and information regarding other Extreme Networks publications.

## Purpose

---

This document provides information on features in VSP Operating System Software (VOSS). VOSS runs on the following product families:

- ExtremeSwitching 5420 Series
- ExtremeSwitching 5520 Series
- ExtremeSwitching VSP 4450 Series
- ExtremeSwitching VSP 4900 Series
- ExtremeSwitching VSP 7200 Series
- ExtremeSwitching VSP 7400 Series
- ExtremeSwitching VSP 8200 Series
- ExtremeSwitching VSP 8400 Series
- ExtremeSwitching VSP 8600 Series
- ExtremeSwitching XA1400 Series

### Note

VOSS is licensed on the XA1400 Series as a Fabric Connect VPN (FCVPN) application, which includes a subset of VOSS features. FCVPN transparently extends Fabric Connect services over third-party provider networks.

## Conventions

---

To help you better understand the information presented in this guide, the following topics describe the formatting conventions used for notes, text, and other elements.

## Text Conventions

The following tables list text conventions that can be used throughout this document.

**Table 1: Notes and warnings**

| Icon  | Notice type | Alerts you to...   |
|---|-------------|--|
|  | Tip         | Helpful tips and notices for using the product.          |
|  | Note        | Useful information or instructions.                      |
|  | Important   | Important features or instructions.                      |
|  | Caution     | Risk of personal injury, system damage, or loss of data. |
|  | Warning     | Risk of severe personal injury.                          |

**Table 2: Text Conventions**

| Convention             | Description  |
|------------------------|--|
| Angle brackets ( < > ) | Angle brackets ( < > ) indicate that you choose the text to enter based on the description inside the brackets. Do not type the brackets when you enter the command.<br>If the command syntax is <code>cfm maintenance-domain maintenance-level &lt;0-7&gt;</code> , you can enter <code>cfm maintenance-domain maintenance-level 4</code> . |
| <b>Bold text</b>       | Bold text indicates the GUI object name you must act upon.<br>Examples: <ul style="list-style-type: none"> <li>Click <b>OK</b>.</li> <li>On the <b>Tools</b> menu, choose <b>Options</b>.</li> </ul>   |
| Braces ( { } )         | Braces ( { } ) indicate required elements in syntax descriptions. Do not type the braces when you enter the command.<br>For example, if the command syntax is <code>ip address {A.B.C.D}</code> , you must enter the IP address in dotted, decimal notation.   |

**Table 2: Text Conventions (continued)**

| Convention          | Description  |
|---------------------|--|
| Brackets ( [ ] )    | Brackets ( [ ] ) indicate optional elements in syntax descriptions. Do not type the brackets when you enter the command.<br>For example, if the command syntax is <code>show clock [detail]</code> , you can enter either <code>show clock</code> or <code>show clock detail</code> .  |
| Ellipses ( ... )    | An ellipsis ( ... ) indicates that you repeat the last element of the command as needed.<br>For example, if the command syntax is <code>ethernet/2/1 [ &lt;parameter&gt; &lt;value&gt; ] . . .</code> , you enter <code>ethernet/2/1</code> and as many parameter-value pairs as you need.   |
| Italic Text         | Italics emphasize a point or denote new terms at the place where they are defined in the text. Italics are also used when referring to publication titles that are not active links.   |
| Plain Courier Text  | Plain Courier text indicates command names, options, and text that you must enter. Plain Courier text also indicates command syntax and system output, for example, prompts and system messages.<br>Examples: <ul style="list-style-type: none"> <li><code>show ip route</code></li> <li><code>Error: Invalid command syntax [Failed] [2013-03-22 13:37:03.303 -04:00]</code></li> </ul>           |
| Separator ( > )     | A greater than sign ( > ) shows separation in menu paths.<br>For example, in the Navigation tree, expand the <b>Configuration &gt; Edit</b> folders.   |
| Vertical Line (   ) | A vertical line (   ) separates choices for command keywords and arguments. Enter only one choice. Do not type the vertical line when you enter the command.<br>For example, if the command syntax is <code>access-policy by-mac action { allow   deny }</code> , you enter either <code>access-policy by-mac action allow</code> or <code>access-policy by-mac action deny</code> , but not both. |

## Documentation and Training

Find Extreme Networks product information at the following locations:

[Current Product Documentation](#)

[Release Notes](#)

[Hardware and software compatibility](#) for Extreme Networks products  
[Extreme Optics Compatibility](#)  
[Other resources](#) such as white papers, data sheets, and case studies

Extreme Networks offers product training courses, both online and in person, as well as specialized certifications. For details, visit [www.extremenetworks.com/education/](http://www.extremenetworks.com/education/).

## Help and Support

---

If you require assistance, contact Extreme Networks using one of the following methods:

### Extreme Portal

Search the GTAC (Global Technical Assistance Center) knowledge base; manage support cases and service contracts; download software; and obtain product licensing, training, and certifications.

### The Hub

A forum for Extreme Networks customers to connect with one another, answer questions, and share ideas and feedback. This community is monitored by Extreme Networks employees, but is not intended to replace specific guidance from GTAC.

### Call GTAC

For immediate support: (800) 998 2408 (toll-free in U.S. and Canada) or 1 (408) 579 2826. For the support phone number in your country, visit: [www.extremenetworks.com/support/contact](http://www.extremenetworks.com/support/contact)

Before contacting Extreme Networks for technical support, have the following information ready:

- Your Extreme Networks service contract number, or serial numbers for all involved Extreme Networks products
- A description of the failure
- A description of any actions already taken to resolve the problem
- A description of your network environment (such as layout, cable type, other relevant environmental information)
- Network load at the time of trouble (if known)
- The device history (for example, if you have returned the device before, or if this is a recurring problem)
- Any related RMA (Return Material Authorization) numbers

## Subscribe to Product Announcements

You can subscribe to email notifications for product and software release announcements, Field Notices, and Vulnerability Notices.

1. Go to [The Hub](#).
2. In the list of categories, expand the **Product Announcements** list.
3. Select a product for which you would like to receive notifications.
4. Select **Subscribe**.
5. To select additional products, return to the **Product Announcements** list and repeat steps 3 and 4.

You can modify your product selections or unsubscribe at any time.

## Send Feedback

---

The Information Development team at Extreme Networks has made every effort to ensure that this document is accurate, complete, and easy to use. We strive to improve our documentation to help you in your work, so we want to hear from you. We welcome all feedback, but we especially want to know about:

- Content errors, or confusing or conflicting information.
- Improvements that would help you find relevant information.
- Broken links or usability issues.

To send feedback, do either of the following:

- Access the feedback form at <https://www.extremenetworks.com/documentation-feedback/>.
- Email us at [documentation@extremenetworks.com](mailto:documentation@extremenetworks.com).

Provide the publication title, part number, and as much detail as possible, including the topic heading and page number if applicable, as well as your suggestions for improvement.

# New in this Document

---

## [Notice about Feature Support on page 11](#)

The following sections detail what is new in this document.

## [Ability to Configure Area Names for Multi-area SPB](#)

---

You can configure the area name for home and remote areas.

For more information, see [Configure an IS-IS Area Name](#) on page 1101.

## [Advanced Feature Bandwidth Reservation Enhancements](#)

---

In earlier releases, 5520 Series switches automatically reserved Universal Ethernet ports (24 ports: 1/25 and 1/26, 48 ports: 1/49 and 1/50) as loopback ports for advanced features. Now, if a VIM is not present, 5520 Series switches automatically reserve the VIM slot as loopback ports for advanced features. When used as regular ports, the Universal Ethernet port speed is 40 Gbps as a single channel port. Although the maximum supported single channel port speed is 40 Gbps, the ports can be channelized to operate as four 10 or 25 Gbps channels.

If a VIM is present, the Universal Ethernet ports are used for SPB internal loopback.

For more information, see, [advanced-feature-bandwidth-reservation Boot Flag](#) on page 127

## [Auto-sense Enhancements](#)

---

This release includes the following Auto-sense enhancements:

- In earlier releases, you could not enable Auto-sense on a port that included conflicting feature configuration. Now, if you enable Auto-sense on a port, the software automatically deletes the conflicting configuration from the port. Also, if you disable Auto-sense on a port, the software removes all Auto-sense state configuration and reverts the port to the default configuration.
- Auto-sense supports a port-specific data I-SID to separate the data traffic of one device from another device. Previously, you could only configure a global data I-SID to apply to all Auto-sense enabled ports.
- Auto-sense support for Fabric Attach (FA) is enhanced to match the abilities of Zero Touch Configuration. Depending on the device that the Auto-sense port detects (FA-capable access point, camera, open virtual switch, or FA proxy switch), the software can apply different FA-specific configurations that you define. The I-SID priority for untagged traffic on a port in the FA state is also modified.

- With this release, an Auto-sense port in the UNI state now remains in PVLAN isolated mode when any additional untagged I-SID is applied to the port. Previously, the port changed automatically to PVLAN promiscuous mode. With this change, not only can you assign the onboarding I-SID to an Auto-sense port with PVLAN isolation functionality, but you can also assign other untagged PVLAN isolated pvlan/I-SIDs to an Auto-sense port.
- Auto-sense logical flowcharts to describe the port state detection, how the system configurations can change the logic decision path, and the Auto-sense configuration results.
- You can configure the Auto-sense wait interval, which controls the time to wait for a Link Layer Discovery Protocol (LLDP) neighbor to be detected in the Auto-sense wait state before transitioning to the Auto-sense onboarding state.

For more information, see [Auto-sense](#) on page 16.

---

## Extreme Integrated Application Hosting Enhancements

---

VOSS enhances Extreme Integrated Application Hosting with the ability to view the application name and version used by the virtual service, force overwriting a saved Fabric IPsec Gateway configuration without confirmation, and also with the ability to perform specific actions in a virtual machine (VM) from the VOSS CLI.

For more information, see [Extreme Integrated Application Hosting](#) on page 846.

---

## ExtremeCloud IQ Agent Firmware

---

A command is available to return the ExtremeCloud IQ Agent firmware version on the switch to the version bundled with the VOSS image currently installed on the switch, for example, if you downgrade the VOSS image version and do not reconnect to ExtremeCloud IQ automatically.

For more information, see [Reinstall ExtremeCloud IQ Agent Firmware](#) on page 843.

---

## IPsec Fragmentation Before Encryption Enhancements

---

VSP 4900 Series and VSP 7400 Series switches support IPsec fragmentation before encryption of Fabric Extend tunnels using Fabric IPsec Gateway. EDM support for IPsec fragmentation before encryption is also added for XA1400 Series.

For more information, see [IPsec Fragmentation Before Encryption](#) on page 953.

---

## IS-IS Hello Padding

---

To detect maximum transmission unit (MTU) mismatches, Intermediate System-to-Intermediate System (IS-IS) pads hello packets to the full interface MTU.

For more information, see [IS-IS Hello Padding](#) on page 953.

---

## Link Debounce

---

Link Debounce protects the upper layers from unnecessary state changes by delaying the change of a port link state when the following situations occur:

- There are frequent flaps in a short interval at the physical layer in the case of Fiber WAN services.

- There is a delay in switching from the working path to the protected path in the case of Carrier Wave WAN services.

For more information, see [Link Debounce](#) on page 2228.

---

## Other Command Enhancements

The following enhancements were made for the **show i-sid mac-address-entry** command:

- The TYPE column in the command output shows NON-LOCAL instead of REMOTE for MAC addresses learned from other nodes.
- The command output can be filtered to show only MAC addresses learned in either the home or remote area, or learned from other nodes.

For more information, see [View C-MACs Learned on T-UNI Ports for an I-SID](#) on page 1281.

---

## Secure Shell (SSH) Enhancements

This release includes the following SSH enhancements:

- A new method, **diffie-hellman-group-exchange-sha256**, is available for SSH Key exchange.

For more information, see [Configure the Key-Exchange Method](#) on page 2967.

- Added new command to reset SSH, which previously required two steps and it was not possible to enable SSH after the configuration access was disabled. The new **ssh reset** command terminates all SSH sessions and restarts SSH server.

For more information, see [Resetting the SSH](#) on page 2972

---

## TCP Maximum Segment Size

The ability to adjust the TCP maximum segment size (MSS) is added for VSP 4900 Series and VSP 7400 Series. This functionality was previously supported only on XA1400 Series; configuration commands are modified from the original support.

### Note

If you configured this feature on XA1400 Series prior to VOSS 8.3.1, after you upgrade to VOSS 8.4.2 and save the configuration, the configuration uses the new commands. If you enabled the feature using an auto-derived value, the value is updated to 200 less than the tunnel MTU.

For more information, see [Adjusting the TCP Maximum Segment Size](#) on page 954.

---

## XA1400 Series IPsec-Related Enhancements

For XA1400 Series branch deployments, the VOSS routing IP stack requires the VLAN Management Instance to work in coexistence mode where both the management IP stack and the routing IP stack share the same IP address and default routes. This configuration is required if you need to use the management IP as IPsec source address. You can use the **propagate-to-routing** command to

propagate the management VLAN IP and static routes from the management IP stack to the VOSS routing IP stack on the same VLAN ID.

For more information, see [Configure Management VLAN and VOSS Routing VLAN Coexistence Through Propagation](#) on page 89.

When you deploy the XA1400 Series in an environment where you need more than one provider connection with IPsec, you can configure a source IP address for each IPsec tunnel. You can configure a static source IP address or you can dynamically obtain the source IP address from DHCP.

For more information, see [IPsec Source IP Address Per Tunnel Interface](#) on page 960.

## Notice about Feature Support

---

This document includes content for multiple hardware platforms across different software releases. As a result, the content can include features not supported by your hardware in the current software release.

If a documented command, parameter, tab, or field does not display on your hardware, it is not supported.

For information about physical hardware restrictions, see your hardware documentation.

# Installation and Commissioning Documentation

Use installation and commissioning documentation to install the product hardware and software, and perform the initial configuration.

**Table 3: Installation and commissioning documents**

| Technical document  | Description   |
|---|---|
| 5420 Series   |   |
| <a href="#">ExtremeSwitching 5420 Series Hardware Installation Guide</a>            | This document provides procedures and conceptual information to install the 5420 Series.          |

# Zero Touch Capabilities

---

[Auto-sense on page 16](#)

[IP Phone Support on page 41](#)

[Zero Touch Deployment on page 50](#)

[Zero Touch Provisioning Plus on page 53](#)

[Zero Touch Fabric Configuration on page 56](#)

VOSS supports the following zero touch capabilities:

- Auto-sense support for the following features:
  - Fabric Attach (FA)
  - Extensible Authentication Protocol (EAP) and non-EAPoL (NEAP)
  - IP Phones
- Zero Touch Deployment
- Zero Touch Provisioning Plus (ZTP+)
- Zero Touch Fabric Configuration including Auto-sense for network-to-network (NNI) interfaces

## Note

For bridged or routed reachability of the management servers (DHCP, RADIUS, Extreme Management Center or ExtremeCloud IQ - Site Engine, or ExtremeCloud IQ) the onboarding I-SID must be manually mapped to the management segment on at least one Backbone Edge Bridge (BEB) in the network prior to zero touch deployments of new switches. Additionally, you must enable a Dynamic Nickname server on at least one node. For more information, see [VOSS Release Notes](#).

## Auto-sense

**Table 5: Auto-sense product support**

| Feature  | Product         | Release introduced |
|--|-----------------|--------------------|
| Auto-sense   | 5420 Series     | VOSS 8.4           |
|  | 5520 Series     | VOSS 8.3           |
|  | VSP 4450 Series | VOSS 8.3           |
|  | VSP 4900 Series | VOSS 8.3           |
|  | VSP 7200 Series | VOSS 8.3           |
|  | VSP 7400 Series | VOSS 8.3           |
|  | VSP 8200 Series | VOSS 8.3           |
|  | VSP 8400 Series | VOSS 8.3           |
|  | VSP 8600 Series | Not Supported      |
|  | XA1400 Series   | Not Supported      |
| Auto-sense ports can apply Fabric Attach (FA)-specific configuration | 5420 Series     | VOSS 8.4.2         |
|  | 5520 Series     | VOSS 8.4.2         |
|  | VSP 4450 Series | VOSS 8.4.2         |
|  | VSP 4900 Series | VOSS 8.4.2         |
|  | VSP 7200 Series | VOSS 8.4.2         |
|  | VSP 7400 Series | VOSS 8.4.2         |
|  | VSP 8200 Series | VOSS 8.4.2         |
|  | VSP 8400 Series | VOSS 8.4.2         |
|  | VSP 8600 Series | Not Supported      |
|  | XA1400 Series   | Not Supported      |

Auto-sense is a port-based functionality that supports zero touch capabilities on the switch. Auto-sense dynamically configures the port to act as an IS-IS NNI, Fabric UNI (Flex-UNI), Fabric Attach (FA), or voice (IP phone) interface, based on the Link Layer Discovery Protocol (LLDP) events. Auto-sense provides global configuration options for IS-IS authentication, FA authentication, and voice configuration for IP phones, on the switch. For more information about IP Phone Support, see [IP Phone Support](#) on page 41.

When a switch boots in Zero Touch Fabric Configuration mode, all ports on the switch automatically operate in Auto-sense mode, unless you manually change the port configuration. For more information on Zero Touch Fabric Configuration, see [Zero Touch Fabric Configuration](#) on page 56.

With Auto-sense functionality, ports on a switch can detect whether they connect to a Shortest Path Bridging (SPB) device, an FA client, FA Proxy, Voice IP devices, or an undefined host:

- If a port connects to an SPB device or an FA client, then the system establishes Fabric architecture.
- If a port connects to any undefined host, then the system moves all untagged traffic on the port to an onboarding service network, also known as the onboarding I-SID.

- If a port operates in Auto-sense mode, Extensible Authentication Protocol (EAP) is enabled globally with a RADIUS configuration, and the Auto-sense port does not detect an SPB or Fabric Attach proxy neighbor, then the system automatically activates EAP and Non-EAP (NEAP) authentication on them, for untagged traffic.

When you manually disable Auto-sense on a specific port, the switch removes the dynamic configuration on that port unless you use an optional parameter to convert the dynamic configuration to a manual configuration. If you do not use the optional parameter, the software removes all Auto-sense state configuration and reverts the port to the default configuration.

If you enable Auto-sense on a port with a conflicting feature configuration, the software automatically deletes the conflicting configuration from the port. Conflicting configurations include the following commands or features:

- **access-diffserv** command
- **flex-uni enable** command
- **mac-security limit-learning** command
- **qos 802.1p-override enable** command
- Other feature configurations on the port:
  - brouter port
  - port tagging (encapsulation) - If a port has encapsulation enabled and you enable Auto-sense, the port remains with encapsulation enabled. Disabling Auto-sense transitions the encapsulation value to disabled. If a port has encapsulation disabled and you enable Auto-sense, port encapsulation is enabled.
  - Extensible Authentication Protocol over LAN (EAPoL)
  - FA
  - IS-IS interface
  - Link Aggregation Control Protocol (LACP) and Virtual Link Aggregation Control Protocol (VLACP)
  - LLDP enable
  - LLDP MED network policies
  - private VLAN
  - MLT member
  - Switched UNI (S-UNI) or Transparent Port UNI (T-UNI) interface
  - VLAN member

## Implementation on Upgraded Switches with Existing Configuration

If the switch does not boot in Zero Touch Fabric Configuration mode and you want to use Auto-sense functionality with an existing switch configuration, you must:

- Enable Auto-sense on the applicable port or ports.
- Create a new VLAN 4048. If the existing configuration uses VLAN 4048, you must configure a new VLAN for those original purposes.
- Configure I-SID 15999999 as the Auto-sense onboarding I-SID.
- Assign onboarding I-SID 15999999 to private VLAN 4048.

## Auto-Sense Data I-SID

Auto-sense supports global configuration of a data I-SID on the switch, which applies to all Auto-sense enabled ports. You can also configure Auto-sense data I-SID on each port to separate the data traffic into individual port specific data I-SIDs. For example, if device A and device B connect to different Auto-sense enabled ports and you configure an Auto-sense data I-SID on each port, the switch separates the data traffic of device A from the data traffic of device B. A port-level data I-SID and the global data I-SID can use the same value. The system prioritizes the I-SIDs in the following order:

1. Untagged I-SID assigned per client by EAP/NEAP MHMV
2. Untagged voice I-SID
3. Port data I-SID
4. Global data I-SID
5. Onboarding I-SID

The **show running-config** output includes the configured Auto-sense data I-SID for the port module only if you enable Auto-sense on the port. If you disable Auto-sense on the port, the configuration remains on the switch even though the command output does not include it. If you disable Auto-sense on the port and use the **convert-to-config** parameter, the port remains in the I-SID until you manually remove the data I-SID configuration from the port. If you re-enable Auto-sense on the port, you must reconfigure the data I-SID on the port.

If you remove the Auto-sense data I-SID from a port, then the port uses either the global Auto-sense data I-SID, if one exists, or the Auto-sense onboarding I-SID.

## IS-IS Authentication

Auto-sense supports global configuration of IS-IS authentication key on the switch. All ports operating in Auto-sense mode and transitioned to the NNI state, use the global IS-IS authentication key that you configure using the **auto-sense isis hello-auth type** command. For more information, see [Configure Auto-sense IS-IS Authentication](#) on page 29.

## FA Configuration

Depending on the device that the Auto-sense port detects, the software can apply different FA-specific configurations that you define:

- You can configure an I-SID for FA clients such as FA wap-type 1, FA camera, and FA open-virtual-switch (OVS). The software prefers the FA I-SID over the onboarding I-SID.
- You can configure a specific I-SID and customer VLAN ID to use as the management I-SID when the port is in the Auto-sense FA PROXY state. If you do not configure a management I-SID, the port uses the onboarding I-SID for untagged traffic.
- You can disable EAPoL authentication requirements for specific FA client types (wap-type1, camera, and ovs).

## FA Authentication

Auto-sense supports FA message authentication on switches. You can enable FA message authentication globally on a switch. All ports operating in Auto-sense mode use the global authentication key. A preconfigured authentication key exists on the switch, by default, which you can

change. For more information, see [Configure Auto-sense Fabric Attach \(FA\) Authentication](#) on page 37.

## Auto-sense Voice Capabilities

Auto-sense voice capabilities are based on the events when the switch detects an IP phone in the network. For more information, see [Auto-sense Voice](#) on page 42.

## Loop Prevention

Auto-sense ports between two switches that have transitioned to NNI state are not prone to loops. Any connection can be wired and SPB establishes the shortest path connections. On Auto-sense NNI links BVID information, as well as IS-IS area information, is exchanged enabling Zero Touch Fabric functionality.

Auto-sense ports that connect to non-SPB switches operate in UNI mode, or FA Proxy mode in the case of ERS or EXOS switches. In UNI mode, VOSS devices send Spanning Tree BPDU packets emulating root bridge behavior ensuring that any potential UNI loop is broken by the attached spanning tree enabled devices. For universal hardware switches that transition from EXOS to VOSS, there can be scenarios where certain links are spanning tree blocked.

For more information on the port states, see [Auto-sense Port States](#) on page 19.

## Running Configuration

If you view the running configuration, the global Auto-sense configuration displays under the port module. Use the command **show running-config module port**.

## Auto-sense Port States

The system uses a per-interface state to adapt to all Auto-sense events. Each state transition determines background configuration on the port. The system does not display these configurations in the output of the **show running-config** command or in the saved configuration file but if you disable Auto-sense on the port and use the *convert-to-config* parameter, the dynamic configuration becomes a manual configuration and is visible in the **show running-config** output. Use **show auto-sense** commands to monitor the running states of each port.

### *Port Down State*

If you run the **auto-sense enable** command on a port that is disabled or has an inactive link, the port transitions to the Auto-sense Port Down state. This state transitions to the Auto-sense Wait state after the port becomes operational or the link becomes active.

### *Wait State*

The port modifies outgoing LLDP packets to represent the enhanced properties of the port and analyzes incoming LLDP packets for possible transitions to advanced states like network-to-network interface (NNI), Fabric Attach (FA), or VOICE. If the port does not receive LLDP packets, the port transitions to the UNI state.

### UNI State

This state grants onboarding and data connectivity to the port if you configure the onboarding I-SID, or a data I-SID in the global Auto-sense configuration or at the port level. The system also applies the trusted and untrusted Auto-sense global configuration. As with the Wait state, the port continues to monitor received LLDP packets for transitions to other states.

Network Access Control (NAC) support, through EAP/NEAP, is enabled by default on each Auto-sense port, but disabled globally. If you require EAP/NEAP operation on Auto-sense ports, you must globally enable EAP and configure a RADIUS server.

The system performs the following background configurations on port x:

```
flex-uni enable
eapol status auto
eapol multihost radius-non-eap-enable
eapol multihost eap-oper-mode mhmv
[qos 802.1p-override enable]
[access-diffserv enable]
on port X interface, if onboarding I-SID Y is configured without data I-SID:
eapol guest i-sid Y
on onboarding I-SID interface, if it is configured without data I-SID:
untagged-traffic port X
on data I-SID interface, if it is configured:
untagged-traffic port X
```

An Auto-sense port in the UNI state remains in PVLAN isolated mode when any additional untagged I-SID is applied to the port. Auto-sense ports support multiple VLAN/I-SIDs and PVLAN/I-SIDs on the same port at any time concurrently. Typically, this operational mode is required when you configure NAC support with Multiple Host Multiple VLAN (MHMV). The software then assigns clients to their VLAN/I-SIDs based on their NAC authentication results.

### NNI States

The NNI states are as follows:

- NNI
- NNI onboarding
- NNI IS-IS
- NNI pending

If, while in the Wait state, the port receives a Fabric Connect LLDP packet, the port transitions to the NNI state and adds the IS-IS SPBM instance on the interface. The system tries to establish an IS-IS adjacency and, if successful, transitions the port to the NNI IS-IS state. The port remains in the NNI IS-IS state until the adjacency fails, at which time it returns to the NNI state.

The system performs the following background configurations on port x:

```
isis
isis spbm 1
isis enable
[isis hello-auth ...] inherited from global configuration
```

If the system cannot establish the adjacency, it transitions the port to the NNI onboarding state. The system creates a Switched UNI (S-UNI) with the onboarding I-SID.

The system performs the following background configurations:

```
flex-uni enable
isis
isis spbm 1
isis enable
[isis hello-auth ...] inherited from global configuration
on onboarding i-sid interface, if it exists:
untagged-traffic port X
```

### *Fabric Attach (FA) States*

The FA states are as follows:

- FA - this state is used for FA capable wireless access points, Camera or OVS devices
- FA PROXY - this state used for interaction with ERS and EXOS switches which are capable of FA proxy function
- FA PROXY NOAUTH - this state used for interaction with ERS and EXOS switches which are capable of FA proxy function

LLDP uses the FA TLV to detect FA-capable neighbors.

The port enters the FA state after LLDP detects an access point, an FA client that is not another switch.

The system performs the following background configurations on port x:

```
flex-uni enable
eapol status auto
eapol multihost radius-non-eap-enable
eapol multihost eap-oper-mode mhm
eapol guest i-sid X
fa enable
on onboarding i-sid interface, if it exists:
untagged-traffic port X
```

If LLDP detects an FA proxy switch such as EXOS or ERS switch that uses FA message authentication, the port transitions to the FA PROXY state.

The system performs the following background configurations on port x:

```
flex-uni enable
fa enable
fa message-authentication
fa management-isid
```

#### Note

By default, the FA PROXY state uses the onboarding I-SID as the management I-SID but you can override this with a specific I-SID and customer VLAN ID combination.

If the FA proxy switch does not use FA message authentication, the port transitions to the FA PROXY NOAUTH state.

The system performs the following background configurations on port x:

```
flex-uni enable
fa enable
on onboarding i-sid interface, if it exists:
untagged-traffic port X
```

Depending on the device that the Auto-sense port detects, VOSS can apply different FA-specific configurations that you define. For more information, see [Auto-sense](#) on page 16.

When a port is in the FA state, the system uses the following priority for untagged traffic:

1. EAP/NEAP assigned I-SID
2. WAP, camera, or open virtual switch (OVS) I-SID
3. Onboarding I-SID
4. Drop

*Voice State*

If the port detects an LLDP packet from a phone, the port transitions to the VOICE state. A global Auto-sense voice configuration is not required to transition to the VOICE state except a specific voice VLAN shall be signaled to the phone.

For more information on Auto-sense voice, see [Auto-sense Voice](#) on page 42.

## DHCP Port Snooping

For zero touch onboarding, if a port answers Dynamic Host Configuration Protocol (DHCP) requests sent by the switch and the port is in the Auto-sense UNI state, the system automatically changes the port's Private VLAN configuration from isolated mode to promiscuous mode.

Without this port type change on the Private VLAN, the other devices in the network cannot receive an IP address through the DHCP server if they are in the Zero Touch Fabric Configuration mode unless you disable Auto-sense on the port and manually change the port from isolated mode to promiscuous mode.

## Auto-sense Logical Flowcharts

The system uses a per-interface state to adapt to all Auto-sense events. Each state transition determines background configuration on the port. The system does not display Auto-sense port configurations in the **show running-config** command or in the saved configuration file; instead use the **show auto-sense** commands to show global and port specific Auto-sense information..

The following flowcharts describe the system logic for Auto-sense port state detection, how the system configurations change the logic path, and the Auto-sense configuration results.

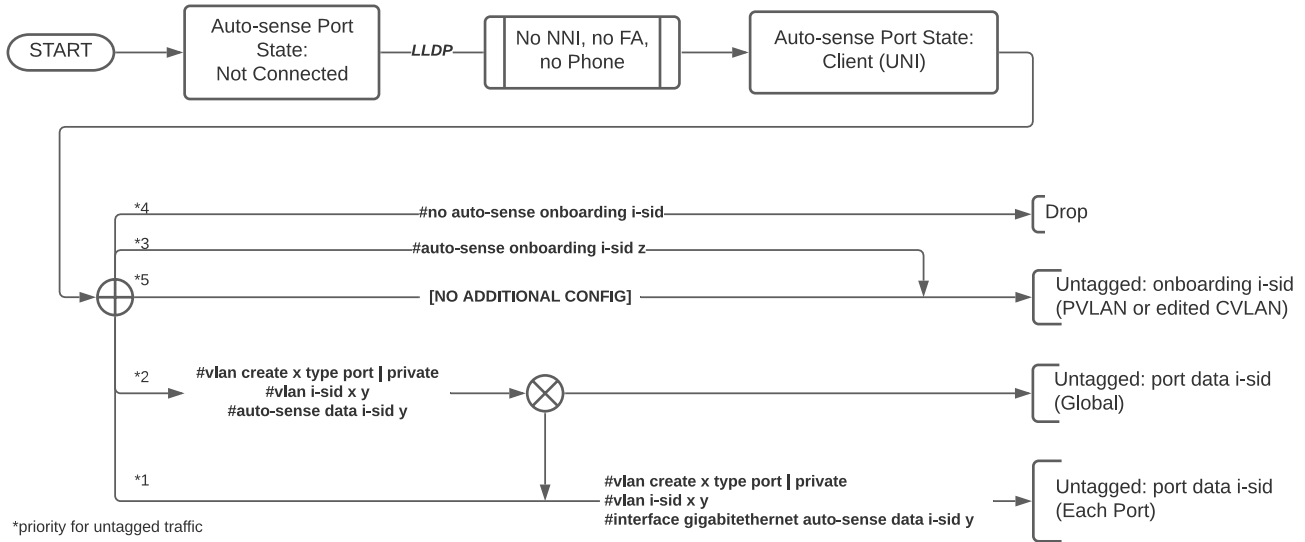

**Note**

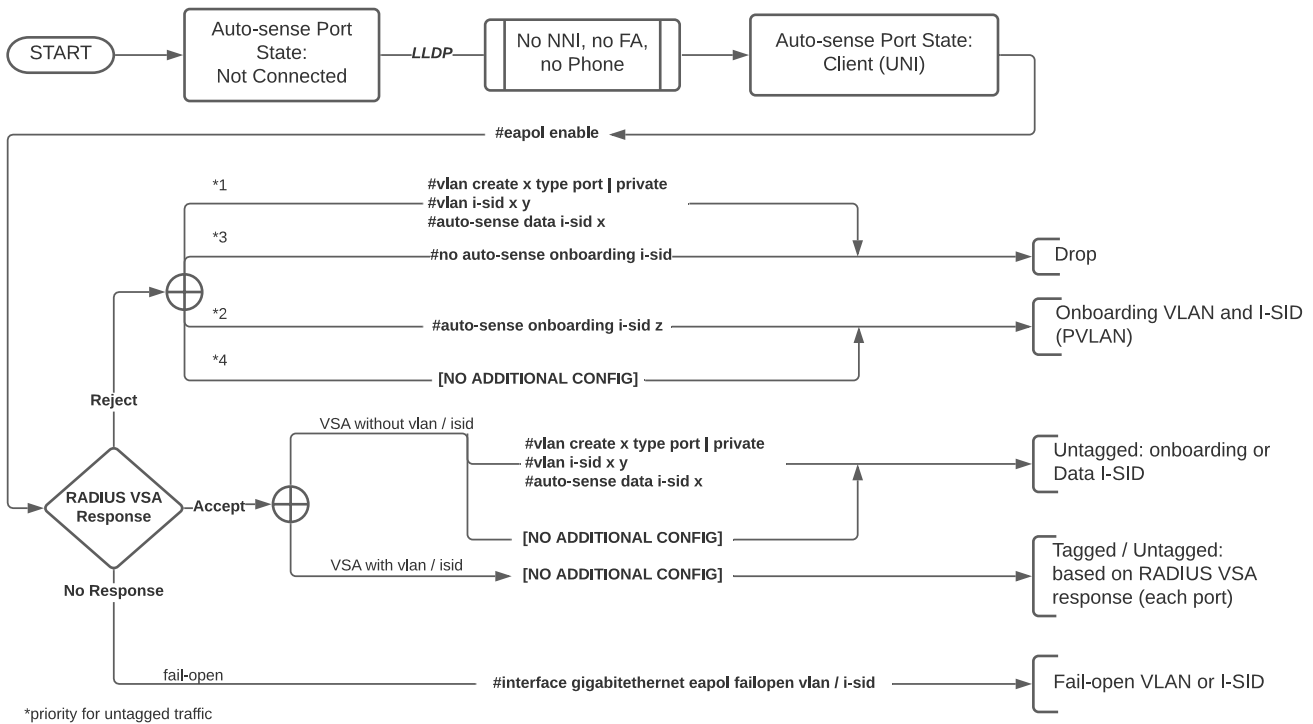

The `vlan create` CLI command examples are not applicable for DvR leaf switch configurations. DvR leaf switches create VLANs automatically.

## Auto-sense Configuration using CLI

To change the Auto-sense configuration on a port using EDM, see [Configure Basic Port Parameters](#) on page 577.

### Enable Auto-sense on Port(s)

**Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

### About This Task

Perform this procedure to manually enable Auto-sense on a specific port.

**Note**

After a switch boots without a configuration file, Auto-sense is enabled on all ports, by default.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Auto-sense on the port:

```
auto-sense enable
```

### Example

Enabling Auto-sense on port 1/2:

```
Switch:1>enable  
Switch:1#configure terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
Switch:1(config)#interface gigabitEthernet 1/2  
Switch:1(config-if)#auto-sense enable  
Warning: Enabling Auto-Sense will default port configurations.
```

### Disable Auto-sense on Port(s)

**Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

## About This Task

Perform this procedure to disable Auto-sense on a specific port. You also have the option to disable Auto-sense on the port but retain the configuration that the system applied dynamically.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable Auto-sense on the port:

```
no auto-sense enable [convert-to-config]
```

## Example

Disable Auto-sense on port 1/2 but retain the configuration. The dynamic configuration becomes a manual configuration and is visible in the **show running-config** output and can be saved to the configuration file using the **save config** command.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface interface gigabitEthernet 1/2
Switch:1(config-if)#no auto-sense enable convert-to-config
Switch:1(config-if)#save config
```

## Variable Definitions

The following table defines parameters for the **no auto-sense enable** command.

| Variable                 | Value   |
|--------------------------|---|
| <i>convert-to-config</i> | Retains the Auto-sense configuration that the system applies dynamically on the specific port. The dynamic configuration becomes a manual configuration and is visible in the <b>show running-config</b> output. If you run the "no auto-sense enable" command without the "convert-to-config" option, then the configuration will be removed from the port and the port returns to the default state where VLAN 1 is assigned. |

*Configure the Auto-sense Wait Interval*

### Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

## About This Task

Perform this task to configure the time, in seconds, for Auto-sense to wait for a Link Layer Discovery Protocol (LLDP) neighbor to be detected in the Auto-sense wait state before transitioning to the Auto-sense onboarding state.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the Auto-sense wait interval:
 

```
auto-sense wait-interval <10-120>
```
3. Verify the Auto-sense wait interval information:
 

```
show auto-sense wait-interval
```

## Example

Configure the Auto-sense wait interval as 50 seconds:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense wait-interval 50
```

Verify the Auto-sense wait-interval information:

```
Switch:1>show auto-sense wait-interval
=====
                        AUTO-SENSE GLOBAL Config
=====
WAIT
INTERVAL
-----
50
-----
-----
0 out of 0 Total Num of AUTO-SENSE entries displayed
-----
```

## Variable Definitions

The following table defines parameters for the **auto-sense wait-interval** command.

| Variable | Value   |
|----------|---|
| <10-120> | Specifies the wait interval, in seconds, for Auto-sense ports. The default value is 35. |

### Configure Auto-sense IS-IS Authentication

#### Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

## Before You Begin

Enable IS-IS globally.

## About This Task

Perform this procedure to configure a global IS-IS authentication key for ports that are operating in Auto-sense mode.

### Note

If the IS-IS authentication keys on auto-sense ports between two switches do not match, then the auto-sense port state will be auto-sense UNI onboarding, until the keys are matching, then an IS-IS adjacency will be established.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the authentication type for IS-IS hello packets on Auto-sense ports:

```
auto-sense isis hello-auth type {none|simple|hmac-md5|hmac-sha-256}  
[key WORD<1-16>] [key-id <1-255>]
```

## Example

Configuring simple authentication for IS-IS hello packets on Auto-sense ports:

```
Switch:1>enable  
Switch:1#configure terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
Switch:1(config)#auto-sense isis hello-auth type simple key Secure
```

## Variable Definitions

The following table defines parameters for the **auto-sense isis hello-auth type** command.

| Variable   | Value  |
|--|--|
| <i>{ none   simple   hmac-md5   hmac-sha-256 }</i> | <p>Specifies the authentication type for IS-IS hello packets on Auto-sense ports:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• simple - simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet.</li> <li>• hmac-md5 - MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet.</li> <li>• hmac-sha-256 - with SHA-256 authentication, the switch adds an hmac-sha-256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest.</li> </ul> <p><b>Note:</b> Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate ISIS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key. This feature is in full compliance with RFC 5310.</p> <p>The default authentication type is none.</p> |
| <i>key WORD&lt;1-16&gt;</i>                        | Specifies the authentication key (password) used by the receiving router to verify the packet.   |
| <i>key-id &lt;1-255&gt;</i>                        | Specifies the key ID.  |

### Configure Auto-sense Access Ports

#### Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

### About This Task

Perform this procedure to configure ports operating in Auto-sense mode to determine the Layer 3 Quality of Service (QoS) actions the switch performs. The Auto-sense access ports override the Differentiated Services Code Point (DSCP) markings.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Configure Auto-sense access ports:
 

```
auto-sense access-diffserv [enable]
```

## Example

Configure the Auto-sense access ports:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)#auto-sense access-diffserv enable
```

## Variable Definitions

The following table defines parameters for the **auto-sense access-diffserv** command.

| Variable      | Value   |
|---------------|---|
| <i>enable</i> | Configures the ports operating in Auto-sense mode to determine the Layer 3 Quality of Service (QoS) actions the switch performs. The Auto-sense access ports override the Differentiated Services Code Point (DSCP) markings. The default configuration is enabled. |

### Disable Auto-sense DHCP Server Detection

#### Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

## About This Task

Perform this procedure to disable Dynamic Host configuration Protocol (DHCP) server detection in Auto-sense mode.

#### Note

By default Auto-sense DHCP server detection is enabled. This ensures automatic detection of the DHCP uplink ports in Zero Touch Deployment.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Disable DHCP server detection:
 

```
no auto-sense dhcp-detection
```

## Example

Enable DHCP server detection:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no auto-sense dhcp-detection
```

*Configure the Auto-sense Onboarding I-SID on the Switch***Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

**About This Task**

Perform this procedure to configure the onboarding I-SID for ports that are operating in Auto-sense mode. The onboarding I-SID is typically used to onboard networking devices such as switches and non FA capable access points. By default, the onboarding I-SID provides automatic reachability when switches are booted from factory without a configuration file. For security reasons, the onboarding I-SID forms an isolated PVLAN/ETREE to block any unwanted port to port cross talk.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the onboarding I-SID:  

```
auto-sense onboarding i-sid <1-16777215>
```

**Example**

Configuring the Auto-sense onboarding I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense onboarding i-sid 15000000
```

**Variable Definitions**

The following table defines parameters for the **auto-sense onboarding** command.

| Variable                  | Value  |
|---------------------------|--|
| <i>i-sid</i> <1-16777215> | Specifies the service instance identifier (I-SID). The default onboarding I-SID value is 15999999. |

*Configure a Auto-sense Global Data I-SID***Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

**Before You Begin**

- Enable Auto-sense on the port.
- Associate a VLAN with the I-SID before you configure it as the global data I-SID.

## About This Task

Perform this task to configure Auto-sense data traffic information for ports that are operating in Auto-sense mode.

### Note

This option applies to the auto-sense UNI and voice states only, it replaces the onboarding I-SID and places an (untagged) client device into a pre-defined global data I-SID.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the data service instance identifier (I-SID):
 

```
auto-sense data i-sid <1-16777215>
```

## Example

Configuring the Auto-sense data I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense data i-sid 1000
```

## Variable Definitions

The following table defines parameters for the **auto-sense data** command.

| Variable                  | Value  |
|---------------------------|--|
| <i>i-sid</i> <1-16777215> | Specifies the service instance identifier (I-SID). |

*Configure a Auto-sense Port Data I-SID*

### Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

## Before You Begin

- Enable Auto-sense on the port.
- Associate a VLAN with the I-SID before you configure it as the data I-SID on the port. This does not apply to a DVR leaf.

## About This Task

Perform this procedure to configure a data I-SID on a port.

### Note

This option applies to the auto-sense UNI and voice states only, it replaces the onboarding I-SID and places an (untagged) client device into a pre-defined port specific data I-SID.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Auto-sense port data I-SID:

```
auto-sense data i-sid <1-16777215>
```

## Example

Configuring the Auto-sense data I-SID for ports 1/1-1/5:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1-1/5
Switch:1(config-if)#auto-sense data i-sid 15000000
```

## Variable Definitions

The following table defines parameters for the **auto-sense data** command.

| Variable                  | Value  |
|---------------------------|--|
| <i>i-sid</i> <1-16777215> | Specifies the service instance identifier (I-SID). |

### Configure Layer 2 Trusted Auto-sense Ports

### Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

## About This Task

Perform this procedure to override incoming 802.1p bits on ports that operate in Auto-sense UNI or voice mode.

## Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure Auto-sense ports as Layer 2 untrusted:  
`auto-sense qos 802.1p-override`

## Example

Configure Auto-sense ports as Layer 2 trusted:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense qos 802.1p-override
```

*Configure EAPoL Authentication Requirements for Auto-sense Fabric Attach Clients*

### Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

You can disable EAPoL authentication for specific Fabric Attach (FA) client types.

## About This Task

By default, authentication is required before the connection is authorized.

## Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure EAPoL authentication requirements from the following choices:
  - For auto-sensed cameras: `auto-sense fa camera eapol status {authorized | auto}`
  - For auto-sensed virtual switches: `auto-sense fa ovs eapol status {authorized | auto}`
  - For auto-sensed wireless access points (WAP): `auto-sense fa wap-type1 eapol status {authorized | auto}`

## Variable Definitions

The following table defines parameters for the **auto-sense** commands related to EAPoL authentication for Fabric Attach (FA).

| Variable                         | Value   |
|----------------------------------|---|
| <code>{authorized   auto}</code> | <p>Configures the EAPoL authentication requirement for the specific client type. Choose from the following options:</p> <ul style="list-style-type: none"> <li><code>authorized</code> – the port skips EAPoL authentication and authorizes the connection.</li> <li><code>auto</code> – authorization depends on the result of EAPoL authentication.</li> </ul> <p>By default, authentication is required before the connection is authorized.</p> |

### Configure Auto-sense Fabric Attach (FA) Authentication

#### Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

## About This Task

Perform this procedure to configure FA authentication for ports that are operating in Auto-sense mode.

## Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Configure the FA authentication key:
 

```
auto-sense fa authentication-key WORD<0-32>
```
3. Enable FA message authentication:
 

```
auto-sense fa message-authentication
```

## Example

Configuring FA message authentication globally:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense fa message-authentication
```

## Variable Definitions

The following table defines parameters for the **auto-sense fa** command.

| Variable   | Value  |
|--|--|
| <i>authentication-key</i><br><i>WORD&lt;0-32&gt;</i> | Specifies the authentication key value.  |
| <i>message-authentication</i>                        | Enables Fabric Attach (FA) message authentication globally, for ports that operate in Auto-sense mode. |

### Configure an I-SID for Auto-sense Fabric Attach Clients

#### Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

For Zero Touch Deployment and assignments of dedicated I-SIDs for FA capable cameras, Wireless Access Points, FA proxy switches and Open Virtual Switches (OVS), configure a specific I-SID to use instead of the onboarding I-SID when a port is in an Auto-sense Fabric Attach (FA) state and detects an FA client.

#### Before You Begin

- Create the I-SID.
- Associate the I-SID with either a platform or private VLAN; this association is not required on a DvR Leaf.

#### About This Task

You can create only one I-SID of each type.

The FA I-SID can be the same as the voice I-SID because they are used by different Auto-sense port states.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the FA I-SID from the following choices:
  - For auto-sensed cameras: `auto-sense fa camera i-sid <1-16777215>`
  - For auto-sensed FA client switches that do not use FA message authentication, like EXOS: `auto-sense fa proxy-no-auth i-sid <1-16777215>`
  - For auto-sensed virtual switches: `auto-sense fa ovs i-sid <1-16777215>`
  - For auto-sensed wireless access points (WAP): `auto-sense fa wap-type1 i-sid <1-16777215>`

## Variable Definitions

The following table defines parameters for the **auto-sense** commands related to Fabric Attach (FA) I-SIDs.

| Variable                              | Value  |
|---------------------------------------|--|
| <code>i-sid &lt;1-16777215&gt;</code> | Specifies the service instance identifier (I-SID). |

### Configure a Management I-SID for Auto-sense Fabric Attach Proxy Switches

#### Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

Configure a specific I-SID and customer VLAN ID to use as the management I-SID when a port is in the Auto-sense FA PROXY state.

## About This Task

The switch creates this I-SID dynamically and uses it instead of the onboarding I-SID.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the management I-SID:
 

```
auto-sense fa proxy management i-sid <1-16777215> c-vid <1-4094>
```

## Variable Definitions

The following table defines parameters for the **auto-sense fa proxy management** command.

| Variable                              | Value  |
|---------------------------------------|--|
| <code>c-vid &lt;1-4094&gt;</code>     | Specifies the customer VLAN ID.                    |
| <code>i-sid &lt;1-16777215&gt;</code> | Specifies the service instance identifier (I-SID). |

### Display Auto-sense Configuration on the Switch

#### Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

## About This Task

Perform this procedure to display the Auto-sense configuration on the switch.

## Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display the Auto-sense configuration:

```
show auto-sense [access-differv] [data] [dhcp-detection] [eapol] [fa]
[isis] [onboarding] [qos] [voice] [wait-interval]
```

3. Display the Auto-sense status and state on a port:

```
show interfaces gigabitEthernet auto-sense [{slot/port[/sub-port]}[-slot/port[/sub-
port]][,...]]
```

### Examples

Display the Auto-sense configuration related to voice:

```
Switch:1>show auto-sense voice
=====
                        AUTO-SENSE VOICE Config
=====
TYPE   LDDP-AUTH ENABLE I-SID      C-VID      DSCP      PRIORITY
-----
phone  FALSE                2000       2000       46        6
-----
1 out of 1 Total Num of AUTO-SENSE entries displayed
=====
```

Display the Auto-sense status and state on a range of ports:

```
Switch:1>show interfaces gigabitEthernet auto-sense 1/1-1/5
=====
                        Port Auto-sense
=====
PORT    AUTO-SENSE  AUTO-SENSE  AUTO-SENSE
NUM     STATUS     STATE      PORT-DATA-ISID
-----
1/1     Enable     UNI-ONBOARDING  500
1/2     Disable    OFF
1/3     Disable    OFF
1/4     Disable    OFF
1/5     Disable    OFF
=====
```

Display the Auto-sense status for Fabric Attach (FA):

```
Switch:1>show auto-sense fa
=====
                        AUTO-SENSE FA Config
=====
MSG-AUTH                      MSG-AUTH-KEY
-----
enabled                        ****
-----

                        AUTO-SENSE FA Client specific config
=====
TYPE           EAPOL STATUS  I-SID  VLANID  C-VID  MGMT I-SID MGMT C-VID
-----
camera         Auto        100    100     untag  -      -
wap-type1      Auto        200    200     untag  -      -
open-virtual-switch Auto        -      -       -      -      -
proxy-no-auth  Auth        300    300     untag  -      -
proxy          Auth        400    n/a     400    400    400
-----
6 out of 6 Total Num of AUTO-SENSE entries displayed
=====
```

Display the Auto-sense wait-interval information.

```
Switch:1>show auto-sense wait-interval
=====
                        AUTO-SENSE GLOBAL Config
=====
WAIT
INTERVAL
-----
50
-----
-----
0 out of 0 Total Num of AUTO-SENSE entries displayed
-----
```

## IP Phone Support

**Table 6: IP Phone product support**

| Feature          | Product         | Release introduced |
|------------------|-----------------|--------------------|
| IP Phone Support | 5420 Series     | VOSS 8.4           |
|                  | 5520 Series     | VOSS 8.3           |
|                  | VSP 4450 Series | VOSS 8.3           |
|                  | VSP 4900 Series | VOSS 8.3           |
|                  | VSP 7200 Series | VOSS 8.3           |
|                  | VSP 7400 Series | VOSS 8.3           |
|                  | VSP 8200 Series | VOSS 8.3           |
|                  | VSP 8400 Series | VOSS 8.3           |
|                  | VSP 8600 Series | Not Supported      |
|                  | XA1400 Series   | Not Supported      |

The IP phone support feature focusses on the following key points:

- Works only on the Flex UNI-enabled and Auto-sense ports.
- For Avaya phones, you can choose to configure and send call server and file server Link Layer Discovery Protocol (LLDP) Type-Length-Value (TLV) options through the **lldp vendor-specific** CLI command.
- To reduce configuration overhead, this feature includes the Auto-sense voice mechanism to detect IP phones from LLDP signalling. After the switch detects the phone, this mechanism manages the following tasks:
  - Provides the voice VLAN to the phone, tagging, Differentiated Services Code Point (DSCP), and priority parameters through the LLDP Media Endpoint Discovery (MED) signaling options.
  - Configures a switched UNI for phone traffic and sends it to the Service Instance Identifier (I-SID) that is associated with the voice VLAN.

- Handles the configuration, whether “trusted” or “untrusted” on the port and priority re-markings.
- Integrates with the Auto-sense functionality. For more information on Auto-sense, see [Auto-sense](#) on page 16.

**Note**

This feature does not support auto-creation of voice VLAN and MultiLink Trunking (MLT) or Split Multi-Link Trunking (SMLT).

This feature has the following connectivity models:

- Standalone IP phone, which connects to a switch port.
- IP Phone with PC behind it, where the IP Phone has a small inbuilt bridge, and a PC connects to that bridge port.

**Note**

Phone traffic is tagged with the voice VLAN whereas the PC traffic is untagged. However, you can configure the phone to send the traffic as untagged.

The IP phone connectivity supports the following scenarios:

- Call server and file Server LLDP TLV options—These TLVs are Avaya proprietary. Use them only with the Avaya IP phones to detect the IP addresses of a Call server and File Server.
- Phone detection through LLDP messaging—Use the Capabilities and Enabled Capabilities field in the LLDP packet to detect a phone. A “T” capability identifies a phone.
- Auto-sense voice option, without Network Access Control (NAC)—Use this functionality to specify the voice VLAN and voice I-SID in a single CLI command.
- Auto-ISID-Offset—Use this functionality if the voice VLAN is received without an I-SID from a Radius response. The Auto-ISID-Offset functionality determines an I-SID automatically to send the data traffic.
- Auto-sense voice, LLDP authentication, and Non- EAP (NEAP) (MAC authentication) connectivity—If you have enabled NEAP, it authorizes all the MAC addresses received on the port and IP phone. With the LLDP authentication option, a device, such as phone, is trusted and does not require a Remote Authentication Dial-in User (RADIUS) authentication. For this authentication, the Extensible Authentication Protocol (EAP) is notified after a phone is detected and the port is in the Auto-sense voice state. Then, the MAC address of the phone is added to EAP or NEAP host table.

## Auto-sense Voice

The Auto-sense voice feature is an addition to the Auto-sense module. Based on the events of the phone discovery in the network, you can use this feature to configure phone devices without manual intervention.

After the switch discovers a Link Layer Discovery Protocol (LLDP) packet with phone capabilities, the port transitions to the “voice” state. The port receives a message on the voice event details.

With the Auto-sense voice feature, you can configure the voice I-SID and the voice VLAN. If you configure the I-SID as untagged, the phone receives VLAN as zero. When you configure Auto-sense voice, switched UNI is configured in VOICE I-SID for each port that is in “voice” state. The switch adds

the Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED) policies for voice and voice-signaling Type-Length-Value (TLVs) to the LLDP packet and sends LLDP packets to the phone. It uses the configured voice VLAN and default values for Differentiated Services Code Point (DSCP) (46) and priority (6). After you run the **auto-sense voice** command, a filter is installed to prioritize the traffic that passes through the configured I-SID. The filter applies to traffic that reaches the VOICE I-SID, which implies the voice traffic.

#### Note

To change the Auto-sense voice configuration on the switch, delete the earlier configured voice I-SID and VLAN entry.

After you configure auto-sense voice, following tasks take place:

- The I-SID <I-SID value> and C-VID <C-VID value> are saved in the control plane.
- The voice I-SID is created.
- The ports that are in the "voice" state process the voice configuration message and begin the dynamic configuration. This configuration includes the following tasks:
  - Creation of voice Switched UNI (S-UNI).
  - Deletion of onboarding and data I-SID, or S-UNI, if you configured auto-sense as "untagged".
  - Addition of LLDP-MED voice and voice-signaling TLVs to the LLDP packet and sending of LLDP packets to the phone.
- The voice filter is updated. After you run the **auto-sense voice** command, a filter is installed to prioritize the traffic that passes through the configured I-SID. The filter applies to the traffic in Voice I-SID. The traffic that passes through this I-SID is internally prioritized with level 6 and forwarded with a dot1p value of 6, for tagged packets. For the IP packets, the DSCP value of 46 is forwarded.

#### Note

- To disable Auto-sense on the port but keep the dynamic configurations made by Auto-sense, use the command **no auto-sense enable convert-to-config**. The voice S-UNI loses its Auto-sense origin and has a config origin instead. The LLDP-MED policies installed by Auto-sense are preserved.
- If you use the **no auto-sense voice** command, the system removes the voice S-UNI and the LLDP-MED policies. The voice I-SID is removed if it was installed by using the **auto-sense voice** command. If the I-SID existed before you used the **auto-sense voice** command, the system does not remove the I-SID but the I-SID does lose its Auto-sense origin.
- A port exits the voice state in one of the following scenarios:
  - If the port is down
  - If the LLDP session fails between the switch and the phone
  - If Auto-sense is disabled on the port that connects to the IP phone

After a port exits the voice state, the Switched UNI (S-UNI), LLDP voice and voice-signaling are deleted.

## IP Phone Configuration using CLI

### Configure Auto-sense Voice Information for IP Phones

#### Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

The switch applies the voice configuration on Auto-sense-enabled ports, after it discovers IP phones on the port through Link Layer Discovery Protocol (LLDP) packets.

#### Before You Begin

If you boot the switch with a configuration file, and not through Zero Touch Fabric Configuration, you must manually enable Auto-sense on specific ports.

#### About This Task

Perform this procedure to configure Auto-sense voice information for IP phones.

A global Auto-sense voice configuration does not require Auto-sense LLDP authentication based on the following cases.

- In a non NAC, a phone is classified based on the phones LLDP signaling.
- In a NAC, a phone is authenticated based on EAP/NEAP radius authenticated, or if configured, it is LLDP authenticated

#### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure the customer VLAN ID:  
`auto-sense voice i-sid <1-16777215> c-vid <c-vid>`
3. Configure the traffic as untagged:  
`auto-sense voice i-sid <1-16777215> untagged`

#### Note

The phone receives VLAN ID as 0 and the tagging is configured as "untagged".

#### Example

Configure VLAN tagging as untagged:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense voice i-sid 1234 untagged
```

## Variable Definitions

The following table defines parameters for the **auto-sense voice** command.

| Variable                      | Value   |
|-------------------------------|---|
| <i>i-sid</i> <1-16777215>     | Specifies the service instance identifier (I-SID).  |
| <i>c-vid</i> < <i>c-vid</i> > | Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch. |
| <i>untagged</i>               | Specifies the VLAN tagging type as untagged.<br><br><b>Note:</b><br>The phone receives VLAN ID as 0 and the tagging is configured as "untagged".                    |

### Enable Auto-sense LLDP Authentication of IP Phones

#### Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

### Before You Begin

- You must enable Extensible Authentication Protocol over LAN (EAPoL) globally.

### About This Task

Perform this procedure to enable Link Layer Discovery Protocol (LLDP) authentication of IP phones. The switch authenticates the phone after it receives LLDP packets from the phone if EAP/NEAP is enabled.

Auto-sense LLDP authentication applies to Auto-sense ports in the VOICE state. Auto-sense LLDP authentication does not require a global Auto-sense voice configuration.

The **no auto-sense eapol voice lldp-auth** command removes all Auto-sense LLDP sessions and removes the Auto-sense LLDP authentication configuration.

The system removes the LLDP session for the following reasons:

- You disable EAPoL globally.
- You disable Auto-sense on the port.
- The LLDP neighbor is removed.

If the LLDP authentication configuration exists and one of the following situations occur, the LLDP session is recreated:

- You reenable EAPoL globally.
- You reenable Auto-sense on the port.
- The LLDP neighbor is recreated.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable LLDP authentication:  

```
auto-sense eapol voice lldp-auth
```

## Example

Enabling LLDP authentication on the switch:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense eapol voice lldp-auth
```

## Variable Definitions

The following table defines parameters for the **auto-sense eapol voice** command.

| Variable         | Value   |
|------------------|---|
| <i>lldp-auth</i> | Enables Link Layer Discovery Protocol (LLDP) authentication of IP phones. By default, LLDP authentication of IP phones is disabled on the switch. |

## Configure LLDP Vendor Specific Information

### About This Task

Use this procedure to configure the Link Layer Discovery Protocol (LLDP) vendor-specific information on a call server or a file server.

#### Note

After you configure LLDP vendor specific call server information, the SIP Proxy of the phone is configured as transport type Transport Layer Security (TLS) port 5061. This option is available depending on the operating system of the call server.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. To configure LLDP vendor-specific information for a call server server, enter:  

```
lldp vendor-specific call-server <1-8> <A.B.C.D>
```
3. To configure LLDP vendor-specific information for a file server, enter  

```
lldp vendor-specific file-server <1-4> <A.B.C.D>
```

## Example

Configure the LLDP vendor-specific information on a call server:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#lldp vendor-specific call-server 1 192.0.2.0
```

## Variable Definitions

The following table defines parameters for the **lldp vendor-specific** command.

| Variable                              | Value  |
|---------------------------------------|--|
| <i>call-server</i> <1-8><br><A.B.C.D> | Specifies the Link Layer Discovery Protocol (LLDP) vendor specific information on the call server number and the IP address. |
| <i>file-server</i> <1-4><br><A.B.C.D> | Specifies an LLDP vendor specific information on the file server number and the IP address.                                  |

*View LLDP Vendor Specific Information*

## About This Task

Use this procedure to view the Link Layer Discovery Protocol (LLDP) vendor-specific information on a call server or a file server.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. To view LLDP vendor-specific information for a call server, enter:  
show lldp vendor-specific *call-server*
3. To configure LLDP vendor-specific information for a file server, enter  
show lldp vendor-specific *file-server*

## Example

Display the LLDP vendor-specific information on a call server:

```
Switch:1>enable
Switch:1#show lldp vendor-specific call-server
=====
                        LLDP Call-Server
=====
NUM          IP
-----
1            192.0.2.0
2            198.51.100.0
-----
All 2 out of 2 Total Num of call-server entries displayed
```

*View LLDP Neighbor Vendor Specific Information*

## About This Task

Use this procedure to view the remote Link Layer Discovery Protocol (LLDP) vendor-specific information on a call server or a file server.

## Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. To view remote LLDP vendor-specific information for a call server, enter:  

```
show lldp neighbor vendor-specific call-server
```
3. To view remote LLDP vendor-specific information for a file server, enter:  

```
show lldp neighbor vendor-specific file-server
```

## Example

Display remote LLDP vendor-specific information on a file server:

```
Switch:1>enable
Switch:1#show lldp neighbor vendor-specific file-server
=====
Remote LLDP File-Server IP Addresses
=====
PORT      IP
-----
203      192.0.2.0, 198.51.100.0, 203.0.113.0
-----
All 3 out of 3 Total Num of remote file-server entries displayed
```

### Enable LLDP Voice Authentication on a Specific Port

#### Note

This procedure does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

## About This Task

Perform this procedure to enable Link Layer Discovery Protocol (LLDP) voice authentication of IP phones on a port.

You cannot manually enable LLDP voice authentication on an Auto-sense-enabled port. If the system detects a phone on an Auto-sense port, then “eapol voice lldp-auth” configuration is automatically applied on the port that connects to the phone. This procedure applies to ports with Auto-sense disabled.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable LLDP voice authentication on a specific port:

```
eapol voice lldp-auth
```

**Example**

Enabling LLDP voice authentication on a specific port:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#eapol voice lldp-auth
```

**Variable Definitions**

The following table defines parameters for the **eapol voice** command.

| Variable         | Value  |
|------------------|--|
| <i>lldp-auth</i> | Enables Link Layer Discovery Protocol (LLDP) voice authentication of IP phones on the selected port. By default, LLDP authentication of IP phones is disabled on the switch. |

**IP Phone Configuration using EDM**

*View Vendor Specific Call Server Information*

**About This Task**

Perform this procedure to view inventory attributes for vendor-specific call server information.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit > Diagnostics > 802\_1ab**.
2. Select **Vendor Specific**.
3. Select the **Call Server** tab.

**Vendor Specific Call Server Field Descriptions**

Use the data in the following table to use the **Call Server** tab.

| Name                         | Description                                       |
|------------------------------|---|
| <b>CallServerNum</b>         | Specifies the call server ID.                     |
| <b>CallServerAddressType</b> | Specifies the IP address type of the call server. |
| <b>CallServerAddress</b>     | Specifies the IP address of the call server.      |

*View Vendor Specific File Server Information*

### About This Task

Perform this procedure to view inventory attributes for vendor-specific file server information.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics > 802\_1ab**.
2. Select **Vendor Specific**.
3. Select the **File Server** tab.

### Vendor Specific File Server Field Descriptions

Use the data in the following table to use the **File Server** tab.

| Name                         | Description                                       |
|------------------------------|---|
| <b>FileServerNum</b>         | Specifies the file server ID.                     |
| <b>FileServerAddressType</b> | Specifies the IP address type of the file server. |
| <b>FileServerAddress</b>     | Specifies the IP address of the file server.      |

## Zero Touch Deployment

**Table 7: Zero Touch Deployment product support**

| Feature               | Product         | Release introduced   |
|-----------------------|-----------------|--|
| Zero Touch Deployment | 5420 Series     | VOSS 8.4   |
|                       | 5520 Series     | VOSS 8.2.5   |
|                       | VSP 4450 Series | VOSS 8.2   |
|                       | VSP 4900 Series | VOSS 8.2<br>VIMs: VIM5-4YE, VIM5-4X,<br>VIM5-4XE, and VIM5-2Y only |
|                       | VSP 7200 Series | VOSS 8.2   |
|                       | VSP 7400 Series | VOSS 8.2   |
|                       | VSP 8200 Series | VOSS 8.2   |
|                       | VSP 8400 Series | VOSS 8.2   |
|                       | VSP 8600 Series | Not supported  |
|                       | XA1400 Series   | VOSS 8.2   |

For the most current information on switches supported by ExtremeCloud™ IQ, see [ExtremeCloud™ IQ Learning What's New](#).

Zero Touch Deployment enables a VOSS switch to be deployed automatically with ExtremeCloud IQ but you still need to onboard the switch on the ExtremeCloud IQ side. When the switch powers on, the Dynamic Host Configuration Protocol (DHCP) Client obtains the IP address and gateway from a DHCP Server, and discovers the Domain Name Server, connecting the switch automatically to Extreme Management Center or ExtremeCloud IQ - Site Engine or to ExtremeCloud IQ cloud management application.

VOSS integrates with ExtremeCloud IQ using IQAgent.

Zero Touch Provisioning Plus (ZTP+) provides Extreme Management Center or ExtremeCloud IQ - Site Engine connectivity to VOSS switches.

For more information about ExtremeCloud IQ Agent, see [ExtremeCloud IQ Agent](#) on page 835. For more information about ZTP+, see [Zero Touch Provisioning Plus](#) on page 53.

To use zero touch functionality, your switch must be in a Zero Touch Deployment-ready configuration mode, which means the switch cannot have existing primary or secondary configuration files loaded. Factory shipped switches are Zero Touch Deployment ready because they deploy without configuration files. However, existing switches require manual preparation before Zero Touch Deployment can function.

To prepare an existing switch for Zero Touch Deployment, the switch must boot without a configuration file. Perform one of the following actions:

- Rename existing primary and secondary configuration files. Use the **mv** command to rename the existing configuration files. For example, **mv config.cfg config.cfg.backup**.

This is the preferred option as it ensures that the primary and secondary files are removed while making a backup of them at the same time. This option also ensures that the switch uses the default config.cfg file for the final configuration after it has successfully onboarded.

- Boot from non-existent configuration files. Use the **boot config choice** command to configure the primary and backup configuration files to reference files that do not exist on the switch:

```
boot config choice primary config-file nonexistent1.cfg
```

```
boot config choice primary backup-config-file nonexistent2.cfg
```

This option also works, however, after the switch has successfully onboarded, it does not use the default config.cfg file but uses the alternative configuration file name provided instead, which might not be desired.

- Delete the existing primary and secondary configuration files. Create a backup of these files before you delete them.

## Configuration Considerations

The switch configuration depends on whether you use factory default mode or Zero Touch Deployment.

### *Zero Touch Deployment Configuration*

With Zero Touch Deployment, the switch configuration consists of the following:

- The ssh and sshd boot configuration flags are enabled by default.
- All ports are Private VLAN isolated ports, except on the XA1400 Series.
- VLAN 4048 is created as an *onboarding-vlan* for host-only connectivity for In Band management. On all other platforms, except the XA1400 Series, all front panel ports are members of VLAN 4048.
- In Band management is enabled.
- Dynamic Host Configuration Protocol (DHCP) client requests are cycled between In Band and Out of Band ports, except on the XA1400 Series and VSP 4450 Series. XA1400 Series and VSP 4450 Series support In Band management only.
- Out of Band management is enabled, except on the XA1400 Series and VSP 4450 Series. XA1400 Series and VSP 4450 Series support In Band management only.
- All ports are administratively enabled, except on the XA1400 Series. Only Port 1/8 is administratively enabled on the XA1400 Series, which means the administrator must plug in and use only port 1/8 for Zero Touch Deployment on an XA1400 Series.
- IQAgent is enabled by default.
- Zero Touch Provisioning Plus (ZTP+) for Extreme Management Center or ExtremeCloud IQ - Site Engine onboarding is enabled by default.
- Initiates Zero Touch Fabric Configuration.
- After the Zero Touch Fabric establishes successfully, the onboarding VLAN 4048 is automatically assigned to onboarding I-SID 15999999.

For information about IQAgent, see [ExtremeCloud IQ Agent](#) on page 835.

### *Factory Default Mode*

The switch continues to support the boot configuration flag **boot config flags factorydefaults** to return an existing switch to factory default configuration.

#### Note

Zero Touch Deployment does not run on a switch returned to factory default configuration in this manner.

For more information, see [Boot Sequence](#) on page 133.

## Zero Touch Provisioning Plus

**Table 8: Zero Touch Provisioning Plus product support**

| Feature                      | Product         | Release introduced |
|------------------------------|-----------------|--------------------|
| Zero Touch Provisioning Plus | 5420 Series     | VOSS 8.4           |
|                              | 5520 Series     | VOSS 8.2.5         |
|                              | VSP 4450 Series | VOSS 8.2.5         |
|                              | VSP 4900 Series | VOSS 8.2.5         |
|                              | VSP 7200 Series | VOSS 8.2.5         |
|                              | VSP 7400 Series | VOSS 8.2.5         |
|                              | VSP 8200 Series | VOSS 8.2.5         |
|                              | VSP 8400 Series | VOSS 8.2.5         |
|                              | VSP 8600 Series | Not Supported      |
|                              | XA1400 Series   | VOSS 8.2.5         |

With zero touch functionality, VOSS switches are automatically discovered on the network within minutes of when they are connected.

Zero Touch Provisioning Plus (ZTP+) enables you to deploy and configure VOSS switches in Extreme Management Center or ExtremeCloud IQ - Site Engine with minimal server configuration and intervention. ZTP+ enabled switches send information, such as the serial number, software version, MAC, management IP, and port information to Extreme Management Center or ExtremeCloud IQ - Site Engine automatically.

When the switch powers on, the DHCP Client obtains the IP address and gateway from the DHCP server, discovers the Domain Name Server, and connects the switch to Extreme Management Center or ExtremeCloud IQ - Site Engine.

ZTP+ uses HTTPS for communication between the switch and the Extreme Management Center or ExtremeCloud IQ - Site Engine server. The switch discovers the Extreme Management Center or ExtremeCloud IQ - Site Engine server by resolving the DNS name *extremecontrol.<domain-name>*.

### Important

This feature requires a Zero Touch Deployment-ready configuration. For more information, see [Zero Touch Deployment](#) on page 50.

## ZTP+ Phases of Operation

Zero Touch Provisioning Plus (ZTP+) auto-provisioning occurs in phases after you connect the switch to the network, if the switch is in factory ship state with no valid configuration saved on the device.

### *Connect*

The Connect phase is the first phase of ZTP+ during which the switch connects to the Extreme Management Center or ExtremeCloud IQ - Site Engine server on the network. The Extreme

Management Center or ExtremeCloud IQ - Site Engine server is discovered by resolving the DNS name *extremecontrol.<domain-name>*.

If the attempt is successful, the Extreme Management Center or ExtremeCloud IQ - Site Engine server responds with an **Accept** message. When connectivity is established, the switch communicates with the Extreme Management Center or ExtremeCloud IQ - Site Engine server securely and transmits information, such as its serial number, model number. The switch then progresses to the next phase of ZTP+.

### *Upgrade*

After a successful connect to the Extreme Management Center or ExtremeCloud IQ - Site Engine server, the next phase of ZTP+ is the Upgrade phase. This phase verifies that the switch is running the image file version that is currently selected as the reference version on the Extreme Management Center or ExtremeCloud IQ - Site Engine server.

Image file validation is initiated by the switch. After a successful connect, the switch sends an image file upgrade request to the Extreme Management Center or ExtremeCloud IQ - Site Engine server with details on the current image file version. If the image file versions on the switch and the Extreme Management Center or ExtremeCloud IQ - Site Engine server match, no upgrade is initiated, and the switch moves to the next phase of ZTP+. If the Extreme Management Center or ExtremeCloud IQ - Site Engine server detects a different image file version, ZTP+ initiates the .tgz image file download from a specified URL location.

After a successful image upgrade, the switch reboots and reconnects to the Extreme Management Center or ExtremeCloud IQ - Site Engine server. If there are errors in the image upgrade process, an event is added to the server log. The switch then retries the image upgrade.

### *Configuration*

The next phase after the image upgrade is ZTP+ Configuration phase. During this phase, the switch queries the Extreme Management Center or ExtremeCloud IQ - Site Engine server for configuration updates, and initiates auto-provisioning by transmitting information, such as the image version, model name, and serial number. The switch then attempts to apply the configuration that is pushed from the Extreme Management Center or ExtremeCloud IQ - Site Engine server.

If the switch can still communicate with the Extreme Management Center or ExtremeCloud IQ - Site Engine server after the configuration is applied, the new configuration is automatically saved on the switch. The switch can be managed through the Extreme Management Center or ExtremeCloud IQ - Site Engine using Simple Network Management Protocol (SNMP). However, if the configuration that is pushed from the Extreme Management Center or ExtremeCloud IQ - Site Engine server breaks switch connectivity to the Extreme Management Center or ExtremeCloud IQ - Site Engine server, the switch reboots without saving the configuration. After the switch reboots, the ZTP+ onboarding restarts.

Any configurations pushed from the Extreme Management Center or ExtremeCloud IQ - Site Engine server to VOSS devices using the initial ZTP+ configuration push are not displayed in the **show log file detail** command output. The logs associated with the Cloud connector are logged internally to *state\_machine.txt* and *ztp\_plus.txt* files located in */intflash/cc/cc\_logs/*.

Extreme Management Center or ExtremeCloud IQ - Site Engine uses ZTP+ to configure the following items:

- Link Layer Discovery Protocol (LLDP) neighbor discovery

**Note**

Based on the LLDP discovery, port templates can be used on the Extreme Management Center or ExtremeCloud IQ - Site Engine server. Enabling or disabling LLDP is not supported.

- Login
- Network Time Protocol (NTP)
- Ports configuration
- SNMP
- VLANs

**Note**

ZTP+ cannot manage VLAN port membership. With ZTP+, new VLANs are created with no ports. Ports cannot be removed from the onboarding VLAN. Ports cannot be added to another VLAN. VLAN port membership is managed through Auto-sense functionality or through manual configuration after initial onboarding is complete.

## ZTP+ Considerations

The following considerations apply to Zero Touch Provisioning Plus (ZTP+) :

- Fabric configurations are not supported with ZTP+. After ZTP+ is configured, Extreme Management Center or ExtremeCloud IQ - Site Engine server can use Simple Network Management Protocol (SNMP) to remotely configure Fabric-related configurations on the switch using SNMP MIBs.
- Only the Out-of-Band (OOB) port or the Management VLAN interface are used to connect the Extreme Management Center or ExtremeCloud IQ - Site Engine server.

**Note**

ZTP+ cannot change the Management VLAN interface. If onboarding started on the Management onboarding VLAN, this cannot be changed while using ZTP+.

## Configuring ZTP+ using the CLI

This section provides procedures to configure and manage Zero Touch Provisioning Plus (ZTP+) using the Command Line Interface (CLI).

After your VOSS device is onboarded, you have access to Extreme Management Center or ExtremeCloud IQ - Site Engine.

**Note**

You must configure a Segmented Management Instance to use ZTP+. For more information, see [Segmented Management Instance Configuration using the CLI](#) on page 77.

For information about onboarding switches, see <https://www.extremenetworks.com/support>.

*View ZTP+ Status***About This Task**

Use this procedure to verify the status of Zero Touch Provisioning Plus (ZTP+) on the switch.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Verify that ZTP+ is enabled:

```
show application auto-provision
```

**Example**

The following is an example output of the **show application auto-provision** command:

```
Switch:1>show application auto-provision

Admin state       : Enabled
Operational state : Running
```

## Zero Touch Fabric Configuration

**Table 9: Zero Touch Fabric Configuration product support**

| Feature                         | Product         | Release introduced |
|---------------------------------|-----------------|--------------------|
| Zero Touch Fabric Configuration | 5420 Series     | VOSS 8.4           |
|                                 | 5520 Series     | VOSS 8.2.5         |
|                                 | VSP 4450 Series | VOSS 7.0           |
|                                 | VSP 4900 Series | VOSS 8.1           |
|                                 | VSP 7200 Series | VOSS 7.0           |
|                                 | VSP 7400 Series | VOSS 8.0.5         |
|                                 | VSP 8200 Series | VOSS 7.0           |
|                                 | VSP 8400 Series | VOSS 7.0           |
|                                 | VSP 8600 Series | Not Supported      |
|                                 | XA1400 Series   | Not Supported      |

You can use Zero Touch Fabric Configuration to deploy Fabric-capable switches in a plug and play manner with no initial configuration. The switches form a new Fabric automatically or they can connect to an existing Fabric that is Auto-sense-capable, obtain an IP address and Domain Name System (DNS) information from a Dynamic Host Configuration Protocol (DHCP) server using the onboarding I-SID/VLAN, which then permits the system to automatically onboard to the management servers, such as ExtremeCloud IQ or Extreme Management Center or ExtremeCloud IQ - Site Engine, to conduct actual provisioning deployment of the switch. For more information about Auto-sense, see [Auto-sense](#) on page 16.

Zero Touch Fabric Configuration automatically configures Shortest Path Bridging MAC (SPBM) and IS-IS without user intervention if you boot the switch in Zero Touch Deployment-ready configuration mode, meaning you boot without a configuration file. Zero Touch Fabric Configuration uses LLDP to signal

Fabric capability and exchanges SPB backbone VLAN IDs information to ensure seamless joining to any existing fabric deployment. The switches use the chassis MAC addresses as their system ID. To ensure participation in the correct area, newly joining ZTF switches listen to IS-IS update packets for area information. A unique nick-name is assigned by a pre-configured nick-name server switch. For more information, see [Zero Touch Deployment](#) on page 50.

### Important

To add new Zero Touch Fabric Configuration devices or implement Zero Touch Fabric Configuration on existing devices, the network requires a nickname server and reachability to the DHCP server. How you implement this depends on if the network is a new deployment or an existing Fabric network that you upgrade. In a new deployment, you can meet the network requirements with one node, known as a seed node. In an existing network, functions may already exist on different nodes. For more information, see [VOSS Release Notes](#).

Zero Touch Fabric Configuration uses the port-based Auto-sense features, that enables all ports on the switch, by default, and all ports operate in Auto-sense mode. With the support of Auto-sense, Zero Touch Fabric Configuration onboards all ports on the switch to an existing network, without having to manually enable each port. Auto-sense automatically detects neighbor capabilities and performs the configuration on the port to reach the desired connectivity with the neighbor without user invention.

With Auto-sense functionality, ports on a switch can detect whether they connect to a Shortest Path Bridging (SPB) device, a Fabric Attach (FA) client, FA Proxy, Voice IP devices, or an undefined host, and then make the necessary configuration. For more information about Auto-sense, see [Auto-sense](#) on page 16.

If you start two nodes in a network without an existing configuration file, then Zero Touch Fabric Configuration, through Auto-sense, dynamically establishes an IS-IS adjacency between them. For more information, see [Establishing IS-IS Adjacencies](#) on page 58.

## Default IS-IS Parameters

Zero Touch Fabric Configuration automatically configures the Shortest Path Bridging (SPB) and Intermediate System-to-Intermediate System (IS-IS) infrastructure to enable Fabric architecture on a switch. The system initializes the following items after you start the switch in Zero Touch Fabric Configuration mode:

- Enables Shortest Path Bridging MAC (SPBM).
- Creates a private VLAN 4048.
- Creates the Auto-sense onboarding I-SID 15999999.
- Assigns the Auto-sense onboarding I-SID 15999999 to private VLAN 4048 and also includes the management VLAN.

### Note

As a best practice, use the onboarding I-SID for onboarding purposes and, whenever possible, configure a management VLAN or management CLIP on a different I-SID after the onboarding procedures have been successfully completed.

- Enables Auto-sense on all ports.
- Configures Auto-sense access ports and layer 2 trusted Auto-sense ports.

- Creates an SPBM instance.
- Enables IS-IS globally.

| Parameter                   | Default value  |
|-----------------------------|--|
| SPBM instance               | 1  |
| Primary B-VLAN              | 4051   |
| Secondary B-VLAN            | 4052   |
| Manual area                 | Initialize to 00.1515.fee1.900d.1515.fee1.900d<br><br><b>Note:</b><br>You can change the manual area dynamically, without disabling IS-IS, only when the area is the Zero Touch Fabric Configuration area.<br>When IS-IS is enabled, you cannot delete the last manual area. |
| Auto-sense onboarding I-SID | 15999999   |

## Establishing IS-IS Adjacencies

Zero Touch Fabric Configuration automatically triggers when the switch boots without a configuration file, the platform enables Intermediate System-to-Intermediate System (IS-IS) without a configured nickname or manual area. The system creates default backbone VLANs (B-VLAN) (4051 and 4052) and IS-IS manual area values. As a result, if you start two nodes in a network without an existing configuration file, then Zero Touch Fabric Configuration dynamically establishes an IS-IS adjacency between them.

The switch uses the Auto-sense functionality with the Zero Touch Fabric Configuration feature to establish the adjacency between two nodes. For more information about how and when the system tries to establish the adjacency, see [Auto-sense Port States](#) on page 19 .

- If you manually configure an SPBM instance on a node, then the system removes the SPBM instance that is dynamically created by Zero Touch Fabric Configuration. The system uses the LLDP Fabric Connect TLV to send user-defined B-VLANs to other nodes in the network. Only the first pair of B-VLANs is learned. If the switch already learned the B-VLANs from neighbor\_A, the switch ignores the B-VLANs received from neighbor\_B, if those are different.
- If a switch operating in Zero Touch Fabric Configuration mode in the network receives B-VLANs from a neighboring switch, which do not match the default B-VLANs configured through Zero Touch Fabric Configuration, then the switch will perform the following actions:
  - Disables ISIS.
  - Deletes its VLANs.
  - Unassigns the B-VLANs.
  - Assigns the values received through LLDP Fabric Connect TLV.
  - Creates the corresponding VLANs.
  - Re enables ISIS and log a message on the console.

*LLDP Fabric Connect TLV*

The system uses an LLDP Fabric Connect TLV to communicate B-VLANs, system IDs, Fabric Attach and EAP events between nodes in the SPB cloud.

**Table 10: LLDP Fabric Connect TLV Format**

| TLV Type | TLV Length | OUI      | Subtype | Fabric Connect Capabilities | B-VLANs Number | B-VLAN-1 | B-VLAN-2 | System ID Length | System ID |
|----------|------------|----------|---------|-----------------------------|----------------|----------|----------|------------------|-----------|
| 7 bits   | 9 bits     | 3 octets | 1 byte  | 1 byte                      | 1 byte         | 2 bytes  | 2 bytes  | 1 byte           | 6 bytes   |

**Table 11: LLDP Fabric Connect TLV Field Descriptions**

| TLV Field                 | Description  |
|---------------------------|--|
| Fabric Connect capability | Fabric Connect capability is enabled on all nodes that support Zero Touch Fabric Configuration. The value is 0 if the LLDP Fabric Connect TLV is not carrying any information in it. By default, the value is set to 1 on all ports.                           |
| B-VLANs number            | Specifies the number of B-VLANs that the TLV can carry. The LLDP Fabric Connect TLV supports an unlimited number of B-VLANs, but Zero Touch Fabric Configuration sends 2 B-VLANs through the TLV. The value is 0 if the node is sending default B-VLAN values. |
| B-VLANs                   | Specifies the B-VLAN that is user-configured or dynamically learned from a neighbor node in the network.   |
| System ID Length          | Specifies the length (in bytes) of the System ID.  |
| System ID                 | Specifies the IS-IS system ID.   |
| OUI                       | Specifies the Extreme OID value (0xd88466).  |

A Management Instance is required to provide access to specific management applications.

With Segmented Management, the Management plane (management protocols) is separated from the Control Plane (routing plane) from a process and data-path perspective. Segmented Management is the only method to manage switches. One or a combination of the following management interface/ management instance types can be used:

- Out-of-Band (OOB) management IP address (IPv4 and IPv6)
- In-band Loopback/circuitless IP (CLIP) management IP address (IPv4 and IPv6)
- In-band management VLAN IP address (IPv4 and IPv6)

#### Important

The Segmented Management Instance provides support for management interfaces that transmit and receive packets directly to and from the system native Linux IP stack. Unlike a traditional management interface, for example, a CLIP in the GRT that is part of the VOSS networking IP stack, Segmented Management Instance interfaces do not route packets through the VOSS networking IP stack.

Segmented Management provides better security because you cannot reach the management instance from outside the VRF (in case of CLIP) or outside VLAN/I-SID (in case of management VLAN), and because it has a built-in firewall for the management plane. There is also more predictability with symmetric traffic flows for management traffic originating from and terminating on the switch, for instance:

- Sessions originated from switch (client mode) - Source IP of packets is determined based on Management IP stack routing table weights (configurable).
- Sessions connecting to switch (server mode) - Source IP is derived from session connection and reply will go out on management interface packet.

## Migration to Segmented Management Instance

---

### Important

VOSS 8.2 introduced changes to Segmented Management Instance that required migration of legacy management interfaces. Before you upgrade to VOSS 8.2 or later from an earlier release, you must consider your management interface configuration and migration scenario requirements. Backup and save your configuration files off the switch before upgrading to this release.

If the switch already runs VOSS 8.2 or later, you can ignore this section. This section does not apply to VSP 8600 Series.

### Important

Management interface access to the switch can be lost if you do not perform the applicable migration scenarios before upgrading to this release. Loss of management access after an upgrade can result in an automatic roll-back to the previous software version.

You must perform a manual software commit after upgrading from VOSS Release 8.1.5.0 or earlier to VOSS 8.2 or later. Management interface access is required to input the `software commit` CLI command within 10 minutes after the upgrade. If the time expires the system initiates an automatic roll-back to the previous release.

You must ensure the switch runs VOSS 8.1.x before you upgrade to VOSS 8.2 or later to support the **migrate-to-mgmt** functionality.

### Note

If the network environment must migrate static IPv6 routes, the switches must run VOSS Release 8.1.2.0 or later before you upgrade to VOSS 8.2 or later.

Not all upgrade paths are validated by Extreme Networks for each new software release. To understand the validated upgrade paths, see [VOSS Release Notes](#).

Ensure you understand the Management Instance interface types before you begin the upgrade and migration. For more information, see [Interface Types](#) on page 68.

You must consider the following legacy management interface migration scenarios before you upgrade to VOSS 8.2 or later:

**Table 13: Management Interface Migration Scenarios**

| Mgmt Interface | Mgmt Scenario                       | Migration Description   |
|----------------|-------------------------------------|---|
| DvR leaf       | Automatic migration during upgrade. | DvR leaf settings migrate automatically during the software upgrade process. The DvR <b>inband-mgmt-ip</b> CLIP automatically becomes the new Segmented Management Instance CLIP.<br><br><b>Note:</b><br>Leaf nodes only support the management CLIP as part of the Global Routing Table (GRT). |
| OOB            | Automatic migration during upgrade. | Out-of-Band management settings migrate automatically during the software upgrade process.  |

**Table 13: Management Interface Migration Scenarios (continued)**

| Mgmt Interface | Mgmt Scenario   | Migration Description   |
|----------------|---|---|
| CLIP           | Specify a Circuitless IP (CLIP) interface for migration to management interface before you upgrade. | <p>You can use this interface type for CLIP management network routing in a Fabric network or Layer 3 routing network.</p> <p>Use the <b>migrate-to-mgmt</b> command in the Loopback Interface Configuration mode of the CLI to specify the CLIP interface for management before starting the software upgrade process.</p> <p>You can designate the IP Shortcut CLIP to migrate to the Management Instance CLIP. After the upgrade, the IS-IS source IP address moves to the Management Instance CLIP. You should configure a new GRT CLIP using a different IP address and assign that as the new IS-IS source IP.</p> <p>Save the configuration before upgrading.</p> <p><b>Important:</b><br/>Ensure that the management CLIP IP address does not fall into the range of a configured VLAN IP address range as this is not allowed.</p> |
| VLAN           | Specify a VLAN interface for migration to management interface before you upgrade.                  | <p>You can use this interface type for management of Layer 2 switches or for Zero-Touch onboarding of newly deployed devices. Use the CLIP Management Instance for routed management.</p> <p>Use the <b>migrate-to-mgmt</b> command in the VLAN Interface Configuration mode of the CLI to specify the VLAN interface for management before starting the software upgrade process.</p> <p><b>Important:</b><br/>Choose a VLAN that does not have an IP interface on it. The upgrade process removes the IP configuration and network connectivity can be impacted.</p> <p>Save the configuration before upgrading.<br/>The VLAN Management Instance does not route to or from the GRT.</p>  |

**Table 13: Management Interface Migration Scenarios (continued)**

| Mgmt Interface | Mgmt Scenario | Migration Description   |
|----------------|---------------|---|
|                |               | Bridged management traffic must ingress on the VLAN or I-SID. |

## Automatic Migration

Out-of-Band management interface and DVR leaf configurations automatically migrate during the upgrade process. The management port interface, and all associated applications are moved to the Segmented Management Instance .

A DVR leaf has a single management interface that also automatically migrates during the upgrade process to the Segmented Management Instance.

## Static Route Migration

When a VLAN designated as management interface or an Out-of-Band management interface migrates to the Segmented Management Instance, static routes might be required for IP reachability. Static routes are always required for Out-of-Band management interfaces but can also be used with in-band VLAN management.

Static route migration is completed by the upgrade process and no commands are necessary to prepare for the migration. The following logic is applied during the upgrade process to the static routes:

- Out-of-Band management interfaces
  - All IPv4 routes in the VRF 512 / mgmtrouter context are moved to the Segmented Management Instance.
  - All IPv6 routes in GRT with a nexthop IP address that exists in the same subnet as the IPv6 address are moved to the Segmented Management Instance.
- In-Band VLAN management
  - All IPv4 routes from the VRF bound to the migrated VLAN and that have a nexthop IP address in the same subnet as the IPv4 address being migrated are moved to the Segmented Management Instance.
  - All IPv6 routes from the VRF bound to the migrated VLAN and that have a nexthop IP address in the same subnet as the IPv6 address being migrated are moved to the Segmented Management Instance.

### Important

The IP interface and all routing protocols attached to the original VLAN are deleted post migration.

Consider the following example of In-Band VLAN management. The static route configuration listed below is in the GRT:

```
ip route 192.168.20.0 255.255.255.0 192.168.10.2 weight 1
ip route 192.168.30.0 255.255.0.0 192.168.10.50 weight 1
ip route 192.168.40.0 255.255.255.0 192.168.20.99 weight 1
ip route 192.168.50.0 255.255.255.0 192.168.10.2 weight 1
no ip route 192.168.50.0 255.255.255.0 192.168.10.2 enable
```

The GRT is associated with VLAN 10 with an IP address of 192.168.10.1. This is the VLAN to be migrated. After the upgrade, the 192.168.20.0, 192.168.30.0, and, 192.168.50.0 routes are migrated to the management instance because their nexthop IP address is associated with the 192.168.10.0/24 subnet.

#### Note

All routes with a nexthop IP address associated with the subnet are migrated. This includes administratively disabled routes. Administratively disabled routes must be manually deleted after the upgrade if the route is not needed.

ECMP static route migration is not supported for the Segmented Management Instance. For an ECMP static route, only the first path in the configuration file migrates.

After upgrading to VOSS Release 8.1.60 or later, any administratively disabled static routes that migrated to the OOB or VLAN Segmented Management Instance subnet become active. Administratively disabled routes must be manually deleted after the upgrade if the route is not needed.

The static route configuration in the Management VLAN configuration block will be the following after the upgrade:

```
mgmt vlan 10
ip address 192.168.10.1/24
ip route 192.168.20.0/24 next-hop 192.168.10.2
ip route 192.168.30.0/16 next-hop 192.168.10.50
ip route 192.168.50.0/24 next-hop 192.168.10.2
```

## Segmented Management Instance Migration

Beginning in VOSS 8.2, you can use the **migrate-to-mgmt** command to move a management VLAN to a different VLAN ID, or a management CLIP to a different VRF. After you complete the command and save the configuration, the migration to management of the selected interface occurs during the next switch reboot. The following is an outline of the steps required for management migration:

1. Configure a new or existing VLAN or CLIP management interface using Interface Configuration mode in the CLI (**interface vlan <vlan\_id>** or **interface loopback <clip\_id>**) or EDM.

#### Important

The IP interface and all routing protocols attached to the original VLAN are deleted post migration.

2. Add required routes to reach management services and subnets from the new interface.
3. Test connectivity to the new interface using ping and traceroute, and from the switch to management stations and servers.
4. Use the **migrate-to-mgmt** command from the new interface CLI mode.
5. Save the configuration and reboot.

#### Note

During boot, the migrate-to-mgmt settings are parsed and override the existing management interface with the new interface.

6. Access and manage the switch from the new interface.

For more information see, [Migrate a VLAN or CLIP IP address to the Segmented Management Instance](#) on page 77 (using CLI) or [Migrate an IP Address to a Segmented Management Instance](#) on page 100 (using EDM).

## XA1400 Series Management Migration with a Fabric Extend Source IP VLAN

Before VOSS Release 8.1.60, a single IP address could be used for both routing or management, however Segmented Management Instance separates the routing and management networking stacks. Because **migrate-to-mgmt** can only move an IP from the routing stack to the management stack, see the following scenario for a before and after upgrade process required to manage an XA1400 Series with the Fabric Extend (FE) tunnel Source IP using Segmented Management Instance:

Before upgrading to VOSS Release 8.1.60 or later:

1. Configure a CLIP Management Instance or designate an existing loopback IP for migration.
2. Save configuration and reboot.

After upgrading to VOSS Release 8.1.60 or later:

1. Manage the XA1400 Series using the CLIP Management Instance.
2. Create the VLAN Management Instance with the same VLAN ID and IP address as the FE tunnel source VLAN.
3. Modify the default route or create static routes to the VLAN Management Instance.
4. Manage the XA1400 Series with the VLAN or CLIP Management Instance.

## Interface Types

The Management Instance supports the following interface types:

- [CLIP](#) on page 69
- [OOB](#) on page 69
- [VLAN](#) on page 70

You can configure a maximum of three Management Instance interfaces, one of each type.

You can configure the route priority for the Segmented Management Instance. The Source IP default route priority is management CLIP (weight 100), then management VLAN (weight 200), then management OOB interface (weight 300). You can route packets through a different management interface than the default configuration, but you must add a specific static route or change the default weight of the management interface.

### Note

If you change the default route weight, the management interface with the lowest weight value becomes the default route for all segmented management interface traffic.

The VSP 8600 Series Segmented Management Instance does not support ACL based filters or use of ping with -Q option to change the internal priority of management traffic.

You can configure the default topology IP for LLDP and SONMP advertisements. Both LLDP and SONMP advertise the same topology IP. SONMP supports only IPv4 addresses. If multiple IPv4

addresses are configured on an OOB or VLAN management interface, the advertised IP priority is static IP address, then DHCP IP address, then link-local IP address.

IPSec is not supported on Segmented Management Instance management interfaces.

## CLIP

You can use this interface type for CLIP management network routing in a Fabric network or Layer 3 routing network.

### Important

A CLIP Management Instance is not a management CLIP created in the GRT. You must create the CLIP Management Instance using the Segmented Management Instance configuration.

The following list defines the abilities of this interface type:

- You can assign a circuitless management IP (CLIP) address bound to a VRF.
- You can associate only one VRF ID with a CLIP Management Instance IP address.
- The IP address is not bound to a physical network; it does not transmit nor receive IPv4 Address Resolution Protocol (ARP) or IPv6 Neighbor Discovery (ND) messages.
- You do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the associated VRF.
- Packets can ingress on any port or VLAN that belongs to the VRF associated with the CLIP Management Instance.
- You must configure accept policies or configure inter-VRF route redistribution to access the CLIP Management Instance from a different VRF. Inter-VRF access is not permitted with traditional IP routing using OSPF, BGP, or RIP. Packets ingressing the switch from a VLAN that belongs to a different VRF without a configured accept policy will not reach the CLIP Management Instance IP address. For more information, see [Redistribution of CLIP Segmented Management Instance Examples](#) on page 97.
- If you migrate the current IS-IS IP source address to the CLIP Management Instance, after the upgrade the IS-IS source IP address moves to the CLIP Management Instance. You must configure a new GRT CLIP using a different IP address and assign that as the new IS-IS source IP.
- Advertisement of the IPv4 or IPv6 address for the CLIP Management Instance to IS-IS in the GRT occurs automatically. Advertisement of the IPv4 or IPv6 address in the VRF Layer 3 VSN bound to the CLIP Management Instance occurs automatically. You must configure route redistribution to advertise the CLIP Management Instance to different protocols. For more information, see [Redistribution of CLIP Segmented Management Instance Examples](#) on page 97.

## OOB

You can use this interface type for OOB management network routing, as an alternative to in-band network routing management.

### Note

The OOB Segmented Management Instance is not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

The following list defines the abilities of this interface type:

- You can assign a management IP address bound to the Out-of-Band (OOB) interface.
- You can associate only one OOB interface with an OOB Management Instance IP address.
- The Dynamic Host Configuration Protocol (DHCP) Client can request an IPv4 address for the OOB Management Instance interface.
- You must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.
- You can configure only Layer 3 networking parameters in the Management Instance Configuration mode (**mgmt OOB**) in CLI.
- You can configure only Layer 1 and Layer 2 networking parameters in the mgmtEthernet Interface Configuration mode (**interface mgmtEthernet mgmt**) in CLI.

## VLAN

You can use this interface type for management of Layer 2 switches or for Zero-Touch onboarding of newly deployed devices.

For more information on Zero-Touch onboarding, see [Zero Touch Capabilities](#) on page 15.

### Note

The VLAN Segmented Management Instance is not supported on VSP 8600 Series.

The following list defines the abilities of this interface type:

- You can assign a Management Instance IP address to an inband VLAN.
- You can associate only one VLAN ID with a VLAN Management Instance IP address.
- The DHCP Client can request an IPv4 address for the VLAN Management Instance interface.
- The interface resides on the physical VLAN segment, behaving as a host for sending and receiving IPv4 ARP and IPv6 ND messages.
- You must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link (other subnets) networks.
- For the VLAN Management Instance to take route priority when used in conjunction with the CLIP Management Instance, you must configure a default route for the VLAN Management Instance with a value lower than 100, or configure static routes for direct communication over the VLAN Management Instance and management networks.
- No internal routing occurs between the VLAN Management Instance and other non Management Instance VLANs. The VLAN Management Instance does not route to or from the GRT. Packets must ingress on one of the ports in the VLAN Management Instance.

Packets sent to the VLAN Management Instance IP address must ingress the switch from a VLAN or NNI port (or contain the VLAN ID) associated with the VLAN Management Instance. The system does not route packets between the VOSS routing VLAN and the VLAN Management Instance.

If you configure the same VLAN ID for VOSS routing and for the VLAN Management Instance, the VOSS routing stack transmits and receives all ARP, ND, and ICMP packets. In this scenario, the packets are only counted and shown in the VOSS routing KHI port statistics. The management statistics and KHI management statistics do not count or show the packets.

- You can bind the VLAN Management Instance to an I-SID, which bridges all management traffic to a single I-SID in a Fabric network. Also, other normal VLAN related operations such as VLAN port member changes are valid.
- Bridged management traffic must ingress on the VLAN or I-SID.
- The VLAN Management Instance can be routed by upstream routers.

### *Co-Existence Restrictions*

IPv4 and IPv6 address co-existence for both a VOSS routing VLAN and VLAN Management Instance is supported, however you must manually match both IP address configurations between the VLANs.

If you configure the VLAN Management Instance with a manual IPv4 address and a DHCP IPv4 address first, you cannot add a IPv4 address to a VOSS routing VLAN.

If you configure the VLAN Management Instance with an IPv6 address first, you can only add one IPv6 global address to a VOSS routing VLAN.

The following restrictions apply when a VLAN Management Instance coexists with a port-based VLAN or with a brouter port:

- If you want a dual stack IPv4 and IPv6 coexistence between a VOSS VLAN and VLAN Management Instance, you must configure the same IPv4 and IPv6 addresses on the VLAN Management Instance and on the VOSS VLAN.

You cannot configure the VLAN Management Instance with both IPv4 and IPv6 and configure the VOSS VLAN with IPv4 or IPv6 only.

- If you disable VOSS routing for IPv4, then you must disable routing for IPv6, and vice versa.

### *Configuration Example - Coexistence with Port-Based VLAN*

The following example shows how the VLAN Management Instance can be configured to share the same IP address as a routing port-based VLAN.

You can configure the VOSS VLAN first and then configure the VLAN Management Instance or vice versa. You can remove or add the coexistence at anytime.

#### **Note**

With the coexistence between VOSS routing stack and the VLAN Management Instance, packets sent to the VLAN Management Instance IP address must ingress the switch from a VLAN port (or contain the VLAN ID) associated with the VLAN Management Instance. The system does not route packets between the VOSS routing VLAN and the VLAN Management Instance.

#### **IPv4**

```
vlan create 10 type port-mstprstp 0
vlan members add 10 1/1
interface vlan 10
ip address 192.0.2.0/24
exit
mgmt vlan 10
ip address 192.0.2.0/24
ip route 0.0.0.0/0 next-hop 192.0.2.1
enable
```

**IPv6**

```

vlan create 10 type port-mstprstp 0
vlan members add 10 1/1
interface vlan 10
ipv6 interface address 2001:DB8::/32
ipv6 interface enable
exit
mgmt vlan 10
ipv6 address 2001:DB8::/32
ipv6 route 0::0/0 next-hop 2001::1
enable

```

*Configuration Example - Coexistence with Port-Based VLAN Zero Touch Deployment*

For XA1400 Series branch deployments, the VOSS routing IP stack requires the VLAN Management Instance to work in coexistence mode where both the management IP stack and the routing IP stack share the same IP address and default routes. This configuration is required if you need to use the management IP as IPsec source address.

You can manually configure the coexistence as in the preceding example, or you can use the **propagate-to-routing** command to propagate the management VLAN IP and static routes from the management IP stack to the VOSS routing IP stack on the same VLAN ID. If you do not include the VRF name, the system uses the existing VRF of the VOSS routing VLAN.

**IPv4**

```

mgmt vlan 10
enable
exit
mgmt dhcp-client vlan
mgmt vlan
propagate-to-routing vrf vrf24

```

*Configuration Example - Coexistence with Brouter Port*

The following example shows how the VLAN Management Instance can be configured to share the same IP address as a brouter interface.

You must configure the brouter interface before you enable the VLAN Management Instance. When the VLAN Management Instance is enabled, you must disable the VLAN Management Instance before you disable the brouter port.

**IPv4**

```

interface GigabitEthernet 1/1
no shutdown
brouter port 1/1 vlan 10 subnet 192.0.2.0/24
mgmt vlan 10
ip address 192.0.2.0/24
enable

```

**IPv6**

```

interface GigabitEthernet 1/1
no shutdown
ipv6 interface vlan 10
ipv6 interface address 2001:DB8::/32
ipv6 interface enable
mgmt vlan 10

```

```
ipv6 address 2001:DB8::/32
enable
```

## Management Applications

The Segmented Management Instance provides support for management interfaces that transmit and receive packets directly to and from the system native Linux IP stack. Unlike a traditional management interface, for example, a CLIP in the GRT that is part of the VOSS networking IP stack, Segmented Management Instance interfaces do not route packets through the VOSS networking IP stack.

The following management applications use the Segmented Management Instance directly to transmit or receive packets with segmented management interfaces and addresses.

### Note

The VSP 8600 Series only supports Ping, Traceroute, and NTPv4.

| Segmented Management Instance Applications and Protocols          | Client         | Server | IPv4 | IPv6 |
|---|----------------|--------|------|------|
| Digital Certificates  | Yes            |        | Yes  |      |
| DHCP Client   | Yes            |        | Yes  |      |
| DNS   | Yes            |        | Yes  | Yes  |
| FTP   | Yes            | Yes    | Yes  | Yes  |
| HTTP/HTTPS  |                | Yes    | Yes  | Yes  |
| IQAgent   | Yes            |        | Yes  |      |
| NTPv4   | Yes            | Yes    | Yes  | Yes  |
| OVSDB protocol support for VXLAN Gateway                          | Yes            | Yes    | Yes  |      |
| Ping  | Yes            | Yes    | Yes  | Yes  |
| RADIUS  | Yes            |        | Yes  | Yes  |
| RADIUS Security (RADSec)  | Yes            |        | Yes  | Yes  |
| Representational State Transfer Configuration Protocol (RESTCONF) |                | Yes    | Yes  |      |
| SSH/SCP/SFTP  | Yes (SSH only) | Yes    | Yes  | Yes  |
| Syslog  | Yes            |        | Yes  | Yes  |
| TACACS+   | Yes            |        | Yes  |      |
| Telnet  | Yes            | Yes    | Yes  | Yes  |

| Segmented Management Instance Applications and Protocols | Client | Server | IPv4 | IPv6 |
|--|--------|--------|------|------|
| TFTP   | Yes    | Yes    | Yes  | Yes  |
| Traceroute   | Yes    | Yes    | Yes  | Yes  |

The following management applications do not use the Segmented Management Instance directly to transmit or receive packets, but can integrate with segmented management interfaces and addresses.

| Applications and Protocols                    | IPv4 | IPv6 |
|---|------|------|
| Link Layer Discovery Protocol (LLDP)          | Yes  | Yes  |
| SynOptics Network Management Protocol (SONMP) | Yes  |      |
| Sampled Flow (sFlow)                          | Yes  |      |
| Remote Network Monitoring version 2 (RMON2)   | Yes  |      |

#### Note

The following management applications do not use the Segmented Management Instance and are deprecated in VOSS.

- NTPv3
- Remote Login (rlogin)
- Remote Shell (RSH)

## Operational Notes for UDP Management Applications

Management applications that use UDP, such as TFTP, RADIUS dynamic server, or SNMP can have restrictions when multiple Segmented Management Instances are configured with overlapping or asymmetrical routing.

#### Note

The restrictions listed do not apply to TCP applications or if a single Management Instance is configured.

Asymmetrical routing can occur in any of the following scenarios. For the first two scenarios you can use the OOB or VLAN Management Instance IP address instead of the CLIP Management Instance IP address. Also, use FTP or SCP file transfer as an alternative because those protocols are TCP based.

In the third scenario, you can configure more specific static routes for networks originating UDP client communication to the OOB or VLAN Management Instance IP address if the CLIP Management Instance is also configured.

1. Client communication to the CLIP Management Instance IP address is from the same subnet as the VLAN Management Instance.
2. Client communication to the CLIP Management Instance IP address when specific static routes or default route with higher preference back to the client network exist on OOB Management Instance or VLAN Management Instance.
3. Client communication to the OOB Management Instance IP address or VLAN Management Instance IP address that relies on a default route with a lower preference than the internal default route used by the CLIP Management Instance.
4. Client communication to the CLIP Management Instance IP address is from the same subnet as the OOB Management Instance (even if the OOB port is down).

## DHCP Client for Segmented Management Instance

---

To support Zero Touch Deployment, a DHCP Client is used for the Segmented Management Instance VLAN management interface or Out-of-Band (OOB) management interface. The DHCP Client configuration supports a VLAN mode, OOB mode, and a cycle mode. DHCP Client cycle mode alternates IP address requests between the VLAN management interface and OOB management interface until an IP address is obtained on one of the interfaces. Priority is given to the OOB management interface.

You can also manually configure the DHCP Client to request an IPv4 address from a DHCP server for the In-band VLAN management interface, or the OOB management interface, or to cycle requests until an IP address is obtained on a VLAN or OOB management interface. The DHCP Client supports IPv4 addresses only, and cannot be enabled on multiple management interfaces simultaneously.

### Note

If a default route is configured on an OOB or VLAN management interface, and then you configure DHCP so that it replaces the default route, the original default route is restored if you disable DHCP.

However, if the DHCP default route is updated or deleted after it is created by DHCP, the default route will not be replaced by the original route when DHCP is disabled.

## DHCP Client Restrictions

DHCP Client for the Segmented Management Instance supports IPv4 addresses only, and cannot be enabled on multiple management interfaces simultaneously. The DHCP Client only supports the in-band

VLAN management interface, or the OOB management interface, or to cycle requests on the the VLAN then OOB management interface until an IP address is obtained on one of the interfaces.

#### Note

The DHCP Client is disabled by default on previously configured or upgraded switches.

The DHCP Client is enabled by default in cycle mode when:

- The switch ships directly from manufacturing with VOSS Release 8.1.60 or later.

The primary and secondary configuration file is not on the switch.

The primary and secondary configuration file fail to load on the switch.

The DHCP Client is not available if RMON2 is configured on a Management Instance, and RMON2 is not available if the DHCP Client is configured on a Management Instance.

When DHCP is enabled on a Management Instance interface, the DHCP Client initial broadcast discovery packet and initial response from the DHCP server are not counted or shown in KHI management statistics for the management interface. Only the packets after the DHCP IP address assignment completes are counted and shown. After an IP address is assigned, a UDP socket opens and packets are counted on the interface.

If you change the DHCP Client configuration between management VLAN, OOB, or cycle, the default route provided by the DHCP server might delete and add with a different nexthop or network. DHCP Client configuration changes can cause interruptions to existing management connections.

DHCP static routes are not saved in the configuration file or displayed in **show running-config**. You can view DHCP static routes with **show mgmt ip route static**. If the DHCP Client adds a default route to an interface, the previous default route is deleted. If you modify a default route created by the DHCP Client, the route type output of **show mgmt ip route static** changes from DHCP to STATIC. You can save the modified to static default route to the configuration file, but on reboot the DHCP Client deletes the modified default route and restores the default static route the DHCP server specifies.

## DHCP Option 43

DHCP option 43 requests specific vendor options from the DHCP server. Only sub-option 226 (EXTREME.cloudiq-ip) is supported to change the value of the ExtremeCloud IQ server IP address on the switch.

With the support of DHCP option 43, DHCP can dynamically configure the IP address of a private/non-public ExtremeCloud IQ server for zero touch deployments when the default ExtremeCloud IQ server (hac.extremecloudiq.com) is not desired.

For information about configuring the switch to support ExtremeCloud IQ, see [ExtremeCloud IQ Agent](#) on page 835.

## DHCP Option 43 Configuration Examples

This section provides examples to configure DHCP Option 43 on a Linux server and on Windows Server.

ISC DHCP Server configuration on Linux:

```
/etc/dhcp/dhcpd.conf
default-lease-time 60;
max-lease-time 7200;
option space EXTREME;
option EXTREME.cloudiq-ip code 226 = ip-address;

class "Edge-without-POE" {
    match if (option vendor-class-identifier = "EXTREME");
    vendor-option-space EXTREME;
    option EXTREME.cloudiq-ip 10.16.231.131;
}

subnet 30.30.30.0 netmask 255.255.255.0 {
    pool {
        range 30.30.30.10 30.30.30.20;
        allow members of "Edge-without-POE";
    }
    option domain-name-servers 10.1.10.1;
    option domain-name "labs.extremenetworks.com";
    option routers 30.30.30.250;
    default-lease-time 3600;
}
```

Windows Server configuration:

1. Go to scope options for defined DHCP pool.
2. Enter the following for Option 43: e2 04 0a 10 e7 83

| Value       | Description  |
|-------------|--|
| e2 04       | vendor ID prefix (e2 is the hexadecimal value of the code 226 used to identify sub-option EXTREME.cloudiq-ip and 04 the hexadecimal value of the length of an IP address in bytes) |
| 0a 10 e7 83 | IP address 10.16.231.131 converted to hexadecimal  |

## Segmented Management Instance Configuration using the CLI

This section provides procedures to configure segmented management instance using the command line interface (CLI).

### Migrate a VLAN or CLIP IP address to the Segmented Management Instance

Use this procedure to designate an existing VLAN or loopback IP address to the Segmented Management Instance during an upgrade. This action moves the IP interface from the VOSS routing stack to the management stack to use with management applications.

#### Important

Choose a VLAN that does not have an IP interface on it. The upgrade process removes the IP configuration and network connectivity will be impacted.

### About This Task

**Note**

Do not migrate interfaces used for routing purposes, for example, where you configure Layer 3 routing protocols.

This command does not apply to the OOB or mgmtEthernet interface. Releases that support this migration procedure automatically move the IP address on the mgmtEthernet interface from the routing stack to the Segmented Management Instance during the upgrade to this release.

### Procedure

1. Enter Interface Configuration mode for either a VLAN or loopback interface:
 

```
enable

configure terminal

interface vlan <1-4059> or interface loopback <1-256>
```
2. Select the interface address for migration:
 

```
migrate-to-mgmt
```
3. View the designated interface addresses selected for migration:
 

```
show mgmt migration
```
4. Save the configuration selected for migration:
 

```
save config
```

### Example

Identify an IP address currently assigned to an inband VLAN to migrate to the Management VLAN. The example assumes you already identified a CLIP address. The VRF column in **show mgmt migration** indicates where the interface is being moved from.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 20
Switch:1(config-if)#migrate-to-mgmt
Switch:1(config-if)#show mgmt migration

=====

## Configure a Segmented Management Instance Using quick-config-mgmt Utility

Use the following procedure to run the quick-config-mgmt utility script to ease the transition to the Segmented Management Instance.

**Note**

XA1400 Series does not support the OOB Management Instance.

**Note**

Product Notice: quick-config-mgmt is not supported on VSP 8600 Series.

The quick-config-mgmt utility recognizes existing configuration. For the OOB Management Instance, you can overwrite the existing configuration only. However, for the VLAN Management Instance, you can overwrite the existing configuration, or you can migrate the existing configuration to a coexistence of IP on both VOSS VLAN and management VLAN.

The quick-config-mgmt utility supports the following:

- IPv4 only
- only one interface at one time
- Out-of-Band management and In-Band VLAN management

### About This Task

You can use this procedure to help you transition to a new Segmented Management Instance. You can configure IPv4, static routes, and DHCP support for the Out-of-Band (OOB) Management Instance or for the In-Band VLAN Management Instance. If configuration exists for the interface type you selected, you are prompted to replace the configured interface or to quit the utility.

**Important**

If you configure DHCP, any other running DHCP instance is stopped and a new DHCP instance is created on the interface. This might cause loss of connectivity.

The default values are given in square brackets. You can input your values at the prompt or you can press `Enter` to accept the default values.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enter the following command to start the utility:  
`quick-config-mgmt`

**Important**

If DHCP mode cycle is enabled, the following warning message displays to inform you that DHCP client will be disabled, if you continue.

```
Continuing will disable dhcp and may affect your connectivity  
to the DUT. Do you want to continue? y/n [n]:
```

### Examples

The following examples show outputs from the **quick-config-mgmt** utility.

Configure the OOB Management Instance:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]:
Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully
```

Replace an existing OOB Management Instance configuration:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]:
MGMT OOB is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [y]:
Please enter management interface type or "q" to quit. [1]:
Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully
```

Configure the In-band port-based VLAN Management Instance by removing parts of or all of the existing VLAN configuration:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
```

```

Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]: 3
MGMT VLAN is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [n]: y
Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
VLAN 2 is already in use.
Do you want to re-use existing vlan configuration? y/n/q: [n]
This option will remove all current config on VLAN 2.
Please enter port to be added to the in-band management VLAN or "q" to quit [1/1]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully

```

Configure the In-band port-based VLAN Management Instance by reusing the existing VLAN configuration:

```

Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]: 3
MGMT VLAN is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [n]: y
Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
VLAN 2 is already in use.
Do you want to re-use existing vlan configuration? y/n/q: [y]
Please enter port to be appended to the in-band management VLAN or leave empty
to keep currently configured ports or "q" to quit []: 1/1
Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully

```

Configure the In-band port-based VLAN Management Instance by reusing the existing VLAN configuration when IP address is configured and coexistence of mgmt and routing on same VLAN is desired:

```

Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
  1 - Out of band management port

```

```

    3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]: 3
MGMT VLAN is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [n]: y
Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
VLAN 2 is already in use.
Do you want to re-use existing vlan configuration? y/n/q: [y]
Please enter port to be appended to the in-band management VLAN or leave empty
to keep currently configured ports or "q" to quit []: 1/1
IP address is already configured on VLAN 2.
Do you want to configure co-existence of mgmt and routing on the same vlan? y/n/q: [y]
Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully

```

Configure the In-band port-based VLAN Management Instance by reusing the existing VLAN configuration when IP address is configured but coexistence of mgmt and routing on same VLAN is not desired:

```

Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
    1 - Out of band management port
    3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]: 3
MGMT VLAN is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [n]: y
Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
VLAN 2 is already in use.
Do you want to re-use existing vlan configuration? y/n/q: [y]
Please enter port to be appended to the in-band management VLAN or leave empty
to keep currently configured ports or "q" to quit []: 1/1
IP address is already configured on VLAN 2.
Do you want to configure co-existence of mgmt and routing on the same vlan? y/n/q: [n]
Management interface created successfully

```

## Create a Segmented Management Instance

You must create a Management Instance to gain access to specific management applications. After you create the Management Instance, you can add an IP address to it and configure route redistribution to advertise reachability of the Management Instance to the rest of the network.

### About This Task

The Management Instance supports different management interface types. When you create the Management Instance, you specify the interface type and the switch automatically creates the appropriate instance ID for that type.

A management VLAN is used for Layer 2 deployments. In a Layer 3 routing or Fabric deployment, use a management CLIP. For Out-of-band Management, use a management OOB.

Each Management Instance supports a IPv4 and IPv6 (global scope) management address for use by management applications.

### Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Create the Management Instance required for your deployment:
  - a. To create a management CLIP:

```
mgmt clip [vrf WORD<1-16>]
```

#### Note

If you do not specify a VRF, the management CLIP uses the GRT. You cannot use mgmtrouter as the VRF.

OR

- b. To create a management OOB:

```
mgmt oob
```

OR

- c. To create a management VLAN and associate it with an existing port-based VLAN:

```
mgmt vlan <2-4059>
```

3. Enable the Management Instance:

```
enable
```

### Example

Create and enable a Management CLIP:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:clip)#enable
```

Create and enable a Management OOB:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt oob
Switch:1(mgmt:oob)#enable
```

Create and enable a Management VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Switch:1(config)#mgmt vlan 20
Switch:1(mgmt:vlan)#enable
```

## Delete a Segmented Management Instance

Use this task to delete a Management Instance. Deleting the Management Instance removes the IP address, and changes the associated VRF for a management CLIP.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Delete the Management Instance:  
`no mgmt {clip | oob | vlan}`

## Configure the DHCP Client for a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure the DHCP Client to obtain an IPv4 address for the Management Instance VLAN interface or Out-of-Band interface.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable and configure the DHCP Client for a management interface:  
`mgmt dhcp-client {cycle | oob | vlan}`

### Example

The following example configures the DHCP Client to cycle IPv4 requests for the management OOB interface, and then the In-Band management VLAN interface; priority is given to the OOB interface. The system cycles attempts until one management interface receives an IP address from the DHCP server:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt dhcp-client cycle
```

*Variable Definitions*

The following table defines parameters for the **mgmt dhcp-client** command.

| Variable     | Value  |
|--------------|--|
| <i>cycle</i> | DHCP Client cycles IP requests for in-band VLAN and Out-of-Band management interfaces. |
| <i>oob</i>   | DHCP Client requests an IP address for the Out-of-Band management interface.           |
| <i>vlan</i>  | DHCP Client requests an IP address for the VLAN management interface.                  |

## Configure an IP Address for a Segmented Management Instance

Use this task to add an IPv4 or IPv6 address to a Management Instance.

### Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.
- If the DHCP client is configured for a Segmented Management Instance, you must manually disable the client. Configuring an IP address does not automatically disable the DHCP client.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enter the configuration mode for the Management Instance:
 

```
mgmt {clip | oob | vlan}
```
3. Add an IPv4 address:
 

```
ip address {A.B.C.D [A.B.C.D] | A.B.C.D/X}
```
4. Add an IPv6 address:
 

```
ipv6 address WORD<0-255>
```

### Example

Add an IPv4 address to the VLAN Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#ip address 192.0.2.12/24
```

Add an IPv4 address to the OOB Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt oob
Switch:1(mgmt:oob)#ip address 192.0.2.12 255.255.255.0
```

Add an IPv6 address to the CLIP Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:clip)#ipv6 address 2001:DB8::1/128
```

## Configure a Segmented Management Instance Interface as Default Topology IP

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure a Management Instance with a default topology IP.

### Note

You can only configure one Management Instance interface as the default topology IP.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enter the configuration mode for the Management Instance:  
`mgmt {clip | oob | vlan}`
3. Configure the Management Instance as the default topology IP.  
`force-topology-ip`

### Example

The following example configures the Segmented Management Instance VLAN as the default topology IP:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#force-topology-ip
```

## Configure Static Routes for a Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure static routes for Management Instances.

### About This Task

For the Management Instance CLIP, you do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the VRF. For more information about

how to associate a VRF with the CLIP interface, see [Create a Segmented Management Instance](#) on page 82.

For the Management Instance OOB and VLAN, you must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.

You can configure up to 100 IPv4 and IPv6 static routes.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter the configuration mode for the Management Instance:

```
mgmt {clip | oob | vlan}
```

3. Configure a static route:

```
ip route <A.B.C.D A.B.C.D | A.B.C.D/X> next-hop <A.B.C.D> [weight <1-65535>]
```

OR

```
ipv6 route WORD<0-255> [next-hop WORD<0-255>] [weight <1-65535>]
```

### Example

Add a static route to configure routing for a Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#ip route 192.0.2.2/24 next-hop 198.51.100.1
```

### Variable definitions

The following table defines parameters for the **ip route** and **ipv6 route** commands.

| Variable                                      | Value   |
|---|---|
| <A.B.C.D A.B.C.D   A.B.C.D/X>                 | Specifies the IP address and mask in one of the following formats: <ul style="list-style-type: none"> <li>• A.B.C.D A.B.C.D</li> <li>• A.B.C.D/X</li> </ul> |
| next-hop <A.B.C.D><br>Or next-hop WORD<0-255> | Specifies the next hop address for the static route.<br>Use an IP in the same subnet as the management VLAN IP address.                                     |

| Variable                            | Value   |
|-------------------------------------|---|
| <code>weight &lt;1-65535&gt;</code> | Specifies the static route cost. The default is 100 for CLIP, 200 for VLAN, and 300 for OOB.<br>The management CLIP uses an internal static route with a weight of 100. If you use both CLIP and VLAN and need to force all default traffic out the management VLAN interface, configure a default static route with a weight lower than 100. |
| <code>WORD&lt;0-255&gt;</code>      | Specifies the IPv6 address.   |

## Configure MAC-offset for a Management VLAN Instance

Use this task to configure MAC-offset for a Management VLAN instance.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enter the MAC-offset for a Management VLAN instance:  

```
mgmt vlan mac-offset <MAC-offset>
```

#### Note

Different hardware platforms support different ranges.

### Example

Configure the MAC-offset for the Management VLAN instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#mac-offset <0-511>
```

### Variable Definitions

The following table defines parameters for the `mgmt vlan` interface.

| Variable   | Value  |
|--|--|
| <code>mac-offset</code><br><code>&lt;MAC-offset&gt;</code> | Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help. |

## Configure Management VLAN and VOSS Routing VLAN Coexistence Through Propagation

### Note

This procedure only applies to XA1400 Series.

For XA1400 Series branch deployments, the VOSS routing IP stack requires the VLAN Management Instance to work in coexistence mode where both the management IP stack and the routing IP stack share the same IP address and default routes. This is required for an IPsec source address.

### About This Task

You can manually configure the coexistence or you can use the **propagate-to-routing** command to propagate the management VLAN IP and static routes from the management IP stack to the VOSS routing IP stack on the same VLAN ID. If you do not include the VRF name, the system uses the existing VRF of the VOSS routing VLAN.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enter the configuration mode for the Management Instance VLAN:  

```
mgmt vlan
```
3. Configure the coexistence:  

```
propagate-to-routing [vrf WORD<0-16>]
```

## View Segmented Management Instance Information

Use this task to view Management Instance information.

### Procedure

1. To enter User EXEC mode, log on to the switch.
  2. View general configuration information:  

```
show mgmt interface [clip | oob | vlan]
```
  3. View operational routes for the Management Instance:  

```
show mgmt ip route [clip | oob | vlan]
```
- OR
- ```
show mgmt ipv6 route [clip | oob | vlan]
```

### Note

Routes with a type of LOCAL have a metric equal to 1.

4. View configured static routes for the Management Instance:  
`show mgmt ip route static [vlan | oob | clip]`

OR

`show mgmt ipv6 route static [vlan | oob | clip]`

#### Note

Routes with a type of LOCAL have a metric equal to 256.

5. View the ARP or Neighbor Discovery cache information for the Management Instance:

`show mgmt ip arp [clip | oob | vlan]`

OR

`show mgmt ipv6 neighbor [clip | oob | vlan]`

### Example

```
Switch:1>show mgmt interface vlan
```

#### Mgmt Interface Information

| INST | DESCR     | TYPE | ADMIN  | VLAN | PORT | VRF | PHYSICAL    |
|------|-----------|------|--------|------|------|-----|-------------|
| 4    | Mgmt-vlan | VLAN | enable | 2    | -    |     | 192.0.2.188 |

1 out of 1 Total Num of mgmt interfaces displayed

```
Switch:1>show mgmt ip route
```

#### Mgmt IPv4 Route Information - Table main

| DEST/MASK      | NEXTHOP | METRIC | INTERFACE | TYPE     |
|----------------|---------|--------|-----------|----------|
| 0.0.0.0/0      | 0.0.0.0 | 100    | Mgmt-clip | INTERNAL |
| 0.0.0.0/0      | 0.0.0.0 | 300    | Mgmt-oob1 | DHCP     |
| 192.0.2.189/24 | 0.0.0.0 | 256    | Mgmt-vlan | LOCAL    |

2 out of 2 Total Num of mgmt ip route displayed

```
Switch:1>show mgmt ip route static
```

#### Mgmt IPv4 Static Route Information - Table main

| INTERFACE | DEST/MASK       | NEXTHOP   | METRIC | STATE  | TYPE   |
|-----------|-----------------|-----------|--------|--------|--------|
| Mgmt-vlan | 192.0.2.1/24    | 10.0.0.30 | 200    | ACTIVE | STATIC |
| Mgmt-vlan | 198.51.100.5/24 | 10.0.0.40 | 200    | ACTIVE | STATIC |
| Mgmt-oob1 | 0.0.0.0/0       | 192.0.2.5 | 300    | ACTIVE | DHCP   |

```
Switch:1>show mgmt ipv6 route static
```

#### Mgmt IPv6 Static Route Information - Table main

| INTERFACE | DEST/MASK           | NEXTHOP           | METRIC | STATE  |

## View IP Address Information for a Segmented Management Instance

Use this task to view the IP address information for a Management Instance.

### Procedure

- To enter User EXEC mode, log on to the switch.
- View Segmented Management Instance IP address information:  

```
show mgmt ip [<clip | oob | vlan>]
```

OR

```
show mgmt ipv6 [<clip | oob | vlan>]
```
- View Segmented Management Instance topology IP address information:  

```
show mgmt topology-ip
```

### Example

```
Switch:1>#show mgmt ip vlan
```

```

=====
Mgmt IP Information
=====
INST  DESCR  IPV4  IPV6 GLOBAL/PREFIX LENGTH  IPV6 LINKLOCAL
-----
4     Mgmt-vlan  192.0.2.12/24  0:0:0:0:0:0:0:0/0  0:0:0:0:0:0:0:0

```

```
1 out of 1 Total Num of mgmt ip displayed
```

```
Switch:1>)#show mgmt topology-ip
```

```

=====
Mgmt Topology IP Information
=====

```

```
IPv4:
  Address: 192.0.2.10
  Instance: 1
  Description: oob1
```

```
IPv6:
  No address to display
```

```
Force-topology-ip setting: none
```

## View Segmented Management Instance Statistics

Use this task to view Management Instance statistics.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View general Segmented Management Instance statistics:

```
show mgmt statistics [clip | oob | vlan]
```

3. View ICMP statistics for the Management Instance:

#### Note

This step does not apply to VSP 8600 Series.

```
show mgmt ip icmp-statistics
```

OR

```
show mgmt ipv6 icmp-statistics
```

4. View IP statistics for the Management Instance:

#### Note

This step does not apply to VSP 8600 Series.

```
show mgmt ip ip-statistics
```

OR

```
show mgmt ipv6 ip-statistics
```

5. View the TCP connections for the Management Instance:

#### Note

This step does not apply to VSP 8600 Series.

```
show mgmt ip tcp-connections
```

OR

```
show mgmt ipv6 tcp-connections
```

6. View the TCP statistics for the Management Instance:

**Note**

This step does not apply to VSP 8600 Series.

```
show mgmt ip tcp-statistics
```

OR

```
show mgmt ipv6 tcp-statistics
```

7. View the UDP endpoints for the Management Instance:

**Note**

This step does not apply to VSP 8600 Series.

```
show mgmt ip udp-endpoints
```

OR

```
show mgmt ipv6 udp-endpoints
```

8. View the UDP statistics for the Management Instance:

**Note**

This step does not apply to VSP 8600 Series.

```
show mgmt ip udp-statistics
```

OR

```
show mgmt ipv6 udp-statistics
```

9. Enter Privileged EXEC mode:

```
enable
```

10. (Optional) Clear all of the statistics for the Management Instance:

```
clear mgmt statistics
```

### Examples

```
Switch:1>show mgmt statistics
```

```

## Redistribution of CLIP Segmented Management Instance Examples

The CLIP Management Instance is added as a LOCAL route in the Control Processor Route Table Manager table and change list infrastructure. Existing route redistribution mechanisms redistribute local routes into the desired routing protocols within the associated VRF or across VRF instances.

### *Redistribute IPv4 CLIP Management Instance to OSPF in GRT*

```

router ospf
 redistribute direct
 redistribute direct enable
 exit
 ip ospf apply redistribute direct

```

### *Redistribute IPv6 CLIP Management Instance to OSPF in GRT*

```

router ospf
 ipv6 redistribute direct
 ipv6 redistribute direct enable
 ipv6 ospf apply redistribute direct

```

*Redistribute IPv4 CLIP Management Instance to OSPF in VRF*

```
router vrf red
ip ospf redistribute direct
ip ospf redistribute direct enable
exit
ip ospf apply redistribute direct vrf red
```

*Redistribute IPv6 CLIP Management Instance to OSPF in VRF*

```
router vrf red
ipv6 ospf redistribute direct
ipv6 ospf redistribute direct enable
exit
ipv6 ospf apply redistribute direct vrf red
```

*Redistribute IPv4 CLIP Management Instance to BGP in GRT*

```
router bgp
redistribute direct
redistribute direct enable
ip bgp apply redistribute direct
```

*Redistribute IPv6 CLIP Management Instance to BGP in GRT*

```
router vrf
redistribute ipv6-direct
redistribute ipv6-direct enable
ipv6 bgp apply redistribute direct
```

*Redistribute IPv4 CLIP Management Instance to BGP in VRF*

```
router vrf red
ip bgp redistribute direct
ip bgp redistribute direct enable
exit
ip bgp apply redistribute direct vrf red
```

*Redistribute IPv6 CLIP Management Instance to BGP in VRF*

```
router vrf red
ip bgp redistribute ipv6-direct
ip bgp redistribute ipv6-direct enable
exit
ipv6 bgp apply redistribute direct vrf red
```

*Accept Policy for IPv4 CLIP Management Instance in GRT to VRF Red (I-SID 200)*

```
#grt-->vrf
router vrf red
isis accept i-sid 0
isis accept i-sid 0 enable
isis redistribute direct
isis redistribute direct enable
exit
isis apply accept vrf red
isis apply redistribute direct vrf red

#vrf-->grt
router isis
accept i-sid 200
accept i-sid 200 enable
```

```
exit
isis apply accept
```

*Accept Policy for IPv6 CLIP Management Instance in GRT to VRF Red (I-SID 200)*

```
#grt-->vrf
router vrf red
ipv6 isis accept i-sid 0
ipv6 isis accept i-sid 0 enable
ipv6 isis redistribute direct
ipv6 isis redistribute direct enable
exit
ipv6 isis apply accept vrf red
ipv6 isis apply redistribute direct vrf red

#vrf-->grt
router isis
ipv6 accept i-sid 200
ipv6 accept i-sid 200 enable
exit
ipv6 isis apply accept
```

*Accept Policy for IPv4 CLIP Management Instance in VRF Blue (I-SID 300) to GRT*

```
#vrf --> grt
router isis
accept i-sid 300
accept i-sid 300 enable
redistribute direct
redistribute direct enable
exit
isis apply accept
isis apply redistribute direct

#grt --> vrf
router vrf blue
isis accept i-sid 0
isis accept i-sid 0 enable
exit
isis apply accept vrf blue
```

*Accept Policy for IPv6 CLIP Management Instance in VRF Blue (I-SID 300) to GRT*

```
#vrf --> grt
router isis
ipv6 accept i-sid 300
ipv6 accept i-sid 300 enable
ipv6 redistribute direct
ipv6 redistribute direct enable
exit
ipv6 isis apply accept
ipv6 isis apply redistribute direct

#grt --> vrf
router vrf blue
ipv6 isis accept i-sid 0
ipv6 isis accept i-sid 0 enable
exit
ipv6 isis apply accept vrf blue
```

## Segmented Management Instance Configuration for VOSS using EDM

### Note

This section does not apply to VSP 8600 Series.

This section provides procedures to configure segmented management instance using the EDM.

### Migrate an IP Address to a Segmented Management Instance

### Note

This procedure is not applicable for VOSS release 8.1.60 or later. You can only configure the migrate to management for a pre-existing VLAN or loopback management interface before you upgrade to this release.

This procedure does not apply to VSP 8600 Series.

Use this procedure to designate an existing VLAN or loopback IP address as a Segmented Management Instance. This action moves the IP interface from the VOSS routing stack to the management stack to use with management applications.

### Important

Choose a VLAN that does not have an IP interface on it. The upgrade process removes the IP configuration and network connectivity will be impacted.

### About This Task

You cannot migrate interfaces used for routing purposes, for example, where you configure Layer 3 routing protocols.

This command does not apply to the OOB or mgmtEthernet interface. Releases that support this migration procedure automatically move the IP address on the mgmtEthernet interface from the routing stack to the Segmented Management Instance.

### Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Migrate** tab.
5. Select **Insert**.
6. Select the instance type, either **clip** or **vlan**.
7. Specify the existing VLAN or loopback ID.
8. Select **Insert**.

#### *Migrate field descriptions*

Use the data in the following table to use the **Migrate** tab.

| Name                    | Description                                            |
|-------------------------|--------------------------------------------------------|
| <b>Instanceld</b>       | Specifies the interface instance to migrate.           |
| <b>InterfaceIndex</b>   | Shows the interface index of the identified interface. |
| <b>InterfaceType</b>    | Shows the interface type.                              |
| <b>Description</b>      | Shows the interface description.                       |
| <b>VlanId</b>           | Specifies the VLAN ID for a port-based VLAN.           |
| <b>LoopbackId</b>       | Specifies the loopback ID.                             |
| <b>VrfName</b>          | Shows the VRF associated with the loopback interface.  |
| <b>IpAddress</b>        | Shows the IPv4 address to migrate.                     |
| <b>IpMask</b>           | Shows the subnet mask for the IPv4 address.            |
| <b>Ipv6Address</b>      | Shows the IPv6 address to migrate.                     |
| <b>Ipv6PrefixLength</b> | Shows the prefix length for the IPv6 address.          |

## Configure a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

You must create a Management Instance to gain access to specific management applications.

### About This Task

The Management Instance supports different management interface types. When you create the Management Instance, you specify the interface type and the switch automatically creates the appropriate instance ID for that type.

In a Layer 2 routing deployment, use a management VLAN. In a Layer 3 routing or Fabric deployment, use a management CLIP. To separate management network from Layer 2 and Layer 3, use a management OOB.

Each Management Instance supports a IPv4 and IPv6 (global scope) management address for use by management applications.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Interface** tab.
5. Select **Insert**.
6. In the **Instanceld** field, select the type of Management Instance to create.

- (Optional) For a CLIP Management Instance, in the **VrfName** field, type the VRF name to associate with the CLIP instance.

**Note**

If you want to associate the GRT with the CLIP instance, type **GlobalRouter** in the **VrfName** field. You cannot use mgmtrouter as the VRF.

- For a VLAN Management Instance, in the **VlanId** field, type the VLAN ID to associate the management VLAN with an existing port-based VLAN.
- For an OOB Management Instance, in the **OOBIndex** field, select the interface port number to associate for Out-of-Band management.
- Select the **State** check box to enable the instance.
- To specify the interface as the default topology IP for LLDP advertisements, select **InterfaceTopologyIpFlag**.
- To administratively enable RMON for the interface, select **RmonAdminEnable**.
- Select **Insert**.

**Interface** field descriptions

Use the data in the following table to use the **Interface** tab.

| Name                           | Description                                                                       |
|--------------------------------|-----------------------------------------------------------------------------------|
| <b>InstanceId</b>              | Indicates the Management Instance type associated with this entry.                |
| <b>InterfaceType</b>           | Indicates the interface type.                                                     |
| <b>VlanId</b>                  | Specifies the VLAN ID to associate with the management VLAN.                      |
| <b>OOBIndex</b>                | Specifies the interface ID to associate with the management OOB.                  |
| <b>VrfName</b>                 | Specifies the VRF name to associate with the management CLIP .                    |
| <b>State</b>                   | Indicates if the interface is enabled for this instance. The default is disabled. |
| <b>InterfaceMacAddr</b>        | Indicates the MAC address for the interface.                                      |
| <b>InterfaceName</b>           | Indicates the interface name.                                                     |
| <b>InterfaceTopologyIpFlag</b> | Specifies if the interface is the default topology source IP.                     |
| <b>ZtpOn</b>                   | Identifies the Zero Touch Provisioning status for the interface.                  |
| <b>RmonAdminEnable</b>         | Specifies if RMON is administrative enabled for the interface.                    |
| <b>RmonOperEnable</b>          | Indicates the RMON operational status for the interface.                          |
| <b>RmonIpAddress</b>           | Indicates the RMON IP address for the interface.                                  |
| <b>MacOffset</b>               | Translates the IP address into a MAC address.                                     |

Configure DHCP Client for a Segmented Management Instance

**Note**

This procedure does not apply to VSP 8600 Series.

Use this task to configure a DHCP Client on a management interface.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Dhcp** tab.
5. In the **Client** field, select an option to configure the DHCP Client.
6. Select **Apply**.

*Dhcp Field Descriptions*

Use the data in the following table to use the **Dhcp** tab.

| Name                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Client</b>                   | Specifies the DHCP client configuration: <ul style="list-style-type: none"> <li>• <b>oob</b> - DHCP Client on the Out-of-Band management interface.</li> <li>• <b>vlan</b> - DHCP Client on the VLAN management interface.</li> <li>• <b>cycle</b> - DHCP Client cycles between in-band and Out-of-Band management interfaces until an IP address is obtained on one management interface.</li> <li>• <b>disable</b> - DHCP Client is disabled.</li> </ul> |
| <b>ClientPreferredInterface</b> | Shows the DHCP Client preferred management interface when in cycle mode. On reboot, the system first attempts to acquire a DHCP IP address on the preferred interface.                                                                                                                                                                                                                                                                                     |

## View IPv4 ARP Information for a Segmented Management Instance

**Note**

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv4 Address Resolution Protocol (ARP) information.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpArp** tab.

*IpArp Field Descriptions*

Use the data in the following table to use the **IpArp** tab.

| Name            | Description                                                                                                                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Address</b>  | Shows the IPv4 address of the ARP entry.                                                                                                                                                                        |
| <b>Instance</b> | Shows the Management Instance ID.                                                                                                                                                                               |
| <b>IntfName</b> | Shows the Management Instance interface name for the ARP entry.                                                                                                                                                 |
| <b>MacAddr</b>  | Shows the MAC address for the ARP entry.                                                                                                                                                                        |
| <b>State</b>    | Shows the state of the ARP entry. The state can be one of the following: <ul style="list-style-type: none"> <li>• reachable</li> <li>• stale</li> <li>• permanent</li> <li>• failed</li> <li>• delay</li> </ul> |

## View IPv6 ND Information for a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv6 Neighbor Discovery (ND) information.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6Neighbor** tab.

### *Ipv6Neighbor Field Descriptions*

Use the data in the following table to use the **Ipv6Neighbor** tab.

| Name            | Description                                                                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Addr</b>     | Shows the IPv6 address of the neighbor entry.                                                                                                                                                                        |
| <b>Instance</b> | Shows the Management Instance ID.                                                                                                                                                                                    |
| <b>IntfName</b> | Shows the Management Instance interface name for the neighbor entry.                                                                                                                                                 |
| <b>MacAddr</b>  | Shows the MAC address for the neighbor entry.                                                                                                                                                                        |
| <b>State</b>    | Shows the state of the neighbor entry. The state can be one of the following: <ul style="list-style-type: none"> <li>• reachable</li> <li>• stale</li> <li>• permanent</li> <li>• failed</li> <li>• delay</li> </ul> |

## Configure IPv4 Static Routes for a Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure IPv4 static routes for Management Instances.

### About This Task

For the Management Instance CLIP, you do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the VRF. For more information about how to associate a VRF with the CLIP interface, see [Configure a Segmented Management Instance](#) on page 101.

For the Management Instance OOB and VLAN, you must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.

You can configure up to 100 IPv4 and IPv6 static routes.

### Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpStaticRoute** tab.
5. Select **Insert**.
6. For the **Instance**, select the type of Management Instance interface.
7. Type the destination IP address and mask.
8. Type the next hop IP address.
9. Type a metric value.
10. Select **Insert**.

### **IpStaticRoute** Field Descriptions

Use the data in the following table to use the **IpStaticRoute** tab.

| Name            | Description                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Instance</b> | Specifies the Management Instance.                                                                                           |
| <b>DestAddr</b> | Specifies the destination IP address.                                                                                        |
| <b>DestMask</b> | Specifies the destination mask.                                                                                              |
| <b>NextHop</b>  | Specifies the next hop address for the static route. Use an IP address in the same subnet as the management VLAN IP address. |
| <b>IntfName</b> | Specifies the Management Instance interface name for the route entry.                                                        |

| Name          | Description                                                                                                                                                                                                                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Metric</b> | Specifies the static route cost. The default is 200. The management CLIP uses an internal static route with a weight of 100. If you use both CLIP and VLAN and need to force all default traffic out the management VLAN interface, configure a default static route with a weight lower than 100. |
| <b>State</b>  | Shows if the route is active or inactive.                                                                                                                                                                                                                                                          |

## Configure IPv6 Static Routes for a Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure IPv6 static routes for Management Instances.

### About This Task

For the Management Instance CLIP, you do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the VRF. For more information about how to associate a VRF with the CLIP interface, see [Configure a Segmented Management Instance](#) on page 101.

For the Management Instance OOB and VLAN, you must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.

You can configure up to 100 IPv4 and IPv6 static routes.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6StaticRoute** tab.
5. Select **Insert**.
6. For the **Instance**, select elect the type of Management Instance interface.
7. Type the destination IPv6 address and prefix length.
8. Type the next hop IPv6 address.
9. Type a metric value.
10. Select **Insert**.

### *Ipv6StaticRoute Field Descriptions*

Use the data in the following table to use the **Ipv6StaticRoute** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Instance</b>      | Specifies the Management Instance.                                                                                                                                                                                                                                                                 |
| <b>DestAddr</b>      | Specifies the destination IP address.                                                                                                                                                                                                                                                              |
| <b>DestPrefixLen</b> | Specifies the destination prefix length.                                                                                                                                                                                                                                                           |
| <b>NextHop</b>       | Specifies the next hop address for the static route. Use an IP address in the same subnet as the management VLAN IP address.                                                                                                                                                                       |
| <b>IntfName</b>      | Specifies the Management Instance interface name for the route entry.                                                                                                                                                                                                                              |
| <b>Metric</b>        | Specifies the static route cost. The default is 200. The management CLIP uses an internal static route with a weight of 100. If you use both CLIP and VLAN and need to force all default traffic out the management VLAN interface, configure a default static route with a weight lower than 100. |
| <b>State</b>         | Shows if the route is active or inactive.                                                                                                                                                                                                                                                          |

## View IPv4 Operational Routes for a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv4 operational routes.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpRoute** tab.

### *IpRoute Field Descriptions*

Use the data in the following table to use the **IpRoute** tab.

| Name            | Description                                                                                                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DestAddr</b> | Shows the destination address of the route entry.                                                                                                                                                           |
| <b>DestMask</b> | Shows the destination mask of the route entry.                                                                                                                                                              |
| <b>Metric</b>   | Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 1. |
| <b>Instance</b> | Shows the Management Instance ID.                                                                                                                                                                           |
| <b>NextHop</b>  | Shows the next hop for the route entry.                                                                                                                                                                     |

| Name            | Description                                                       |
|-----------------|-------------------------------------------------------------------|
| <b>IntfName</b> | Shows the Management Instance interface name for the route entry. |
| <b>Type</b>     | Shows the type of route entry.                                    |

## View IPv6 Operational Routes for a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv6 operational routes.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6Route** tab.

### *Ipv6Route Field Descriptions*

Use the data in the following table to use the **Ipv6Route** tab.

| Name             | Description                                                                                                                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DestAddr</b>  | Shows the destination address of the route entry.                                                                                                                                                             |
| <b>PrefixLen</b> | Shows the destination prefix length of the route entry.                                                                                                                                                       |
| <b>Metric</b>    | Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 256. |
| <b>Instance</b>  | Shows the Management Instance ID.                                                                                                                                                                             |
| <b>NextHop</b>   | Shows the next hop for the route entry.                                                                                                                                                                       |
| <b>IntfName</b>  | Shows the Management Instance interface name for the route entry.                                                                                                                                             |
| <b>Type</b>      | Shows the type of route entry.                                                                                                                                                                                |

## View Topology IP for a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to view the default topology IP address for a Segmented Management Instance.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **TopologyIp** tab.

*TopologyIp Field Descriptions*

Use the data in the following table to use the **TopologyIp** tab.

| Name                 | Description                                                               |
|----------------------|---------------------------------------------------------------------------|
| <b>AddrType</b>      | Shows the IP address type for the topology IP.                            |
| <b>Addr</b>          | Shows the IP address for the topology IP.                                 |
| <b>InterfaceName</b> | Shows the interface name of the identified interface for the topology IP. |
| <b>Instancelid</b>   | Specifies the interface instance for the topology IP.                     |

**Configure an IP Address for a Segmented Management Instance****Note**

This procedure does not apply to VSP 8600 Series.

Use this task to configure and view IPv4 address information for a Segmented Management Instance.

**Before You Begin**

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.
- If the DHCP client is configured for a Segmented Management Instance, you must manually disable the client. Configuring an IP address does not automatically disable the DHCP client.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpAddress** tab.
5. Select **Insert**.
6. Select the Segmented Management Instance interface type.
7. Type the address information.
8. Select **Insert**.

*IpAddress Field Descriptions*

Use the data in the following table to use the **IpAddress** tab.

| Name              | Description                                                                                                                                                                              |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Instanceld</b> | Specifies the interface instance.                                                                                                                                                        |
| <b>Address</b>    | Specifies IPv4 address for the interface instance. Ensure that the management CLIP IP address does not fall into the range of a configured VLAN IP address range as this is not allowed. |
| <b>Mask</b>       | Specifies the subnet mask of the IP address.                                                                                                                                             |
| <b>AddrOrigin</b> | Shows the IP address origin.                                                                                                                                                             |
| <b>IntfName</b>   | Shows the interface name.                                                                                                                                                                |

## Configure an IPv6 Address for a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure or view IPv6 address information for a Segmented Management Instance.

### Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6Address** tab.
5. Select **Insert**.
6. Select the Segmented Management Instance interface type.
7. Type the address information.
8. Select **Insert**.

### *Ipv6Address* Field Descriptions

Use the data in the following table to use the **Ipv6Address** tab.

| Name                | Description                                                                                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Instanceld</b>   | Specifies the interface instance.                                                                                                                                                            |
| <b>Address</b>      | Specifies the IPv6 address for the interface instance. Ensure that the management CLIP IP address does not fall into the range of a configured VLAN IP address range as this is not allowed. |
| <b>PrefixLength</b> | Specifies the prefix length for the IPv6 address.                                                                                                                                            |
| <b>AddrOrigin</b>   | Shows the IPv6 address origin.                                                                                                                                                               |

| Name             | Description                               |
|------------------|-------------------------------------------|
| <b>IntfName</b>  | Shows the interface name.                 |
| <b>DadStatus</b> | Shows the IPv6 DAD status of the address. |

## View Segmented Management Instance Statistics

### Note

This procedure does not apply to VSP 8600 Series.

View operational statistics for the Management Instance.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Interface** tab.
5. Select a Management Instance by placing the cursor in a cell within the applicable row.
6. Select **Graph**.

### Interface Counters Field Descriptions

Use the data in the following table to use the **Interface Counters** tab.

| Name           | Description                                                                          |
|----------------|--------------------------------------------------------------------------------------|
| <b>RxPkts</b>  | Counts the packets received on the Segmented Management Instance.                    |
| <b>RxError</b> | Counts the packets received with errors on the Segmented Management Instance.        |
| <b>RxDrop</b>  | Counts the packets received and dropped on the Segmented Management Instance.        |
| <b>TxPkts</b>  | Counts the packets transmitted on the Segmented Management Instance.                 |
| <b>TxError</b> | Counts the packets transmitted with errors on the Segmented Management Instance.     |
| <b>TxDrop</b>  | Counts the packets dropped before transmission on the Segmented Management Instance. |

## View IP Address Statistics for a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IP address statistics for a Segmented Management Instance.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

*IP Field Descriptions*

Use the data in the following table to use the **IP** tab.

| Name                   | Description                                                  |
|------------------------|--------------------------------------------------------------|
| <b>InReceives</b>      | Shows the inbound packet statistics.                         |
| <b>InHdrErrors</b>     | Shows the inbound packets with header errors statistics.     |
| <b>InAddrErrors</b>    | Shows the inbound packets with address errors statistics.    |
| <b>InUnknownProtos</b> | Shows the inbound packets with unknown protocols statistics. |
| <b>InDiscards</b>      | Shows the inbound packets discarded statistics.              |
| <b>InDelivers</b>      | Shows the inbound packets delivered statistics.              |
| <b>OutRequests</b>     | Shows the outbound packet requests statistics.               |
| <b>OutDiscards</b>     | Shows the outbound packets discarded statistics.             |
| <b>OutNotRoutes</b>    | Shows the outbound packets with no routes statistics.        |
| <b>ForwDatagrams</b>   | Shows the forwarded datagram packets statistics.             |
| <b>ReasmTimeout</b>    | Shows the packet reassembly timeouts statistics.             |
| <b>ReasmReqds</b>      | Shows the packet reassembly requests statistics.             |
| <b>ReasmOKs</b>        | Shows the successfully reassembled packets statistics.       |
| <b>ReasmFails</b>      | Shows the failed reassembled packets statistics.             |
| <b>FragOKs</b>         | Shows the successfully fragmented packets statistics.        |
| <b>FragFails</b>       | Shows the failed fragmented packets statistics.              |
| <b>FragCreates</b>     | Shows the fragments created statistics.                      |

## View IPv6 Address Statistics for a Segmented Management Instance

**Note**

This procedure does not apply to VSP 8600 Series or XA1400 Series.

Use this task to view IPv6 address statistics for a Segmented Management Instance.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IPv6** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

### IPv6 Field Descriptions

Use the data in the following table to use the **IPv6** tab.

| Name                   | Description                                                                          |
|------------------------|--------------------------------------------------------------------------------------|
| <b>InReceives</b>      | Shows the inbound packet statistics.                                                 |
| <b>InHdrErrors</b>     | Shows the inbound packets with header errors statistics.                             |
| <b>InAddrErrors</b>    | Shows the inbound packets with address errors statistics.                            |
| <b>InUnknownProtos</b> | Shows the inbound packets with unknown protocols statistics.                         |
| <b>InDiscards</b>      | Shows the inbound packets discarded statistics.                                      |
| <b>InDelivers</b>      | Shows the inbound packets delivered statistics.                                      |
| <b>InTooBigErrors</b>  | Shows the inbound packets too big errors statistics.                                 |
| <b>InNoRoutes</b>      | Shows the inbound packets with no routes statistics.                                 |
| <b>InTruncatedPkts</b> | Shows the inbound packets truncated statistics.                                      |
| <b>InMcastPkts</b>     | Shows the inbound multicast packets statistics.                                      |
| <b>InOctets</b>        | Shows the inbound octets statistics.                                                 |
| <b>InMcastOctets</b>   | Shows the inbound multicast octets statistics.                                       |
| <b>InBcastOctets</b>   | Shows the inbound broadcast octets statistics.                                       |
| <b>InNoECTPkts</b>     | Shows the inbound packets with no Explicit Congestion Notification (ECN) statistics. |
| <b>InECT1Pkts</b>      | Shows the inbound packets with ECT(1) statistics.                                    |
| <b>InECT0Pkts</b>      | Shows the inbound packets with ECT(0) statistics.                                    |
| <b>InCEPkts</b>        | Shows the inbound packets with Congestion Encountered (CE) statistics.               |
| <b>OutRequests</b>     | Shows the outbound packet requests statistics.                                       |
| <b>OutDiscards</b>     | Shows the outbound packets discarded statistics.                                     |
| <b>OutNoRoutes</b>     | Shows the outbound packets with no routes statistics.                                |

| Name                    | Description                                            |
|-------------------------|--------------------------------------------------------|
| <b>OutForwDatagrams</b> | Shows the forwarded datagram packets statistics.       |
| <b>OutMcastPkts</b>     | Shows the outbound multicast packets statistics.       |
| <b>OutOctets</b>        | Shows the outbound octets statistics.                  |
| <b>OutMcastOctets</b>   | Shows the outbound multicast octets statistics.        |
| <b>OutBcastOctets</b>   | Shows the outpound broadcast octets statistics.        |
| <b>ReasmTimeout</b>     | Shows the packet reassembly timeouts statistics.       |
| <b>ReasmReqds</b>       | Shows the packet reassembly requests statistics.       |
| <b>ReasmOKs</b>         | Shows the successfully reassembled packets statistics. |
| <b>ReasmFails</b>       | Shows the failed reassembled packets statistics.       |
| <b>FragOKs</b>          | Shows the successfully fragmented packets statistics.  |
| <b>FragFails</b>        | Shows the failed fragmented packets statistics.        |
| <b>FragCreates</b>      | Shows the fragments created statistics.                |

## View IP ICMP Statistics for a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IP ICMP statistics for a Segmented Management Instance.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP-ICMP** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

### IP-ICMP Field Descriptions

Use the data in the following table to use the **IP-ICMP** tab.

| Name                  | Description                                           |
|-----------------------|-------------------------------------------------------|
| <b>InMsgs</b>         | Shows the inbound messages statistics.                |
| <b>InErrors</b>       | Shows the inbound errors statistics.                  |
| <b>InCsumErrors</b>   | Shows the inbound checksum errors statistics.         |
| <b>InDestUnreachs</b> | Shows the inbound destination unreachable statistics. |

| Name             | Description                                            |
|------------------|--------------------------------------------------------|
| InTimeExcds      | Shows the inbound time exceeded statistics.            |
| InParmProbs      | Shows the inbound parameter problems statistics.       |
| InSrcQuenchs     | Shows the inbound source quenchs statistics.           |
| InRedirects      | Shows the inbound redirects statistics.                |
| InEchos          | Shows the inbound echos statistics.                    |
| InEchoReps       | Shows the inbound echo replies statistics.             |
| InTimestamps     | Shows the inbound timestamps statistics.               |
| InTimestampsReps | Shows the inbound timestamp replies statistics.        |
| InAddrMasks      | Shows the inbound address masks statistics.            |
| InAddrMaskReps   | Shows the inbound address mask replies statistics.     |
| OutMsgs          | Shows the outbound messages statistics.                |
| OutErrors        | Shows the outbound errors statistics.                  |
| OutDestUnreachs  | Shows the outbound destination unreachable statistics. |
| OutTimeExcds     | Shows the outbound time exceeded statistics.           |
| OutParmProbs     | Shows the outbound parameter problems statistics.      |
| OutSrcQuenchs    | Shows the outbound source quenchs statistics.          |
| OutRedirects     | Shows the outbound redirects statistics.               |
| OutEchos         | Shows the outbound echos statistics.                   |
| OutEchoReps      | Shows the outbound echo replies statistics.            |
| OutTimestamps    | Shows the outbound timestamps statistics.              |
| OutTimestampReps | Shows the outbound timestamps replies statistics.      |
| OutAddrMasks     | Shows the outbound address masks statistics.           |
| MsgInType0       | Shows the inbound Type0 messages statistics.           |
| MsgOutType8      | Shows the outbound Type8 messages statistics.          |

## View IPv6 ICMP Statistics for a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv6 ICMP statistics for a Segmented Management Instance.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.

4. Select the **IPv6-ICMP** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

#### IPv6-ICMP Field Descriptions

Use the data in the following table to use the **IPv6-ICMP** tab.

| Name                            | Description                                            |
|---------------------------------|--------------------------------------------------------|
| <b>InMsgs</b>                   | Shows the inbound messages statistics.                 |
| <b>InErrors</b>                 | Shows the inbound errors statistics.                   |
| <b>InCsumErrors</b>             | Shows the inbound checksum errors statistics.          |
| <b>InDestUnreachs</b>           | Shows the inbound destination unreachable statistics.  |
| <b>InTimeExcds</b>              | Shows the inbound time exceeded statistics.            |
| <b>InParmProbs</b>              | Shows the inbound parameter problems statistics.       |
| <b>InPktTooBigs</b>             | Shows the inbound packets too big statistics.          |
| <b>InRedirects</b>              | Shows the inbound redirects statistics.                |
| <b>InEchos</b>                  | Shows the inbound echos statistics.                    |
| <b>InEchoReplies</b>            | Shows the inbound echo replies statistics.             |
| <b>InGroupMembQueries</b>       | Shows the inbound group member queries statistics.     |
| <b>InGroupMembResponses</b>     | Shows the inbound group member responses statistics.   |
| <b>InGroupMembReductions</b>    | Shows the inbound group member reductions statistics.  |
| <b>InRouterSolicits</b>         | Shows the inbound router solicits statistics.          |
| <b>InRouterAdvertisements</b>   | Shows the inbound router advertisements statistics.    |
| <b>InNeighborSolicits</b>       | Shows the inbound neighbor solicits statistics.        |
| <b>InNeighborAdvertisements</b> | Shows the inbound neighbor advertisements statistics.  |
| <b>InMLDv2Reports</b>           | Shows the inbound MLDv2 reports statistics.            |
| <b>InType134</b>                | Shows the inbound type134 statistics.                  |
| <b>InType136</b>                | Shows the inbound type136 statistics.                  |
| <b>OutMsgs</b>                  | Shows the outbound messages statistics.                |
| <b>OutErrors</b>                | Shows the outbound errors statistics.                  |
| <b>OutDestUnreachs</b>          | Shows the outbound destination unreachable statistics. |
| <b>OutTimeExcds</b>             | Shows the outbound time exceeded statistics.           |
| <b>OutParmProbs</b>             | Shows the outbound parameter problems statistics.      |

| Name                             | Description                                            |
|----------------------------------|--------------------------------------------------------|
| <b>OutPktTooBig</b> s            | Shows the outbound packets too big statistics.         |
| <b>OutRedirects</b>              | Shows the outbound redirects statistics.               |
| <b>OutEchos</b>                  | Shows the outbound echos statistics.                   |
| <b>OutEchoReps</b>               | Shows the outbound echo replies statistics.            |
| <b>OutGroupMembQueries</b>       | Shows the outbound group member queries statistics.    |
| <b>OutGroupMembResponses</b>     | Shows the outbound group member responses statistics.  |
| <b>OutGroupMembReductions</b>    | Shows the outbound group member reductions statistics. |
| <b>OutRouterStatistics</b>       | Shows the outbound router statistics                   |
| <b>OutRouterAdvertisements</b>   | Shows the outbound router advertisements statistics.   |
| <b>OutNeighborSolicits</b>       | Shows the outbound neighbor solicits statistics.       |
| <b>OutNeighborAdvertisements</b> | Shows the outbound neighbor advertisements statistics. |
| <b>OutMLDv2Reports</b>           | Shows the outbound MLDv2 reports statistics.           |
| <b>OutType133</b>                | Shows the outbound Type133 statistics.                 |
| <b>OutType135</b>                | Shows the outbound Type135 statistics.                 |
| <b>OutType143</b>                | Shows the outbound Type143 statistics.                 |

## View UDP Statistics for a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to view UDP statistics for a Segmented Management Instance.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP/IPv6 UDP** tab.

### **IP/IPv6 UDP** Field Descriptions

Use the data in the following table to use the **IP/IPv6 UDP** tab.

| Name               | Description                                   |
|--------------------|-----------------------------------------------|
| <b>IPVersion</b>   | Shows the IP address version as ipv4 or ipv6. |
| <b>InDatagrams</b> | Shows the input datagram statistics.          |

| Name                | Description                                          |
|---------------------|------------------------------------------------------|
| <b>NoPorts</b>      | Shows the number of ports statistics.                |
| <b>InErrors</b>     | Shows the input errors statistics.                   |
| <b>OutDatagrams</b> | Shows the output datagram statistics.                |
| <b>IgnoredMulti</b> | Show the ignored multiport statistics.               |
| <b>RcvbufErrors</b> | Shows the received buffer errors statistics.         |
| <b>SndbufErrors</b> | Shows the send buffer errors statistics.             |
| <b>InCsumErrors</b> | Shows the input checksum errors statistics.          |
| <b>Clear</b>        | Specifies to clear the statistics. Default is false. |

## View TCP Statistics for a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to view TCP statistics for a Segmented Management Instance.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP/IPv6 TCP** tab.

### **IP/IPv6 TCP** Field Descriptions

Use the data in the following table to use the **IP/IPv6 TCP** tab.

| Name                | Description                                             |
|---------------------|---------------------------------------------------------|
| <b>IPVersion</b>    | Shows the IP address version as ipv4 or ipv6.           |
| <b>ActiveOpens</b>  | Shows the active open TCP connections statistics.       |
| <b>PassiveOpens</b> | Shows the passive open TCP connections statistics.      |
| <b>AttemptFails</b> | Shows the TCP connection attempt failures statistics.   |
| <b>EstabResets</b>  | Shows the TCP connection established resets statistics. |
| <b>InSegs</b>       | Shows the input segments statistics.                    |
| <b>OutSegs</b>      | Shows the output segments statistics.                   |
| <b>RetransSegs</b>  | Shows the retransmit segments statistics.               |
| <b>InErrs</b>       | Shows the input checksum errors statistics.             |
| <b>OutRsts</b>      | Shows the output resets statistics.                     |

| Name                | Description                                          |
|---------------------|------------------------------------------------------|
| <b>InCsumErrors</b> | Shows the input checksum errors statistics.          |
| <b>Clear</b>        | Specifies to clear the statistics. Default is false. |

## View TCP Connections and UDP Endpoints Statistics for a Segmented Management Instance

### Note

This procedure does not apply to VSP 8600 Series.

Use this task to view TCP connections and UDP endpoints statistics for a Segmented Management Instance.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP/IPv6 Socket (TCP/UDP)** tab.

### *IP/IPv6 Socket (TCP/UDP) Field Descriptions*

Use the data in the following table to use the **IP/IPv6 Socket (TCP/UDP)** tab.

| Name                       | Description                                   |
|----------------------------|-----------------------------------------------|
| <b>IPVersion</b>           | Shows the IP address version as ipv4 or ipv6. |
| <b>Type</b>                | Shows the connection type as tcp or udp.      |
| <b>Index</b>               | Shows the index ID for the connection.        |
| <b>State</b>               | Shows the link state for the connection.      |
| <b>RecvQ</b>               | Shows the connection received quantity.       |
| <b>SendQ</b>               | Shows the connection sent quantity.           |
| <b>LocalAddressAndPort</b> | Shows the local IP address and port.          |
| <b>PeerAddressAndPort</b>  | Shows the peer IP address and port.           |

## Segmented Management Instance Configuration for VSP 8600 Series using EDM

### Note

This section only applies to VSP 8600 Series.

This section provides procedures to configure segmented management instance using the EDM.

## Configure a Segmented Management Instance

### Note

This procedure only applies to VSP 8600 Series.

You must create a Management Instance to gain access to specific management applications.

### About This Task

The Management Instance supports different management interface types. When you create the Management Instance, you specify the interface type and the switch automatically creates the appropriate instance ID for that type.

In a Layer 3 routing or Fabric deployment, use a management CLIP.

Each Management Instance supports a single IPv4 and IPv6 (global scope) management address for use by management applications.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtInterface** tab.
4. Select **Insert**.
5. Select the type of Management Instance to create.
6. (Optional) For a CLIP Management Instance, in the **VrfName** field, type the VRF name to associate with the CLIP instance.

### Note

If you want to associate the GRT with the CLIP instance, type **GlobalRouter** in the **VrfName** field. You cannot use `mgmtrouter` as the VRF.

If you specify a non-default VRF, you must enable Layer 3 VSN to achieve IPv6 CLIP connectivity.

7. Select the **State** check box to enable the instance.
8. Select **Insert**.

### **MgmtInterface** field descriptions

Use the data in the following table to use the **MgmtInterface** tab.

| Name                 | Description                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InstanceId</b>    | Shows a value that identifies the Management Instance type associated with this entry.                                                             |
| <b>InterfaceType</b> | Indicates the interface type.                                                                                                                      |
| <b>VlanId</b>        | Specifies the ID of a port based VLAN to associate with a particular management IP instance, if the management VLAN interface is supported.        |
| <b>OOBIndex</b>      | Specifies the interface index of the OOB port to associate with a particular management IP instance, if the management OOB interface is supported. |

| Name                    | Description                                                                       |
|-------------------------|-----------------------------------------------------------------------------------|
| <b>VrfName</b>          | Specifies the VRF name to associate with the management CLIP .                    |
| <b>State</b>            | Indicates if the interface is enabled for this instance. The default is disabled. |
| <b>InterfaceMacAddr</b> | Shows the MAC address for the interface.                                          |
| <b>InterfaceName</b>    | Shows the interface name.                                                         |

## Configure a Segmented Management Instance IP Address

### Note

This procedure only applies to VSP 8600 Series.

After you create the Management Instance, you can add an IP address to it, and then configure route redistribution to advertise reachability of the Management Instance to the rest of the network.

### Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtAddress** tab.

### Tip

If you create the interface and assign an IP address during the same EDM session, you may need to select **Refresh** on the **MgmtAddress** tab before you see the new interface to configure.

4. To assign an IPv4 address:
  - a. Select the **IpAddress** field, and then type the IPv4 address value.
  - b. Select the **IpMask** field, and then type the IPv4 Mask value.
5. To assign an IPv6 address:
  - a. Select the **Ipv6Address** field, and then type the IPv6 address value.
  - b. Select the **Ipv6PrefixLength** field, and then type the IPv6 prefix value.
6. Select **Apply**.

### **MgmtAddress** Field Descriptions

Use the data in the following table to use the **MgmtAddress** tab.

| Name              | Description                                                                            |
|-------------------|----------------------------------------------------------------------------------------|
| <b>InstanceId</b> | Shows a value that identifies the Management Instance type associated with this entry. |
| <b>IpAddress</b>  | Specifies the IPv4 management address.                                                 |

| Name                     | Description                                                                                                                                   |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpMask</b>            | Specifies the subnet mask of the IPv4 management address.                                                                                     |
| <b>Ipv6Address</b>       | Specifies the IPv6 management address. Each Management Instance supports a single IPv6 management address for use by management applications. |
| <b>Ipv6PrefixLength</b>  | Specifies the prefix length of the IPv6 management address. It is /128 for a loopback interface.                                              |
| <b>Ipv6LinkLocalAddr</b> | Shows the automatically generated link local address.                                                                                         |
| <b>InterfaceName</b>     | Shows the interface name.                                                                                                                     |

## View IPv4 Operational Routes for a Segmented Management Instance

### Note

This procedure only applies to VSP 8600 Series.

Use this task to view IPv4 operational routes.

### Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtIpRoute** tab.

### *MgmtIpRoute Field Descriptions*

Use the data in the following table to use the **MgmtIpRoute** tab.

| Name            | Description                                                                                                                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DestAddr</b> | Shows the destination address of the route entry.                                                                                                                                                                |
| <b>DestMask</b> | Shows the destination mask of the route entry.                                                                                                                                                                   |
| <b>Metric</b>   | Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used.<br>Routes with a type of LOCAL have a metric equal to 256. |
| <b>Instance</b> | Shows the Management Instance ID.                                                                                                                                                                                |
| <b>NextHop</b>  | Shows the next hop for the route entry.                                                                                                                                                                          |
| <b>IntfName</b> | Shows the Management Instance interface name for the route entry.                                                                                                                                                |
| <b>Type</b>     | Shows the type of route entry.                                                                                                                                                                                   |

## View IPv6 Operational Routes for a Segmented Management Instance

### Note

This procedure only applies to VSP 8600 Series.

Use this task to view IPv6 operational routes.

### Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtIpv6Route** tab.

### *MgmtIpv6Route Field Descriptions*

Use the data in the following table to use the **MgmtIpv6Route** tab.

| Name             | Description                                                                                                                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DestAddr</b>  | Shows the destination address of the route entry.                                                                                                                                                             |
| <b>PrefixLen</b> | Shows the destination prefix length of the route entry.                                                                                                                                                       |
| <b>Metric</b>    | Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 256. |
| <b>Instance</b>  | Shows the Management Instance ID.                                                                                                                                                                             |
| <b>NextHop</b>   | Shows the next hop for the route entry.                                                                                                                                                                       |
| <b>IntfName</b>  | Shows the Management Instance interface name for the route entry.                                                                                                                                             |
| <b>Type</b>      | Shows the type of route entry.                                                                                                                                                                                |

## Migrate an IP Address to a Segmented Management Instance

### Note

This procedure only applies to VSP 8600 Series.

Use this procedure to designate an existing VLAN or loopback IP address as a Segmented Management Instance. This action moves the IP interface from the VOSS routing stack to the management stack to use with management applications.

### About This Task

You cannot migrate interfaces used for routing purposes, for example, where you configure Layer 3 routing protocols.

This command does not apply to the OOB or mgmtEthernet interface. Releases that support this migration procedure automatically move the IP address on the mgmtEthernet interface from the routing stack to the Segmented Management Instance.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtMigrate** tab.
4. Select **Insert**.
5. Select the instance type, either **clip** or **vlan**.
6. Specify the existing VLAN or loopback ID.
7. Select **Insert**.

### *MgmtMigrate field descriptions*

Use the data in the following table to use the **MgmtMigrate** tab.

| Name                    | Description                                            |
|-------------------------|--------------------------------------------------------|
| <b>InstanceId</b>       | Specifies the interface instance to migrate.           |
| <b>InterfaceIndex</b>   | Shows the interface index of the identified interface. |
| <b>InterfaceType</b>    | Shows the interface type.                              |
| <b>Description</b>      | Shows the interface description.                       |
| <b>VlanId</b>           | Specifies the VLAN ID for a port-based VLAN.           |
| <b>LoopbackId</b>       | Specifies the loopback ID.                             |
| <b>VrfName</b>          | Shows the VRF associated with the loopback interface.  |
| <b>IpAddress</b>        | Shows the IPv4 address to migrate.                     |
| <b>IpMask</b>           | Shows the subnet mask for the IPv4 address.            |
| <b>Ipv6Address</b>      | Shows the IPv6 address to migrate.                     |
| <b>Ipv6PrefixLength</b> | Shows the prefix length for the IPv6 address.          |

## View Segmented Management Instance Statistics

### Note

This procedure only applies to VSP 8600 Series.

View operational statistics for the Management Instance.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **Mgmt Instance** tab.

4. Select a Management Instance by placing the cursor in a cell within the applicable row.
5. Select **Graph**.

#### *Interface Counters Field Descriptions*

Use the data in the following table to use the **Interface Counters** tab.

| Name           | Description                                                                          |
|----------------|--------------------------------------------------------------------------------------|
| <b>RxPkts</b>  | Counts the packets received on the Segmented Management Instance.                    |
| <b>RxError</b> | Counts the packets received with errors on the Segmented Management Instance.        |
| <b>RxDrop</b>  | Counts the packets received and dropped on the Segmented Management Instance.        |
| <b>TxPkts</b>  | Counts the packets transmitted on the Segmented Management Instance.                 |
| <b>TxError</b> | Counts the packets transmitted with errors on the Segmented Management Instance.     |
| <b>TxDrop</b>  | Counts the packets dropped before transmission on the Segmented Management Instance. |

# Basic Administration

---

[Fundamentals on page 126](#)

[Basic Configuration on page 151](#)

[Verification on page 176](#)

[Basic Administration Procedures using CLI on page 181](#)

[Basic administration procedures using EDM on page 197](#)

[Boot parameter configuration using the CLI on page 199](#)

[Run-time process management using CLI on page 215](#)

[Hardware status using EDM on page 223](#)

The following topics provide instructions to perform basic configuration of, and administrative tasks for, the switch and software.

Examples and network illustrations may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

## Fundamentals

---

This section includes the minimum, but essential, configuration steps to:

- provide a default, starting point configuration
- establish basic security on the node

For more information about hardware specifications and installation procedures, see the following documents:

## advanced-feature-bandwidth-reservation Boot Flag

**Table 14: Advanced Feature Bandwidth Reservation product support**

| Feature                                                                                                                                                | Product         | Release introduced                                |
|--------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|---------------------------------------------------|
| <b>Note:</b><br>If your switch does not have this boot flag, it is because the hardware reserves the bandwidth automatically with no user interaction. | 5420 Series     | VOSS 8.4                                          |
|                                                                                                                                                        | 5520 Series     | VOSS 8.2.5                                        |
|                                                                                                                                                        | VSP 4450 Series | Not Supported                                     |
|                                                                                                                                                        | VSP 4900 Series | Not Supported                                     |
|                                                                                                                                                        | VSP 7200 Series | Not Supported                                     |
|                                                                                                                                                        | VSP 7400 Series | VOSS 8.0                                          |
|                                                                                                                                                        | VSP 8200 Series | Not Supported                                     |
|                                                                                                                                                        | VSP 8400 Series | Not Supported                                     |
|                                                                                                                                                        | VSP 8600 Series | Not Supported                                     |
|                                                                                                                                                        | XA1400 Series   | VOSS 8.0.50<br>XA1480 only- demonstration feature |

The switch enables the **boot config flags advanced-feature-bandwidth-reservation** command by default to use advanced features on the switch. If you disable the **boot config flags advanced-feature-bandwidth-reservation** command and attempt to enable an advanced feature, the switch displays an error message to explain why the advanced feature failed to start, and to remind you that you must enable this boot configuration flag for that advanced feature.

### Important

If you change the configuration, you must save the configuration, and then reboot the switch for the change to take effect.

If you disable this feature and save the configuration, any configuration for advanced features remains saved in the configuration file but is not used.

### *5420 Series, 5520 Series, and VSP 7400 Series*

By default, this boot configuration flag is enabled with following options:

- low level option for 5420 Series and VSP 7400 Series switches.
- vim level option for 5520 Series switches (if vim port is available and VIM is not installed, else low level option is enabled).

When disabled, you can use all ports for Layer 2 or Layer 3 forwarding of standard unicast and multicast features. Use this mode if you are not configuring advanced features. The syntax for disabling this boot configuration flag is **no boot config flags advanced-feature-bandwidth-reservation**.

When enabled, also known as Full Feature mode, the switch supports advanced features by reassigning some of the front panel ports to be loopback ports. The following advanced features require loopback ports:

- Fabric Extend
- SPB
- SMLT
- vIST
- VXLAN Gateway
- Fabric RSPAN (Mirror to I-SID)
- Application Telemetry
- IS-IS Accept Policies
- Segmented Management Instance CLIP interface

**Note**

Full Feature mode does not support PIM.

The syntax for enabling the boot flag for this mode is: **boot config flags advanced-feature-bandwidth-reservation [low | high | vim]**.

The *high* level parameter means that the switch reserves the maximum bandwidth for the advanced features.

The *low* level parameter means that the switch reserves less bandwidth to support minimum functionality for advanced features.

The *vim* level parameter means that the switch uses Versatile Interface Module (VIM) ports as loopback ports.

**Note**

Product Notice: The 5420 Series only supports *low* level.

Product Notice: The 5520 Series only supports *low* and *vim* level.

Product Notice: The VSP 7400 Series only supports *high* and *low* level.

After the switch reserves the appropriate ports to become loopback ports, the ports are no longer visible in the output when you enter **show interfaces gigabitEthernet**.

By default, for the 5520 Series switches, if you do not install a VIM in the switch, the switch reserves *vim* parameter. In this configuration, the VIM ports are used as loopback ports and the Universal Ethernet ports are used as regular uplink ports. When used as regular uplink ports, the port speed is 40 Gbps as a single channel port. Although the maximum supported single channel port speed is 40 Gbps, the ports can be channelized to operate as four 10 or 25 Gbps channels. If a VIM is already installed in the switch, the switch reserves *low* parameter that uses Universal Ethernet ports as loopback ports and VIM ports as regular uplink ports.

If you want to change which ports a 5520 Series switch to uses as the loopback ports, you must change the Advanced Feature Bandwidth Reservation configuration before you install or remove a VIM from the switch. For example, the switch reserves *vim* parameter and uses VIM ports as loopback ports, if you

want to install a VIM to the switch, before installing you must run the boot flag **boot config flags advanced-feature-bandwidth-reservation low** command to change the boot flag configuration to use Universal Ethernet ports as loopback ports.

#### Important

If you change the configuration, you must save the configuration, and then reboot the switch for the change to take effect.

If you disable this feature and save the configuration, any configuration for advanced features remains saved in the configuration file but is not used.

The following table lists the ports reserved as loopback ports:

| Product                                                                                                                                                                                                                                                        | Reserved loopback ports                                                                                                                                                                    |

| VSP 7400-48Y                                                                                                                                                                                                                                                   | Low reserves ports 1/55 and 1/56.<br>High reserves ports 1/53, 1/54, 1/55, and 1/56                                                                                                        |

#### Important

You must ensure your configuration does not include reserved ports before you enable this feature. If the configuration includes reserved ports after you enable this feature and restart the switch, the switch stops loading the configuration.

*XA1400 Series*

**Note**

Product Notice: This feature is available in demo mode only on XA1480 and supports low level parameter configuration automatically, which cannot be modified.

When disabled, all I-SID bindings are removed and the switch can only operate as a Backbone Core Bridge (BCB). The syntax for disabling this boot configuration flag is: **no boot config flags advanced-feature-bandwidth-reservation**.

When enabled, the switch reserves CPU cores for Backbone Edge Bridge (BEB) functionality. The syntax for enabling the boot flag for this mode is: **boot config flags advanced-feature-bandwidth-reservation low**.

spbm-config-mode boot flag

**Table 15: spbm-config-mode product support**

| Feature                                                        | Product         | Release introduced |
|----------------------------------------------------------------|-----------------|--------------------|

|                                                                | VSP 8200 Series | VSP 8200 4.0.1     |
|                                                                | VSP 8400 Series | VOSS 4.2           |
|                                                                | VSP 8600 Series | VSP 8600 4.5       |
|                                                                | XA1400 Series   | Not Supported      |

Shortest Path Bridging (SPB) and Protocol Independent Multicast (PIM) cannot interoperate with each other on the switch at the same time. To ensure that SPB and PIM stay mutually exclusive, the software uses a boot flag called **boot config flags spbm-config-mode**.

- The **boot config flags spbm-config-mode** flag is enabled by default. This enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface.
- If you disable the boot flag, save the configuration, and then reboot with the saved configuration. When the flag is disabled, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

**Important**

After you change the **boot config flags spbm-config-mode** flag, you must save the configuration, and then reboot the switch for the change to take effect.

For more information about this boot flag and Simplified vIST, see [IP Multicast](#) on page 1431.

## nni-mstp boot config flag

**Table 16: nni-mstp boot flag product support**

| Feature                                                  | Product         | Release introduced |
|----------------------------------------------------------|-----------------|--------------------|
| nni-mstp boot flag ( <b>boot config flags nni-mstp</b> ) | 5420 Series     | VOSS 8.4           |
|                                                          | 5520 Series     | VOSS 8.2.5         |
|                                                          | VSP 4450 Series | VOSS 6.0           |
|                                                          | VSP 4900 Series | VOSS 8.1           |
|                                                          | VSP 7200 Series | VOSS 6.0           |
|                                                          | VSP 7400 Series | VOSS 8.0           |
|                                                          | VSP 8200 Series | VOSS 6.0           |
|                                                          | VSP 8400 Series | VOSS 6.0           |
|                                                          | VSP 8600 Series | Not Supported      |
|                                                          | XA1400 Series   | Not Supported      |

The nni-mstp boot flag changes the default behavior of the MSTP on SPBM NNI ports. The Common and Internal Spanning Tree (CIST) is disabled automatically on the NNI, and the NNI ports can only be members of backbone VLANs (B-VLAN).

- During startup, if you have non-B-VLAN on SPBM NNI ports in your configuration file, the system sets the nni-mstp flag to true (if it was not already set to true) and enables MTSP on SPBM NNI ports, and all other configurations remain the same. Save your configuration file. If you do not save your configuration, you continue to see the following message on reboot:

```
Warning
Detected brouter and/or vlans other than BVLANS on NNI ports. Setting the boot config
flag nni-mstp to true. Saving configuration avoids repetition of this warning on
reboot.
```

**Note**

When the nni-mstp flag is set to true, only MSTI 62 is disabled on the SPBM NNI ports. You can add the SPBM NNI ports to any VLAN.

- If you configure the nni-mstp boot configuration flag to false (default), the system checks to make sure that the SPBM NNI ports do not have brouter (IPv4 or IPv6) or non-SPBM VLANs configured. The nni-mstp flag is then set to false. Save your configuration file, and reboot the switch for the configuration change to take effect.

**Note**

Ensure that all SPBM NNI ports in non-B-VLAN are removed prior to setting the nni-mstp flag to false.

*Example: Configuring nni-mstp to true*

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags nni-mstp
Warning: Please save the configuration and reboot the switch for this configuration to
```

```
take effect.  
Switch:1(config)#
```

## System Connections

Connect the serial console interface (an RJ-45 jack) to a PC or terminal to monitor and configure the switch. The port uses a RJ-45 connector that operates as data terminal equipment (DTE). Some switches also provide a USB port or micro USB port for serial console interface connectivity. See your hardware documentation for available ports.

The default communication protocol settings for the console port are:

- Baud rate:
  - 5420 Series — 115200
  - 5520 Series — 115200
  - VSP 4450 Series — 9600
  - VSP 4900 Series — 115200
  - VSP 7200 Series — 9600
  - VSP 7400 Series — 115200
  - VSP 8200 Series — 9600
  - VSP 8400 Series — 9600
  - VSP 8600 Series — 115200
  - XA1400 Series — 115200
- 8 data bits
- 1 stop bit
- No parity
- No flow control.

To use the console port, you need a terminal or teletypewriter (TTY)-compatible terminal, or a portable computer with a serial port and terminal-emulation software. Depending on the hardware platform, the console port can display as console port or 10101.

## Boot Sequence

**Table 17: Linux kernel version product support**

| Feature                                                                                                                                                                                                                                                                                                                      | Product         | Release introduced     |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|------------------------|
| <b>Important:</b><br>For VSP 4450 Series, VSP 7200 Series, VSP 8200, and VSP 8400 Series, kernel version 4.9 has special upgrade considerations the first time you upgrade to a release that supports it. You must first upgrade to a stepping-stone release, 6.1.x , before you upgrade to the release with the new kernel. | 5420 Series     | 4.14 as of VOSS 8.4    |

|                                                                                                                                                                                                                                                                                                                              | VSP 4900 Series | 4.14 as of VOSS 8.1    |
|                                                                                                                                                                                                                                                                                                                              | VSP 7200 Series | 4.9 as of VOSS 7.0     |
|                                                                                                                                                                                                                                                                                                                              | VSP 7400 Series | 4.14 as of VOSS 8.0    |
|                                                                                                                                                                                                                                                                                                                              | VSP 8200 Series | 4.9 as of VOSS 7.0     |
|                                                                                                                                                                                                                                                                                                                              | VSP 8400 Series | 4.9 as of VOSS 7.0     |
|                                                                                                                                                                                                                                                                                                                              | VSP 8600 Series | 4.9 as of VSP 8600 8.0 |
|                                                                                                                                                                                                                                                                                                                              | XA1400 Series   | 4.14 as of VOSS 8.1    |

The switch goes through a boot sequence before it becomes fully operational. After you turn on power to the switch, the system starts.

The boot sequence consists of the following stages:

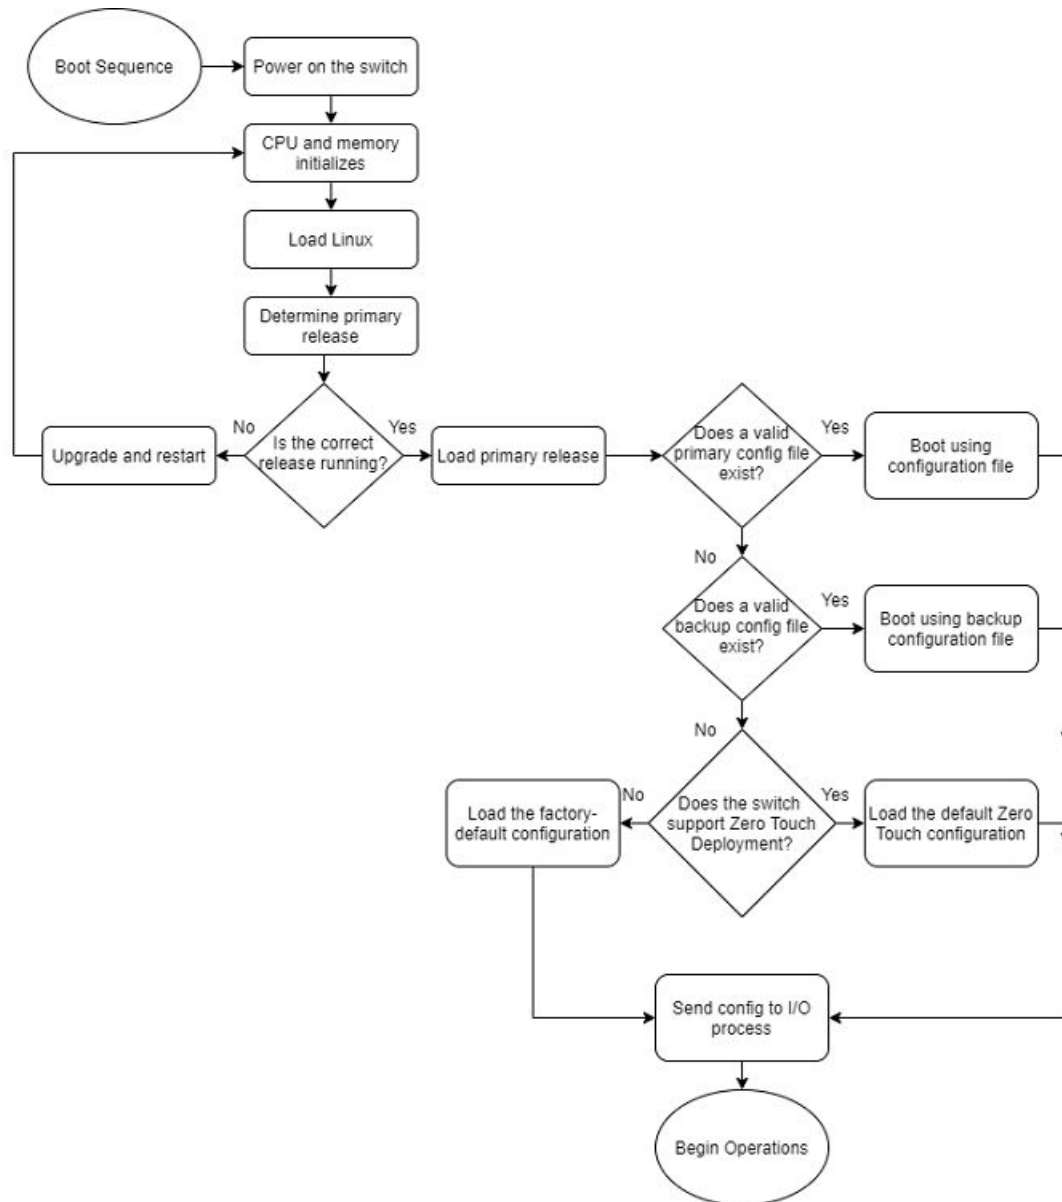

- [Loading Linux](#) on page 134
- [Loading the Primary Release](#) on page 135
- [Deploying Zero Touch](#) on page 135 or [Loading the Configuration File](#) on page 135

### Note

Extreme Networks offers universal hardware products that support more than one Network Operating System (NOS) personality. The first time you start a universal hardware product, the boot sequence can be different from what is documented in this section. The boot sequence documented in this section assumes a NOS selection of VOSS is already established. For more information on NOS personalities, see [Network Operating System Personalities](#) on page 2390.

The following figure shows a summary of the boot sequence.

**Figure 9: Boot Sequence**

*Loading Linux*

Depending on the Linux kernel used, the boot image is stored either in a boot flash partition, Secure Digital (SD), or Solid State Drive (SSD) flash card. The boot image includes the boot loader, and the Linux kernel and applications.

The boot location contains two versions of the boot image: a committed version (the primary release) and a backup version. A committed version is one that is marked as good (if you can start the system using that version). The system automatically uses the backup version if the system fails the first time you start with a new version.

### *Loading the Primary Release*

The switch can install a maximum of six releases but can only load one of two—a primary (committed) release or a backup release.

#### **Note**

You can store only two software releases on 5520 Series and 5420 Series switches.

The system saves software image files to the `/intflash/release/` directory.

After loading the primary release, the CPU and basic system devices, such as the console port, initializes. Depending on the hardware platform, the console port displays as console or 10101. At this stage, the I/O ports are not available; the system does not initialize the I/O ports until the port sends configuration data.

### *Deploying Zero Touch*

#### **Important**

Zero Touch Deployment does not function if primary or secondary configuration files exist.

After the system loads the primary release and the switch is in a Zero Touch Deployment-ready configuration mode, the switch automatically deploys without intervention.

For more information, see [Zero Touch Deployment](#) on page 50.

### *Loading the Configuration File*

After the system loads the primary release, it identifies the location and file name of the primary configuration file. You can save this file in internal flash.

If the primary configuration file does not exist, the system looks for the backup configuration file, as identified by `version.cfg`. If this file does not exist, the system initiates Zero Touch functionality on the switch that enables Zero Touch Fabric Configuration. For more information, see [Zero Touch Fabric Configuration](#) on page 56.

#### **Note**

Exception: for VSP 8600 Series and XA1400 Series, if the configuration file does not exist, the system loads the factory-default configuration, which is the equivalent of using the **boot config flags factorydefaults** command.

The switch configuration consists of higher-level functionality, including:

- Chassis configuration
- Port configuration
- Virtual LAN (VLAN) configuration
- Routing configuration
- IP address assignments
- Remote monitoring (RMON) configuration

The default switch configuration in Zero Touch Fabric Configuration mode includes the following:

- Shortest Path Bridging MAC (SPBM) instance is created.
- Intermediate System-to-Intermediate System (IS-IS) is enabled.
- All ports are enabled and operating in Auto-sense mode.
- The switch issues DHCP requests on the out-of-band (OOB) management port and the management VLAN.

The default switch configuration in factory default mode includes the following:

- A single, port-based default VLAN with a VLAN identification number of 1
- No interface assigned IP addresses
- Traffic priority for all ports configured to normal priority
- All ports as untagged ports
- Default communication protocol settings for the console port. For more information about these protocol settings, see [System Connections](#) on page 132.

### Configuration File Statements

In the configuration file, statements preceded by both the number sign (#) and exclamation point (!) load prior to the general configuration parameters. Statements preceded by only the number sign are comments meant to add clarity to the configuration; they do not load configuration parameters. The following table illustrates the difference between these two statement formats.

**Table 18: Configuration file statements**

| Sample statement             | Action                                                                                  |
|------------------------------|-----------------------------------------------------------------------------------------|
| # software version : 4.0.0.0 | Adds clarity to the configuration by identifying the software version.                  |
| #!no boot config flags sshd  | Configures the flag to the false condition, prior to loading the general configuration. |

### Boot Sequence Modification

You can change the boot sequence in the following ways:

- Change the primary designations for file sources.
- Change the file names from the default values. You can store several versions of the configuration file and specify a particular one by file name. The specified configuration file only gets loaded when the chassis starts. To load a new configuration file, you need to restart the system.
- Start the system without loading an existing configuration file so that the system uses the factory default configuration. Bypassing the system configuration does not affect saved system configuration; the configuration simply does not load. You can do this by running the **boot config flags factorydefaults** command.
- Start the system in Zero Touch Deployment mode, which includes Zero Touch Fabric Configuration. For more information, see [Zero Touch Deployment](#) on page 50.

### Run Time

After the switch is operational, you can use the run-time commands to perform configuration and management functions necessary to manage the system. These functions include the following

- Resetting or restarting the switch
- Adding, deleting, and displaying address resolution protocol (ARP) table entries
- Pinging another network device
- Viewing and configuring variables for the entire system and for individual ports
- Configuring and displaying MultiLink Trunking (MLT) parameters
- Creating and managing port-based VLANs or policy-based VLANs

To access the run-time environment you need a connection from a PC or terminal to the switch. You can use a direct connection to the switch through the console port or remotely through Telnet, rlogin, or Secure Shell (SSH) sessions.

#### Note

rlogin is only supported on VSP 8600 Series.

#### Important

Before you attempt to access the switch using one of the preceding methods, ensure you first enable the corresponding daemon flags.

## System logon

After the platform boot sequence is complete, the system opens the logon prompt. The following table shows the default values for logon and password for console and Telnet sessions.

#### Note

With enhanced secure mode enabled, the person in the role-based authentication level of administrator configures the login and password values for the other role-based authentication levels. The administrator initially logs on to the switch using the default login of `admin` and the default password of `admin`. After the initial login, the switch prompts the administrator to create a new password.

**Table 19: Access levels and default logon values**

| Access level       | Description                                                                                                                                    | Default logon | Default password |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------|---------------|------------------|
| Read-only          | Permits view-only configuration and status information. Is equivalent to Simple Network Management Protocol (SNMP) read-only community access. | ro            | ro               |
| Layer 1 read/write | View most switch configuration and status information and change physical port settings.                                                       | l1            | l1               |

**Table 19: Access levels and default logon values (continued)**

| Access level       | Description                                                                                                                                                                                    | Default logon | Default password |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|------------------|
| Layer 2 read/write | View and change configuration and status information for Layer 2 (bridging and switching) functions.                                                                                           | l2            | l2               |
| Layer 3 read/write | View and change configuration and status information for Layer 2 and Layer 3 (routing) functions.                                                                                              | l3            | l3               |
| Read/write         | View and change configuration and status information across the switch. You cannot change security and password settings. This access level is equivalent to SNMP read/write community access. | rw            | rw               |
| Read/write/all     | Permits all the rights of read/write access and the ability to change security settings, including CLI and web-based management user names and passwords and the SNMP community strings.       | rwa           | rwa              |

## System flags

After you enable or disable certain modes and functions, you need to save the configuration and restart the switch for your change to take effect. This section lists parameters and indicates if they require a switch restart.

The following table lists parameters you configure in CLI using the **boot config flags** command. For information on system flags and their configuration, see [Configure Boot Flags](#) on page 201.

### Note

Flag support can vary across hardware models.

**Table 20: Boot config flags**

| CLI flag                                                                                           | Restart |
|----------------------------------------------------------------------------------------------------|---------|
| <i>advanced-feature-bandwidth-reservation</i>                                                      | Yes     |
| <b>Note:</b><br>Exception: only supported on 5420 Series, 5520 Series, VSP 7400 Series and XA1480. |         |
| <i>block-snmp</i>                                                                                  | No      |
| <i>debug-config</i>                                                                                | Yes     |
| <i>debugmode</i>                                                                                   | Yes     |
| <i>dvr-leaf-mode</i>                                                                               | Yes     |

**Table 20: Boot config flags (continued)**

| CLI flag                                                                                       | Restart                                                                                             |
|------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <i>enhancedsecure-mode</i>                                                                     | Yes                                                                                                 |
| <i>factorydefaults</i>                                                                         | Yes                                                                                                 |
| <i>flow-control-mode</i>                                                                       | Yes                                                                                                 |
| <b>Note:</b><br>Exception: not supported on VSP 8600 Series.                                   |                                                                                                     |
| <i>ftpd</i>                                                                                    | No                                                                                                  |
| <i>ha-cpu</i>                                                                                  | Yes, the standby CPU restarts automatically. Modifying this flag does not require a system restart. |
| <b>Note:</b><br>Exception: only supported on VSP 8600 Series.                                  |                                                                                                     |
| <i>hsecure</i>                                                                                 | Yes                                                                                                 |
| <i>linerate-directed-broadcast</i>                                                             | Yes                                                                                                 |
| <i>ipv6-egress-filter</i>                                                                      | Yes                                                                                                 |

**Table 23: Secure Shell product support**

| Feature                          | Product         | Release introduced |
|----------------------------------|-----------------|--------------------|
| Secure Shell (SSH) server (IPv4) | 5420 Series     | VOSS 8.4           |
|                                  | 5520 Series     | VOSS 8.2.5         |
|                                  | VSP 4450 Series | VSP 4000 4.0       |
|                                  | VSP 4900 Series | VOSS 8.1           |
|                                  | VSP 7200 Series | VOSS 4.2.1         |
|                                  | VSP 7400 Series | VOSS 8.0           |
|                                  | VSP 8200 Series | VSP 8200 4.0       |
|                                  | VSP 8400 Series | VOSS 4.2           |
|                                  | VSP 8600 Series | VSP 8600 4.5       |
|                                  | XA1400 Series   | VOSS 8.0.50        |
| Secure Shell (SSH) client (IPv4) | 5420 Series     | VOSS 8.4           |
|                                  | 5520 Series     | VOSS 8.2.5         |
|                                  | VSP 4450 Series | VSP 4000 4.0       |
|                                  | VSP 4900 Series | VOSS 8.1           |
|                                  | VSP 7200 Series | VOSS 4.2.1         |
|                                  | VSP 7400 Series | VOSS 8.0           |
|                                  | VSP 8200 Series | VSP 8200 4.0       |
|                                  | VSP 8400 Series | VOSS 4.2           |
|                                  | VSP 8600 Series | VSP 8600 4.5       |
|                                  | XA1400 Series   | VOSS 8.0.50        |

**Table 23: Secure Shell product support (continued)**

| Feature                                           | Product         | Release introduced |
|---------------------------------------------------|-----------------|--------------------|
| Secure Sockets Layer (SSL) certificate management | 5420 Series     | VOSS 8.4           |

|                                                                                                                   | VSP 8600 Series | VSP 8600 6.1       |
|                                                                                                                   | XA1400 Series   | VOSS 8.1           |

The client-server model partitions tasks between servers that provide a service and clients that request a service.

For active CLI clients, users initiate a client connection from the switch to another device.

#### Note

Both FTP and TFTP clients are supported by the switch. The switch does not launch FTP and TFTP clients explicitly as a separate command; you can launch them through the CLI **copy** command. If you have configured the username through the **boot config host** command, the FTP client is used to transfer files to and from the switch using the CLI **copy** command; If you have not configured the username, the TFTP client is used to transfer files to and from the switch using the CLI **copy** command.

Configuring the `boot config flags ftpd` or `boot config flags tftpd` enables the FTP or TFTP Servers on the switch.

For non-active clients, the client exists on the switch and the switch console initiates the request, with no intervention from users after the initial setup. For instance, Network Time Protocol (NTP) is a non active client. The switch initiates the client request to the central server to obtain the up-to-date time.

## Password encryption

The platform stores passwords in encrypted format and not in the configuration file.

#### Important

For security reasons, configure the passwords to values other than the factory defaults.

## Enterprise Device Manager

The switch includes Enterprise Device Manager (EDM), an embedded graphical user interface (GUI) that you can use to manage and monitor the platform through web-based access without additional installations.

For more information about EDM, see [Enterprise Device Manager](#) on page 251.

### *Enterprise Device Manager access*

To access EDM, enter one of the following addresses in your web browser:

- `http://<A.B.C.D>`
- `https://<A.B.C.D>`

Where <A.B.C.D> is the device IP address.

Ensure you use a supported browser version. For more information about supported browsers, see [Supported Browsers](#) on page 252.

#### Important

- You must enable the web server from CLI to enable HTTP access to the EDM. If you want HTTP access to the device, you must also disable the web server secure-only option. The web server secure-only option, allowing for HTTPS access to the device, is enabled by default. Take the appropriate security precautions within the network if you use HTTP.
- EDM access is available to read-write users only.

If you experience any issues while connecting to the EDM, check the proxy settings. Proxy settings may affect EDM connectivity to the switch. Clear the browser cache and do not use proxy when connecting to the device. This should resolve the issue.

#### Default user name and password

The following table contains the default user name and password that you can use to log on to the switch using EDM. For more information about changing the passwords, see [Change Passwords](#) on page 3048.

**Table 24: EDM default username and password**

| Username | Password |
|----------|----------|
| admin    | password |

#### Important

The default passwords and community strings are documented and well known. As a best practice, change the default passwords and community strings immediately after you first log on. For more information about changing user names and passwords, see [Change Passwords](#) on page 3048.

#### TLS server for secure HTTPS

**Table 25: TLS server for secure HTTPS product support**

| Feature                                                                  | Product         | Release introduced |
|--------------------------------------------------------------------------|-----------------|--------------------|
| <b>Note:</b><br>VOSS Releases 6.0 and 6.0.1 do not support this feature. | 5420 Series     | VOSS 8.4           |
|                                                                          | 5520 Series     | VOSS 8.2.5         |
|                                                                          | VSP 4450 Series | VOSS 5.1.2         |
|                                                                          | VSP 4900 Series | VOSS 8.1           |
|                                                                          | VSP 7200 Series | VOSS 5.1.2         |
|                                                                          | VSP 7400 Series | VOSS 8.0           |
|                                                                          | VSP 8200 Series | VOSS 5.1.2         |
|                                                                          | VSP 8400 Series | VOSS 5.1.2         |
|                                                                          | VSP 8600 Series | VSP 8600 6.1       |
|                                                                          | XA1400 Series   | VOSS 8.0.50        |

This feature enhances communications security by implementing Mocana NanoSSL to secure HTTPS server using Transport Layer Security (TLS) cryptographic protocol.

The following are the key properties of Secure web server with TLS:

- This feature can be implemented on a maximum of only 10 concurrent client connections.
- The switch supports version TLS 1.2 and above by default. You can explicitly configure TLS 1.0 and TLS 1.1 version support using CLI or EDM.
- This feature replaces SSL 3.0 with TLS. SSL 3.0 is not supported.

- TLS server does not support RC4, DES, TDES, and MD5 based cipher suites.
- The minimum password length for the web server is 8 characters, by default. You can change this using CLI or EDM.

For information about the certificate order priority when the Transport Layer Security (TLS) server and switch connect, see [Certificate Order Priority](#) on page 3002.

## IP Address for the Management Port

At startup, the system loads the runtime configuration file, which is stored in the internal flash of the CPU. If the file is present, the system assigns the IP address for the management port from that file.

You can configure an IP address for the management port if one is not in the configuration file. For more information, see [Configure an IP Address for the Management Port](#) on page 544. This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management](#) on page 60.

## Basic Configuration

---

### Connect a Terminal

#### Before You Begin

- To use the console port, you need the following equipment:
  - A terminal or TeleTypewriter (TTY)-compatible terminal, or a portable computer with a serial port and terminal-emulation software.
  - A specific cable with an RJ-45 or USB connector for the console port on the switch. The other end of the cable must use a connector appropriate to the serial port on the computer or terminal.
- To comply with emissions regulations and requirements, you must shield the cable that connects to the console port.

#### Note

If you are using the VSP 4900 Series, 5420 Series, or 5520 Series USB console port with a terminal running Windows 10, you must install the CP210x USB to UART Bridge Virtual COM Port (VCP) driver from Silicon Labs before you connect to the terminal.

#### About This Task

Connect a terminal to the serial console interface to monitor and configure the system directly.

#### Procedure

1. Configure the terminal protocol as follows:
  - 9600 baud or 115200 baud, depending on the hardware platform.
  - 8 data bits
  - 1 stop bit
  - No parity
  - No flow control

2. Connect the RJ-45 or USB cable to the console port on the switch.
3. Connect the other end of the cable to the terminal or computer serial port.
4. Turn on the terminal.
5. Log on to the switch.

## Changing passwords

Configure new passwords for each access level, or change the logon or password for the different access levels of the switch. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change encrypted passwords.

If you enable the `hsecure` flag, after the aging time expires, the system prompts you to change your password. If you do not configure the aging time, the default is 90 days.

If you enable enhanced secure mode with the `boot config flags enhancedsecure-mode` command, you enable new access levels, along with stronger password complexity, length, and minimum change intervals. For more information on system access fundamentals and configuration, see [System access fundamentals](#) on page 3299.

### Before You Begin

- You must use an account with read-write-all privileges to change passwords. For security, the switch saves passwords to a hidden file.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Change a password:  

```
cli password WORD<1-20> {layer1|layer2|layer3|read-only|read-write|read-write-all}
```
3. Enter the old password.
4. Enter the new password.
5. Re-enter the new password.
6. Configure password options:  

```
password [access-level WORD<2-8>] [aging-time day <1-365>] [default-lockout-time <60-65000>] [lockout WORD<0-46> time <60-65000>] [min-passwd-len <10-20>] [password-history <3-32>]
```

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Change a password:
```

```
Switch:1(config)# cli password rwa read-write-all
```

Enter the old password: \*\*\*

Enter the new password: \*\*\*

Re-enter the new password: \*\*\*

Set password to an access level of read-write-all and the expiration period for the password to 60 days:

```
Switch:1(config)#password access-level rwa aging-time 60
```

### Variable Definitions

Use the data in the following table to use the **cli password** command.

| Variable                                                        | Value                                               |
|-----------------------------------------------------------------|-----------------------------------------------------|
| <i>layer1 layer2 layer3 read-only read-write read-write-all</i> | Changes the password for the specific access level. |
| <i>WORD&lt;1-20&gt;</i>                                         | Specifies the user logon name.                      |

Use the data in the following table to use the **password** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>access-level WORD&lt;2-8&gt;</i>                   | Permits or blocks this access level. The available access level values are as follows: <ul style="list-style-type: none"> <li>• layer1</li> <li>• layer2</li> <li>• layer3</li> <li>• read-only</li> <li>• read-write</li> <li>• read-write-all</li> </ul>                |
| <i>aging-time day &lt;1-365&gt;</i>                   | Configures the expiration period for passwords in days, from 1-365. The default is 90 days.                                                                                                                                                                               |
| <i>default-lockout-time &lt;60-65000&gt;</i>          | Changes the default lockout time after three invalid attempts. Configures the lockout time, in seconds, and is in the 60-65000 range. The default is 60 seconds.<br>To configure this option to the default value, use the <b>default</b> operator with the command.      |
| <i>lockout WORD&lt;0-46&gt; time &lt;60-65000&gt;</i> | Configures the host lockout time. <ul style="list-style-type: none"> <li>• <i>WORD&lt;0-46&gt;</i> is the host IPv4 or IPv6 address.</li> <li>• <i>&lt;60-65000&gt;</i> is the lockout-out time, in seconds, in the 60-65000 range. The default is 60 seconds.</li> </ul> |

| Variable                                   | Value                                                                                                                                                                                                                                                |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>min-passwd-len &lt;10-20&gt;</code>  | Configures the minimum length for passwords in high-secure mode. The default is 10 characters. To configure this option to the default value, use the <b>default</b> operator with the command.                                                      |
| <code>password-history &lt;3-32&gt;</code> | Specifies the number of previous passwords the switch stores. You cannot reuse a password that is stored in the password history. The default is 3. To configure this option to the default value, use the <b>default</b> operator with the command. |

## Configuring system identification

Configure system identification to specify the system name, contact person, and location of the switch.

### Procedure

1. Log on as rwa.
2. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
3. Change the system name:  

```
sys name WORD<0-255>
```
4. Configure the system contact:  

```
snmp-server contact WORD<0-255>
```
5. Configure the system location:  

```
snmp-server location WORD<0-255>
```

### Example

Change the system name, configure the system contact, and configure the system location:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys name Floor3Lab2
Floor3Lab2:1(config)#snmp-server contact http://companyname.com
Floor3Lab2:1(config)#snmp-server location "12 Street, City, State, Zip"
```

### Variable Definitions

Use the data in the following table to use the system-level commands.

| Variable                                | Value                                                                                                                                                                     |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>contact WORD&lt;0-255&gt;</code>  | Identifies the contact person who manages the node. To include blank spaces in the contact, use quotation marks (") around the text.                                      |
| <code>location WORD&lt;0-255&gt;</code> | Identifies the physical location of the node. To include blank spaces in the location, use quotation marks (") around the text.                                           |
| <code>name WORD&lt;0-255&gt;</code>     | Configures the system or root level prompt name for the switch. <code>WORD&lt;0-255&gt;</code> is an ASCII string from 1-255 characters (for example, LabSC7 or Closet4). |

## Configuring the CLI Banner

Configure the logon banner to display a message to users before authentication and configure a system login message-of-the-day in the form of a text banner that displays after each successful logon.

### About This Task

You can use the custom logon banner to display company information, such as company name and contact information. For security, you can change the default logon banner of the switch, which contains specific system information, including platform type and software release.

Use the custom message-of-the-day to update users on a configuration change, a system update or maintenance schedule. For security purposes, you can also create a message-of-the-day with a warning message to users that, "Unauthorized access to the system is forbidden."

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the switch to use a custom banner or use the default banner:

```
banner <custom|static>
```

3. Create a custom banner:

```
banner WORD<1-80>
```

#### Note

To enter multiple lines for a message, use the **banner** command before each new line of the message. To provide a string with spaces, include the text in quotation marks.

4. Create the message-of-the-day:

```
banner motd WORD<1-1516>
```

#### Note

To enter multiple lines for a message, use the **banner motd** command before each new line of the message. To provide a string with spaces, include the text in quotation marks.

5. Enable the custom message-of-the-day:  

```
banner displaymotd
```
6. Save the configuration:  

```
save config
```
7. Display the banner information:  

```
show banner
```
8. Logon again to verify the configuration.
9. (Optional) Disable the banner:  

```
no banner [displaymotd] [motd]
```

### Example

Configure the custom banner to “Company, www.Companyname.com.” and configure the message of the day to “Unauthorized access to this system is forbidden. Please logout now.”

```
Switch:1> enable
Switch:1#configure terminal
Switch:1(config)# banner custom
Switch:1(config)# banner Company
Switch:1(config)# banner www.Companyname.com
Switch:1(config)# banner motd "Unauthorized access to this system is forbidden"
Switch:1(config)# banner motd "Please logout now"
Switch:1(config)#banner displaymotd
Switch:1(config)#show banner
Company
www.company.com
                defaultbanner : false
                custom banner :

                displaymotd : true
                custom motd :
Unauthorized access to this system is forbidden
Please logout now
```

### Variable definitions

Use the data in the following table to use the **banner** command.

| Variable                         | Value                                                                                                     |
|----------------------------------|-----------------------------------------------------------------------------------------------------------|
| <i>custom</i>                    | Disables the use of the default banner.                                                                   |
| <i>static</i>                    | Activates the use of the default banner.                                                                  |
| <i>WORD</i> <1-80>               | Adds lines of text to the CLI logon banner.                                                               |
| <i>motd</i> <i>WORD</i> <1-1516> | Create the message of the day. To provide a string with spaces, include the text in quotation marks (“”). |
| <i>displaymotd</i>               | Enable the custom message of the day.                                                                     |

## Configure the Date

Configure the calendar time in the form of month, day, year, hour, minute, and second.

## About This Task

Log on as rwa to perform this procedure.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Configure the date:  

```
clock set <MMddyymmhhmmss>
```
3. Verify the configuration:  

```
show clock
```

## Example

Configure the date and time, and then verify the configuration.

```
Switch:1>enable
Switch:1#clock set 19042014063030
Switch:1#show clock
Wed Mar 19 06:30:32 2014 EDT
```

### Variable Definitions

Use the data in the following table to use the **clock set** command.

| Variable              | Value                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------|
| <i>MMddyymmhhmmss</i> | Specifies the date and time in the format month, day, year, hour, minute, and second. |

## Enable Remote Access Services

### Before You Begin

- When you enable the rlogin flag, you must configure an access policy to specify the user name of who can access the switch. For more information about the access policy commands, see [Access Policies for Services](#) on page 2990.

#### Note

Rlogin is only supported on VSP 8600 Series.

## About This Task

Enable the remote access service to provide multiple methods of remote access.

File Transfer Protocol (FTP), Trivial File Transfer Protocol (TFTP) and Telnet server support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```

2. Enable the access service:  

```
boot config flags {ftpd | rlogind | sshd | telnetd | tftpd}
```
3. Repeat as necessary to activate the desired services.
4. Save the configuration.

**Example**

Enable the access service for Telnet:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags telnetd
```

*Variable Definitions*

The following table defines parameters for the **boot config flags** command.

| Variable                                                                                                                                                                                                                                                                                                                                                                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><i>advanced-feature-bandwidth-reservation [low   high   vim]</i></p> <p><b>Note:</b><br/>                     Exception: only supported on 5420 Series, 5520 Series, VSP 7400 Series, and XA1480.<br/>                     Exception: only low level supported on 5420 Series.<br/>                     Exception: only low level and vim level is supported on 5520 Series.</p> | <p>Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work.<br/>                     The default varies depending on the platform:<br/>                     The default for XA1400, VSP 7400 and 5420 Series is enabled with low level.<br/>                     The default for 5520 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else low level is enabled.</p> <ul style="list-style-type: none"> <li>• The high level means that the switch reserves the maximum bandwidth for the advanced features.</li> <li>• The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features.</li> <li>• The vim level means that the switch VIM ports as loopback ports and the Universal Ethernet ports for uplinks.</li> </ul> <p>If you change this parameter, you must restart the switch.</p> |
| <p><i>block-snmp</i></p>                                                                                                                                                                                                                                                                                                                                                            | <p>Activates or disables Simple Network Management Protocol management. The default value is false (disabled), which permits SNMP access.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Variable                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>debug-config [console]   [file]</i> | <p>Enables you to debug the configuration file during loading configuration at system boot up. The default is disabled. You do not have to restart the switch after you enable debug-config, unless you want to immediately debug the configuration. After you enable debug-config and save the configuration, the debug output either displays on the console or logs to an output file the next time the switch reboots.</p> <p>The options are:</p> <ul style="list-style-type: none"> <li>• debug-config [console]—Displays the line-by-line configuration file processing and result of the execution on the console while the device loads the configuration file.</li> <li>• debug-config [file]— Logs the line-by-line configuration file processing and result of the execution to the debug file while the device loads the configuration file. The system logs the debug config output to /intflash/debugconfig_primary.txt for the primary configuration file. The system logs the debug config output to /intflash/debugconfig_backup.txt for the backup configuration, if the backup configuration file loads.</li> </ul> |
| <i>debugmode</i>                       | <p>Enables a TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. Works on console connection only. The default is disabled.</p> <p><b>Important:</b><br/>Do not change this parameter unless directed by technical support.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>dvr-leaf-mode</i>                   | <p>Enables an SPB node to be configured as a DvR Leaf.</p> <p>A node that has this flag set cannot be configured as a DvR Controller.</p> <p>The boot flag is disabled by default.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Variable                                                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enhancedsecure-mode {jitc   non-jitc}</code>                                                 | <p>Enables enhanced secure mode in either the JITC or non-JITC sub-modes.</p> <p><b>Note:</b><br/>As a best practice, enable the enhanced secure mode in the non-JITC sub-mode, because the JITC sub-mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting.</p> <p>When you enable enhanced secure mode in either the JITC or non-JITC sub-modes, the switch provides role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use.</p> |
| <code>factorydefaults</code>                                                                       | <p>Specifies whether the switch uses the factory default settings at startup. The default value is disabled. This flag is automatically reset to the default setting after the CPU restarts. If you change this parameter, you must restart the switch.</p>                                                                                                                                                                                                                                                                                                                                                                      |
| <code>flow-control-mode</code><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series. | <p>Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.</p> <p>The default is disabled.</p>                                                                                                                                                                                                                                                     |

| <p><i>verify-config</i></p>                                                                                                                                                | <p>Activates syntax checking of the configuration file. The default is enabled.</p> <ul style="list-style-type: none"> <li>Primary config behavior: When the verifyconfig flag is enabled, the primary config file is pre-checked for syntax errors. If the system finds an error, the primary config file is not loaded, instead the system loads the backup config file.</li> </ul> <p>If the verify-config flag is disabled, the system does not pre-check syntax errors. When the verify-config flag is disabled, the system ignores any lines with errors during loading of the primary config file. If the primary config file is not present or cannot be found, the system tries to load the backup file.</p> <ul style="list-style-type: none"> <li>Backup config behavior: If the system loads the backup config file, the system does not check the backup file for syntax errors. It does not matter if the verify-config flag is disabled or enabled. With the backup config file, the system ignores any lines with errors during the loading of the backup config file.</li> </ul> <p>If no backup config file exists, the system defaults to factory defaults.</p> <p>As a best practice, disable the verify-config flag.</p> |
| <p><i>vrf-scaling</i></p>                                                                                                                                                  | <p>Increases the maximum number of VRFs and Layer 3 VSNs that the switch supports. This flag is disabled by default.</p> <p><b>Important:</b><br/>If you enable both this flag and the spbmconfig-mode flag, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see <a href="#">VOSS Release Notes</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <p><i>vxlan-gw-full-interworking-mode</i></p> <p><b>Note:</b><br/>Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.</p> | <p>Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vIST. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag.</p> <p>The no operator is the default Base Interworking Mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments. For more information about feature support, see <a href="#">VOSS Feature Support Matrix</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Using Telnet to log on to the device

### About This Task

Use Telnet to log on to the device and remotely manage the switch.

### Procedure

1. From a PC or terminal, start a Telnet session:  
`telnet <ipv4 or ipv6 address>`
2. Enter the logon and password when prompted.

### Example

```
C:\Users\jsmith>telnet 192.0.2.40
Connecting to 192.0.2.40.....
Login:rwa
Password:rwa
```

## Enable the Web Management Interface

### About This Task

#### Note

DEMO FEATURE - Read Only User for EDM is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

Enable the web management interface to provide management access to the switch using a web browser.

HTTP and HTTPS, and FTP support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

#### Important

If you want to allow HTTP access to the device, then you must disable the web server secure-only option. If you want to allow HTTPS access to the device, the web server secure-only option is enabled by default. The TFTP server supports both IPv4 and IPv6 TFTP clients.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable the web server:  
`web-server enable`
3. To enable the secure-only option (for HTTPS access), enter:  
`web-server secure-only`
4. (Optional) To disable the secure-only option (for HTTP access), enter:  
`no web-server secure-only`

5. Configure the username and the access password:

```
web-server password rwa WORD<1-20>
```

### Important

The default passwords and community strings are documented and well known. Change the default passwords and community strings immediately after you first log on.

6. Enter and confirm your password.

7. Enable read-only user:

```
web-server read-only-user enable
```

8. Save the configuration:

```
save config
```

9. Display the web server status:

```
show web-server
```

### Example

Enable the secure-only web-server. Configure the Read-Write-All access level username to smith2 and the password to 90Go2437. Enable read-only-user for the web server. Configure the read-only-user username to jones6 and the password to G69s8672.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#web-server enable
Switch:1(config)#web-server secure-only
Switch:1(config)#web-server read-only-user enable
Switch:1(config)#web-server password rwa smith2
Enter the New password : *****
Re-enter the New password : *****
Password changed.
Switch:1(config)#web-server password ro jones6
Enter the New password : *****
Re-enter the New password : *****
Password changed.
Switch:1(config)#show web-server
```

#### Web Server Info :

```
Status : on
Secure-only : enabled
TLS-minimum-version : tlsv12
RO Username Status : enabled
RO Username : jones6
RO Password : *****
RWA Username : smith2
RWA Password : *****
Def-display-rows : 30
Inactivity timeout : 900 sec
Html help tftp source-dir :
HttpPort : 80
HttpsPort : 443
NumHits : 0
NumAccessChecks : 0
NumAccessBlocks : 0
NumRxErrors : 0
NumTxErrors : 0
NumSetRequest : 0
Minimum password length : 8
```

```
Last Host Access Blocked : 0.0.0.0
In use certificate       : Self signed
```

### Variable Definitions

Use the data in the following table to use the **web-server** command.

| Variable                                             | Value                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>def-display-rows &lt;10-100&gt;</code>         | Configures the number of rows each page displays, between 10 and 100.                                                                                                                                                                                                                                                                                   |
| <code>enable</code>                                  | Enables the web interface. To disable the web server, use the <b>no</b> form of this command:<br><code>no web-server [enable]</code>                                                                                                                                                                                                                    |
| <code>help-tftp &lt;WORD/0-256&gt;</code>            | Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/peer:/ [<dir>]. The path can use 0-256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> <li>• 192.0.2.1:/help</li> <li>• 192.0.2.1/</li> </ul>                                                  |
| <code>http-port &lt;80-49151&gt;</code>              | Configures the web server HTTP port. The default port is 80.                                                                                                                                                                                                                                                                                            |
| <code>https-port &lt;443-49151&gt;</code>            | Configure the web server HTTPS port. The default port is 443.                                                                                                                                                                                                                                                                                           |
| <code>inactivity-timeout&lt;30-65535&gt;</code>      | Configures the web-server session inactivity timeout. The default is 900 seconds (15 minutes).                                                                                                                                                                                                                                                          |
| <code>password {ro   rwa} WORD&lt;1-20&gt;</code>    | Configures the logon and password for the web interface.                                                                                                                                                                                                                                                                                                |
| <code>password min-passwd-len&lt;1-32&gt;</code>     | Configures the minimum password length. By default, the minimum password length is 8 characters.                                                                                                                                                                                                                                                        |
| <code>read-only-user</code>                          | Enables read-only user for the web server.<br><br><b>Note:</b><br><b>read-only-user enable</b> is available for demonstration purposes on some products. For more information, see <a href="#">VOSS Feature Support Matrix</a> .                                                                                                                        |
| <code>secure-only</code>                             | Enables secure-only access for the web server.                                                                                                                                                                                                                                                                                                          |
| <code>tls-min-ver&lt;tlsv10 tlsv11 tlsv12&gt;</code> | Configures the minimum version of the TLS protocol supported by the web-server. You can select among the following: <ul style="list-style-type: none"> <li>• tlsv10 – Configures the version to TLS 1.0.</li> <li>• tlsv11 – Configures the version to TLS 1.1.</li> <li>• tlsv12 – Configures the version to TLS 1.2</li> </ul> The default is tlsv12. |

## Enable the Web Server RO User

### About This Task

#### Note

DEMO FEATURE - Read Only User for EDM is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

Perform this procedure to enable the web server RO user, which is disabled by default after a software upgrade.

### Procedure

1. Enter Global Configuration mode:  

```
enable

configure terminal
```
2. Enable the read-only user:  

```
web-server read-only-user enable
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
```

Enable the default ro username:

```
Switch1:(config)#web-server read-only-user enable
```

Display the output of the **show web-server** command with the ro username enabled:

```
Switch:1(config)#show web-server
Web Server Info :

      Status                : on
      Secure-only            : enabled
      TLS-minimum-version    : tlsv1.2
      RO Username Status     : enabled
      RO Username            : jones6
      RO Password            : *****
      RWA Username           : smith2
      RWA Password           : *****
      Def-display-rows       : 30
      Inactivity timeout     : 900 sec
      Html help tftp source-dir :
      HttpPort               : 80
      HttpsPort              : 443
      NumHits                 : 87
      NumAccessChecks        : 4
      NumAccessBlocks        : 0
      NumRxErrors            : 73
      NumTxErrors            : 0
      NumSetRequest          : 0
      Minimum password length : 8
      Last Host Access Blocked : 0.0.0.0
      In use certificate      : Self signed
```

## Setting the TLS protocol version

The switch by default supports version TLS 1.2 and above. You can explicitly configure TLS 1.0 and TLS 1.1 version support using CLI.

### About This Task

Disable the web server before changing the TLS version. By disabling the web server, other existing users with a connection to the web server are not affected from changing to a different version after you run the **tls-min-ver** command.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Disable the web server:  

```
no web-server enable
```
3. Set the TLS protocol version:  

```
web-server tls-min-ver [tlsv10 | tlsv11 | tlsv12]
```
4. Enable the web server:  

```
web-server enable
```
5. Verify the protocol version:  

```
show web-server
```

### Example

```
Switch> enable
Switch# configure terminal
Switch(config)# web-server tls-min-ver tlsv11
```

Verify the protocol version.

```
Switch> show web-server

Web Server Info :

      Status                : on
      Secure-only            : disabled
      TLS-minimum-version    : tlsv11
      RWA Username           : admin
      RWA Password           : *****
      Def-display-rows       : 30
      Inactivity timeout     : 900 sec
      Html help tftp source-dir :
      HttpPort               : 80
      HttpsPort              : 443
      NumHits                 : 198
      NumAccessChecks        : 8
      NumAccessBlocks        : 0
      NumRxErrors             : 198
      NumTxErrors            : 0
      NumSetRequest          : 0
      Minimum password length : 8
      Last Host Access Blocked : 0.0.0.0
      In use certificate      : Self signed
```

## Variable Definitions

Use the data in the following table to use the **web-server** command.

| Variable                                             | Value                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>def-display-rows &lt;10-100&gt;</code>         | Configures the number of rows each page displays, between 10 and 100.                                                                                                                                                                                                                                                                                   |
| <code>enable</code>                                  | Enables the web interface. To disable the web server, use the <b>no</b> form of this command:<br><code>no web-server [enable]</code>                                                                                                                                                                                                                    |
| <code>help-tftp &lt;WORD/0-256&gt;</code>            | Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d;/peer:/ [<dir>]. The path can use 0-256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> <li>• 192.0.2.1:/help</li> <li>• 192.0.2.1/</li> </ul>                                                  |
| <code>http-port &lt;80-49151&gt;</code>              | Configures the web server HTTP port. The default port is 80.                                                                                                                                                                                                                                                                                            |
| <code>https-port &lt;443-49151&gt;</code>            | Configure the web server HTTPS port. The default port is 443.                                                                                                                                                                                                                                                                                           |
| <code>inactivity-timeout&lt;30-65535&gt;</code>      | Configures the web-server session inactivity timeout. The default is 900 seconds (15 minutes).                                                                                                                                                                                                                                                          |
| <code>password {ro   rwa} WORD&lt;1-20&gt;</code>    | Configures the logon and password for the web interface.                                                                                                                                                                                                                                                                                                |
| <code>password min-passwd-len&lt;1-32&gt;</code>     | Configures the minimum password length. By default, the minimum password length is 8 characters.                                                                                                                                                                                                                                                        |
| <code>read-only-user</code>                          | Enables read-only user for the web server.<br><br><b>Note:</b><br><b>read-only-user enable</b> is available for demonstration purposes on some products. For more information, see <a href="#">VOSS Feature Support Matrix</a> .                                                                                                                        |
| <code>secure-only</code>                             | Enables secure-only access for the web server.                                                                                                                                                                                                                                                                                                          |
| <code>tls-min-ver&lt;tlsv10 tlsv11 tlsv12&gt;</code> | Configures the minimum version of the TLS protocol supported by the web-server. You can select among the following: <ul style="list-style-type: none"> <li>• tlsv10 – Configures the version to TLS 1.0.</li> <li>• tlsv11 – Configures the version to TLS 1.1.</li> <li>• tlsv12 – Configures the version to TLS 1.2</li> </ul> The default is tlsv12. |

## Access the Switch Through the Web Interface

### Before You Begin

You must enable the web server using CLI.

### About This Task

Monitor the switch through a web browser from anywhere on the network. The web interface uses a 15-minute timeout period. If no activity occurs for 15 minutes, the system logs off the switch web interface, and you must reenter the password information.

Hypertext Transfer Protocol (HTTP) and Hypertext Transfer Protocol Secure (HTTPS) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

#### Note

By default the web server is configured with the secure-only option, which requires you to use HTTPS to access EDM. To access EDM using HTTP, you must disable the secure-only option. For more information about configuring the secure-only option, see [Enable the Web Management Interface](#) on page 165.

### Procedure

1. Start your web browser.
2. Type the switch IP address as the URL in the web address field.
3. In the **User Name** box, type `admin` and in the **Password** box, type `password`.
4. Select **Login**.

## Configuring the minimum version of the TLS protocol

Use the following procedure to configure the minimum version of the TLS protocol.

Earlier releases used a self-signed certificate generated using the OpenSSL API, and this self-signed certificate was installed in `/inflash/.ssh`. The self-signed certificate is now generated with the Mocana API.

Disable the web server before changing the TLS version. By disabling the web server, other existing users with a connection to the web server are not affected by changing to a different version.

The switch by default supports version TLS 1.2 and above. You can explicitly configure TLS 1.0 and TLS 1.1 version support.

### Procedure

1. In the navigation tree, open the following folders: **Configuration** > **Security** > **Control Path**.
2. Click **General** and select **Web** tab.
3. In the **TlsMinimumVersion** field, select the TLS version you want to configure as the minimum on the system.

**Web** Field Descriptions

Use the data in the following table to use the **Web** tab.

| Name                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>WebRWAUserName</b>                                                                    | Specifies the RWA username from 1-20 characters. The default is admin.                                                                                                                                                                                                                                                                                                                                              |
| <b>WebRWAUserPassword</b>                                                                | Specifies the password from 1-32 characters. The default is 12345678.                                                                                                                                                                                                                                                                                                                                               |
| <b>WebROEnable</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series.   | Enables the web server read-only (RO) user, which is disabled by default after a software upgrade.                                                                                                                                                                                                                                                                                                                  |
| <b>WebROUserName</b>                                                                     | Specifies the RO username from 1-20 characters. The default is user.<br><br><b>Note:</b><br>Product Notice: For VSP 8600 Series the web server RO username must be enabled in CLI.                                                                                                                                                                                                                                  |
| <b>WebROUserPassword</b>                                                                 | Specifies the password from 1-32 characters. The default is password.                                                                                                                                                                                                                                                                                                                                               |
| <b>MinimumPasswordLength</b>                                                             | Configures the minimum password length. By default, the minimum password length is 8 characters.                                                                                                                                                                                                                                                                                                                    |

| Name                                    | Description                                                                                                                                                                                                                                                                                            |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HelpTftp/Ftp_SourceDir</b>           | Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/peer:/ [<dir>]. The path can use 0–256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> <li>• 192.0.2.1:/Help</li> <li>• 192.0.2.1/</li> </ul> |
| <b>DefaultDisplayRows</b>               | Configures the web server display row width between 10–100. The default is 30.                                                                                                                                                                                                                         |
| <b>LastChange</b>                       | Shows the last web-browser initiated configuration change.                                                                                                                                                                                                                                             |
| <b>NumHits</b>                          | Shows the number of hits to the web server.                                                                                                                                                                                                                                                            |
| <b>NumAccessChecks</b>                  | Shows the number of access checks performed by the web server.                                                                                                                                                                                                                                         |
| <b>NumAccessBlocks</b>                  | Shows the number of access attempts blocked by the web server.                                                                                                                                                                                                                                         |
| <b>LastHostAccessBlockedAddressType</b> | Shows the address type, either IPv4 or IPv6, of the last host access blocked by the web server.                                                                                                                                                                                                        |
| <b>LastHostAccessBlockedAddress</b>     | Shows the IP address of the last host access blocked by the web server.                                                                                                                                                                                                                                |
| <b>NumRxErrors</b>                      | Shows the number of receive errors the web server encounters.                                                                                                                                                                                                                                          |
| <b>NumTxErrors</b>                      | Shows the number of transmit errors the web server encounters.                                                                                                                                                                                                                                         |
| <b>NumSetRequest</b>                    | Shows the number of set-requests sent to the web server.                                                                                                                                                                                                                                               |

## Saving the configuration

Save the configuration to a file to retain the configuration settings.

### About This Task

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

#### Note

If you use File Transfer Protocol (FTP) or Trivial File Transfer Protocol (TFTP), ensure that you enable the FTP or TFTP server.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Save the running configuration:

```
save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]
```

**Example**

```
Switch:1> enable
```

Save the file to the default location:

```
Switch:1# save config
```

*Variable Definitions*

Use the data in the following table to use the **save config** command.

| Variable                 | Value                                                                                                                                                                                                                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>backup</i> WORD<1-99> | Saves the specified file name and identifies the file as a backup file.<br>WORD<br>uses one of the following formats: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> </ul> The file name, including the directory structure, can include up to 99 characters. |
| <i>file</i> WORD<1-99>   | Specifies the file name in one of the following formats: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> </ul> The file name, including the directory structure, can include up to 99 characters.                                                              |
| <i>verbose</i>           | Saves the default and current configuration. If you omit this parameter, the command saves only parameters you change.                                                                                                                                                                                              |

**Backing up configuration files**

Before and after you upgrade your switch software, make copies of the configuration files. If an error occurs, use backup configuration files to return the switch to a previous state.

**Before You Begin**

- If you use File Transfer Protocol (FTP) or Trivial File Transfer Protocol (TFTP), ensure that you enable the FTP or TFTP server. File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

**About This Task**

Keep several copies of backup files.

**Procedure**

1. Enter Privileged EXEC mode:

```
enable
```

2. Determine the configuration file names:  

```
show boot config choice
```
3. Save the configuration files. Assuming the files use the default file names, enter:  

```
save config
```
4. Copy the files to a safe place:  

```
copy /intflash/config.cfg /intflash/config_backup.cfg
```

```
copy /intflash/config.cfg a.b.c.d:/dir/config_backup.cfg
```

### Example

Determine the configuration file names, save the configuration files, and copy the files to a safe place.

```
Switch:1>enable
Switch:1#show boot config choice
choice primary config-file "/intflash/config.cfg"
choice primary backup-config-file "/intflash/config.cfg"
Switch:1#save config
Switch:1#copy /intflash/config.cfg 00:11:f9:5b:10:42/dir/config_backup.cfg
Do you want to continue? (y/n)
y
```

## Resetting the platform

### About This Task

Reset the platform to reload system parameters from the most recently saved configuration file.

### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Reset the switch:  

```
reset [-y]
```

### Example

Reset the switch:

```
Switch:1>enable
Switch:1#reset
Are you sure you want to reset the switch? (y/n)
y
```

### Variable Definitions

Use the data in the following table to use the **reset** command.

| Variable | Value                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| -y       | Suppresses the confirmation message before the switch resets. If you omit this parameter, you must confirm the action before the system resets. |

## Remove a Software Build

Use the following procedure to remove a software build for the switch.

### Important

A maximum of 6 software releases can be installed on VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series, VSP 8600 Series, and XA1400 Series. When the limit is reached, you are prompted to remove one release before you can proceed with adding and activating a new software release.

### Note

A maximum of 2 software releases can be installed on 5420 Series and 5520 Series. When the limit is reached, you are prompted for a confirmation to overwrite the non-primary release before you can install a new software release. For more information, see [Upgrade the Software](#) on page 276.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Remove the software build:  
`software remove WORD<1-99>`

### Example

Remove the software build:

```
Switch:1>enable
Switch:1#software remove w.x.y.z
```

## Verification

### Verify Boot Configuration Flags

Verify the boot configuration flags to verify boot configuration settings. Boot configuration settings only take effect after you reset the system. Verification of these parameters is essential to minimize system downtime and the resets to change them.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Verify the flags:  
`show boot config flags`

## Example

### Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags ha-cpu true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags linerate-directed-broadcast false
flags logging true
flags nni-mstp false
flags reboot true
flags rlogind false
flags savetostandby true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
flags vxlan-gw-full-interworking-mode false
```

## Verify the Software Release

### About This Task

Use CLI to verify your installed software. It is important to verify your software version before you place a device into a production environment.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Verify the software release:  
show software detail

### Example

The following is an example of the output of the show software detail command.

```
Switch:1#show software detail
```

```
=====
```

```

                                software releases in /intflash/release/
=====

## Verifying the software version on the slots

### Note

This procedure only applies to VSP 8600 Series.

### About This Task

Use CLI to verify the software version running on each slot.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Verify the software version running on each slot:  
show software slot

### Example

The following is an example of the output of the **show software slot** command.

```

Switch:1#show software slot

=====
                                Software running on chassis

```

```

=====
Slot      Release
-----
1         VOSS8600.voss_4.5.0.0int011
2         VOSS8600.voss_4.5.0.0int011
4         VOSS8600.voss_4.5.0.0int011
SF 1     VOSS8600.voss_4.5.0.0int011
SF 2     VOSS8600.voss_4.5.0.0int011

```

## Display local alarms

View local alarms to monitor alarm conditions.

Local alarms are raised and cleared by applications running on the switch. Local alarms are an automatic mechanism run by the system that do not require any additional user configuration. The raising and clearing of local alarms also creates a log entry for each event. Check alarms occasionally to ensure no alarms require additional operator attention.

For more information, see [Alarm Database](#) on page 3480.

### Procedure

- To enter User EXEC mode, log on to the switch.
- Display local alarms:

```
show alarm database
```

### Example

Display local alarms:

#### Note

The switches that support SF cards display warning messages when SFIs are down.

```

Switch:1#show alarm database
SLOT      ALARM      EVENT      ALARM      ALARM      SEVERITY  CREATION  UPDATED    CLEARED
ID        CODE       TYPE       STATUS     FREQ      TIME      TIME      TIME      REASON

```

## Display log files

Use this procedure to display log files.

### Procedure

- To enter User EXEC mode, log on to the switch.
- Display log files:

```
show logging file
```

## Example

Display log files:

```
Switch:1>show logging file

## Basic Administration Procedures using CLI

The following section describes common procedures that you use while you configure and monitor the switch operations using the Command Line Interface (CLI).

### Note

Unless otherwise stated, to perform the procedures in this section, you must log on to the Privileged EXEC mode in the CLI. For more information about how to use CLI, see [CLI Procedures](#) on page 241.

## Restarting the platform

### Before You Begin

### Note

The command mode is key for this command. If you are logged on to a different command mode, such as Global Configuration mode, rather than Privileged EXEC mode, the system displays different options for this command.

### About This Task

Restart the switch to implement configuration changes or recover from a system failure. When you restart the system, you can specify the boot config file name. If you do not specify a boot source and file, the boot command uses the configuration files on the primary boot device defined by the `boot config choice` command.

After the switch restarts normally, it sends a cold trap within 45 seconds after the restart.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Restart the switch:  
`boot [config WORD<1-99>] [-y]`

### Important

If you enter the `boot` command with no arguments, you cause the switch to start using the current boot choices defined by the `boot config choice` command.

If you enter a boot command and the configuration file name without the directory, the device uses the configuration file from `/intflash/`.

### Example

```
Switch:1> enable
```

Restart the switch:

```
Switch:1# boot config /intflash/config.cfg
```

```
Switch:1# Do you want to continue? (y/n)
```

```
Switch:1# Do you want to continue? (y/n) y
```

### Variable Definitions

The following table defines parameters for the **boot** command.

| Variable                             | Value                                                                                                                                                                                                                                                                |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>config WORD&lt;1-99&gt;</code> | Specifies the software configuration device and file name in one of the following formats: <ul style="list-style-type: none"> <li><code>/intflash/ &lt;file&gt;</code></li> </ul> The file name, including the directory structure, can include up to 99 characters. |
| <code>-y</code>                      | Suppresses the confirmation message before the switch restarts. If you omit this parameter, you must confirm the action before the system restarts.                                                                                                                  |

## Resetting the platform

### About This Task

Reset the platform to reload system parameters from the most recently saved configuration file.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Reset the switch:

```
reset [-y]
```

### Example

```
Switch:1> enable
```

Reset the switch:

```
Switch:1# reset
```

```
Are you sure you want to reset the switch? (y/n) y
```

### Variable Definitions

The following table defines parameters for the **reset** command.

| Variable        | Value                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-y</code> | Suppresses the confirmation message before the switch resets. If you omit this parameter, you must confirm the action before the system resets. |

## Shutting Down the System

Use the following procedure to shut down the system.

### Caution

Before you unplug the AC power cord, always perform the following shutdown procedure.

This procedure:

- Flushes any pending data to ensure data integrity.
- Ensures the completion of recent configuration save actions, thus preventing the system from inadvertently booting up with incorrect configuration.

### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Shut down the system:  

```
sys shutdown
```
3. Before you unplug the power cord, wait until you see the following message:  

```
System Halted, OK to turn off power
```

### Example

Shut down a running system.

```
Switch:1#sys shutdown
Are you sure you want shutdown the system? Y/N (y/n) ? y
CP1 [05/08/14 15:47:50.164] 0x00010813 00000000 GlobalRouter HW INFO System shutdown

## Configure the Default Ping and Traceroute Context

### About This Task

Ping commands and traceroute commands execute in Global Router (GRT) context by default. You can configure ping commands and traceroute commands to execute in management (mgmt) context or in Virtual Router Forwarding (vrf) context.

#### Note

This procedure is not supported on VSP 8600 Series.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the default ping command and traceroute command context:
 

```
sys default-ping-context {grt | mgmt | vrf}
```

### Variable Definitions

The following table defines parameters for the **sys default-ping-context** command.

#### Note

The **sys default-ping-context** command is not supported on VSP 8600 Series.

| Variable | Value                                                                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| grt      | Specifies Global Routing Table (grt) context as the default context for ping commands and traceroute commands. The default configuration is grt as the default context.      |
| mgmt     | Specifies management (mgmt) context as the default context for ping commands and traceroute commands. The default configuration is grt as the default context.               |
| vrf      | Specifies Virtual Router Forwarding (vrf) context as the default context for ping commands and traceroute commands. The default configuration is grt as the default context. |

## Calculate and Verify the MD5 Checksum for a File on the Switch

Perform this procedure to verify that the software files are downloaded properly to the switch. The MD5 checksum for each release is available on the Extreme Networks Support website.

### About This Task

Calculate and verify the MD5 checksum after you download software files.

### Before You Begin

- Download the MD5 checksum to an intermediate workstation or server where you can open and view the contents.

- Download the image file to the switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the list of files:

```
ls *.tgz
```

OR

```
ls *.voss
```

3. Calculate the MD5 checksum for the file:
 

```
file-checksum md5 WORD<1-99>
```
4. Compare the number generated for the file on the switch with the number that displays in the MD5 checksum on the workstation or server. Ensure that the MD5 checksum of the software suite matches the system output generated from calculating the MD5 checksum from the downloaded file.

### Example

View the contents of the MD5 checksum on the workstation or server:

```
3242309ad6660ef09be1b945be15676d VSP8200.4.0.0.0_edoc.tar
d000965876dee2387f1ca59cf081b9d6 VSP8200.4.0.0.0_mib.txt
897303242c30fd944d435a4517f1b3f5 VSP8200.4.0.0.0_mib.zip
2fbd5eab1c450d1f5feae865b9e02baf VSP8200.4.0.0.0_modules.tgz
a9d6d18a979b233076d2d3de0e152fc5 VSP8200.4.0.0.0_OpenSource.zip
8ce39996a131de0b836db629b5362a8a VSP8200.4.0.0.0_oss-notice.html
80bfe69d89c831543623aaad861f12aa VSP8200.4.0.0.0.tgz
a63a1d911450ef2f034d3d55e576eca0 VSP8200.4.0.0.0.zip
62b457d69cedd44c21c395505dcf4a80 VSP8200v400_HELP_EDM_gzip.zip
```

Calculate the MD5 checksum for the file on the switch:

```
Switch:1>ls *.tgz
-rw-r--r--  1 0      0      44015148 Dec  8 08:18 VSP8200.4.0.0.0.tgz
-rw-r--r--  1 0      0      44208471 Dec  8 08:19 VSP8200.4.0.1.0.tgz
Switch:1>file-checksum md5 VSP8200.4.0.0.0.tgz
MD5 (VSP8200.4.0.0.0.tgz) = 80bfe69d89c831543623aaad861f12aa
```

### Variable Definitions

The following table defines parameters for the **file-checksum md5** command:

| Variable                | Value                    |
|-------------------------|--------------------------|
| <i>WORD&lt;1-99&gt;</i> | Specifies the file name. |

## Calculate and Verify the MD5 Checksum for a File on a Client Workstation

Perform this procedure on a Unix or Linux machine to verify that the software files downloaded properly. The MD5 checksum for each release is available on the Extreme Networks Support website.

## About This Task

Calculate and verify the MD5 checksum after you download software files.

## Procedure

1. Calculate the MD5 checksum of the downloaded file:

```
$ /usr/bin/md5sum <downloaded software-filename>
```

Typically, downloaded software files are in the form of compressed Unix file archives (.tgz files) or .voss files.

2. Verify the MD5 checksum of the software suite:

```
$ more <md5-checksum output file>
```

3. Compare the output that displays on the screen. Ensure that the MD5 checksum of the software suite matches the system output generated from calculating the MD5 checksum from the downloaded file.

## Example

Calculate the MD5 checksum of the downloaded file:

```
$ /usr/bin/md5sum VSP4K.4.0.40.0.tgz
02c7ee0570a414becf8ebb928b398f51 VSP4K.4.0.40.0.tgz
```

View the MD5 checksum of the software suite:

```
$ more VSP4K.4.0.40.0.md5

```

## Calculating the File Checksum

### About This Task

Perform the following procedure to calculate or compare the MD5 or SHA512 digest for a specific file. The **file-checksum** command calculates the MD5 or SHA512 digest for files on the internal flash and either shows the output on screen or stores the output in a file that you specify. The **file-checksum** command compares the calculated MD5 or SHA512 digest with that in a checksum file on flash, and the

compared output displays on the screen. By verifying the MD5 or SHA512 checksum, you can verify that the file is transferred properly to the switch.

### Important

- If the MD5 key file parameters change, you must remove the old file and create a new file.
- Use the **file-checksum** command with reserved files (for example, a password file) only if you possess sufficient permissions to access these files.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Calculate the file checksum:

```
file-checksum {md5 | sha512} WORD<1-99> [-a] [-c] [-f WORD<1-99>] [-r]
```

### Example

```
Switch:1>file-checksum md5 password -a -f password.md5
```

### Variable Definitions

The following table defines parameters for the **file-checksum** command.

| Variable      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>md5</i>    | Calculates or compares the MD5 digest for a specific file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>sha512</i> | Calculates or compares the SHA512 digest for a specific file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>-a</i>     | Adds data to the output file instead of overwriting it.<br>You cannot use the <i>-a</i> option with the <i>-c</i> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>-c</i>     | Compares the checksum of the specified file with the MD5 checksum present in the checksum file name. You can specify the checksum file name using the <i>-f</i> option. If the checksum filename is not specified, the file <code>/intflash/checksum.md5</code> is used for comparison.<br>If the supplied checksum filename and the default file are not available on flash, the system displays the following error message on the switch:<br>Error: Checksum file <i>&lt;filename&gt;</i> not present.<br>The <i>-c</i> option also <ul style="list-style-type: none"> <li>• calculates the checksum of the specified files</li> <li>• compares the checksum with all keys in the checksum file, even if filenames do not match</li> <li>• displays the output of comparison</li> </ul> |

| Variable                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-f</code>               | <p>Stores the result of MD5 checksum to a file on internal flash.</p> <p>If the output file specified with the <code>-f</code> option is reserved filenames on the switch, the command fails with the error message:</p> <pre>Error: Invalid operation.</pre> <p>If the output file specified with the <code>-f</code> option is files for which to compute MD5 checksum, the command fails with the error message:</p> <pre>Switch:1# md5 *.cfg -f config.cfg Error: Invalid operation on file &lt;filename&gt;</pre> <p>If the checksum filename specified by the <code>-f</code> option exists on the switch (and is not one of the reserved filenames), the system displays the following message on the switch:</p> <pre>File exists. Do you wish to overwrite? (y/n)</pre> |
| <code>-r</code>               | <p>Reverses the output. Use with the <code>-f</code> option to store the output to a file.</p> <p>You cannot use the <code>-r</code> option with the <code>-c</code> option.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>WORD&lt;1-99&gt;</code> | Specifies the file name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Resetting system functions

### About This Task

Reset system functions to reset all statistics counters on the console port. Depending on your hardware platform, the console port displays as console or 10101.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Reset system functions:
 

```
sys action reset {console|counters}
```

### Example

```
Switch:1> enable
```

Reset the statistics counters:

```
Switch:1# sys action reset counters
```

```
Are you sure you want to reset system counters (y/n)? y
```

## Variable Definitions

The following table defines parameters for the **sys action** command.

| Variable                              | Value                                                                                                                                                                                                                                       |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>reset {console counters}</code> | Reinitializes the hardware universal asynchronous receiver transmitter (UART) drivers. Use this command only if the console connection does not respond. Resets all the statistics counters in the switch to zero. Resets the console port. |

## Sourcing a Configuration

Source a configuration to merge a script file into the running configuration or verify the syntax of a configuration file.

### About This Task

The **source** cli command is intended for use with a switch that is running with a factory default configuration to quick load a pre-existing configuration from a file. If you source a configuration file to merge that configuration into a running configuration, it can result in operational configuration loss if the sourced configuration file contains any configuration that has dependencies on or conflicts with the running configuration. Use the source command to merge smaller portions of a configuration into the existing configuration.

Not all CLI commands are included in configuration files. Typical examples include, but are not limited to some operational and security-related commands. Ensure that you understand what configuration options are included or not included in a configuration file, when you use that file to build new configurations.

The operational modes in the boot configuration file must be configured for some features (for example, **spbm-config-mode true/false**). Before sourcing a configuration file, you need to configure the **boot config flag**, save the configuration, and reboot the system. After the reboot, you can source the configuration file without fail.

### Important

Do not source a verbose configuration (verbose.cfg) with the `debug stop` option. The sourcing process cannot complete if you use these two options with a verbose configuration.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Source a configuration:
 

```
source WORD<1-99> [debug] [stop] [syntax]
```

### Example

```
Switch:1> enable
```

Debug the script output:

```
Switch:1# source testing.cfg debug
```

### Variable Definitions

The following table defines parameters for the **source** command.

| Variable                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>debug</i>            | Debugs the script by outputting the configuration commands to the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>stop</i>             | Stops the sourcing of a configuration if an error occurs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>syntax</i>           | Checks the syntax of the configuration file. This parameter does not load the configuration file; only verifies the syntax.<br>If you use this parameter with the <i>stop</i> parameter ( <b>source WORD&lt;1-99&gt; stop syntax</b> ), the output displays on screen and verification stops if it encounters an error.<br>If you use this parameter with the <i>debug</i> parameter ( <b>source WORD&lt;1-99&gt; debug syntax</b> ), the output does not stop if it encounters an error; you must review the on-screen output to verify if an error exists.<br>If you use this parameter by itself, it does not output to the screen or stop on error; it shows an error message, <i>syntax errors in script</i> , to indicate if errors exist in the configuration file. |
| <i>WORD&lt;1-99&gt;</i> | Specifies a filename and location in one of the following format: <ul style="list-style-type: none"> <li>a.b.c.d:&lt;file&gt;</li> <li>/intflash/&lt;file&gt;</li> </ul> <file> is a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Using the USB Device

The following sections describe common procedures that you can use with the USB device.

### Save a File to an External USB Device

Use the following procedure to save the configuration file or log file to an external USB device.

#### Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

#### Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Save the file to an external USB device:
  - a. To save the configuration file to an external USB device, enter:

```
save config file WORD<1-99>
```

- b. To save the log file to an external USB device, enter:

```
save log file WORD<1-99>
```

### Example

```
Switch:1#save config file /usb/test.cfg
CP-1: Save config to file /usb/test.cfg successful.
WARNING: Choice Primary Node Config file is "/intflash/soak.cfg".

Switch:1#

Switch:1#save log file /usb/test.log

Save log to file /usb/test.log successful.
Save log to file /usb/test.log successful.
Switch:1#
```

### Variable definitions

The following table defines parameters for the save command.

| Variable                  | Value                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| config file<br>WORD<1-99> | Specifies the software configuration device and configuration file name in one of the following formats: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> <li>• /usb/&lt;file&gt;</li> </ul> <p>The file name, including the directory structure, can include up to 99 characters.</p> |
| log file<br>WORD<1-99>    | Specifies the software configuration device and log file name in one of the following formats: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> <li>• /usb/&lt;file&gt;</li> </ul> <p>The file name, including the directory structure, can include up to 99 characters.</p>           |

### Back Up and Restore the Compact Flash to an External USB Device

Perform this procedure to back up and restore the contents of the internal compact flash to a USB flash device without entering multiple **copy** commands. This procedure is useful if you want to copy the complete compact flash contents to another chassis.

#### Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

### Before You Begin

-  **Important**  
Disable logging using the command: `no boot config logging`.
- You must have a USB storage device ready to use that is at least 2 GB. The switch supports USB 1 and 2.

## About This Task

The system verifies that the USB flash device has enough available space to perform the backup operation. If the USB flash device does not have enough available space, the system displays an error message. The backup command uses the following filepath on the USB flash device: `/usb/intflash/intflashbackup_yyyymmddhhmmss.tgz`.

The backup action can take up to 10 minutes.

## Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Backup the internal flash to USB:  
`backup intflash`
3. Restore the data to the internal flash:  
`restore intflash`

## Example

```
Switch:1#backup intflash
```

```
Warning: Command will backup all data from /intflash to /usb/intflash.
         It will take a few minutes and may cause high CPU utilization.

         Are you sure you want to continue? (y/n) ? y

For file system /intflash:
    7252475904 total bytes on the filesystem
    990920704 used bytes on the filesystem
    6261555200 free bytes on the filesystem

For file system /usb:
    2021216256 total bytes on the filesystem
    12038144 used bytes on the filesystem

cd /intflash ; /bin/tar -czvf /usb/intflash/intflashbackup_20140610074501.tgz *
; /bin/sync

Info: Backup /intflash to filename /usb/intflash/intflashbackup_20140610074501.tgz is
complete!

         Do you want to stop the usb? (y/n) ? n
```

### *Copy Configuration and Log Files from a USB Device to Intflash*

Copy configuration and log files from an external USB device to the internal Flash memory.

## Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Copy configuration or log files from the USB device to Intflash:  
`copy /usb/<srcfile> /intflash/<destfile>`

**Example**

```
Switch:1#enable
```

```
Switch:1#copy /usb/test.cfg /intflash/test.cfg
```

**Variable Definitions**

The following table defines parameters for the `copy` command.

| Variable   | Value                                                                                                                                                                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <destfile> | Specifies the name of the configuration or log file when copied to the internal Flash memory. The destination file name must be lower case and have a file extension of .cfg or .log. For example, test.cfg or test.log.<br>The file name, including the directory structure, can include up to 255 characters. |
| <srcfile>  | Specifies the name of the configuration or log file on the USB device. For example, test.cfg or test.log.<br>The file name, including the directory structure, can include up to 255 characters.                                                                                                                |

*Display the Contents of a USB File*

Use the following procedure to view content of a USB file.

**Caution**

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

**Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. Display content of a USB file:  
`more WORD<1-99>`

**Example**

```
Switch:1#enable
```

```
Switch:1#more /usb/test.cfg
```

**Variable definitions**

The following table defines parameters for the `more` command.

| Variable   | Value                                                                                                                                                                                                     |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<1-99> | Specifies the file name in the following format: <ul style="list-style-type: none"> <li>• /usb/&lt;file&gt;</li> </ul> The file name, including the directory structure, can include up to 99 characters. |

### Move a File to or from a USB Device

Use the following procedure to move a file from the internal Flash memory (Intflash) to an external USB device, or from a USB device to Intflash.

**Caution**

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

**Procedure**

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Move a file to a safe location:
  - a. To move a file from Intflash to a USB device:
 

```
mv /intflash/<srcfile> /usb/<destfile>
```
  - b. To move a file from a USB device to Intflash:
 

```
mv /usb/<srcfile> /intflash/<destfile>
```

**Example**

```
Switch:1#enable
Switch:1#mv /intflash/test.cfg /usb/test.cfg

Switch:1#enable
Switch:1#mv /usb/test.cfg /intflash/test.cfg
```

**Variable Definitions**

The following table defines parameters for the `mv` command.

| Variable   | Value                                                                                                                                                                                                                                                                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <destfile> | Specifies the name of the configuration or log file when moved to the USB device. The destination file name must be lower case and have a file extension of <code>.cfg</code> or <code>.log</code> . For example, <code>test.cfg</code> or <code>test.log</code> . The file name, including the directory structure, can include up to 255 characters. |
| <srcfile>  | Specifies the name of the configuration or log file on the internal flash memory. For example, <code>test.cfg</code> or <code>test.log</code> . The file name, including the directory structure, can include up to 255 characters.                                                                                                                    |

### Delete a File from a USB Device

Use the following procedure to delete a file from an external USB device.

**Caution**

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

**Procedure**

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Delete a file from a USB device:
 

```
delete WORD<1-255>
```

**Example**

```
Switch:1#enable
```

```
Switch:1#delete /usb/test.cfg
Are you sure (y/n) ? y
```

**Variable Definitions**

The following table defines parameters for the `delete` command.

| Variable            | Value                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-255> | Specifies the file name in the following format: <ul style="list-style-type: none"> <li>• /usb/&lt;file&gt;</li> </ul> |

**Back Up Configuration Files to ZIP**

**Table 26: Extreme Management Center or ExtremeCloud IQ - Site Engine backup configuration ZIP file product support**

| Feature                                                                                                                                                                                         | Product         | Release introduced |

Extreme Management Center or ExtremeCloud IQ - Site Engine has a configuration backup feature with a requirement to be able to backup configuration related files. Release 6.1.2 introduces new CLI commands to backup configuration related files and package them into a single zip file, or to restore configuration files that were backed up.

**Note**

License files are not backed up.

*Backing up configuration files to a ZIP file***About This Task**

Use this procedure to back up configuration files.

**Important**

Only the RWA user can use the **backup** command.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Use the backup command:  
backup configure WORD<1-99>

**Example**

```
Switch:1>enable
Switch:1#backup configure /intflash/backup02072018

Successfully backed up config /intflash to /intflash/backup02072018.tgz
```

*Restoring configuration files from a ZIP file***About This Task**

Use the following procedure to restore previously backed up configuration files.

**Before You Begin**

- Download the backup file to the /intflash directory.
- If restoring the configuration files on a new switch, you must do one of the following:
  - Disable ISIS on the old switch .
  - Power the old switch down.
  - Remove the old switch from the network.
- If restoring the configuration files on a different switch, use the “isis dup-detection-temp-disable” command on the new switch to suspend duplicate detection prior to its insertion into the existing SPBM topology.

**Important**

This must be done after the original unit has been completely removed or isolated from the SPBM topology.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Run the restore command to restore the configuration files.  
restore configure WORD<1-99>

**Example**

```
Switch:1>enable
Switch:1#restore configure /intflash/backup02072018.tgz
```

```
Warning: Command will restore your backup setup and access files
The current files will be overwritten.

Are you sure you want to continue? (y/n) ?y

Restore /intflash from /intflash/backup02072018.tgz is complete!
Reboot is required for the new configuration to be effective
```

## Basic administration procedures using EDM

---

The following section describes common procedures that you use while you configure and monitor the switch operations using Enterprise Device Manager (EDM).

### Reset the Platform

#### About This Task

Reset the platform to reload system parameters from the most recently saved configuration file. Use the following procedure to reset the device using EDM.

#### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **System** tab.
5. Locate **ActionGroup4** near the bottom of the screen.
6. Select **softReset** from **ActionGroup4**.
7. Click **Apply**.

### Show the MTU for the System

#### About This Task

Perform this procedure to show the MTU configured for the system.

#### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click on the **Chassis** tab.
5. Verify the selection for the MTU size.

## Save the Configuration

### About This Task

After you change the configuration, you must save the changes on the device. Save the configuration to a file to retain the configuration settings.

#### Note

When you logout of the EDM interface, a dialog box automatically prompts if you want to save the configuration. If you want to save the configuration, click **OK**. If you want to close without saving the configuration, click **Cancel**. If you no longer see the prompt, clear your browser cache, restart your browser and reconnect.

### Procedure

1. In the Device Physical View tab, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **System** tab.
5. (Optional) Specify a filename in **ConfigFileName**.  
If you do not specify a filename, the system saves the information to the default file.
6. In **ActionGroup1**, select **saveRuntimeConfig**.
7. Click **Apply**.

## View UBoot Version and Status

#### Note

This procedure only applies to 5420 Series and 5520 Series.

### About This Task

Use this information to verify the integrity of the software and hardware. A representative from Customer Support will instruct you to obtain this information when required.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **UBoot** tab.

### *UBoot* Field Descriptions

Use the data in the following table to use the **UBoot** tab.

| Name                    | Description                           |
|-------------------------|---------------------------------------|
| <b>DefaultVersion</b>   | Displays the default UBoot version.   |
| <b>AlternateVersion</b> | Displays the alternate UBoot version. |

| Name                         | Description                                                                 |
|------------------------------|-----------------------------------------------------------------------------|
| <b>VersionUsed</b>           | Displays the UBoot version in use, either the default or alternate.         |
| <b>TrustedDeliveryStatus</b> | Displays the status of the chain of trust image signature validation steps. |

## Boot parameter configuration using the CLI

Use the procedures in this section to configure and manage the boot process.

### Modify the Boot Sequence

#### About This Task

Modify the boot sequence to prevent the switch from using the factory default settings or, conversely, to prevent loading a saved configuration file.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Bypass the loading of the switch configuration file and load the factory defaults:  

```
boot config flags factorydefaults
```
3. Use a configuration file and not the factory defaults:  

```
no boot config flags factorydefaults
```

#### Important

If the switch fails to read and load a saved configuration file after it starts, check the log file to see if the log file indicates that the factorydefaults setting was enabled, before you investigate other options.

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags factorydefaults
```

### Configuring the remote host logon

#### Before You Begin

- The FTP server must support the FTP passive (PASV) command. If the FTP server does not support the passive command, the file transfer is aborted, and then the system logs an error message that indicates that the FTP server does not support the passive command.

### About This Task

Configure the remote host logon to modify parameters for FTP and TFTP access. The defaults enable TFTP transfers. If you want to use FTP as the transfer mechanism, you need to change the password to a non-null value.

#### Important

tftp-debug should be used exclusively to transfer small files less than 1MB in size. Using it for larger files might cause unwanted behavior, such as transfer failure.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Define conditions for the remote host logon:

```
boot config host {ftp-debug|password WORD<0-16>|tftp-debug|tftp-hash|  
tftp-rexmit <1-120>|tftp-timeout <1-120>|user WORD<0-16>}
```

3. Save the changed configuration.

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Enable console tftp/tftpd debug messages:

```
Switch:1# boot config host tftp-debug
```

```
Switch:1# save config
```

## Changing the primary or secondary boot configuration files

### About This Task

Change the primary or secondary boot configuration file to specify which configuration file the system uses to start.

Configure the primary boot choices.

You have a primary configuration file that specifies the full directory path and a secondary configuration file that also contains the full directory path.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Change the primary boot choice:

```
boot config choice primary {backup-config-file|config-file} WORD<0-255>
```

3. Save the changed configuration.
4. Restart the switch.

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Specify the configuration file in internal flash memory as the primary boot source:

```
Switch:1(config)# boot config choice primary config-file /intflash/config.cfg
```

```
Switch:1(config)# save config
```

```
Switch:1(config)# reset
```

### Variable Definitions

The following table defines parameters for the **boot config** command.

| Variable                                | Value                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{backup-config-file config-file}</i> | Specifies that the boot source uses either the configuration file or a backup configuration file.                                                                                                                                                                                                                                                                                                    |
| <i>WORD&lt;0-255&gt;</i>                | Identifies the configuration file. <i>WORD&lt;0-255&gt;</i> is the device and file name, up to 255 characters including the path, in one of the following format: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /usb/&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> </ul> To set this option to the default value, use the <b>default</b> operator with the command. |

## Configure Boot Flags

### Before You Begin

- If you enable the hsecure flag, you cannot enable the flags for the web server or SSH password-authentication.

#### Important

After you change certain configuration parameters using the **boot config flags** command, you must save the changes to the configuration file.

## About This Task

Configure the boot flags to enable specific services and functions for the chassis.

### Note

Flag support can vary across hardware models.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable boot flags:

```
boot config flags <advanced-feature-bandwidth-reservation [low | high
| vim] | block-snmp | debug-config [file] | debugmode | dvr-leaf-mode
| enhancedsecure-mode <jitc|non-jitc> | factorydefaults | flow-
control-mode | ftpd | ha-cpu | hsecure | ipv6-egress-filter | ipv6-
mode | linerate-directed-broadcast | logging | nni-mstp | reboot |
rlogind | savetostandby | spanning-tree-mode <mstp|rstp> | spbm-
config-mode | sshd | syslog-rfc5424-format | telnetd | tftpd | trace-
logging | urpf-mode | verify-config | vrf-scaling | vxlan-gw-full-
interworking-mode>
```

3. Disable boot flags:

```
no boot config flags <advanced-feature-bandwidth-reservation | block-
snmp | debug-config [file] | debugmode | enhancedsecure-mode <jitc|
non-jitc> | dvr-leaf-mode | factorydefaults | flow-control-mode | ftpd
| ha-cpu | hsecure | ipv6-egress-filter | ipv6-mode | linerate-
directed-broadcast | logging | nni-mstp | reboot | rlogind |
savetostandby | spanning-tree-mode <mstp|rstp> | spbm-config-mode |
sshd | syslog-rfc5424-format | telnetd | tftpd | trace-logging | urpf-
mode | verify-config | vrf-scaling | vxlan-gw-full-interworking-mode>
```

4. Configure the boot flag to the default value:

```
default boot config flags <advanced-feature-bandwidth-reservation |
block-snmp | debug-config [file] | debugmode | enhancedsecure-mode
<jitc|non-jitc> | dvr-leaf-mode | factorydefaults | flow-control-mode
| ftpd | ha-cpu | hsecure | ipv6-egress-filter | ipv6-mode | linerate-
directed-broadcast | logging | nni-mstp | reboot | rlogind |
savetostandby | spanning-tree-mode <mstp|rstp> | spbm-config-mode |
sshd | syslog-rfc5424-format | telnetd | tftpd | trace-logging | urpf-
mode | verify-config | vrf-scaling | vxlan-gw-full-interworking-mode>
```

5. Save the changed configuration.

6. Restart the switch.

### Examples

```
Switch:1>enable
Switch:1#configure terminal
```

Activate High Secure mode:

```
Switch:1(config)# boot config flags hsecure
Switch:1(config)# save config
Switch:1(config)# reset
```

Activate High Availability mode:

```
Switch:1(config)#boot config flags ha-cpu
Switch:1(config)#save config
```

### Variable Definitions

The following table defines parameters for the **boot config flags** command.

| Variable                                                                                                                                                                                                                                                                                                                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><i>advanced-feature-bandwidth-reservation [low   high   vim]</i></p> <p><b>Note:</b><br/>           Exception: only supported on 5420 Series, 5520 Series, VSP 7400 Series, and XA1480.<br/>           Exception: only low level supported on 5420 Series.<br/>           Exception: only low level and vim level is supported on 5520 Series.</p> | <p>Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work.</p> <p>The default varies depending on the platform:<br/>           The default for XA1400, VSP 7400 and 5420 Series is enabled with low level.<br/>           The default for 5520 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else low level is enabled.</p> <ul style="list-style-type: none"> <li>• The high level means that the switch reserves the maximum bandwidth for the advanced features.</li> <li>• The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features.</li> <li>• The vim level means that the switch VIM ports as loopback ports and the Universal Ethernet ports for uplinks.</li> </ul> <p>If you change this parameter, you must restart the switch.</p> |
| <i>block-snmp</i>                                                                                                                                                                                                                                                                                                                                     | <p>Activates or disables Simple Network Management Protocol management. The default value is false (disabled), which permits SNMP access.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Variable                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>debug-config [console]   [file]</i> | <p>Enables you to debug the configuration file during loading configuration at system boot up. The default is disabled. You do not have to restart the switch after you enable debug-config, unless you want to immediately debug the configuration. After you enable debug-config and save the configuration, the debug output either displays on the console or logs to an output file the next time the switch reboots.</p> <p>The options are:</p> <ul style="list-style-type: none"> <li>• debug-config [console]—Displays the line-by-line configuration file processing and result of the execution on the console while the device loads the configuration file.</li> <li>• debug-config [file]— Logs the line-by-line configuration file processing and result of the execution to the debug file while the device loads the configuration file. The system logs the debug config output to /intflash/debugconfig_primary.txt for the primary configuration file. The system logs the debug config output to /intflash/debugconfig_backup.txt for the backup configuration, if the backup configuration file loads.</li> </ul> |
| <i>debugmode</i>                       | <p>Enables a TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. Works on console connection only. The default is disabled.</p> <p><b>Important:</b><br/>Do not change this parameter unless directed by technical support.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>dvr-leaf-mode</i>                   | <p>Enables an SPB node to be configured as a DvR Leaf.</p> <p>A node that has this flag set cannot be configured as a DvR Controller.</p> <p>The boot flag is disabled by default.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Variable                                                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

With the backup config file, the system ignores any lines with errors during the loading of the backup config file.</li> </ul> <p>If no backup config file exists, the system defaults to factory defaults.</p> <p>As a best practice, disable the verify-config flag.</p> |
| <i>vrf-scaling</i>                                                                                                                                                         | <p>Increases the maximum number of VRFs and Layer 3 VSNs that the switch supports. This flag is disabled by default.</p> <p><b>Important:</b><br/>If you enable both this flag and the spbmconfig-mode flag, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see <a href="#">VOSS Release Notes</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <p><i>vxlan-gw-full-interworking-mode</i></p> <p><b>Note:</b><br/>Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.</p> | <p>Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vIST. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag.</p> <p>The no operator is the default Base Interworking Mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments. For more information about feature support, see <a href="#">VOSS Feature Support Matrix</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Specify the Primary CPU and the Standby Delay

### Note

This procedure only applies to VSP 8600 Series.

Specify the primary CPU to designate which CPU becomes the primary after the switch performs a full power cycle. This procedure applies only to hardware with two CPUs.

### About This Task

Configure the standby delay to set the number of seconds a standby CPU waits before trying to become the primary CPU. The standby delay applies when two CP modules boot at the same time. The designated standby CP waits for the configured number of seconds before attempting to assert itself as the primary. Only one CP can be the primary in a chassis.

### Caution

If you configure the standby delay to too short a value, the configured standby CP can become a primary. If you configure the standby delay to too long, it can delay the standby CP asserting itself and continue booting when the designated CP is inserted, but fails booting.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. View the current configuration for the primary CPU:  
`show boot config master`
3. Specify the slot of the primary CPU:  
`boot config master <1-2>`
4. Save the changed configuration.
5. Configure the number of seconds a standby CPU waits before trying to become the primary CPU:  
`boot config delay <0-255>`
6. Save the changed configuration.
7. Restart the switch.

### Example

```
Switch:1>enable
Switch:1#configure terminal
```

Specify the slot number, either 1 or 2, for the primary CPU:

```
Switch:1(config)# boot config master 2
Switch:1(config)# save config
```

Specify the number of seconds a standby CPU waits before trying to become the primary CPU:

```
Switch:1(config)# boot config delay 30
Switch:1(config)# save config
Switch:1(config)# reset
```

### Variable Definitions

The following table defines parameters for the **boot config master** command.

| Variable | Value                                                                                       |
|----------|---------------------------------------------------------------------------------------------|
| <1-2>    | Specifies the slot number, either 1 or 2, for the primary CPU. The default value is slot 1. |

## Reserving Bandwidth for Advanced Features

Use this procedure if you want the switch to support advanced features. When you enable this boot flag, you need to save and reboot with the new configuration.

### Before You Begin

Product Notice: For 5420 Series, 5520 Series, and VSP 7400 Series, you must ensure your configuration does not include reserved ports before you enable this feature. If the configuration includes reserved ports after you enable this feature and restart the switch, the switch stops loading the configuration.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable the boot flag:  

```
boot config flags advanced-feature-bandwidth-reservation [low | high | vim]
```
3. Save the configuration, and then reboot the switch.

#### Important

A change to the advanced-feature-bandwidth-reservation boot flag requires a reboot for the change to take effect.

4. Verify the boot flag configuration:  

```
show boot config flags
```
5. Verify that the switch reserved the ports as loopback ports. Reserved ports are not visible in the output of the following command:

#### Note

This step only applies to 5420 Series, 5520 Series and VSP 7400 Series.

```
show interfaces gigabitEthernet
```

### Example

Enable this feature to the low level.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags advanced-feature-bandwidth-reservation low
```

```
Warning: Please note that the configuration for the following ports 1/25-1/26
        will be removed from the configuration file.
Are you sure you want to continue (y/n) ? y
Warning: Please save the configuration and reboot the switch
        for this to take effect.
Flag advanced-feature-bandwidth-reservation is changed to enable (low).
```

## Display Advanced Feature Bandwidth Reservation Ports

### Note

This procedure applies to 5420 Series, 5520 Series, and VSP 7400 Series.

After you configure the **advanced-feature-bandwidth-reservation** boot flag and reboot with the new configuration, you can use the following procedure to verify that the switch reserved ports for configuring advanced features such as Fabric Extend, SPB, SMLT, vIST, VXLAN Gateway, Fabric RSPAN (Mirror to I-SID), Application Telemetry, or IS-IS Accept Policies.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Advanced Feature Bandwidth Reservation mode and reserved ports:

```
show sys-info
```

### Example

```
Switch# show sys-info

General Info :

SysDescr      : Switch1 (w.x.y.z)   BoxType: Switch1
SysName       : Switch1
.
.
.

Advanced Feature Bandwidth Reservation:
-----

Reservation Mode : low
Port Usage Info  : 1/31 and 1/32 are not available to use
```

## Display the Boot Configuration

### About This Task

Display the configuration to view current or changed settings for the boot parameters.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. View the configuration:
 

```
show boot config <choice|flags|general|host|master|running-config
[verbose]|sio>
```

## Example

Show the current boot configuration. (If you omit `verbose`, the system only displays the values that you changed from their default value.):

```
Switch:1>enable

Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.

Switch:1#(config)#show boot config running-config
#
#Mon Feb 13 13:32:58 2017 EST
#
boot config flags debug-config file
boot config flags debugmode
boot config flags ftpd
no boot config flags spbm-config-mode
boot config flags sshd
boot config flags telnetd
boot config flags tftpd
no boot config flags verify-config
boot config choice primary backup-config-file "/intflash/config.cfg"
#boot config sio console baud 115200
```

## Variable Definitions

The following table defines parameters for the **show boot config** command.

| Variable                                  | Value                                                                                                                                                                                                                       |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>choice</i>                             | Shows the current boot configuration choices.                                                                                                                                                                               |
| <i>flags</i>                              | Shows the current flag settings.                                                                                                                                                                                            |
| <i>general</i>                            | Shows system information.                                                                                                                                                                                                   |
| <i>host</i>                               | Shows the current host configuration.                                                                                                                                                                                       |
| <i>master</i>                             | Shows the master information.                                                                                                                                                                                               |
| <i>running-config</i><br><i>[verbose]</i> | Shows the current boot configuration. If you use <i>verbose</i> , the system displays all possible information. If you omit <i>verbose</i> , the system displays only the values that you changed from their default value. |
| <i>sio</i>                                | Specifies the current configuration of the serial ports.                                                                                                                                                                    |

## Configure Serial Port Devices

Configure the serial port devices to define connection settings for the console port. Depending on your hardware platform the console port displays as console or 10101.

### Note

These commands do not apply on all hardware platforms.

## Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. View the current baud rate configuration:  
`show boot config sio`
3. Change the console baud rate:  
`boot config sio console baud <9600-115200> <1-8>|<SF1-SF3>`
4. Save the changed configuration.
5. Restart the switch.

## Example

```
Switch:1>enable
Switch:1#config terminal
Switch:1(config)#show boot config sio
sio console baud 115200 2
sio console baud 115200 5
sio console baud 115200 8
sio console baud 115200 SF1
sio console baud 115200 SF3
```

Configure the baud rate to 9600 for the console port in IOC module slot 2:

```
Switch:1(config)#boot config sio console baud 9600 2
Switch:1(config)#show boot config sio
sio console baud 9600 2
sio console baud 115200 5
sio console baud 115200 8
sio console baud 115200 SF1
sio console baud 115200 SF3
```

## Variable Definitions

The following table defines parameters for the **boot config sio console** command.

| Variable                                                                                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Run-time process management using CLI

Configure and manage the run-time process using the Command Line Interface (CLI).

### Configuring the time zone

#### About This Task

Configure the time zone to use an internal system clock to maintain accurate time. The time zone data in Linux includes daylight changes for all time zones up to the year 2038. You do not need to configure daylight savings.

The default time zone is Coordinated Universal Time (UTC).

#### Important

In October 2014, the government of Russia moved Moscow from UTC+4 into the UTC+3 time zone with no daylight savings.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```

2. Configure the time zone by using the following command:  

```
clock time-zone WORD<1-10> WORD<1-20> WORD<1-20>
```
3. Save the changed configuration.

### Example

Configure the system to use the time zone data file for Vevay:

```
Switch:1(config)# clock time-zone America Indiana Vevay
```

### Variable Definitions

The following table defines parameters for the **clock time-zone** command.

| Variable                                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD&lt;1-10&gt;</i>                  | Specifies a directory name or a time zone name in /usr/share/zoneinfo, for example, Africa, Australia, Antarctica, or US. To see a list of options, enter<br><pre>clock time-zone</pre> at the command prompt without variables.                                                                                                                                                                                                                                                                                                          |
| <i>WORD&lt;1-20&gt; WORD&lt;1-20&gt;</i> | The first instance of <i>WORD&lt;1-20&gt;</i> is the area within the timezone. The value represents a time zone data file in /usr/share/zoneinfo/ <i>WORD&lt;1-10&gt;/</i> , for example, Shanghai in Asia.<br>The second instance of <i>WORD&lt;1-20&gt;</i> is the subarea. The value represents a time zone data file in /usr/share/zoneinfo/ <i>WORD&lt;1-10&gt;/WORD&lt;1-20&gt;/</i> , for example, Vevay in America/Indiana. To see a list of options, enter <code>clock time-zone</code> at the command prompt without variables. |

## Configure the Run-time Environment

### About This Task

Configure the run-time environment to define generic configuration settings for CLI sessions.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Change the login prompt:  

```
login-message WORD<1-1513>
```
3. Change the password prompt:  

```
passwordprompt WORD<1-1510>
```

4. Configure the number of supported rlogin sessions:

```
max-logins <0-8>
```

**Note**

This step only applies to VSP 8600 Series.

5. Configure the number of supported inbound Telnet sessions:

```
telnet-access sessions <0-8>
```

6. Configure the idle timeout period before automatic logoff for CLI and Telnet sessions:

```
cli timeout <30-65535>
```

7. Configure the number of lines in the output display:

```
terminal length <8-64>
```

8. Configure scrolling for the output display:

```
terminal more <disable|enable>
```

**Example**

```
Switch:1> enable
```

```
Switch:# configure terminal
```

Use the default option to enable use of the default logon string:

```
Switch:(config)# default login-message
```

Use the default option before this parameter to enable use of the default string:

```
Switch:(config)# default passwordprompt
```

Configure the allowable number of inbound remote CLI logon sessions:

```
Switch:(config)# max-logins 5
```

Configure the allowable number of inbound Telnet sessions:

```
Switch:(config)# telnet-access sessions 8
```

Configure the timeout value, in seconds, to wait for a Telnet or CLI login session before terminating the connection:

```
Switch:(config)# cli timeout 900
```

Configure the number of lines in the output display for the current session:

```
Switch:(config)# terminal length 30
```

Configure scrolling for the output display:

```
Switch:(config)# terminal more disable
```

### Variable Definitions

The following table defines parameters for the **login-message** command.

| Variable             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-1513> | Changes the CLI logon prompt. <ul style="list-style-type: none"> <li>• <i>WORD</i>&lt;1-1513&gt; is an American Standard Code for Information Interchange (ASCII) string from 1-1513 characters.</li> <li>• Use the default option before this parameter, <code>default login-message</code>, to enable use of the default logon string.</li> <li>• Use the no operator before this parameter, <code>no login-message</code>, to disable the default logon banner and display the new banner.</li> </ul> |

Use the data in the following table to use the **passwordprompt** command.

| Variable             | Value                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-1510> | Changes the CLI password prompt. <ul style="list-style-type: none"> <li>• <i>WORD</i>&lt;1-1510&gt; is an ASCII string from 1-1510 characters.</li> <li>• Use the default option before this parameter, <code>default passwordprompt</code>, to enable using the default string.</li> <li>• Use the no operator before this parameter, <code>no passwordprompt</code>, to disable the default string.</li> </ul> |

Use the data in the following table to use the **max-logins** command.

| Variable                                                      | Value                                                                                         |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <0-8>                                                         | Configures the allowable number of inbound remote CLI logon sessions. The default value is 8. |
| <b>Note:</b><br>Exception: only supported on VSP 8600 Series. |                                                                                               |

Use the data in the following table to use the **telnet-access sessions** command.

| Variable | Value                                                                               |
|----------|-------------------------------------------------------------------------------------|
| <0-8>    | Configures the allowable number of inbound Telnet sessions. The default value is 8. |

Use the data in the following table to use the **cli time-out** command.

| Variable   | Value                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------------|
| <30-65535> | Configures the timeout value, in seconds, to wait for a Telnet or CLI login session before terminating the connection. |

Use the data in the following table to use the **terminal** command.

| Variable              | Value                                                                                                                                                                                                                                       |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <8-64>                | Configures the number of lines in the output display for the current session. To configure this option to the default value, use the <b>default</b> operator with the command. The default is value 23.                                     |
| <i>disable enable</i> | Configures scrolling for the output display. The default is enabled. Use the <b>no</b> operator to remove this configuration. To configure this option to the default value, use the <b>default</b> operator with the command.<br><b>no</b> |

## Configuring CLI logging

### About This Task

Use CLI logging to track all CLI commands executed and for fault management purposes. The CLI commands are logged to the system log file as CLILOG module.

#### Note

The platform logs CLILOG and SNMPLOG as INFO. Normally, if you configure the logging level to WARNING, the system skips all INFO messages. However, if you enable CLILOG and SNMPLOG the system logs CLI Log and SNMP Log information regardless of the logging level you set. This is not the case for other INFO messages.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Enable CLI logging:  
clilog enable
3. Disable CLI logging:  
no clilog enable
4. Ensure that the configuration is correct:  
show clilog
5. View the CLI log:  
show logging file module clilog

- View the CLI log.

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#cliolog enable
```

### Variable Definitions

The following table defines parameters for the **cliolog** commands.

| Variable      | Value                                                                              |
|---------------|------------------------------------------------------------------------------------|
| <i>enable</i> | Activates CLI logging. To disable, use the <code>no cliolog enable</code> command. |

## Configure System Parameters

### About This Task

Configure individual system-level switch parameters to configure global options for the switch.

### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Change the system name:
 

```
sys name WORD<0-255>
```
- Enable support for Jumbo frames:
 

```
sys mtu <1522-9600>
```
- Enable the User Datagram Protocol (UDP) checksum calculation:
 

```
udp checksum
```

### Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Configure the system, or root level, prompt name for the switch:

```
Switch:1(config)#sys name Floor3Lab2
```

## Variable Definitions

The following table defines parameters for the **sys** command.

| Variable                                                                                      | Value                                                                                                                                                               |
|-----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>clipId-topology-ip</i><br><b>Note:</b><br>Exception: Only supported on VSP 8600 Series     | Configures the topology ip from the available CLIP.<br><i>WORD</i> <1-256>specifies the Circuitless IP interface id.                                                |
| <i>control tcp-timestamp</i>                                                                  | Enables or disables TCP Timestamp.                                                                                                                                  |
| <i>force-msg</i>                                                                              | Adds forced message control pattern.<br><i>WORD</i> <4-4> Enter force message pattern.                                                                              |
| <i>force-topology-ip-flag</i><br><b>Note:</b><br>Exception: Only supported on VSP 8600 Series | Flags set to force choice of topology flag.<br><i>enable</i>                                                                                                        |
| <i>msg-control</i>                                                                            | Configures system message control feature.                                                                                                                          |
| <i>mtu</i> <1522-9600>                                                                        | Configures Jumbo frame support for the data path. The value can be either 1522, 1950 (default), or 9600 bytes.                                                      |
| <i>name</i> <i>WORD</i> <0-255>                                                               | Configures the system, or root level, prompt name for the switch.<br><i>WORD</i> <0-255> is an ASCII string from 0-255 characters (for example, LabSC7 or Closet4). |
| <i>power</i>                                                                                  | Enables power to specified slot(s).                                                                                                                                 |
| <i>security-console</i>                                                                       | Enables the security console.                                                                                                                                       |
| <i>software</i>                                                                               | Configures software configuration.                                                                                                                                  |
| <i>priv-exec-password</i>                                                                     | Enables authentication for the Privileged EXEC CLI command mode.                                                                                                    |

## Configuring system message control

### About This Task

Configure system message control to suppress duplicate error messages on the console, and to determine the action to take if they occur.

### Procedure

- Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
- Configure system message control action:  

```
sys msg-control action <both|send-trap|suppress-msg>
```

3. Configure the maximum number of messages:  
`sys msg-control max-msg-num <2-500>`
4. Configure the interval:  
`sys msg-control control-interval <1-30>`
5. Enable message control:  
`sys msg-control`

**Example**

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Configure system message control to suppress duplicate error messages on the console and send a trap notification:

```
Switch:1(config)# sys msg-control action both
```

Configure the number of occurrences of a message after which the control action occurs:

```
Switch:1(config)# sys msg-control max-msg-num 2
```

Configure the message control interval in minutes:

```
Switch:1(config)# sys msg-control control-interval 3
```

Enable message control:

```
Switch:1(config)# sys msg-control
```

*Variable Definitions*

The following table defines parameters for the **sys msg-control** command.

| Variable                                    | Value                                                                                                                                                                                |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>action</i> <both send-trap suppress-msg> | Configures the message control action. You can either suppress the message or send a trap notification, or both. The default is suppress.                                            |
| <i>control-interval</i> <1-30>              | Configures the message control interval in minutes. The valid options are 1-30. The default is 5.                                                                                    |
| <i>max-msg-num</i> <2-500>                  | Configures the number of occurrences of a message after which the control action occurs. To configure the maximum number of occurrences, enter a value from 2-500. The default is 5. |

**Extending system message control**

**About This Task**

Use the force message control option to extend the message control feature functionality to the software and hardware log messages.

To enable the message control feature, you must specify an action, control interval, and maximum message number. After you enable the feature, the log messages, which get repeated and cross the maximum message number in the control interval, trigger the force message feature. You can either suppress the message or send a trap notification, or both.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the force message control option:
 

```
sys force-msg WORD<4-4>
```

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Configure the force message control option. (If you specify the wildcard pattern (\*\*\*\*), then all messages undergo message control:

```
Switch:1(config)# sys force-msg ****
```

### Variable Definitions

The following table defines parameters for the **sys force-msg** command.

| Variable               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD&lt;4-4&gt;</i> | Adds a forced message control pattern, where <i>WORD&lt;4-4&gt;</i> is a string of 4 characters. You can add a four-byte pattern into the force-msg table. The software and the hardware log messages that use the first four bytes that match one of the patterns in the force-msg table undergo the configured message control action. You can specify up to 32 different patterns in the force-msg table, including a wildcard pattern (****) as well. If you specify the wildcard pattern, all messages undergo message control. |

## Hardware status using EDM

This section provides methods to check the status of basic hardware in the chassis using Enterprise Device Manager (EDM).

### Configure Polling Intervals

#### About This Task

Enable and configure polling intervals to determine how frequently EDM polls for port and LED status changes or detects the hot swap of installed ports.

### Procedure

1. In the navigation pane, expand **Configuration > Device**.
2. Click **Preference Setting**.
3. Enable polling or hot swap detection.
4. Configure the frequency to poll the device.
5. Click **Apply**.

### *Preference Setting* field descriptions

Use the data in the following table to use the **Preference Setting** tab.

| Name                                       | Description                                                                                   |
|--------------------------------------------|-----------------------------------------------------------------------------------------------|
| <b>Enable</b>                              | Enables polling for port and LED status changes. The default is disabled.                     |
| <b>Poll Interval</b>                       | Specifies the polling interval, if enabled. The default is 60 seconds.                        |
| <b>Enable</b>                              | Detects the hot swap of installed ports. The default is disabled.                             |
| <b>Detection per Status Poll Intervals</b> | Specifies the number of poll intervals for detection, if enabled. The default is 2 intervals. |

## View Module Information

View the administrative status for modules in the chassis.

### About This Task

This command is not available for hardware platforms with fixed configurations. It is only available for platforms where the user can install modules in slots.

### Procedure

1. In the Device Physical View tab, select a module slot.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Card**.
4. Click the **Card** tab.

### *Card* field descriptions

Use the data in the following table to use the **Card** tab.

| Name                    | Description                                       |
|-------------------------|---------------------------------------------------|
| <b>CardType</b>         | Displays the model number of the module.          |
| <b>CardDescription</b>  | Shows a description of the installed module.      |
| <b>SerialNum</b>        | Shows the serial number for the installed module. |
| <b>PartNumber</b>       | Shows the part number.                            |
| <b>CardAssemblyDate</b> | Shows the date the module was assembled.          |

| Name                           | Description                                                             |
|--------------------------------|-------------------------------------------------------------------------|
| <b>CardHWConfig</b>            | Shows the hardware revision.                                            |
| <b>AdminStatus</b>             | Changes the administrative status for the module.                       |
| <b>OperStatus</b>              | Shows the operational status for the module.                            |
| <b>PowerManagementPriority</b> | Specifies the slot priority for power management as either high or low. |

## View Module Storage Usage

View the storage usage for modules in the chassis.

### About This Task

You cannot perform this procedure on hardware platforms with fixed configurations. It is only available for platforms where you can install modules in slots.

### Procedure

1. In the Device Physical View tab, select a module slot.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Card**.
4. Click the **Storage Usage** tab.

### **Storage Usage** Field Descriptions

Use the data in the following table to use the **Storage Usage** tab.

| Name                     | Description                                                               |
|--------------------------|---------------------------------------------------------------------------|
| <b>IntflashBytesUsed</b> | Specifies the number of bytes used in internal flash memory.              |
| <b>IntflashBytesFree</b> | Specifies the number of bytes available for use in internal flash memory. |
| <b>IntflashNumFiles</b>  | Specifies the number of files in internal flash memory.                   |
| <b>UsbBytesUsed</b>      | Specifies the number of bytes used in USB device.                         |
| <b>UsbBytesFree</b>      | Specifies the number of bytes available for use in USB device.            |
| <b>UsbNumFiles</b>       | Specifies the number of files in USB device.                              |

## View Power Supply Parameters

Perform this procedure to view information about the operating status of the power supplies.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Power Supply**.

**Details** Field Descriptions

Use the data in the following table to use the **Details** tab.

| Name                         | Description                                                                                                                                                                                                                                                                          |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                    | Specifies the ID number.<br>This field is not supported on all hardware platforms.                                                                                                                                                                                                   |
| <b>Type</b>                  | Describes the type of power used.                                                                                                                                                                                                                                                    |
| <b>Description</b>           | Provides a description of the power supply.                                                                                                                                                                                                                                          |
| <b>SerialNumber</b>          | Specifies the power supply serial number.                                                                                                                                                                                                                                            |
| <b>HardwareRevision</b>      | Specifies the hardware revision number.                                                                                                                                                                                                                                              |
| <b>PartNumber</b>            | Specifies the power supply part number.                                                                                                                                                                                                                                              |
| <b>PowerSupplyOperStatus</b> | Specifies the status of the power supply as one of the following: <ul style="list-style-type: none"> <li>on (up)</li> <li>off (down)</li> </ul>                                                                                                                                      |
| <b>InputLineVoltage</b>      | Displays the input line voltage: <ul style="list-style-type: none"> <li>low 110v—power supply connected to a 110 Volt source</li> <li>high 220v—power supply connected to a 220 Volt source</li> <li>ac110vOr220v—power supply connected to a 110 Volt or 220 Volt source</li> </ul> |
| <b>OutputWatts</b>           | Displays the output power of this power supply.                                                                                                                                                                                                                                      |
| <b>InputOperLineVoltage</b>  | Displays the operating input line voltage.<br>If the power supplies in a chassis are not of identical input line voltage values, the operating line voltage shows the low 110v value.<br>This field is not supported on all hardware platforms.                                      |
| <b>InputPower</b>            | Displays the input power of this power supply.<br>This field is not supported on all hardware platforms.                                                                                                                                                                             |

## View Power Supply Information

**Note**

This tab does not apply in all hardware platforms.

**About This Task**

Perform this procedure to view information about the operating status of the power supplies.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Power Supply Information**.

**Details** Field Descriptions

Use the data in the following table to use the **Details** tab.

| Name                         | Description                                                                                                                                                                                                                                                                          |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                    | Specifies the ID number.<br>This field is not supported on all hardware platforms.                                                                                                                                                                                                   |
| <b>Type</b>                  | Describes the type of power used.                                                                                                                                                                                                                                                    |
| <b>Description</b>           | Provides a description of the power supply.                                                                                                                                                                                                                                          |
| <b>SerialNumber</b>          | Specifies the power supply serial number.                                                                                                                                                                                                                                            |
| <b>HardwareRevision</b>      | Specifies the hardware revision number.                                                                                                                                                                                                                                              |
| <b>PartNumber</b>            | Specifies the power supply part number.                                                                                                                                                                                                                                              |
| <b>PowerSupplyOperStatus</b> | Specifies the status of the power supply as one of the following: <ul style="list-style-type: none"> <li>on (up)</li> <li>off (down)</li> </ul>                                                                                                                                      |
| <b>InputLineVoltage</b>      | Displays the input line voltage: <ul style="list-style-type: none"> <li>low 110v—power supply connected to a 110 Volt source</li> <li>high 220v—power supply connected to a 220 Volt source</li> <li>ac110vOr220v—power supply connected to a 110 Volt or 220 Volt source</li> </ul> |
| <b>OutputWatts</b>           | Displays the output power of this power supply.                                                                                                                                                                                                                                      |
| <b>InputOperLineVoltage</b>  | Displays the operating input line voltage.<br>If the power supplies in a chassis are not of identical input line voltage values, the operating line voltage shows the low 110v value.<br>This field is not supported on all hardware platforms.                                      |
| <b>InputPower</b>            | Displays the input power of this power supply.<br>This field is not supported on all hardware platforms.                                                                                                                                                                             |

## View System Temperature Information

View information about the temperature for each sensor on the device.

The system triggers an alarm when one of the zones exceeds the threshold temperature value.

### Note

This procedure does not apply to all hardware models.

### Procedure

1. In the Device Physical View tab, select the chassis.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **System Temperature** tab.

**System Temperature** field descriptions

Use the data in the following table to use the **System Temperature** tab.

| Name                                 | Description                                                                                                                                                                                                              |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SensorIndex</b>                   | Specifies the range of sensors on the device.                                                                                                                                                                            |
| <b>SensorDescription</b>             | Specifies the name of the sensor.                                                                                                                                                                                        |
| <b>Temperature (degrees celsius)</b> | Specifies the sensor temperature measured in Celsius degrees.                                                                                                                                                            |
| <b>WarningThreshold</b>              | Specifies the temperature value of the warning threshold for the sensor. When the temperature crosses the warning threshold a warning message is generated.                                                              |
| <b>CriticalThreshold</b>             | Species the temperature value of the critical threshold for the sensor. When the temperature crosses the critical threshold, a critical message is generated or the system shuts down, depending on hardware capability. |
| <b>Status</b>                        | Specifies the current temperature status based on the warning and critical thresholds.                                                                                                                                   |

## View Temperature on the Chassis

You can view information about the temperature on the chassis.

**Note**

This tab applies only on the VSP 8600 Series switch.

**About This Task**

The system triggers an alarm when one of the zones exceeds the threshold temperature value, and clears the alarm after the zone temperature falls below the threshold value.

When an elevated temperature triggers a temperature alarm, the fan speed increases, and the LED color changes on the front panel of the switch.

**Procedure**

1. In the Device Physical View tab, select the chassis.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Chassis**.
4. Select the **Temperature** tab.

**Temperature** field descriptions

Use the data in the following table to use the **Temperature** tab.

| Name                   | Description                                                                                             |
|------------------------|---------------------------------------------------------------------------------------------------------|
| <b>CpuTemperature</b>  | Current CPU temperature in Celsius.                                                                     |
| <b>MacTemperature</b>  | Current MAC component temperature in Celsius.                                                           |
| <b>Phy1Temperature</b> | Current PHY 1 component temperature in Celsius.<br>This field does not apply on all hardware platforms. |
| <b>Phy2Temperature</b> | Current PHY 2 component temperature in Celsius.<br>This field does not apply on all hardware platforms. |

|                              | VSP 8600 Series | VSP 8600 4.5       |
|                              | XA1400 Series   | VOSS 8.0.50        |

## Command Line Interface Fundamentals

---

This section describes the Command Line Interface (CLI).

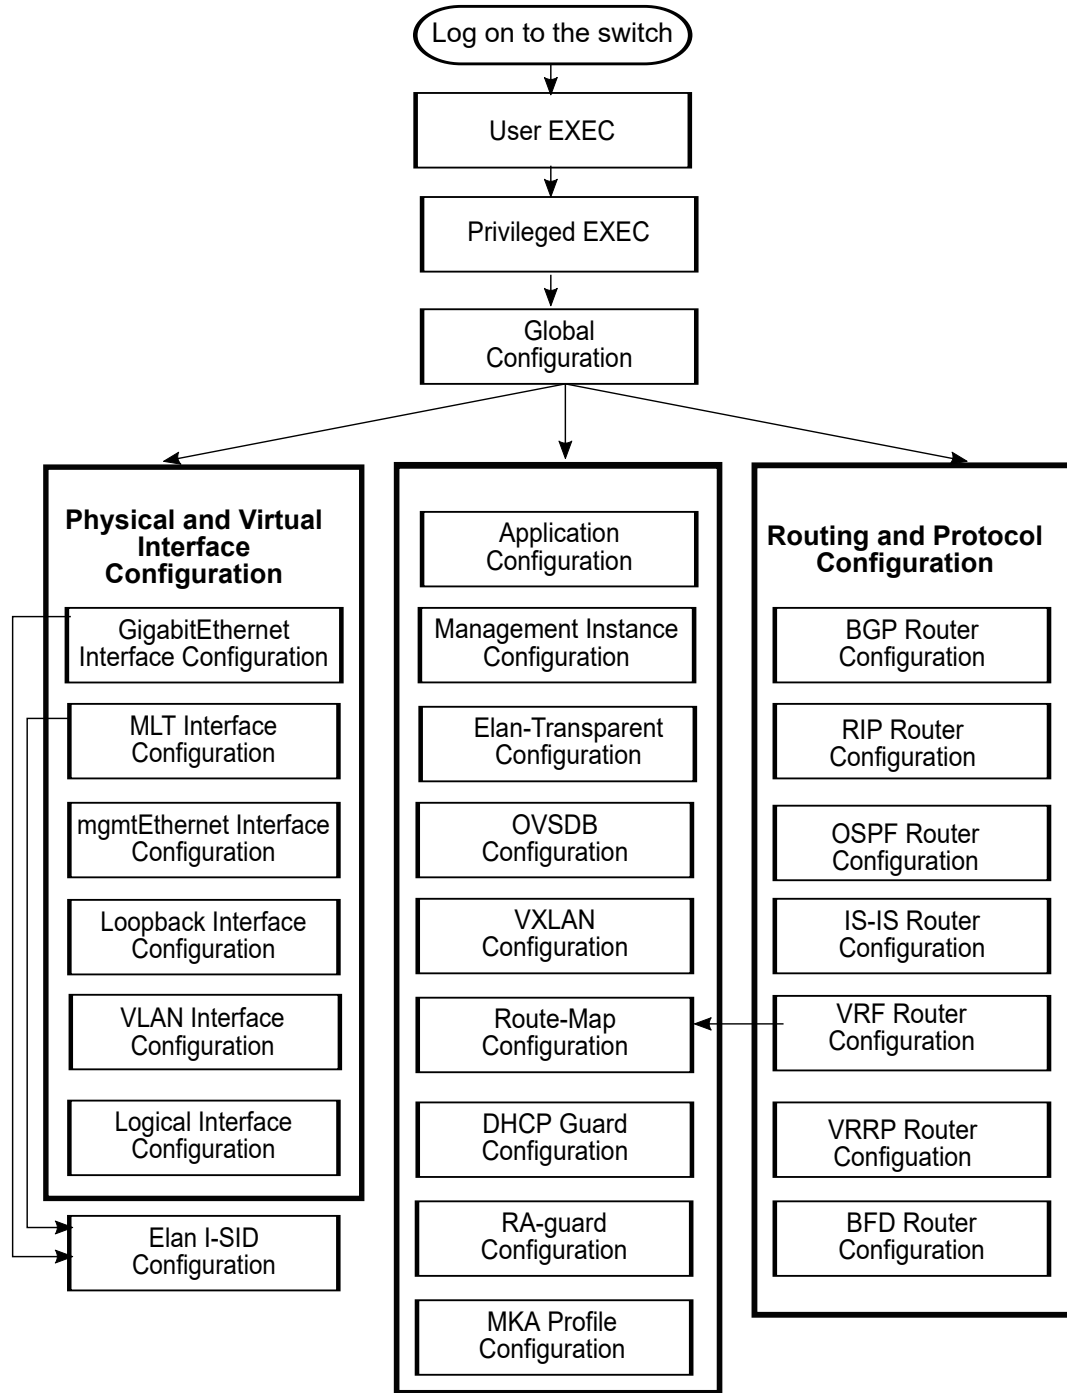

CLI is an industry standard command line interface that you can use for single-device management.

### CLI Command Modes

CLI command modes provide specific sets of CLI commands. When you log onto the switch, you are in User EXEC mode with limited commands. While in a higher mode, you can access most commands from lower modes, except if they conflict with commands of your current mode.

There are two categories of CLI commands: show commands and configuration commands. You can use show commands from multiple command modes with the same results; they show the same configuration information regardless of the command mode. Configuration command results, however, might be dependent on the command mode from which a configuration command is used. For example, an **enable** command used in Global Configuration mode will enable a feature globally for all devices, and the same command used from one of the interface command modes will enable a feature for a specific interface only.

The following figure illustrates the navigation paths for the various command modes:

**Figure 10: CLI Command Mode Navigation**

Your user authorization credentials determine what commands are available to you in Privileged EXEC mode and all higher-level modes. See [System Access](#) on page 3299 for more information.

To navigate from higher-level modes to lower-level modes, use the following commands:

- **exit** to navigate from a higher-level mode to a lower-level mode, down to Privileged EXEC mode
- **end** to navigate from any command mode directly to Privileged EXEC mode
- **disable** to navigate from Privileged EXEC mode to User EXEC mode
- **logout** to terminate the CLI session from any command mode

The following table describes the various command modes, including the CLI command to access each mode, the command prompt that displays in each mode, and a description of the purpose of the mode.

#### Note

Some command modes are hardware dependent. If any of the following commands modes do not display on your hardware, they are not supported or applicable.

**Table 28: CLI Command Mode Summary**

| Command mode                            | Command to access mode                                                                                                                                                                                                                          | Prompt displayed in mode | Description                                                                                                                                          |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| User EXEC                               | None required; default mode                                                                                                                                                                                                                     | >                        | View configuration settings and connection status.                                                                                                   |
| Privileged EXEC                         | enable                                                                                                                                                                                                                                          | #                        | Configure limited device-wide settings.                                                                                                              |
|                                         | <b>Note:</b><br>Depending on feature configuration, you can be prompted to enter a username and password to access Privileged EXEC mode. For more information, see <a href="#">Authentication for Privileged EXEC Command Mode</a> on page 241. |                          |                                                                                                                                                      |
| Global Configuration                    | configure<br>{terminal <br>network}                                                                                                                                                                                                             | (config) #               | From a terminal or TFTP server, configure device-wide global parameters on a running configuration, or specify the filename of a configuration file. |
| GigabitEthernet Interface Configuration | interface<br>GigabitEthernet<br>{slot/port[/sub-<br>port] [-slot/<br>port[/subport]]<br>[, ...]}                                                                                                                                                | (config-if) #            | Configure chassis operations and features on a physical port.                                                                                        |

| DHCP-guard Configuration       | ipv6 fhs dhcp-guard policy<br>WORD<1-64>  | (config-dhcpguard) #     | Configure DHCPv6 for advertised address-based, prefix-based, and preference-based filtering.                                                                             |
| RA-guard Configuration         | ipv6 fhs ra-guard policy WORD<1-64>       | (config-raguard) #       | Configure RA Guard for advertised IPv6 and MAC address-based, IPv6 prefix-based, preference-based, hop count limit-based, and default router preference-based filtering. |
| VXLAN Configuration            | vnid <1-16777215><br>i-sid <1-16777215>   | (vxlan:<1-16777215>) #   | Associate port or MLT interface VLANs, configure VXLAN endpoints and untagged traffic.                                                                                   |
| MKA Profile Configuration      | macsec mka profile<br>WORD<1-16>          | (mka-profile) #          | Configure replay protection and confidentiality offset for an MKA profile.                                                                                               |
| BFD Router Configuration       | router bfd                                | (router-bfd) #           | Configure device-wide BFD settings.                                                                                                                                      |

*Special CLI Command Modes*

A special CLI command mode provides a set of specific CLI commands that are different from the standard CLI command modes and the CLI commands available in them. For example, a set of CLI commands that are specifically introduced to configure services on a Virtual Machine (VM) through a specific CLI command mode.

**Note**

Special CLI command modes are hardware dependent. If they do not display on your hardware, they are not supported or applicable.

The following table describes the special command mode.

**Table 29: Special CLI Command Mode Summary**

| Special command mode              | Command mode navigation              | Command to access mode                                                                            | Prompt displayed in mode | Description                                                                                                               |
|-----------------------------------|--------------------------------------|---------------------------------------------------------------------------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------|
| Fabric IPsec Gateway              | Accessible from Privileged EXEC      | virtual-service<br>WORD<1-128><br>console<br><br><b>Note:</b><br>Type CTRL+Y to exit the console. | FIGW>                    | Configure services like IPsec, fragmentation and reassembly, and to manage the Fabric IPsec Gateway VM.                   |
| IS-IS Router Remote Configuration | Accessible from Global Configuration | router isis<br>remote                                                                             | config-isis-remote>      | Configure the Multi-area SPB parameters like area virtual node, Shortest Path Bridging MAC (SPBM), manual area and so on. |

## Default User Names and Passwords for CLI

The following table contains the default user names and passwords that you can use to log on to the switch using the command line interface (CLI). For more information about how to change passwords, see [Security](#) on page 2987.

**Table 30: CLI default user names and passwords**

| User name | Password | Description    |
|-----------|----------|----------------|
| rwa       | rwa      | read-write-all |
| rw        | rw       | read-write     |
| ro        | ro       | read-only      |
| l1        | l1       | layer 1        |
| l2        | l2       | layer 2        |
| l3        | l3       | layer 3        |

You can create up to a maximum of 10 CLI users for each role. For more information, see [Multiple CLI Users for Each Role](#) on page 3305.

If you enable enhanced secure mode, the user names and passwords are different than the default values documented in the preceding table. For more information on enhanced secure mode, see [Enhanced secure mode authentication access levels](#) on page 3306.

### Important

The default passwords and community strings are documented and well known. As a best practice, change the default passwords and community strings immediately after you first log on. For more information about how to change user names and passwords, see [Security](#) on page 2987.

## Documentation convention for the port variable

Commands that require you to enter one or more port numbers on the switch use the parameter `{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}` in the syntax. The following table specifies the rules for using `{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`.

| Syntax                                                             | How to use                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]}</code>                                | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.<br>For example, 1/1 indicates the first port on slot 1. 1/41/1 indicates the first channel on slot 1, port 41.                                                                                                                                                                                                         |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.<br>For example, 1/1-1/3 indicates ports 1 to 3 on slot 1, or 1/41/1,1/41/3 indicates the first and third channels of slot 1, port 41. |

## Command completion

The CLI provides potential command completions to the command string. Completions are provided by using a question mark (?) or by using the CLI autocompletion feature.

### ? command completion

The ? command completion is available for any valid command. By typing a command and using a ? as the last argument in the command, the system returns a list of possible command completions from the point of the ?. A short description is provided with each possible completion.

If you enter the following command:

```
Switch:1(config-isis)#redistribute ?
```

CLI provides a list of completions for the **redistribute ?** command.

```
Switch:1(config-isis)#redistribute ?
  direct      isis redistribute direct command
  ospf        isis redistribute ospf command
  rip         isis redistribute rip command
  static      isis redistribute static command
```

All the parameters listed under `redistribute` indicate sub-context commands.

You must use one of the available completions, and if necessary, use the command completion help again to find the next completion.

```
Switch:1(config-isis)#redistribute direct ?
  enable      Enable isis redistribute direct command
  metric      Isis route redistribute metric
  metric-type Set isis redistribute metric type
  route-map   Set isis redistribute direct route-policy
  subnets    Set isis redistribute subnets
<cr>
```

When you see `<cr>` (Carriage Return/Enter Key) in the list with the additional choices, this means that no additional parameters are required to execute the CLI command. However, the additional choices listed could be peer commands or sub-context commands.

For example, the parameters listed under **`redistribute direct ?`** are peer commands. You can enter these peer commands on the same line as the root command, for example **`redistribute direct enable`**. However, the `<cr>` indicates that you can also enter the **`redistribute direct`** command only and this command does not require any additional parameters at this level.

### *CLI autocompletion*

CLI autocompletion is a feature that you can use to automatically fill in the unique parts of a command string rather than typing the entire command. Autocompletion makes the CLI experience easier and prevents mistakes in spelling that force you to re-enter the command.

Autocompletion completes the token in the command as soon as it becomes unique.

The `Tab` key autocompletes the command without executing the command, and places the cursor immediately after the last character. The `Enter` key autocompletes the command and executes it.

To enable redistribution of ISIS direct routes,

```
Switch:1(config-isis)#redistribute direct
```

When you use `redistribute ?`, you see four possible sub-context commands.

```
direct
static
ospf
rip
```

If you type the following without pressing `Enter`:

```
Switch:1(config-isis)#redistribute direct m
```

and press the `Tab` key, the system completes the command to the following point:

```
redistribute direct metric
```

Two possible completions exist. You can type `-t`, and then press `Tab` to finish the command:

```
Switch:1(config-isis)#redistribute direct metric-type
```

## default command operator

You can reset the modified configuration of a command to the default configuration by using the default operator. For more information about the default value for each command, see [VOSS Command Line Interface Commands Reference](#).

Use the ? command completion along with the default keyword in each configuration mode, to view the list of commands that support the default operator. For more information, see [Command completion](#) on page 236.

### Examples

Configure **csnp-interval** to its default value. The default value of **csnp-interval** is 10 seconds.

```
Switch:1>show isis

## no command operator

You can use the **no** operator in a command to negate a configuration. Based on the functionality of the command, you can perform negations, such as disable, delete, remove, or reset to the default configuration. For more information about the **no** operator for each command, see [VOSS Command Line Interface Commands Reference](#).

Use the ? command completion along with the **no** keyword to view the list of commands that support the **no** operator in each configuration mode. For more information, see [Command completion](#) on page 236.

Negate the automatic virtual link that provides automatic dynamic backup link for OSPF traffic.

```

Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router ospf
Switch:1(config-ospf)#no auto-vlink

```

Remove an IP address configuration from VLAN.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 3
Switch:1(config-if)#no ip address 192.0.2.4
```

View the commands that can negate a configuration in RIP router configuration mode.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router rip
Switch:1(config-rip)#no ?
Negate a command or set its defaults
ipv6          Disable ipv6 configurations
network       Disable rip on an ip network
redistribute  To disable/delete redistribute globally
Switch:1(config-rip)#no network ?
{A.B.C.D} Network ip address
Switch:1(config-rip)#no network 192.0.2.4 ?
<cr>
```

## GREP with CLI show command

You can use Global Regular Expression Print (GREP) with **show** commands to filter the output based on match criteria.

Enter the **show** command followed by the pipe (|) character, followed by the GREP filter command. The **show** command output contains only the lines that match the GREP filter pattern.

**Note**

The **show fulltech** command does not support GREP filters.

The following GREP filter commands are supported.

| GREP filter function | Description                                                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>begin</i>         | Displays the output of a command starting from the first line, which matches the given pattern.                           |
| <i>count</i>         | Counts the number of lines in the output of a command.                                                                    |
| <i>exclude</i>       | Displays only the output lines which do not match the given pattern. The lines matching the pattern are discarded.        |
| <i>head</i>          | Limits the output of a command to the first few lines. If a number is not specified then only the first 10 lines display. |
| <i>include</i>       | Displays only the output lines which match the given pattern.                                                             |

| GREP filter function | Description                                                                                                                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>no-more</i>       | Temporarily disables pagination for the output of an CLI command. When the lines of output exceed the terminal length, you are not prompted to continue or quit but the entire output of the command continues to be displayed. The effect is similar to setting terminal length 0 but only for the current command. |
| <i>tail</i>          | Limits the output of a command to the last few lines. If a number is not specified then only the last 10 lines display.                                                                                                                                                                                              |

## Timestamp in show command outputs

The output for all CLI show commands includes a timestamp header to indicate when the command output was generated. This information can be helpful when communicating with Support.

The following command output shows a timestamp example.

```
Switch:1#show alarm statistics
*****
                Command Execution Time: Wed Nov 07 19:55:15 2018 UTC
*****

=====
                        ALARM STATISTICS
=====
PERSISTENT PERSISTENT PERSISTENT PERSISTENT DYNAMIC DYNAMIC DYNAMIC DYNAMIC
ALARM      ACTIVE      CLEARED      WRPRD      ALARM      ACTIVE      CLEARED      WRPRD
0           0           0           0           11         8           3           0
```

## Authentication for Privileged EXEC Command Mode

For enhanced security, you can request user authentication to enter Privileged EXEC command mode. When you configure password authentication, the switch prompts you to enter a username and password to access Privileged EXEC command mode from User EXEC command mode. You use the same username and password used to Telnet or SSH to the switch.

For more information about configuring Privileged EXEC authentication, see [Authentication for Privileged EXEC Command Mode](#) on page 2994.

## CLI Procedures

This section contains information about common CLI tasks. You can access CLI during runtime to manage the switch.

### Logging on to the software

#### Before You Begin

- The first time you connect to the switch, you must log on to CLI using the direct console port.

## About This Task

After you first connect to CLI you can log on to the software using the default user name and password. For more information about the default user names and passwords, see [Default User Names and Passwords for CLI](#) on page 235.

## Procedure

1. At the login prompt, enter the user name.
2. At the password prompt, enter the password.

## View the Configuration

You can view the running configuration using the show command.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the running configuration:  
show running-config

## Example

```
VSP-8284XSQ:1#show running-config
Preparing to Display Configuration...
#
# Sat Mar 13 14:35:01 2021 UTC
# box type           : VSP-8284XSQ
# software version   : 8.4.0.0
# cli mode           : ECLI
#
#Card Info :

#
config terminal

#
# BOOT CONFIGURATION
#

boot config flags ftpd
boot config flags sshd
boot config flags telnetd

#boot config sio console baud 9600 1
# end boot flags
```

## Saving the configuration

After you change the configuration, you must save the changes to the module. Save the configuration to a file to retain the configuration settings.

### About This Task

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Save the running configuration:  
`save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]`

### Example

Save the configuration to the default location:

```
Switch:1#save config
```

Identify the file as a backup file and designate a location to save the file:

```
Switch:1#save config backup 198.51.100.1/configs/backup.cfg
```

*Variable definitions*

Use the data in the following table to use the **save config** command.

| Variable                  | Value                                                                                                                                                                                                                                                                                                       |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>backup</i> WORD<1-99>  | Saves the specified file name and identifies the file as a backup file.<br>WORD<1-99> uses one of the following formats: <ul style="list-style-type: none"> <li>a.b.c.d:&lt;file&gt;</li> <li>/intflash/&lt;file&gt;</li> </ul> The file name, including the directory structure, up to 1 to 99 characters. |
| <i>file</i> WORD<1-99>    | Specifies the file name in one of the following formats: <ul style="list-style-type: none"> <li>/intflash/&lt;file&gt;</li> <li>a.b.c.d:&lt;file&gt;</li> </ul> The file name, including the directory structure, up to 1 to 99 characters.                                                                 |
| <i>verbose</i>            | Saves the default and current configuration. If you omit this parameter, the command saves only parameters you change.                                                                                                                                                                                      |
| <i>standby</i> WORD<1-99> | Specifies the standby file name in the following format: <ul style="list-style-type: none"> <li>/intflash/&lt;file&gt;</li> </ul> The file name, including the directory structure, up to 1 to 99 characters.                                                                                               |

## Configure the Web Server

**Note**

DEMO FEATURE - Read Only User for EDM is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

Perform this procedure to enable and manage the web server using the Command Line Interface (CLI). After you enable the web server, you can connect to EDM.

HTTP and FTP support both IPv4 and IPv6 addresses, with no difference in functionality or configuration. The TFTP server supports both IPv4 and IPv6 addresses. The TFTP client is not supported, only the server.

## About This Task

This procedure assumes that you use the default port assignments. You can change the port number used for HTTP and HTTPS.

### Important

If you want to allow HTTP access to the device, you must disable the web server secure-only option. If you want to allow HTTPS access to the device, the web server secure-only option is enabled by default.

## Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable the web server:  
`web-server enable`
3. Disable the secure-only option (for HTTP access) :  
`no web-server secure-only`
4. Enable the secure-only option (for HTTPS access) :  
`web-server secure-only`
5. Enable read-only user:  
`web-server read-only-user enable`
6. Display the web server status:  
`show web-server`

## Example

Enable the secure-only web-server. Configure the Read-Write-All access level username to smith2 and the password to 90Go2437. Enable read-only-user for the web server. Configure the read-only-user username to jones6 and the password to G69s8672.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#web-server enable
Switch:1(config)#web-server secure-only
Switch:1(config)#web-server read-only-user enable
Switch:1(config)#web-server password rwa smith2
Enter the New password : *****
Re-enter the New password : *****
Password changed.
Switch:1(config)#web-server password ro jones6
Enter the New password : *****
Re-enter the New password : *****
Password changed.
Switch:1(config)#show web-server

Web Server Info :

      Status                : on
      Secure-only            : enabled
      TLS-minimum-version    : tlsv12
      RO Username Status     : enabled
```

```

RO Username           : jones6
RO Password           : *****
RWA Username          : smith2
RWA Password          : *****
Def-display-rows     : 30
Inactivity timeout    : 900 sec
Html help tftp source-dir :

Minimum password length : 8
Last Host Access Blocked : 0.0.0.0
In use certificate    : Self signed

```

### Variable Definitions

Use the data in the following table to use the **web-server** command.

| Variable                              | Value                                                                                                                                                                                                                                                                                                     |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>def-display-rows</i> <10-100>      | Configures the number of rows each page displays, between 10 and 100.                                                                                                                                                                                                                                     |
| <i>enable</i>                         | Enables the web interface. To disable the web server, use the <b>no</b> form of this command:<br>no web-server [enable]                                                                                                                                                                                   |
| <i>help-tftp</i> <WORD/0-256>         | Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/  peer:/ [<dir>]. The path can use 0-256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> <li>• 192.0.2.1:/help</li> <li>• 192.0.2.1:/</li> </ul> |
| <i>http-port</i> <80-49151>           | Configures the web server HTTP port. The default port is 80.                                                                                                                                                                                                                                              |
| <i>https-port</i> <443-49151>         | Configure the web server HTTPS port. The default port is 443.                                                                                                                                                                                                                                             |
| <i>inactivity-timeout</i> <30-65535>  | Configures the web-server session inactivity timeout. The default is 900 seconds (15 minutes).                                                                                                                                                                                                            |
| <i>password</i> {ro   rwa} WORD<1-20> | Configures the logon and password for the web interface.                                                                                                                                                                                                                                                  |
| <i>password min-passwd-len</i> <1-32> | Configures the minimum password length. By default, the minimum password length is 8 characters.                                                                                                                                                                                                          |

| Variable                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>read-only-user</code>                          | Enables read-only user for the web server.<br><br><b>Note:</b><br><b>read-only-user enable</b> is available for demonstration purposes on some products. For more information, see <a href="#">VOSS Feature Support Matrix</a> .                                                                                                                                                                             |
| <code>secure-only</code>                             | Enables secure-only access for the web server.                                                                                                                                                                                                                                                                                                                                                               |
| <code>tls-min-ver&lt;tlsv10 tlsv11 tlsv12&gt;</code> | Configures the minimum version of the TLS protocol supported by the web-server. You can select among the following: <ul style="list-style-type: none"> <li>• <code>tlsv10</code> - Configures the version to TLS 1.0.</li> <li>• <code>tlsv11</code> - Configures the version to TLS 1.1.</li> <li>• <code>tlsv12</code> - Configures the version to TLS 1.2</li> </ul> The default is <code>tlsv12</code> . |

## Using GREP CLI show command filters

Use the following GREP filters to output only the command lines specified by the filter.

### Procedure

- Count the number of lines in the output:

```
<CLI command> | count
```
- Display the output of a command starting from the first line that matches the given pattern:

```
<CLI command> | begin WORD<0-255> [field <number>] [ignore-case]
[header <number>]
```
- Display only the output lines that match the given pattern:

```
<CLI command> | include <pattern> [field <number>] [ignore-case]
[header <number>]
```
- Display only the output lines that do not match the given pattern:

```
<CLI command> | exclude <pattern> [field <number>] [ignore-case]
[header <number>]
```
- Temporarily disable pagination for the output of a CLI command:

```
<CLI command> | no-more
```

There is no prompt to continue or to quit when the lines of output exceed the terminal length.
- Limit the output of a command to the first few lines:

```
<CLI command> | head [<number>]
```

If a number is not specified, the first 10 lines display.
- Limit the output of a command to the last few lines:

```
<CLI command> | tail [<number>] [from-line <number>] [header <number>]
```

If a number is not specified, the last 10 lines display.

**Example**

```
Switch:1>enable
Switch:1#configure terminal
```

Count the number of lines in the output:

```
Switch1:#show vlan basic | count
Count: 17 lines
```

Display only the output lines that match the given pattern:

```
Switch:1(config)#show vlan basic | include byPort field 3 header 6

```

### Variable definitions

The GREP filters use the following parameters:

| Parameter                 | Description                                                                                                                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>field</i> <number>     | Specifies the field in each line to match against the pattern. Fields are separated by white spaces and are counted starting with 1 for the left-most field.<br>If the output is formatted as a table, whitespaces are not counted as fields. |
| <i>from-line</i> <number> | Specifies the remaining output starting with a given line.                                                                                                                                                                                    |
| <i>head</i> <number>      | Specifies the number of lines to keep from the beginning of the output.                                                                                                                                                                       |
| <i>header</i> <number>    | Specifies a number of lines from the start of the output to display unchanged before trying to match the pattern. This parameter is useful to keep the header of a table intact. This filter skips the header lines.                          |
| <i>ignore-case</i>        | Specifies letters to match in the pattern regardless of case.                                                                                                                                                                                 |
| <number>                  | Specifies the number of lines of output to keep, either from the beginning of the output or from the end of the output.                                                                                                                       |
| <pattern>                 | Specifies the regular expression to match against each line of output. Use quotations if the parameter contains spaces.                                                                                                                       |

## Enterprise Device Manager Fundamentals

This section details Enterprise Device Manager (EDM).

EDM is a web-based graphical user interface (GUI) you can use to configure a single switch. EDM runs from the switch and you can access it from a web browser. You do not need to install additional client software, and you can access it with all operating systems.

## Supported Browsers

Use the following browser versions to access Enterprise Device Manager (EDM):

- Microsoft Edge 80+
- Microsoft Internet Explorer 11+
- Mozilla Firefox 85+
- Google Chrome 88+
- Safari 14+

For optimal performance, use Mozilla Firefox or Google Chrome.

## Enterprise Device Manager Access

To access EDM, open `http://<deviceip>/login.html` or `https://<deviceip>/login.html` from Microsoft Edge, Microsoft Internet Explorer, Google Chrome, or Mozilla Firefox. Ensure you use a supported browser version.

### Important

- You must enable the web server from CLI (see [Configure the Web Server](#) on page 244) to enable HTTP access to the EDM. If you want HTTP access to the device, you must also disable the web server secure-only option. The web server secure-only option, allowing for HTTPS access to the device, is enabled by default. As a best practice, take the appropriate security precautions within the network if you use HTTP
- EDM access is available to read-write users only

If you experience issues while connecting to the EDM, check the proxy settings. Proxy settings can affect EDM connectivity to the switch. Clear the browser cache and do not use proxy when connecting to the device.

## Default User Name and Password for EDM

The following table contains the default user name and password that you can use to log on to the switch using EDM. For more information about changing the passwords, see [Security](#) on page 2987.

**Table 32: EDM default username and password**

| Username | Password |
|----------|----------|
| admin    | password |

For information about creating CLI accounts for each user role on the switch, see [Multiple CLI Users for Each Role](#) on page 3305.

### Important

The default passwords and community strings are documented and well known. Change the default passwords and community strings immediately after you first log on. For more information about changing user names and passwords, see [Security](#) on page 2987.

## Device Physical View

After you access EDM, the system displays a real-time physical view of the front panel of the device. From the front panel view, you can view fault, configuration, and performance information for the device or a single port. You can open this tab by clicking the **Device Physical View** tab above the device view.

You can use the device view to determine the operating status of the various ports in your hardware configuration. You can also use the device view to perform management tasks on specific objects. In the device view, you can select a port or the entire chassis. To select an object, click the object. EDM outlines the selected object in yellow, indicating your selection.

The conventions on the device view are similar to the actual device appearance. The port LEDs and the ports are color-coded to provide status. Green indicates the module or port is up and running, red indicates the module or port is disabled, dark pink indicates a protocol is down, and amber indicates an enabled port that is not connected to anything. For information about LED behavior, see your hardware documentation.

## EDM Window

The following list identifies the different sections of the EDM window:

- Navigation pane—Located on the left side of the window, the navigation pane displays all the available command tabs in a tree format. A row of buttons at the top of the navigation pane provides a quick method to perform common functions.
- Content pane—Located on the right side of the window, the content pane displays the tabs and dialog boxes where you can view or configure parameters on the switch.
- Menu bar—Located at the top of the content pane, the menu bar shows the most recently accessed primary tabs and their respective secondary tabs.
- Toolbar—Located just below the menu bar, the toolbar provides quick access to the most common operational commands such as Apply, Refresh, and Help.

The following figure shows an example of the Device Physical View tab within the EDM window.

### Note

The system displays the Device Physical View tab on your hardware differently than the following example.

**Figure 11: EDM window**

## Navigation Pane

You can use the navigation pane to see what commands are available and to quickly browse through the command hierarchy. A row of buttons at the top of the navigation pane provides a quick method to perform common functions.

**Note**

For module-based chassis, menu options related to a specific module are activated only after you install and select the required module.

The following table describes the buttons that display at the top of the navigation pane.

**Table 33: Navigation pane buttons**

| Button | Name             | Description                                                                                     |
|--------|------------------|-------------------------------------------------------------------------------------------------|
|        | Save Config      | Saves the running configuration.                                                                |
|        | Refresh Status   | Refreshes the Device Physical View.                                                             |
|        | Edit             | Edits the selected item in the Device Physical View.                                            |
|        | Graph            | Opens the graph options for the selected item in the Device Physical View.                      |
|        | Help Setup Guide | Opens instructions about how to install the Help files and configure EDM to use the Help files. |

Expand a folder by clicking it. Some folders have subfolders such as the Edit folder, which has the Port, Diagnostics, and other subfolders.

Within each folder and subfolder menu, there are numerous options, which provide access to tabs. To open an option, select it. The selected tab displays in the menu bar and opens in the content pane. The following table describes the main folders in the navigation pane.

**Table 34: Navigation Pane Folders**

| Menu             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Device           | <p>Use the Device menu to refresh and update device information or enable polling.</p> <ul style="list-style-type: none"> <li>• Preference Setting — Enable polling or hot swap detection. Configure the frequency to poll the device.</li> <li>• Refresh Status — Use this option to refresh the device view.</li> <li>• Rediscover Device — Use this to trigger a rediscovery to update all of the device information.</li> </ul>                                                                                                                                                                                                                                                                        |
| VRF Context view | <p>Use the VRF Context view to switch to another VRF context when you use the embedded EDM. GlobalRouter is the default view at log in. You can configure both Global Router (GRT) and Virtual Routing and Forwarding (VRF) instances when you launch a VRF context view. You can open only five tabs for each EDM session.</p>                                                                                                                                                                                                                                                                                                                                                                            |
| Edit             | <p>Use the Edit menu to view and configure parameters for the chassis hardware or for the currently selected object. The selected object can be one or more ports. You can also use the Edit menu to perform the following tasks:</p> <ul style="list-style-type: none"> <li>• check and configure ports, including the internal Extreme Integrated Application Hosting ports, on the device</li> <li>• run diagnostic tests</li> <li>• change the configuration of many features, including but not limited to, the file system, NTP, OVSDB, SMTP, Link-state tracking, service delivery, Fabric Attach, VTEP, DvR, Management Instance, Endpoint Tracking, and SNMPv3 settings for the device</li> </ul> |
| Graph            | <p>Use the Graph menu to view and configure EDM statistics and to produce graphs of the chassis or port statistics.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Power Management | <p>Use the Power Management menu to view and configure Energy Saver.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| VLAN             | <p>Use the VLAN menu to view and configure VLANs, spanning tree groups (STG), MultiLink Trunks/LACP, SMLT, and SLPP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| IS-IS            | <p>Use the IS-IS menu to view and configure IS-IS, Shortest Path Bridging MAC (SPBM), statistics, I-SIDs, and Multi-area SPB.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| VRF              | <p>Use the VRF menu to view and create VRFs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 34: Navigation Pane Folders (continued)**

| Menu           | Description                                                                                                                                                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Security       | Use the Security menu to view and configure access policies, ACL filters, certificates, and features such as RADIUS, RADIUS CoA, SSH, IPSec, TACACS+, and EAPoL.                                                                                                              |
| QOS            | Use the QOS menu to view and configure mapping tables, QoS port states, CoS Queue Stats, and Queue Profiles.                                                                                                                                                                  |
| Serviceability | Use the Serviceability menu to enable, configure, or view: <ul style="list-style-type: none"> <li>• RMON</li> <li>• sFlow</li> <li>• Application Telemetry</li> <li>• SLA Monitor</li> <li>• RESTCONF</li> <li>• Virtual services</li> <li>• ExtremeCloud IQ Agent</li> </ul> |

## Menu Bar

The menu bar is above the content pane and consists of two rows of tabs.

- The top row displays the tabs you can open through the navigation pane. The system displays these primary tabs in the sequence in which you open them.
- After you click a primary tab, the secondary tabs associated with it display in the bottom row. Click a secondary tab to display it in the content pane.

In both the top and bottom rows of the menu bar, if the number of tabs exceeds the viewable space, the system displays left- and right-pointing arrows. Click an arrow to scroll to the required tab.

To reduce the number of tabs on the top row, you can click the X on the right corner of a tab to remove it from the row. The following figure shows a sample menu bar.

**Figure 12: Menu bar**

## Toolbar

The toolbar buttons provide quick access to commonly used operational commands. The system displays the buttons that vary depending on the tab you select. However, the Apply, Refresh, and Help

buttons are on almost every screen. Other common buttons are Insert and Delete. The following list detail the common toolbar buttons.

- Apply—Use this button to execute all edits that you make.
- Refresh—Use this button to refresh all data on the screen.
- Help—Use this button to display online help that is context sensitive to the current dialog box.
- Insert—Use this button to display a secondary dialog box related to the selected tab. After you edit the configurable parameters, click the Insert button in the dialog box. This causes a new entry to display in the dialog box of the selected tab.
- Delete—Use this button to delete a selected entry.

The following figure shows a sample toolbar.

**Figure 13: Toolbar**

## Content Pane

The content pane is the main area on the right side of the window that displays the configuration tabs and dialog boxes. Use the content pane to view or configure parameters on the switch.

### Note

You can view valid ranges for all configurable parameters on EDM tabs.

The following figure is a sample that shows the content pane for the Port 1/3 General, Interface tab. If you want to compare the information in two tabs, you can undock one, then open another tab. For more information about undocking a tab, see [Undocking and docking tabs](#) on page 265.

**Figure 14: Content pane**

## EDM user session extension

If the EDM user session remains unused for a duration of ten minutes, the system displays the following message:

Your session will expire in about 5 minute(s). Would you like to extend the session?

If you do not respond, EDM automatically ends the session with the following message: `Your session has expired.`

You can log on again if you want to continue to use EDM.

## EDM interface procedures

---

This section contains procedures for starting and using Enterprise Device Manager (EDM). The software is built-in to the switch, and you do not need to install additional software.

### Connect to EDM

#### Before You Begin

- Ensure that the switch is running.
- Note the IP address of the switch.
- Ensure that you use a supported browser version.
- Ensure that you enable the web server using CLI.

#### About This Task

Perform this procedure to connect to EDM to configure and maintain your network through a graphical user interface.

#### Procedure

1. In the address field, enter the IP address of the system using the following formats: **https://<IP\_address>** (default) or **http://<IP\_address>**.

#### Note

By default the web server is configured with the secure-only option, which requires you to use HTTPS to access EDM. To access EDM using HTTP, you must disable the secure-only option.

2. In the **User Name** field, type the user name.  
The default is admin.
3. In the **Password** field, type a password.  
The default is password.
4. Select **Log On**.

### Configure the Web Management Interface

#### Note

DEMO FEATURE - Read Only User for EDM is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

### Before You Begin

- Enable the web server.
- For VSP 8600 Series, enable the web server RO user in CLI.

### About This Task

Configure the web management interface to change the user names and passwords for management access to the switch using a web browser.

HTTP, FTP, and TFTP server supports both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

You can also use the CLI interface for creating users.

### Procedure

1. In the navigation pane, open the **Configuration > Security > Control Path** folders.
2. Select **General**.
3. Select the **Web** tab.
4. Complete the **WebRWAUserName** and **WebRWAUserPassword** fields to specify the user name and password for access to the web interface.  
This user will have full permission.
5. To enable the RO user for the web server, select **WebROEnable**.

#### Note

This step does not apply to VSP 8600 Series.

6. Complete the **WebROUserName** and **WebROUserPassword** fields to specify the user name and password for access to the web interface.  
This user will have read only permission.
7. Select **Apply**.

### Web Field Descriptions

Use the data in the following table to use the **Web** tab.

| Name                                                                               | Description                                                                                        |
|------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>WebRWAUserName</b>                                                              | Specifies the RWA username from 1-20 characters. The default is admin.                             |
| <b>WebRWAUserPassword</b>                                                          | Specifies the password from 1-32 characters. The default is 12345678.                              |
| <b>WebROEnable</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series. | Enables the web server read-only (RO) user, which is disabled by default after a software upgrade. |

| Name                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>WebROUserName</b>                                                                     | Specifies the RO username from 1–20 characters. The default is user.<br><br><b>Note:</b><br>Product Notice: For VSP 8600 Series the web server RO username must be enabled in CLI.                                                                                                                                                                                                                                  |
| <b>WebROUserPassword</b>                                                                 | Specifies the password from 1–32 characters. The default is password.                                                                                                                                                                                                                                                                                                                                               |
| <b>MinimumPasswordLength</b>                                                             | Configures the minimum password length. By default, the minimum password length is 8 characters.                                                                                                                                                                                                                                                                                                                    |
| <b>HttpPort</b>                                                                          | Specifies the HTTP port for web access. The default value is 80.                                                                                                                                                                                                                                                                                                                                                    |
| <b>HttpsPort</b>                                                                         | Specifies the HTTPS port for web access. The default value is 443.                                                                                                                                                                                                                                                                                                                                                  |
| <b>SecureOnly</b>                                                                        | Controls whether the secure-only option is enabled. The default is enabled.                                                                                                                                                                                                                                                                                                                                         |
| <b>InactivityTimeout</b>                                                                 | Specifies the idle time (in seconds) to wait before the EDM login session expires. The default value is 900 seconds (15 minutes).                                                                                                                                                                                                                                                                                   |
| <b>TlsMinimumVersion</b>                                                                 | Configures the minimum version of the TLS protocol supported by the web-server. You can select from the following options: <ul style="list-style-type: none"> <li>• <code>tlsv10</code> – Configures the version to TLS 1.0.</li> <li>• <code>tlsv11</code> – Configures the version to TLS 1.1.</li> <li>• <code>tlsv12</code> – Configures the version to TLS 1.2</li> </ul> The default is <code>tlsv12</code> . |
| <b>InUseCertType</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series. | Shows if the certificate is self-signed or user-installed.<br><br><b>Note:</b><br>Product Notice: For VSP 8600 Series use the <b>show web-server</b> command in CLI to view this information.                                                                                                                                                                                                                       |
| <b>HelpTftp/Ftp_SourceDir</b>                                                            | Configures the TFTP or FTP directory for Help files, in one of the following formats: <code>a.b.c.d:/peer:/ [&lt;dir&gt;]</code> . The path can use 0–256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> <li>• <code>192.0.2.1:/Help</code></li> <li>• <code>192.0.2.1/</code></li> </ul>                                                                |
| <b>DefaultDisplayRows</b>                                                                | Configures the web server display row width between 10–100. The default is 30.                                                                                                                                                                                                                                                                                                                                      |
| <b>LastChange</b>                                                                        | Shows the last web-browser initiated configuration change.                                                                                                                                                                                                                                                                                                                                                          |

| Name                                    | Description                                                                                     |
|-----------------------------------------|-------------------------------------------------------------------------------------------------|
| <b>NumHits</b>                          | Shows the number of hits to the web server.                                                     |
| <b>NumAccessChecks</b>                  | Shows the number of access checks performed by the web server.                                  |
| <b>NumAccessBlocks</b>                  | Shows the number of access attempts blocked by the web server.                                  |
| <b>LastHostAccessBlockedAddressType</b> | Shows the address type, either IPv4 or IPv6, of the last host access blocked by the web server. |
| <b>LastHostAccessBlockedAddress</b>     | Shows the IP address of the last host access blocked by the web server.                         |
| <b>NumRxErrors</b>                      | Shows the number of receive errors the web server encounters.                                   |
| <b>NumTxErrors</b>                      | Shows the number of transmit errors the web server encounters.                                  |
| <b>NumSetRequest</b>                    | Shows the number of set-requests sent to the web server.                                        |

## Using the chassis shortcut menu

### About This Task

Perform the following procedure to display the chassis shortcut menu.

### Procedure

1. In the Device Physical View, select the chassis.
2. Right-click the chassis.

### **Chassis shortcut menu** field descriptions

Use the data in the following table to use the **Chassis** shortcut menu.

| Name                         | Description                                                                                                                                    |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Edit</b>                  | Edits chassis parameters.                                                                                                                      |
| <b>Graph</b>                 | Graphs chassis statistics.                                                                                                                     |
| <b>Refresh Status</b>        | Refreshes the status of the chassis and MDAs.                                                                                                  |
| <b>Refresh Port Tooltips</b> | Refreshes the port tooltip data of the system. The port tooltip data contains the following variables: Slot/Port, PortName, and PortOperSpeed. |

## Using the port shortcut menu

### About This Task

Perform this procedure to display the port shortcut menu.

### Procedure

1. In the Device Physical View, select a port.
2. Right-click the selected port.

### **Port shortcut menu** field descriptions

Use the data in the following table to use the port shortcut menu.

| Name                          | Description                                  |
|-------------------------------|----------------------------------------------|
| <b>Edit General</b>           | Configures the general options for the port. |
| <b>Edit IP</b>                | Configures the IP options for the port.      |
| <b>Edit IPv6</b>              | Configures the IPv6 options for the port.    |
| <b>Channelization Enable</b>  | Enables channelization for the port.         |
| <b>Channelization Disable</b> | Disables channelization for the port.        |
| <b>Graph</b>                  | Displays the statistics for the port.        |
| <b>Enable</b>                 | Enables the port.                            |
| <b>Disable</b>                | Disables the port.                           |

## Using a table-based tab

### About This Task

Change an existing configuration using a table-based tab. You cannot edit grey-shaded fields in the table. The following procedure is an illustration on how to use a table-based tab.

#### Note

You can expand the appropriate folders for any feature you configure and select a table-based tab.

### Procedure

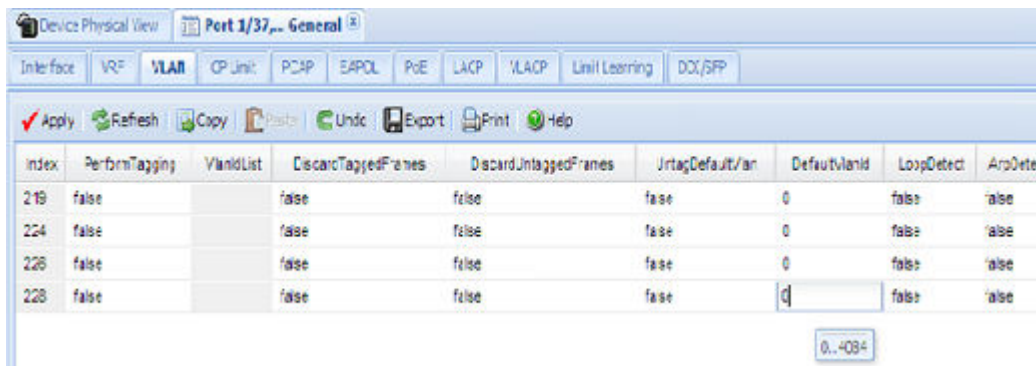

1. In the Device Physical View, select multiple ports.
2. In the navigation pane, expand the **Configuration > Edit > Port > General** folders.
3. Click the **VLAN** tab.
 

The system displays a table-based tab with the VLAN information.
4. Select a table-based tab.
5. Double-click a white-shaded field to edit the value.

- Click the arrow in the list field to view the options, and then select the appropriate value.

- In a text-entry field, double-click, and then edit the value.

- Click **Apply** to save the configuration changes.

## Monitor Multiple Ports and Configuration Support

### About This Task

You can monitor or apply the same configuration changes to more than one port by using the multiple port selection function. You can use the standard menu or the shortcut menu to edit the configuration settings for multiple ports.

**Tip**

A selected port shows a yellow outline around the port.

### Procedure

- Click the **Device Physical View** tab.
- To select multiple ports, press the **Control** key, and then click the required ports.

**Note**

When you use the Enterprise Device Manager (EDM) embedded in the software, you can select a maximum of 24 ports.

No port limitation exists for COM users.

## Open Folders and Tabs

### About This Task

Perform this procedure to navigate in EDM.

### Procedure

1. In the navigation pane, expand the **Configuration** folder.
2. Click a subfolder to expand the subfolder and see the list of menu options, for example, the **VLAN** folder.
3. In a folder or subfolder menu, click an option to open the related tabs.

## Undocking and docking tabs

### About This Task

Perform this procedure to undock a tab. You can undock tabs to have more than one tab visible at a time.

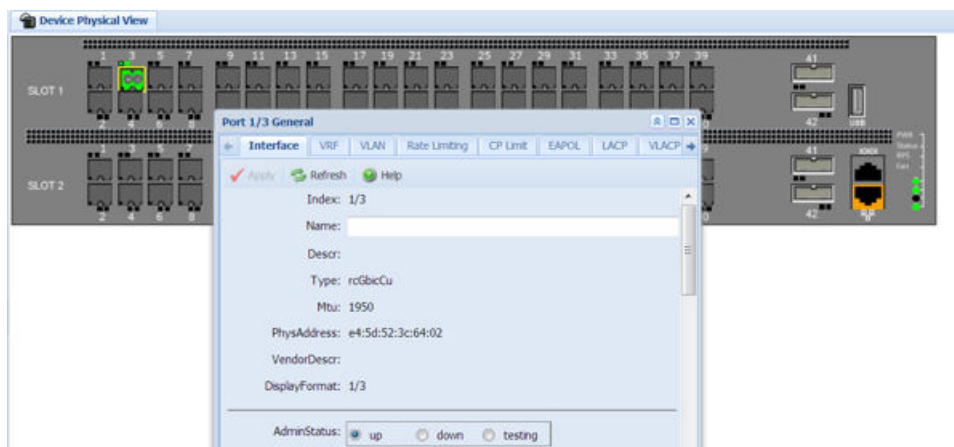

### Procedure

1. In the navigation pane, click a tab.
2. In the menu bar, click and drag a tab to undock it.
3. In the top right corner of the tab, click **pages** to dock the tab.

*Example of undocking and docking tabs*

### Procedure

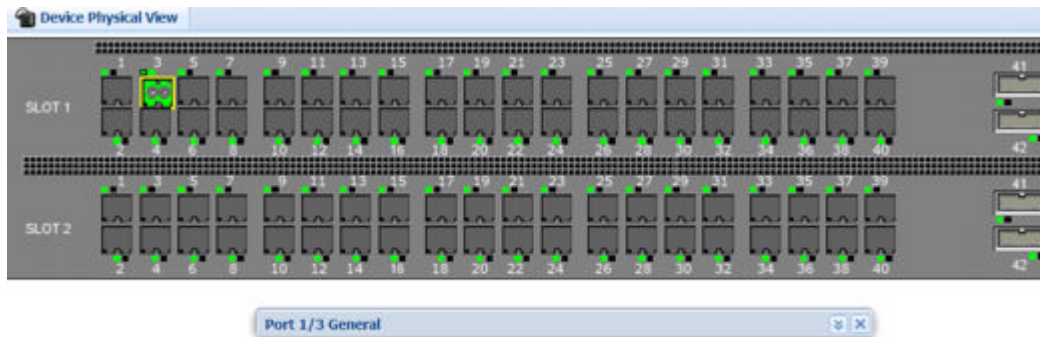

1. Click the **Device Physical View** tab.
2. In the Device Physical View, select a port. In this example, right-click port 3.
3. In the **Port** shortcut menu, click **Edit General**.
4. Click and drag the **Port 1/3 General** tab wherever you want on the screen as shown in the following figure.

5. To reposition the tab anywhere on the screen, click and drag the title bar.
6. To manipulate the tab, click on the buttons in the top-right of the dialog box.

- Click the up arrowhead to minimize the tab as shown in the following figure.

- Click the down arrowhead to restore the tab to its original size.
- Click the pages to dock the tab back into the menu bar.
- Click the X to close the tab.

## Installing EDM help files

While the EDM GUI is bundled with the switch software, the associated EDM help files are not. To access the help files from the EDM GUI, you must install the EDM help files on a TFTP or FTP server in your network.

Use the following procedure to install the EDM help files on a TFTP or FTP server, and configure EDM to use the help files

### Before You Begin

If you use an FTP server to store the help files, ensure that you configure the switch with the host user name and password.

### Procedure

- Download the EDM help file.
- On a TFTP or FTP server reachable from the switch, create a directory called **Help**.

#### Tip

You can name the directory anything that will help you remember its purpose.

- Unzip the EDM help zip file into the directory created in the preceding step.
- In the EDM navigation pane, expand the **Configuration > Security > Control Path** folders.
- Click **General**.
- Click **Web**.
- In the **HelpTftp/Ftp\_SourceDir** field, enter the IP address of the file server and the path to the help files, for example, 192.0.2.15:/home/Help/.

## File Management in EDM

This section contains procedures for managing files with Enterprise Device Manager (EDM).

Use the File System tab to perform the following tasks:

- Copy a file.
- Check the amount of memory used and the number of files stored in the internal flash memory.
- Verify the name, size, and storage date of each file present in the internal flash memory.
- Display USB file information.

## Copy a File

### About This Task

Copy files on the internal flash.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **File System**.
3. Click the **Copy File** tab.
4. Edit the fields as required.
5. Click **Apply**.

### **Copy File** Field Descriptions

Use the data in the following table to use the **Copy File** tab.

| Name               | Description                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Source</b>      | Identifies the device and file name to copy. You must specify the full path and filename, for example, <deviceip-ftp server>: /<filename>                                                                                                                                               |
| <b>Destination</b> | Identifies the location to which to copy the source file with the filename, for example, /intflash/<filename>                                                                                                                                                                           |
| <b>Action</b>      | Starts or stops the copy process.                                                                                                                                                                                                                                                       |
| <b>Result</b>      | Specifies the result of the copy process: <ul style="list-style-type: none"> <li>• none</li> <li>• inProgress</li> <li>• success</li> <li>• fail</li> <li>• invalidSource</li> <li>• invalidDestination</li> <li>• outOfMemory</li> <li>• outOfSpace</li> <li>• fileNotFound</li> </ul> |

## Display Storage Use

### About This Task

Display the amount of memory used, memory available, and the number of files for internal flash memory.

#### Note

5420 Series supports 512 MB of flash memory but only 390 MB is available for use.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **File System**.
3. Click the **Storage usage** tab

### *Storage Usage* Field Descriptions

Use the data in the following table to use the **Storage Usage** tab.

| Name                     | Description                                                               |
|--------------------------|---------------------------------------------------------------------------|
| <b>IntflashBytesUsed</b> | Specifies the number of bytes used in internal flash memory.              |
| <b>IntflashBytesFree</b> | Specifies the number of bytes available for use in internal flash memory. |
| <b>IntflashNumFiles</b>  | Specifies the number of files in internal flash memory.                   |
| <b>UsbBytesUsed</b>      | Specifies the number of bytes used in USB device.                         |
| <b>UsbBytesFree</b>      | Specifies the number of bytes available for use in USB device.            |
| <b>UsbNumFiles</b>       | Specifies the number of files in USB device.                              |

## Display Internal Flash File Information

### About This Task

Display information about the files in internal flash memory on this device.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **File System**.
3. Click the **Flash Files** tab.

### *Flash Files* field descriptions

Use the data in the following table to use the **Flash Files** tab.

| Name        | Description                               |
|-------------|-------------------------------------------|
| <b>Slot</b> | Specifies the slot number.                |
| <b>Name</b> | Specifies the directory name of the file. |

| Name        | Description                                              |
|-------------|----------------------------------------------------------|
| <b>Date</b> | Specifies the creation or modification date of the file. |
| <b>Size</b> | Specifies the size of the file.                          |

## Display USB File Information

### About This Task

Display information about the files on a USB device to view general file information.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **File System**.
3. Click the **USB Files** tab.

### *USB Files* field descriptions

Use the data in the following table to use the **USB Files** tab.

| Name        | Description                                              |
|-------------|----------------------------------------------------------|
| <b>Slot</b> | Specifies the slot number of the device.                 |
| <b>Name</b> | Specifies the directory name of the file.                |
| <b>Date</b> | Specifies the creation or modification date of the file. |
| <b>Size</b> | Specifies the size of the file.                          |

# Image Management

---

[Image Upgrades](#) on page 270

[Image Naming Conventions](#) on page 271

[Interfaces](#) on page 271

[File Storage Options](#) on page 271

[Boot Loader Image on Universal Hardware](#) on page 272

[Before You Upgrade](#) on page 272

[Saving the Configuration](#) on page 275

[Upgrade the Software](#) on page 276

[Verifying the upgrade](#) on page 280

[Committing an upgrade](#) on page 281

[Downgrade the Software](#) on page 281

[Remove a Software Build](#) on page 283

[Update the Complex Programmable Logic Device \(CPLD\) Image](#) on page 283

[Upgrade the Boot Loader Image](#) on page 286

This section details what you must know to manage the software image on the switch.

## Image Upgrades

---

Install new software upgrades to add functionality to the switch. Major and minor upgrades are released depending on how many features the upgrade adds or modifies.

### Upgrade time requirements

Image upgrades take less than 30 minutes to complete. The switch continues to operate during the image download process. A service interruption occurs during the installation and subsequent reset of the device. The system returns to an operational state after a successful installation of the new software and device reset.

### Before you upgrade the software image

Before you upgrade the switch, ensure that you read the entire upgrading procedure.

You must keep a copy of the previous configuration file (config.cfg), in case you need to return to the previous version. The upgrade process automatically converts, but does not save, the existing configuration file to a format that is compatible with the new software release. The new configuration file may not be backward compatible.

---

## Image Naming Conventions

---

The switch software use a standardized dot notation format.

### Software Images

Software image names use one of the following number formats to identify release and maintenance values:

```
Product Name.Major Release.Minor Release.Maintenance Release.Maintenance  
Release Update.tgz
```

```
Product Name.Major Release.Minor Release.Maintenance Release.Maintenance  
Release Update.voss
```

For example, the image file name `VOSS4K.4.2.1.0.tgz` denotes a software image for the VSP 4450 Series product with a major release version of 4, a minor release version of 2, a maintenance release version of 1 and a maintenance release update version of 0. Similarly, the image file name `VSP4K.3.0.1.0.tgz` denotes a software image for the VSP 4450 Series product with a major release version of 3, a minor release version of 0, a maintenance release version of 1 and a maintenance release update version of 0. TGZ is the file extension.

#### Note

Product Notice: Image files for 5520 Series and 5420 Series use a `.voss` extension rather than a `.tgz` extension.

---

## Interfaces

---

You can apply upgrades to the switch using the Command Line Interface (CLI).

For more information about CLI, see [Command Line Interface](#) on page 230.

---

## File Storage Options

---

This section details what you must know about the internal boot and system flash memory and Universal Serial Bus (USB) mass-storage device, which you can use to store the files that start and operate the switch.

The switch file system uses long file names.

### Internal flash

The switch has two internal flash memory devices: the boot flash memory and the system flash memory. The system flash memory size is 2 gigabytes (GB).

Boot flash memory is split into two banks that each contain a different copy of the boot image files. Only the Image Management feature can make changes to the boot flash.

The system flash memory stores configuration files, runtime images, the system log, and other files. You can access files on the internal flash through the `/intflash/` folder.

## USB device

The switch can use a USB device for additional storage or configuration files, release images, and other files. The USB device provides a convenient, removable mechanical to copy files between a computer and a switch, or between switches. In cases where network connectivity has not yet been established, or network file transfer is not feasible, you can use a USB device to upgrade the configuration and image files on the switch.

## File Transfer Protocol

You can use File Transfer Protocol (FTP) to load the software directly to the switch, or to download the software to the internal flash memory or to an installed USB device.

The switch can act as an FTP server or client. If you enable the FTP daemon (ftpd), you can use a standards-based FTP client to connect to the switch by using the CLI log on parameters. Copy the files from the client to either the internal flash memory or USB device.

## Boot Loader Image on Universal Hardware

---

On universal hardware products, new VOSS software activations automatically detect the uboot image, check if it is valid, and then compare the version of the uboot image with the version currently on the system. If the system started with the default uboot image, indicated by `Boot Version Used` in the **show sys-info uboot** command output, and the uboot image in the activated software release is newer, image synchronization performs a default uboot upgrade. After the default uboot upgrade is complete, the **show sys-info uboot** command output displays the uboot version from the system boot time, so it still shows the previous version, but it also indicates that the default uboot was upgraded and that a system reboot is required.

After you reboot the system for a default uboot upgrade, if a temporary default uboot upgrade file is present on the system, if the system started with the default uboot image, and if the default and alternate uboot versions are not the same, the alternate uboot is upgraded. You must restart the system for the alternate uboot upgrade to take effect.

## Before You Upgrade

---

This section provides important feature impacts you need to understand before you upgrade the switch software.

### Important Upgrade Note for Systems using IPv6 Static Neighbors

Due to an issue in VOSS 4.2.1 and later releases, the port number for an IPv6 static neighbor is saved with the wrong value in the configuration file if the port is part of an MLT or SMLT. You can view the incorrect port number by using the **show running-config** command.

If performing a named boot (e.g. **boot config.cfg**), the configuration loading fails and the switch remains in a default configuration. You can manually source the configuration file (e.g. **source config.cfg**) to retrieve/reapply the configuration (minus the IPv6 neighbor configuration with the invalid port value).

If you boot the switch without a specified configuration (e.g. `reset -y`), the primary configuration fails to load and the backup configuration file is loaded instead.

#### Caution

You should never configure an IPv6 static neighbor on a port belonging to an MLT or SMLT.

## Pre-upgrade Instructions for IS-IS Metric Type

The command used to redistribute routes into IS-IS supports a parameter called `metric-type`, which can take one of two values: **internal** or **external**. In releases that do not support the external metric type, the routes are always advertised into IS-IS as internal, irrespective of whether you configure the metric-type to internal or external. The saved configuration itself correctly shows the value that you selected.

If the configuration file has redistribution commands that set the metric-type to external, after you upgrade to a release that supports the external metric type, the routes will be advertised into IS-IS as external routes. This constitutes a change in how the routes are advertised into IS-IS after the upgrade as compared to before the upgrade. This configuration can cause unintended traffic issues if the other switches in the network are not yet upgraded to a release that recognizes external routes in IS-IS.

To know which release supports the external metric type on your platform, see [VOSS Release Notes](#) for interoperability considerations.

To avoid unintentionally impacting traffic immediately following an upgrade, as a best practice, check the existing IS-IS redistribution configuration of a switch to determine if the metric-type is set to external in the redistribution commands. If metric-type external is not used in the redistribution, the switch can be upgraded using the normal upgrade procedures. If the metric-type external is used with any redistribution command, change it to internal, and then save the configuration. After this the switch can be upgraded using the normal upgrade procedures.

*Commands to check metric-type in redistribution configuration:*

```
Switch:1(config-isis)#show ip isis redistribute [vrf WORD<1-16>]
=====
  ISIS Redistribute List - GlobalRouter
=====
SOURCE MET MTYPE      SUBNET  ENABLE LEVEL  RPOLICY
-----
RIP      0   internal  allow   TRUE   11
OSPF     0   external  allow   TRUE   11
LOC      0   external  allow   TRUE   11
```

*Commands to change metric-type to internal for GRT:*

```
router isis
isis redistribute <protocol> metric-type internal
save config
```

The protocol above could be one of the following: direct, ospf, static, rip or bgp.

*Commands to change metric-type to internal for VRF:*

```
router vrf WORD<1-16>
isis redistribute <protocol> metric-type internal
save config
```

The protocol above could be one of the following: direct, ospf, static, rip or bgp.

## VLAN and MLT Upgrade Considerations

### *VLAN or MLT Name Uses all Numbers*

Representational State Transfer Configuration Protocol (RESTCONF) does not allow VLAN or MLT names that contain all numbers. Beginning with VOSS 8.0, the VLAN or MLT name cannot use all numbers. If, in a release prior to 8.0, you configured a name that was all numbers, see the following table to understand the impact of upgrading to a newer release.

**Table 35: Upgrade impact on interface names with all numbers**

| Target upgrade release            | Impact after upgrade                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VOSS 8.0.5.x, 8.0.6.x, or 8.0.7.x | The system prepends VLAN- or MLT- , and appends -01, to the name during the upgrade. For example, the VLAN name 222 becomes VLAN-222-01.                                                                                                                                                                                               |
| VOSS 8.0.8 and later              | If you plan to enable RESTCONF, you must check interface names for invalid special characters or conflicts, and make necessary modifications manually. For information about how to check interface names, see the RESTCONF content in <a href="#">Representational State Transfer Configuration Protocol (RESTCONF)</a> on page 2768. |
| VOSS 8.1 or 8.1.1.x               | The system prepends VLAN- or MLT- , and appends -01, to the name during the upgrade. For example, the VLAN name 222 becomes VLAN-222-01.                                                                                                                                                                                               |
| VOSS 8.1.2 and later              | If you plan to enable RESTCONF, you must check interface names for invalid special characters or conflicts, and make necessary modifications manually. For information about how to check interface names, see the RESTCONF content in <a href="#">Representational State Transfer Configuration Protocol (RESTCONF)</a> on page 2768. |

## Digital Certificate Upgrade Considerations

### *Public Key Length*

To support SNMP walk for rcDigitalCertTable where the public key length exceeds 2,048 characters, VOSS 8.1 and later configures MAX\_KEY\_LEN to 2,048 to extend PublicKey to hold a maximum of 4,096-bit key. After this key length is updated, the format for /intflash/.cert/cert\_info.cfg

changes based on the new public key maximum length and you will be unable to restore the CertInfoTable from this file.

If you upgrade to VOSS 8.1 or later from an earlier release, you must reconfigure the certificates because you cannot restore the old certificate configuration after reboot.

The switch displays the following log message after you upgrade to VOSS 8.1, or later, and reboot:

```
GlobalRouter DIGITALCERT ERROR Unable to restore info from /
intflash/.cert/cert_info.cfg due to different/wrong format
```

## Fast PoE and Perpetual PoE Upgrade Considerations

When you upgrade from VOSS 8.1.X to VOSS 8.1.5, the POE Controller undergoes a firmware update, which reverts previously configured Fast PoE and Perpetual PoE settings back to the default values. The system displays a message to inform you about this change.

## Saving the Configuration

Save the configuration

- When you make a change to the configuration.
- To create a backup configuration file before you upgrade the software on the switch.

After you change the configuration, you must save the changes on the device. Save the configuration to a file to retain the configuration settings.

Note that not all CLI commands are included in configuration files. Typical examples include, but are not limited to some operational and security-related commands.

### Note

When loading large configuration files or large sections of a configuration file, avoid copying and pasting of the files into the console or terminal window as it can lead to the loss of configuration. You must either source the file or boot to the intended configuration file. Sourcing and booting allow for the debug and verification of the configuration file using the boot config flags. For more information about booting, sourcing, and debugging or verification using boot flags, see [VOSS Command Line Interface Commands Reference](#).

### About This Task

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support IPv4 and IPv6 addresses.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Save the running configuration:  
`save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]`

**Example**

```
Switch:1> enable
```

Save the configuration to the default location:

```
Switch:1# save config
```

Identify the file as a backup file and designate a location to save the file:

```
Switch:1# save config backup /usb/PreUpgradeBackup.cfg
```

**Variable Definitions**

The following table defines parameters for the **save config** command.

| Variable                 | Value                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>backup</i> WORD<1-99> | Saves the specified file name and identifies the file as a backup file.<br>WORD<1-99> uses one of the following format: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> <li>• /usb/&lt;file&gt;</li> </ul> The file name, including the directory structure, can include up to 99 characters. |
| <i>file</i> WORD<1-99>   | Specifies the file name in one of the following format: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> <li>• /usb/&lt;file&gt;</li> </ul> The file name, including the directory structure, can include up to 99 characters.                                                                 |
| <i>verbose</i>           | Saves the default and current configuration. If you omit this parameter, the command saves only parameters you change.                                                                                                                                                                                                                             |

**Upgrade the Software****Important**

Upgrades from some releases require release-specific steps. For more information, see [VOSS Release Notes](#).

Perform this procedure to upgrade the software on the switch. This procedure shows how to upgrade the software using the internal flash memory as the file storage location.

Use one of the following options to upload the file with the new software to the switch:

- Use FTP or SFTP to transfer the file.

- Download the image file to your computer. Copy the file to a USB device and insert the USB device into the USB port on the switch.

You can store up to six software releases on VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series, VSP 8600 Series, and XA1400 Series. If you have six releases already stored on the switch, you are prompted to remove one release before you can proceed to add and activate a new software release.

For information about how to remove a software release, see [Remove a Software Build](#) on page 176.

You can store only two software releases on 5420 Series and 5520 Series switches. If you attempt to add a third software release, you are prompted for a confirmation to overwrite the non-primary release. You can also use the **software add <filename> -y** command to bypass the confirmation question and automatically overwrite the non-primary release.

### Before You Begin

- To obtain the new software, go to the Extreme Networks support site: <http://www.extremenetworks.com/support>. You need a valid user or site ID and password.
- Back up the configuration files.
- Use an FTP or SFTP application or USB device to transfer the file with the new software release to the switch.
- Ensure that you have not configured a VLAN above 4059. If you have, you must port all configuration on this VLAN to another VLAN, before you begin the upgrade.

#### Caution

Only VLAN range 2 to 4059 is supported. All configuration on a higher numbered VLAN from earlier releases will be lost after the upgrade.

#### Note

Software upgrade configurations are case-sensitive.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. If you are using the USB port to transfer files, go to the next step. If you are using FTP or SFTP to download the files, start the FTP daemon on the switch and enable the `ftpd` flag for FTP or `sshd` flag for SFTP:

#### Note

Start an FTP session from your computer to the switch using the same username and password used to Telnet or SSH to the switch. Upload or copy the image to the switch.

```
boot config flag <ftpd | sshd>
```

```
end
```

3. Download the files to the switch through FTP or SFTP, or transfer them to the switch through the USB port.

4. Enter Privileged EXEC configuration mode by exiting the Global Configuration mode.

```
exit
```

5. Extract the release distribution files to the `/intflash/release/` directory:

```
software add WORD<1-99> -y
```

#### Note

The `.voss` file, which applies to 5420 Series and 5520 Series is removed after the **software add** command runs.

6. Install the image:

```
software activate WORD<1-99>
```

7. Restart the switch:

```
reset
```

#### Important

After you restart the system, you have the amount of time configured for the commit timer to verify the upgrade and commit the software to gold. If you do not commit the software to gold and auto-commit is not enabled, the system restarts with the last known working version after the commit timer has expired. This feature ensures you can regain control of the system if an upgrade fails. By default, auto-commit is enabled.

8. After you restart the switch, enter Privileged EXEC configuration mode:

```
rwa
```

```
enable
```

9. Confirm the software is upgraded:

```
show software
```

10. Commit the software:

```
software commit
```

#### Important

If you disable the auto-commit feature, you must run the **software commit** command manually before the commit timer expires to commit the new software version, otherwise the system restarts automatically to the previous (committed) version. By default, auto-commit is enabled.

## Examples

#### Note

The image file name is switch dependent. See [VOSS Release Notes](#) for information about file names.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags ftpd
Switch:1(config)#end
```

```

Switch:1(config)#copy /usb/VOSS8K.5.0.0.0.tgz /intflash/VOSS8K.5.0.0.0.tgz
Switch:1(config)#exit
Switch:1#software add VOSS8K.5.0.0.0.tgz
Switch:1#software activate VOSS8K.5.0.0.0.GA
Switch:1#reset
Switch:1#show software

## Variable Definitions

The following table defines parameters for the **software** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>activate</i> <i>WORD</i> <1-99>                                           | Copies the software version to the boot flash file. When you use the software activate command, the system checks for hardware dependencies and prevents a downgrade if it detects a dependency. For example, if a hardware component has a minimum software version dependency, you cannot downgrade to an incompatible software version or install the hardware component in a chassis that runs an incompatible software version. |
| <i>add</i> <i>WORD</i> <1-99>                                                | Unpacks a software release <version>.                                                                                                                                                                                                                                                                                                                                                                                                |
| -y<br><b>Note:</b> Exception: only supported on 5420 Series and 5520 Series. | Suppresses the confirmation message to automatically overwrite the non-primary image. If you omit this parameter, you must confirm the action to overwrite the non-primary image.                                                                                                                                                                                                                                                    |

## Verifying the upgrade

Verify your upgrade to ensure proper switch operation.

### Procedure

1. Check for alarms or unexpected errors:  
show logging file tail
2. Verify all modules and slots are online:  
show sys-info

## Committing an upgrade

---

Perform the following procedure to commit an upgrade.

### About This Task

The software commit functionality for software upgrades allows maximum time set by the commit timer (the default is 10 minutes) to ensure that the upgrade is successful. If you enable the auto-commit option, the system automatically commits to the new software version after the commit timer expires.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. (Optional) Configure the timer to activate the software:  

```
sys software commit-time <10-60>
```

The default is 10 minutes.

#### Note

VSP 8600 Series default is 15 minutes.

3. **(Optional)** Extend or reduce the time to commit the software:  

```
software reset-commit-time [<1-60>]
```
4. Commit the upgrade:  

```
software commit
```

#### Important

If you disable the auto-commit feature, you must run the **software commit** command manually before the commit timer expires to commit the new software version, otherwise the system restarts automatically to the previous (committed) version. By default, auto-commit is enabled.

## Downgrade the Software

---

Perform this procedure to downgrade the switch from the current trusted version to a previous release.

#### Important

MACsec connectivity association (CA) configurations fail during downgrade. If you plan to downgrade MACsec to an earlier version, delete the MACsec CA entries, perform the downgrade, and then reconfigure the MACsec CA entries. This applies to both 2AN and 4AN modes.

### Before You Begin

Ensure that you have a previous version installed.

## About This Task

### Note

The image file name is switch dependent. See [VOSS Release Notes](#) for information about file names.

## Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Extract the release distribution files to the /intflash/release/ directory:

```
software add WORD<1-99>
```

3. Activate a prior version of the software:

```
software activate WORD<1-99>
```

4. Restart the switch:

```
reset
```

### Important

After you restart the system, you have the amount of time configured for the commit timer to verify the software change and commit the software to gold. If you do not commit the software to gold and auto-commit is not enabled, the system restarts with the last known working version after the commit timer expires. This feature ensures you can regain control of the system if an upgrade fails. By default, auto-commit is enabled.

5. Commit the software change:

```
software commit
```

### Important

If you disable the auto-commit feature, you must run the **software commit** command manually before the commit timer expires to commit the new software version, otherwise the system restarts automatically to the previous (committed) version. By default, auto-commit is enabled.

6. Verify the downgrade:

- Check for alarms or unexpected errors using the `show logging file tail` command.
- Verify all modules and slots are online using the `show sys-info` command.

7. (Optional) Remove unused software:

```
software remove WORD<1-99>
```

## Variable Definitions

The following table defines parameters for the `software` command.

| Variable            | Value                                                                           |
|---------------------|---------------------------------------------------------------------------------|
| activate WORD<1-99> | Specifies the name of the software release image.                               |
| add WORD<1-99>      | Specifies the path and version of the compressed software release archive file. |
| remove WORD<1-99>   | Specifies the path and version of the compressed software release archive file. |

## Remove a Software Build

Use the following procedure to remove a software build for the switch.

### Important

A maximum of 6 software releases can be installed on VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series, VSP 8600 Series, and XA1400 Series. When the limit is reached, you are prompted to remove one release before you can proceed with adding and activating a new software release.

### Note

A maximum of 2 software releases can be installed on 5420 Series and 5520 Series. When the limit is reached, you are prompted for a confirmation to overwrite the non-primary release before you can install a new software release. For more information, see [Upgrade the Software](#) on page 276.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Remove the software build:  
`software remove WORD<1-99>`

### Example

Remove the software build:

```
Switch:1>enable
Switch:1#software remove w.x.y.z
```

## Update the Complex Programmable Logic Device (CPLD) Image

### Note

This procedure only applies to 5420 Series, 5520 Series, VSP 4900 Series.

During the device bootup, if an older version of a CPLD module is detected, the system displays a log message to upgrade the CPLD module image.

The following is an example of the log message:

```
1 2020-01-17T13:08:16.630Z VSP-4900-12MXU-12XE CP1 - 0x0026050d -
00000000 GlobalRouter SW INFO cpu CPLD/FPGA module is running older
version. Recommended to upgrade using command cpld-install.
```

You can also use **show sys-info cpld** command to check the current version of the CPLD module on the device.

### Before You Begin

Upgrade the software on the switch to the latest build.

### About This Task

The **cpld-install** command compares the image version of the modules with the current version on the device:

- If the versions are the same, the command exits.
- If the current version is an earlier version, you must update the image version of the specific module.

The device automatically restarts after successful installation of the specific module.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Update one of the following CPLDs:
  - APP:  

```
cpld-install app [WORD<1-99>]
```
  - BOOT:  

```
cpld-install boot [WORD<1-99>]
```
  - CPU:  

```
cpld-install cpu [WORD<1-99>]
```
  - Field-Programmable Gate Array (FPGA):  

```
cpld-install fgpa [WORD<1-99>]
```
  - Main CPLD module:  

```
cpld-install main [WORD<1-99>]
```
  - Port:  

```
cpld-install port [WORD<1-99>]
```
  - VIM (Versatile Interface Module):  

```
cpld-install vim [WORD<1-99>]
```
3. When prompted, type **y** to continue with the CPLD update.

**Example**

Update CPLD for port module.

```
Switch:1>cpld-install port /intflash/1.1.8_sd_portpld.tgz
image file md5 checksum passed
Current port CPLD version is 0x1108, 1.1.08

Do you want to continue with cpld update? (y/n) ? y

WARNING: Upgrading FPGA requires writing to a device

WARNING: It will take about a minute or so to complete.

WARNING: DO NOT TURN POWER OFF OR MAKE ANY HARDWARE CHANGES ONCE YOU START THIS OPERATION.

## Variable Definitions

The following table defines parameters for the **cpld-install** command.

The following table applies to 5420 Series and 5520 Series.

| Variable                | Value                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>app</i>              | Updates the APP module.                                                                                                                                                                            |
| <i>boot</i>             | Updates the BOOT module.                                                                                                                                                                           |
| <i>main</i>             | Updates the main CPLD module.                                                                                                                                                                      |
| <i>port</i>             | Updates the Port module.                                                                                                                                                                           |
| <i>WORD&lt;1-99&gt;</i> | Specifies the image filename.<br><br><b>Note:</b> This parameter is optional. If you do not specify the filename, the command checks the .tgz file for the image from the running VOSS filesystem. |

The following table applies to VSP 4900 Series.

| Variable                | Value                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>cpu</i>              | Updates the CPU module.                                                                                                                                                                            |
| <i>fpga</i>             | Updates the FPGA module.                                                                                                                                                                           |
| <i>port</i>             | Updates the Port module.                                                                                                                                                                           |
| <i>vim</i>              | Updates the VIM module.                                                                                                                                                                            |
| <i>WORD&lt;1-99&gt;</i> | Specifies the image filename.<br><br><b>Note:</b> This parameter is optional. If you do not specify the filename, the command checks the .tgz file for the image from the running VOSS filesystem. |

## Upgrade the Boot Loader Image

### Note

This procedure does not apply to 5420 Series, 5520 Series, VSP 4900 Series, VSP 7400 Series, and XA1400 Series.

### Warning

This command is an advanced-level command that upgrades the device uboot image. Only use this command if specifically advised to do so by Technical Support. Improper use of this command can result in permanent damage to the device and render it unusable.

If the need to use this command arises, instructions on usage will be provided by technical support.

### Before You Begin

- Transfer the image to the `/intflash/` directory on the switch.

## About This Task

For information about the boot loader image on universal hardware, see [Boot Loader Image on Universal Hardware](#) on page 272.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the current uboot version:  
show sys-info uboot
3. Upgrade the boot loader image:  
uboot-install *WORD<1-99>*
4. Restart the system.

## Example

```
Switch:1#>show sys-info uboot

U-Boot Info :
-----
      Default Version      : 2.3.2.1
      Alternate Version    : 2.3.2.1
      Boot Version Used    : Default
      Trusted Delivery Status : Boot Image Verified
```

## Variable Definitions

The following table defines parameters for the **uboot-install** command.

| Variable                | Value                                                               |
|-------------------------|---------------------------------------------------------------------|
| <i>WORD&lt;1-99&gt;</i> | Specifies the full path and filename that contains the uboot image. |

---

## Address Resolution Protocol

---

Network stations using the IP protocol need both a physical address and an IP address to transmit a packet. In situations where the station knows only the network host IP address, the network station uses Address Resolution Protocol (ARP) to determine the physical address for a network host by binding a 32-bit IP address to a 48-bit MAC address. A network station can use ARP across a single network only, and the network hardware must support physical broadcasts.

The network station uses ARP to determine the host physical address as follows:

- The network station broadcasts a special packet, called an ARP request, that asks the host at the specified IP address to respond with its physical address.
- All network hosts receive the broadcast request.
- Only the specified host responds with its hardware address.
- The network station then maps the host IP address to its physical address and saves the results in an address-resolution cache for future use.
- The network station ARP table displays the associations of the known MAC address to IP address.

You can create ARP entries, and you can delete individual ARP entries.

### Enable ARP traffic

The switch accepts and processes ARP traffic, spanning tree bridge packet data units (BPDU), and Topology Discovery Protocol packets on port-based VLANs with the default port action of drop. If a filter port action is drop for a packet, ARP packets are also dropped. As a result, ARP entries on that port are cleared and are not relearned when the ARP aging timer expires.

To prevent dropped ARP packets, configure the following options:

- A user-defined protocol-based VLAN for ARP EtherType (byprotocol usrDefined 0x0806).
- Ports as static members to this VLAN with the default port action of drop.
- The port default VLAN ID to the correct port-based VLAN where the ARPs are processed.

You do not need to make configuration changes for the BPDU and Topology Discovery Protocol packets.

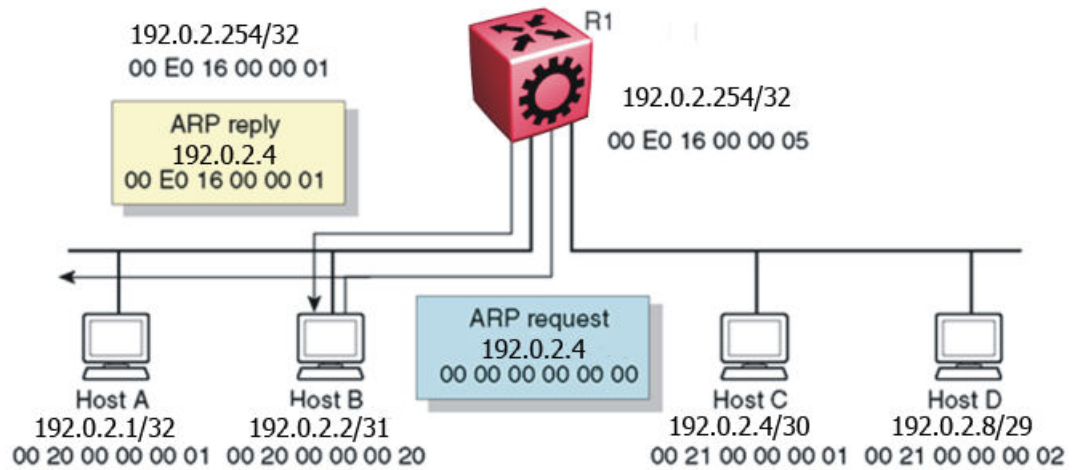

Only one user-defined protocol-based VLAN for ARP is allowed for each Spanning Tree Group (STG). If the ports with the default port action of drop are in different STGs, you must create additional user-defined protocol-based VLANs.

### Proxy ARP

A network station uses proxy ARP to respond to an ARP request from a locally attached host or end station for a remote destination. The network station sends an ARP response back to the local host with its own MAC address of the network station interface for the subnet on which the ARP request was received. The reply is generated only if the device has an active route to the destination network.

The following figure shows an example of proxy ARP operation. In this example, the system displays host C with mask 24 to be locally attached to host B with mask 16, so host B sends an ARP request for

host C. However, the switch is between the two hosts. To enable communication between the two hosts, the switch responds to the ARP request with the IP address of host C but with its own MAC address.

**Figure 15: Proxy ARP operation**

### Loop detection

To prevent cases of ARP looping, configure the ARP loop detection flag to detect this situation. When a loop is detected, the port is shut down.

### Flushing router tables

For administrative or troubleshooting purposes, sometimes you must flush the routing tables. Flush routing tables either by VLAN or by port. In a VLAN context, all entries associated with the VLAN are flushed. In a port context, all entries associated with the port are flushed.

## Reverse Address Resolution Protocol

Certain devices use the Reverse Address Resolution Protocol (RARP) to obtain an IP address from a RARP server. MAC address information for the port is broadcast on all ports associated with an IP protocol-based or port-based VLAN. To enable a device to request an IP address from a RARP server outside its IP VLAN, you must create a RARP protocol-based VLAN.

RARP has the format of an ARP frame but its own Ethernet type (8035). You can remove RARP from the IP protocol-based VLAN definition and treat it as a separate protocol, thus creating a RARP protocol-based VLAN.

A typical network topology provides desktop switches in wiring closets with one or more trunk ports that extend to one or more data center switches where attached servers provide file, print, and other services. Use RARP functionality to define all ports in a network that require access to a RARP server as potential members of a RARP protocol-based VLAN. You must define all tagged ports and data center RARP servers as static or permanent members of the RARP VLAN. Therefore, a desktop host broadcasts an RARP request to all other members of the RARP VLAN. In normal operation, these

members include only the requesting port, tagged ports, and data center RARP server ports. Because all other ports are potential members of this VLAN and RARP is only transmitted at startup, all other port VLAN memberships expire. With this feature, one or more centrally located RARP servers extend RARP services across traditional VLAN boundaries to reach desktops globally.

## ARP configuration using the CLI

Network stations that use IP protocol require both a physical address and an IP address to transmit packets. In situations where the station knows only the network host IP address, the Address Resolution Protocol (ARP) lets you use the network station to determine a network host physical address by binding a 32-bit IP address to a 48-bit MAC address.

A network station can use ARP across a single network only, and the network hardware must support physical broadcasts. If a network station wants to send a packet to a host but knows only the host IP address, the network station uses ARP to determine the host physical address.

ARP response is enabled by default.

### Enabling ARP on a port or a VLAN

Enable ARP on the device so that it answers local ARP requests.

#### About This Task

You can enable or disable ARP responses on the device. You can also enable ARP proxy, which lets a router answer a local ARP request for a remote destination.

#### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable ARP on the device:

```
ip arp-response
```

#### Example

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface vlan 200  
Switch:1(config-if)#ip arp-response
```

## Enabling ARP proxy

### About This Task

Configure an ARP proxy to allow the platform to answer a local ARP request for a remote destination. ARP proxy is disabled by default.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable ARP proxy on the device:

```
ip arp-proxy enable
```

Use the no operator to disable ARP proxy: `no ip arp-proxy [enable]`

### Example

Enable ARP proxy on VLAN 200:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 200
Switch:1(config-if)#ip arp-proxy enable
```

## View ARP Information

The **show ip arp** command displays all of the configured and dynamically learned ARP entries in the ARP table.

### Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display ARP information for a specified port or for all ports:

```
show ip arp interface gigabitethernet [slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]]
```

3. Display ARP information for a VLAN:

```
show ip arp interface vlan <1-4059>
```

### Example

```
Switch:1>show ip arp interface
```

```
=====
```

```

Variable definitions

Use the data in the following table to use the **show ip arp** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>A.B.C.D</i>                                               | Specifies the IP address of a network.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                             |
| <i>interface</i>                                             | Displays ARP interface configuration information.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>spbm-tunnel-as-mac</i>                                    | Displays the remote host name in the TUNNEL column for the SPBM ARP entry.                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>-s</i>                                                    | Specifies a subnet.<br>You must indicate the IP address followed by the subnet mask expressed as <A.B.C.D> <A.B.C.D>.                                                                                                                                                                                                                                                                                                                                                     |
| <i>vlan &lt;1-4059&gt;</i>                                   | Displays ARP entries for a particular VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

| Variable                              | Value                                                                                                                                                                                                                                                                                |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF name expressed as text from 1 to 16 characters in length.<br>The total number of ARPs listed in the summary line of the <b>show ip arp</b> output represents the total number of ARPs on the chassis, including all VRFs (which includes the Management Router VRF). |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a range of VRFIDs as text from 0 to 512 characters in length.<br>The total number of ARPs listed in the summary line of the <b>show ip arp</b> output represents the total number of ARPs on the chassis, including all VRFs (which includes the Management Router VRF).   |

Use the data in the following table to help you understand the **show ip arp interface** command output.

| Variable | Value                                                                                        |
|----------|----------------------------------------------------------------------------------------------|
| PORT_NUM | Indicates the port number.                                                                   |
| DOPROXY  | Indicates if ARP proxy responses are enabled or disabled on the specified interface.         |
| DORESP   | Indicates if the sending of ARP responses is enabled or disabled on the specified interface. |

Use the data in the following table to help you understand the **show ip arp interface vlan** command output.

| Variable | Value                                                                                        |
|----------|----------------------------------------------------------------------------------------------|
| VLAN_ID  | Indicates the VLAN ID.                                                                       |
| DOPROXY  | Indicates if ARP proxy responses are enabled or disabled on the specified interface.         |
| DORESP   | Indicates if the sending of ARP responses is enabled or disabled on the specified interface. |

## Configuring IP ARP static entries

### About This Task

Configure ARP static entries to modify the ARP parameters on the device. The only way to change a static ARP is to delete the static ARP entry and create a new entry with new information.

#### Note

Static multicast ARP entries are not supported for NLB Unicast or NLB Multicast operations.

## Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure ARP static entries on the device:

```
ip arp <A.B.C.D> 0x00:0x00:0x00:0x00:0x00:0x00 {slot/port[-slot/port]
[,...]}
```

## Example

Configure ARP static entries:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip arp 192.0.2.10 00-16-76-7D-80-C2 2/1
```

## Variable Definitions

Use the data in the following table to use the **ip arp** command.

| Variable                                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>request-threshold</code><br><code>&lt;50-1000&gt;</code> | Configures the maximum number of outstanding ARP requests that a device can generate. The range is 50-1000. The default value is 500.<br>To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>timeout</code> <code>&lt;1-32767&gt;</code>              | Configures the length of time in seconds an entry remains in the ARP table before timeout. The range is 1-32767.<br>To configure this option to the default value, use the <b>default</b> operator with this command.<br><br><b>Note:</b><br>The aging of ARP records is tied to the aging of MAC records. The ARP record for a given IP address is not removed unless the associated MAC record ages out and the router stops receiving a response to ARP requests for that IP address. In cases where the ARP aging time is set to less than the MAC aging time, the switch waits until the MAC ages out before deleting the ARP for an inactive host. |
| <code>&lt;A.B.C.D&gt;</code>                                   | Adds ARP entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Clearing ARP entries

Use this procedure to clear dynamic ARP table entries associated with the interface or VLAN.

## Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear ARP entries:

```
clear ip arp interface <gigabitethernet|vlan> <slot/port[/sub-port] [-slot/port[/sub-port]][, ...] | <1-4059>>
```

## Example

Clear ARP entries:

```
Switch:1> enable
Switch:1# clear ip arp interface gigabitethernet 1/16
```

### Variable definitions

Use the data in the following table to use the **clear ip arp interface** command.

| Variable                                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                                       | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>gigabitethernet vlan</i>                                    | Specifies the interface type.                                                                                                                                                                                                                                                                                                                                                                                              |
| { <i>slot/port[/sub-port] [-slot/port[/sub-port]][, ...]</i> } | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

## Showing ARP table information

Show ARP information to view the configuration information in the ARP table.

### About This Task

When you use the *interface* parameter with the **show ip arp** command you can display ARP configuration information only for a specific switch.

The **show ip arp** command displays all of the configured and dynamically learned ARP entries in the ARP table.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the ARP table:  
show ip arp [<A.B.C.D>] [-s <A.B.C.D>] [gigabitEthernet <slot/port[/sub-port]>] [interface <gigabitEthernet|vlan>] [nlb] [spbm-tunnel-as-mac] [vlan <1-4059>] [vrf WORD<1-16>] [vrffids WORD<0-512>]

## Example

```
Switch:1#show ip arp
=====
                        IP Arp - GlobalRouter
=====

```

### Variable definitions

Use the data in the following table to help you use the **show ip arp** command.

| Variable               | Value                                               |
|------------------------|-----------------------------------------------------|
| -s                     | Specifies the subnet for the table.                 |
| <i>gigabitEthernet</i> | Displays the entries for a particular brouter port. |

| Variable                         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>interface</i>                 | Displays ARP interface configuration information. Use the following parameters to display ARP table information specifically for: <ul style="list-style-type: none"> <li>gigabitethernet {slot/port[-slot/port][,...]} displays IP ARP gigabitethernet interface information</li> <li>VLAN &lt;1-4059&gt; displays IP ARP VLAN interface information</li> </ul> Example: <code>show ip arp interface vlan 1</code>                                                                                                                                                                                                                                                                                                                                       |
| <i>nlb</i>                       | Displays the Network Load Balancing (NLB) ARP entries on the switch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>spbm-tunnel-as-mac</i>        | Displays the remote host name in the TUNNEL column for the SPBM ARP entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>vlan</i>                      | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. Use these parameters to display ARP table information specifically for: <ul style="list-style-type: none"> <li>vrf WORD&lt;1-16&gt;—the VLAN VRF name in a range from 1 to 16 characters</li> <li>vrfids WORD&lt;0-512&gt;—the VLAN VRF ID in a range from 0 to 512</li> </ul> Example: <code>show ip arp vlan 1 vrf 1</code> |
| <i>vrf WORD &lt;1-16&gt;</i>     | Specifies the name of the VRF. The total number of ARPs listed in the summary line of the "show ip arp" display represents the total number of ARPs on the chassis including all VRFs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>vrfids WORD &lt;0-512&gt;</i> | Specifies the VRF ID. The total number of ARPs listed in the summary line of the "show ip arp" display represents the total number of ARPs on the chassis including all VRFs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>&lt;A.B.C.D&gt;</i>           | Specifies the network IP address for the table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Use the data in the following table to help you understand the output of the **show ip arp** command.

| Parameter   | Description                                        |
|-------------|----------------------------------------------------|
| IP_ADDRESS  | Indicates the IP address where ARP is configured.  |
| MAC_ADDRESS | Indicates the MAC address where ARP is configured. |

| Parameter              | Description                                                                                                                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLAN                   | Indicates the VLAN address where ARP is configured.                                                                                                                                                         |
| PORT                   | Indicates the port where ARP is configured.                                                                                                                                                                 |
| TYPE                   | Indicates the type of learning (dynamic or local) where ARP is configured.                                                                                                                                  |
| TTL<10 secs>           | Indicates the time to live as tenths of a second where ARP is configured.                                                                                                                                   |
| TUNNEL                 | Displays the remote host name in the TUNNEL column for the SPBM ARP entry.                                                                                                                                  |
| MULTICAST-MAC-FLOODING | Displays whether IP ARP multicast MAC flooding is enabled or disabled. When enabled, the ARP entries for multicast MAC addresses are associated with the VLAN or port interface on which they were learned. |
| AGING (Minutes)        | Displays when the ARP aging timer expires.                                                                                                                                                                  |
| ARP-THRESHOLD          | Displays the maximum number of outstanding ARP requests that a device can generate.                                                                                                                         |

## Configuring Gratuitous ARP

Use the following procedure to configure Gratuitous Address Resolution Protocol (ARP). When Gratuitous ARP is enabled the switch allows all Gratuitous ARP request packets. The default is enabled.

If you disable Gratuitous ARP, the switch only allows Gratuitous ARP packets associated with Routed Split Multi-Link Trunking (RSMLT) or Virtual Router Redundancy Protocol (VRRP), and the switch discards all other Gratuitous ARP request packets.

### About This Task

ARP translates network layer (layer 3) IP addresses into link layer (layer 2) MAC addresses. A host sends a Gratuitous ARP request packet to inform other hosts of the existence of an interface on the network, so other local hosts can update their ARP tables. If the IP or MAC address changes, or in the event of a failover, a host sends a Gratuitous ARP request packet to inform other hosts to update their ARP tables.

VRRP and RSMLT use gratuitous ARP to update the MAC address tables on switches.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable Gratuitous ARP:
 

```
ip gratuitous-arp
```
3. (Optional) Disable Gratuitous ARP:
 

```
no ip gratuitous-arp
```
4. (Optional) Configure Gratuitous ARP to the default value:
 

```
default ip gratuitous-arp
```
5. Save the changed configuration.
 

```
save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]
```

## ARP configuration using Enterprise Device Manager

Network stations using the IP protocol need both a physical address and an IP address to transmit a packet. In situations where the station knows only the network host IP address, the network station can use Address Resolution Protocol (ARP) to determine a network host physical address by binding a 32-bit IP address to a 48-bit MAC address. A network station can use ARP across a single network only, and the network hardware must support physical broadcasts. If a network station wants to send a packet to a host but knows only the host IP address, the network station uses ARP to determine the host physical address.

### Enabling or disabling ARP on the router port or a VRF instance

#### About This Task

After you assign the IP address, you can configure ARP. By default, ARP Response is enabled and Proxy ARP is disabled.

#### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **ARP** tab.
5. In the **DoProxy** check box, select **enable** to enable the Proxy ARP function.
6. In the **DoResp** check box, select **enable** to configure the system to respond to an ARP. The default is enable.
7. Click **Apply**.

The ARP function is available only when the port or VLAN is routed; that is, it is assigned an IP address.

#### *ARP field descriptions*

Use the data in the following table to use the **ARP** tab fields.

| Name           | Description                                                                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DoProxy</b> | Configures the system to respond to an ARP request from a locally attached host or end station for a remote destination. The default value is disable. |
| <b>DoResp</b>  | Configures the system to send ARP responses for this IP interface address. The default value is enable.                                                |

### Enabling or disabling ARP on a VLAN or a VRF instance

#### About This Task

Use the following procedure to enable ARP on VLAN level.

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.

2. Click **VLANs > Basic**.
3. Select a VLAN.
4. Click **IP**.
5. Click the **ARP** tab.
6. In the **DoProxy** field, click **enable** to enable the Proxy ARP function.
7. In the **DoResp** field, click **enable** to configure the system to respond to an ARP. The default is enable.
8. Click **Apply**.

The ARP dialog box is available only if the port or VLAN is routed; that is, it is assigned an IP address.

### **ARP** field descriptions

Use the data in the following table to use the **ARP** tab.

| Name           | Description                                                                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DoProxy</b> | Configures the system to respond to an ARP request from a locally attached host or end station for a remote destination. The default value is disable. |
| <b>DoResp</b>  | Configures the system to send ARP responses for this IP interface address. The default value is enable.                                                |

## Viewing and managing ARP

### About This Task

You can view and manage known MAC address to IP address associations. In addition, you can create or delete individual ARP entries.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **ARP** tab.

### **ARP** field descriptions

Use the data in the following table to use the **ARP** tab.

| Name               | Description                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NetAddress</b>  | Specifies the IP address corresponding to the media-dependent physical address.                                                                                                                                                                    |
| <b>IfIndex</b>     | Identifies the router interface for this ARP entry: <ul style="list-style-type: none"> <li>• Brouter interfaces are identified by the slot/port number of the brouter port.</li> <li>• VLAN interfaces are identified by the vlan name.</li> </ul> |
| <b>PhysAddress</b> | Specifies the media-dependent physical address (that is, the Ethernet address).                                                                                                                                                                    |
| <b>Type</b>        | Specifies the type of ARP entry: <ul style="list-style-type: none"> <li>• local—a locally configured ARP entry</li> <li>• static—a statically configured ARP entry</li> <li>• dynamic—a learned ARP entry</li> </ul>                               |

| Name               | Description                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TimeToLive</b>  | Indicates the time to live where the ARP is configured.                                                                                                                                                                    |
| <b>DestIfIndex</b> | Indicates the slot/port on which the ARP entry was learned. For brouter interfaces this is the same value as IfIndex, but for VLAN interfaces, it designates the particular port in the VLAN on which the ARP was learned. |
| <b>DestVlanId</b>  | VLAN ID where the ARP is configured.                                                                                                                                                                                       |
| <b>BMac</b>        | Identifies the backbone MAC address if the entry is learned from an SPBM network.                                                                                                                                          |
| <b>DestCvid</b>    | Identifies the customer VLAN ID for a Switched UNI port.                                                                                                                                                                   |

## Creating static ARP entries

### About This Task

Use the following procedure to create a static ARP entry.

#### Note

Static multicast ARP entries are not supported for NLB Unicast or NLB Multicast operations.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **ARP** tab.
4. Click **Insert**.
5. In the **NetAddress** field, type the IP address.
6. Click **Port**.  
OR  
Click **Port in VLAN**
7. In the dialog box, select the interface.
8. Click **OK**.
9. In the **PhysAddress** field, type the MAC address.
10. Click **Insert**.

## Configuring ARP proxy

### About This Task

With an ARP proxy, the switch can respond to an ARP request from a locally attached host or end station for a remote destination. Proxy ARP does so by sending an ARP response back to the local host with its own MAC address of the router interface for the subnet on which the ARP request was received. The reply is generated only if the system has an active route to the destination network.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.

2. Click **VLANs > Basic**.
3. Choose a VLAN.
4. Click **IP**.
5. Click **ARP** tab.
6. Select **DoProxy enable**.
7. Click **Apply**.

**Table 37: Alternative routes product support**

| Feature                     | Product         | Release introduced |
|-----------------------------|-----------------|--------------------|
| Alternative routes for IPv4 | 5420 Series     | VOSS 8.4           |
|                             | 5520 Series     | VOSS 8.2.5         |
|                             | VSP 4450 Series | VSP 4000 4.0       |
|                             | VSP 4900 Series | VOSS 8.1           |
|                             | VSP 7200 Series | VOSS 4.2.1         |
|                             | VSP 7400 Series | VOSS 8.0           |
|                             | VSP 8200 Series | VSP 8200 4.0       |
|                             | VSP 8400 Series | VOSS 4.2           |
|                             | VSP 8600 Series | VSP 8600 4.5       |
|                             | XA1400 Series   | VOSS 8.0.50        |
| Alternative routes for IPv6 | 5420 Series     | VOSS 8.4           |
|                             | 5520 Series     | VOSS 8.2.5         |
|                             | VSP 4450 Series | VOSS 5.1           |
|                             | VSP 4900 Series | VOSS 8.1           |
|                             | VSP 7200 Series | VOSS 5.1           |
|                             | VSP 7400 Series | VOSS 8.0           |
|                             | VSP 8200 Series | VOSS 5.1           |
|                             | VSP 8400 Series | VOSS 5.1           |
|                             | VSP 8600 Series | VSP 8600 6.2       |
|                             | XA1400 Series   | Not Supported      |

To avoid traffic interruption, you can globally enable the alternative routes feature so the router can use the next-best route, also known as an alternative route, if the best route becomes unavailable.

Routers learn routes to a destination through routing protocols. Routers maintain a routing table of the learned alternative routes sorted in order by route preference, route costs, and route sources. The first route on the list is the best route and the route that the router prefers to use.

The alternative route concept also applies between routing protocols. For example, if an OSPFv3 route becomes unavailable and an alternative RIPng route is available, the system activates the RIPng route without waiting for the update interval to expire.

## Route Preference

---

On the switch, all standard routing protocols have default preference values that determine the routing priority of the protocol. The router uses default preferences to select the best route when a clash exists in preference between the protocols.

You can modify the global preference for a protocol to give the protocol a higher or lower priority than other protocols. If you change the global preference for a static route and all best routes remain best routes, only the local route tables change. However, if the protocol preference change causes best routes to no longer be best routes, the change affects neighboring route tables.

### Important

Changing route preferences is a process-intensive operation that can affect system performance and network reach while you perform route preference procedures. As a best practice, if you want to change preferences for static routes or routing protocols, do so when you configure routes or during a maintenance window.

If a router learns a route with the same network mask and cost values from multiple sources, the router uses the route preferences to select the best route to add to the forwarding database.

### Note

To modify the preference for a route, you do *not* need to disable a route before you edit the configuration.

## Preferences for Static Routes

---

When you configure a static route on the switch, you can specify a global preference for the route. You can also specify an individual route preference that overrides the global static route preference. The preference value can be between 0 and 255, with 0 reserved for local routes and 255 representing an unreachable route.

## Preferences for Dynamic Routes

---

You can modify the preference value for dynamic routes through route filtering and IP policies, and this value overrides the global preference for the protocol.

The following table shows the default preferences for routing protocols and route types. Use this table to help you modify the global preference value.

**Table 38: Routing protocol default preferences**

| Protocol               | Default preference |
|------------------------|--------------------|
| Local                  | 0                  |

## Alternative Route Configuration using CLI

### Enable IPv4 Alternative Routes

#### About This Task

The default value is enabled. If you disable the alternative-route parameter, all existing alternative routes are removed. After you enable the parameter, all alternative routes are readed.

#### Procedure

- Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
 

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```
- Activate the alternative route feature globally:
 

```
ip alternative-route
```

## Enable IPv6 Alternative Routes

Use this procedure to enable IPv6 alternative routes and view the configuration on the switch.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Enable IPv6 alternative routes:

```
ipv6 alternative-route
```

#### Note

IPv6 alternative routes are enabled by default.

3. Verify the configuration of the IPv6 alternative route:

```
show ipv6 global [vrf WORD<1-16> | vrfids WORD<0-512>]
```

```
show ipv6 route alternative [vrf WORD<1-16> | vrfids WORD<0-512>]
```

*Example:*

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf globalRouter
Switch:1(router-vrf)#ipv6 alternative-route
```

```
Switch:1#show ipv6 global
```

```

## Alternative Route Configuration using EDM

### Enable IPv4 Alternative Routes Globally

#### Before You Begin

- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 3832.

#### About This Task

Globally enable alternative routes so that you can subsequently enable it on interfaces.

#### Procedure

1. In the navigation tree, expand **Configuration > IP**.
2. Select **IP**.
3. Select the **Globals** tab.
4. Select **AlternativeEnable**.

If the **AlternativeEnable** parameter is disabled, all existing alternative routes are removed. After you enable the parameter, all alternative routes are re-added.

5. Select **Apply**.

### Enable IPv6 Alternative Routes Globally

Global configuration includes the following:

- IPv6 alternative routes: To avoid traffic interruption, enable alternative routes globally on the switch, to replace the best route with the next-best route if the best route becomes unavailable. By default, this feature is enabled.

#### Before You Begin

Change the VRF instance as required to configure IPv6 globally on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

#### Procedure

1. In the navigation tree, expand **Configuration > IPv6**.
2. Select **IPv6**.
3. Select the **Globals** tab.
4. To enable IPv6 alternative routes, click **AlternativeRouteEnable**.
5. Select **Apply**.

## IPv6 Alternative Routes Configuration Example

To avoid traffic interruption, you can enable alternative routes globally to replace the best route with the next-best route, if the best route becomes unavailable.

The concept of alternative route applies between routing protocols. For example, if an OSPFv3 route becomes unavailable and an alternative RIPng route is available, the system activates the RIPng route immediately without waiting for an update interval to expire.

By default, the alternative routes feature is globally enabled on the switch.

The following example demonstrates this behavior.

In this example, you configure OSPFv3 and RIPng routes on two switches Switch-1 and Switch-2, as shown in the following figure.

### Configuration on Switch-1

#### VLAN configuration:

On Switch-1, configure VLAN 2 and the IPv6 interface address 2000:0:0:0:0:0:0:1/64.

```
Switch1:1>enable
Switch1:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch1:1(config)#vlan create 2 type port-mstprstp 0
Switch1:1(config)#vlan members 2 4/5
Switch1:1(config)#interface vlan 2
Switch1:1(config-if)#ipv6 interface address 2000:0:0:0:0:0:0:1/64
Switch1:1(config-if)#ipv6 interface enable
Switch1:1(config-if)#exit

Switch1:1(config)#show vlan basic
```

```

## Viewing route and alternative route configuration on the switches

On Switch-1 and Switch-2, the route 3000:0:0:0:0:0:2/64 is learned using the protocols RIPng and OSPFv3. The OSPFv3 route is learned as the best route because of its route preference value of 20. The RIPng route is added as alternative route as it has the route preference 100, which is greater than the OSPFv3 route preference of 20. On Switch-2, the route 3000:0:0:0:0:0:2/64 is a local route.

### Viewing route and alternative route configuration on Switch-1:

```
Switch1:1(config)#show ipv6 route alternative

=====

## Changing the route preference on Switch-1

On the switch, default preferences are assigned to all standard routing protocols. You can modify the global preference for a protocol to give it a higher or lower priority than other protocols. When you change the preference for a static route, if all best routes remain best routes, only the local route tables change. However, if changing the protocol preference causes best routes to no longer be best routes, neighboring route tables can be affected.

In the following example scenario, you configure a different routing preference for the RIPng protocol on Switch-1 and observe the learning of best and alternative routes. The existing route preference for RIPng is 100.

```

Switch1:1#show ipv6 route alternative

=====
IPv6 Routing Table Information - GlobalRouter
=====
Destination Address/PrefixLen  NEXT HOP          VID/BID/TID  PROTO  COST  AGE  TYPE  PREF
-----
2000:0:0:0:0:0:0:1/64         0:0:0:0:0:0:0:0  V-2          LOCAL  1     0    B     0
3000:0:0:0:0:0:0:2/64         fe80:0:0:0:b2ad:aaff:fe4e:5500  V-2          OSPF   2     0    B     20
3000:0:0:0:0:0:0:2/64         fe80:0:0:0:b2ad:aaff:fe4e:5500  V-2          RIP    2     0    A     100

```

Configure a different route preference for the RIPng protocol, for example, 19:

```
Switch1:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch1:1(config)#ipv6 route preference protocol ripng 19
Switch1:1(config)#exit
```

Verify the route preference configuration:

```
Switch1:1#show ipv6 route preference
```

```
=====
                        IPv6 Route Preference - GlobalRouter
=====
PROTOCOL          DEFAULT    CONFIG
-----
LOCAL             0          0
STATIC            5          5
SPBM_L1           7          7
OSPFv3_INTRA     20         20
OSPFv3_INTER     25         25
EBGP              45         45
RIPNG             100        19
OSPFv3_E1        120        120
OSPFv3_E2        125        125
IBGP              175        175
```

View the updated route preference (for RIPng) on Switch-1. The RIPng route is now learnt as the best route as it has lesser value of route preference (19) than that of OSPFv3 (20), as shown below.

```
Switch1:1(config)#show ipv6 route
```

```

Extreme Networks offers two Analytics solutions that monitor traffic on your network:

- sFlow
- Application Telemetry

### Important

You can use either sFlow, or sFlow with Application Telemetry or both at the same time as they can coexist on a switch. Note that to enable Application Telemetry, you must enable sFlow first.

In both solutions, the switch collects flow information and sends it to a central server that processes the information and provides statistical data in the form of reports. Then you can use Extreme Management Center or ExtremeCloud IQ - Site Engine to analyze the reports to give you a full understanding of the applications on your network and learn who is using those applications. Extreme Management Center or ExtremeCloud IQ - Site Engine also provides information such as DoS tracking, security monitoring, and statistics for protocols, ports, and applications.

This section describes how Application Telemetry works and how to configure it. Because there is some commonality between the two features, this section also describes some sFlow features.

For further information about sFlow, see [sFlow Fundamentals](#) on page 3073.

For more information about Extreme Management Center or ExtremeCloud IQ - Site Engine, see the documentation on the Extreme Networks Documentation portal ([www.extremenetworks.com/documentation/](http://www.extremenetworks.com/documentation/)) with special attention to the *Application Analytics User Guide*.

## How Application Telemetry Works

Both sFlow and Application Telemetry mirror packets to a server for deep packet inspection, but they collect streams in very different ways:

- sFlow samples 1 out of  $n$  packets to create flow streams. This methodology achieves scalability and applies to high speed networks, but it provides limited application visibility.
- Application Telemetry does not sample some packets like sFlow; it monitors all traffic and uses policy rules to filter packets for analysis. This pattern matching methodology enables Application Telemetry to monitor all application-level traffic flows at wire speed on all interfaces simultaneously.

The policy rules that Application Telemetry uses are ACL and ACE filters that are pre-configured in a policy configuration file called `sflow.pol`. This policy file is not user configurable. These rules enable the switch to recognize several signatures that represent a combination of the following:

- IP protocol type (TCP/UDP)
- TCP flags
- Layer 4 port numbers
- data patterns (defined as offset/data/mask triplets)

Pattern matching enables Application Telemetry to target very specific, well-defined packets in each flow and not full streams of traffic. Thus, the switch mirrors only a relatively few packets to the Analytics

Engine. It is the Analytics Engine that performs deep packet inspection to create reports of statistical data.

### Important

When you enable Application Telemetry, the switch loads the filter rules based on the logic below:

- Application Telemetry uses the `apptelemetry.pol` or the `sflow.pol` file because the filter rules can exist in either file. The `sflow.pol` file is the default file and is included with the image that is loaded on the switch. This file contains the default filter rules. The `apptelemetry.pol` file is the user-defined file, which can be updated by the Extreme Management Center or ExtremeCloud IQ - Site Engine. To use this file, configure Application Telemetry using the Extreme Management Center or ExtremeCloud IQ - Site Engine. When you run the Application Telemetry LiveUpdate VOSS script from Extreme Management Center or ExtremeCloud IQ - Site Engine, the updated `apptelemetry.pol` file is placed in `/intflash/`.
- When you enable Application Telemetry, the feature uses the files in the following order:
  - If the user-defined file (`apptelemetry.pol`) exists, then the switch loads the rules from this file.
  - If the `apptelemetry.pol` file does not exist or if there is a problem reading this file, then the switch uses the default `sflow.pol` file.

## Common Elements Between sFlow and Application Telemetry

sFlow and Application Telemetry send mirrored packets from a common source to a common destination. sFlow sends samples directly to the destination, while Application Telemetry sends mirrored packets through a GRE tunnel, to the same destination.

The tunnel source is the switch that you want to monitor:

- sFlow sends sampled flows.
- Application Telemetry sends packets that match its policy rules.

Both sFlow and Application Telemetry use an agent to package either the sFlow streams or the Application Telemetry packets. To configure the agent, they both use the `sflow agent-ip` command.

### Note

The switch sends only one mirrored copy, even if the packet matches two or more policies. For information on which mirrored copies take precedence, see [Configuration considerations](#).

The tunnel destination for the mirrored traffic is a server where software performs a deep packet inspection of the mirrored traffic.

- sFlow sends flow and counter samples as datagrams to the sFlow Collector.
- Application Telemetry sends packets that match the policy rules over a GRE tunnel to the Analytics Engine.

To configure the tunnel destination, they both use the **sflow collector <1-2>** command.

### Important

You can configure two Collectors, but Application Telemetry uses Collector 1 only. You must configure Collector 1 before you enable Application Telemetry.

## Operational Considerations and Restrictions

The following section describes operational considerations for deploying Application Telemetry, including general considerations that apply to all platforms, followed by a summary of platform-specific considerations.

### General Considerations

The following section describes general Application Telemetry operational considerations for all platforms.

- When you enable Application Telemetry, it is globally enabled on all ports. You cannot disable the feature on a per-port basis.
- Application Telemetry supports IPv4 and IPv6 packets, although host monitoring is available for IPv4 hosts only.
- Application Telemetry filter rules are not user configurable. However, an updated `app-telemetry.p01` file can be installed through the Extreme Management Center or ExtremeCloud IQ - Site Engine.
- If a user-created filter rule (ACL) conflicts with an Application Telemetry defined filter, the user-created rule always takes precedence.
- There are two configurable sFlow collectors (Collector 1 and Collector 2). However, Application Telemetry uses Collector 1 only and you must configure it before enabling Application Telemetry.
- In a Fabric Extend deployment on VSP 4450 Series, VSP 7200 Series, VSP 8200 Series, VSP 8400 Series, or VSP 8400 Series, Application Telemetry does not mirror ingress NNI to UNI IP Shortcut traffic.

### Platform-Specific Considerations

The following tables provide a summary of operational considerations for different VOSS switches.

**Table 40: Supported flow types**

| Attribute                              | 5420 Series, 5520 Series, VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series | VSP 8600 Series |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Flows that ingress standard VLAN ports | Supported                                                                                                                      | Supported       |
| Flows that ingress UNI ports           | Supported                                                                                                                      | Supported       |

**Table 40: Supported flow types (continued)**

| Attribute                                                       | 5420 Series, 5520 Series, VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series | VSP 8600 Series |
|-----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Flows that ingress NNI ports and egress UNI ports (Layer 2 VSN) | Supported                                                                                                                      | Not supported   |
| Flows that ingress NNI ports and egress UNI ports (Layer 3 VSN) | Supported                                                                                                                      | Not supported   |
| Flows that ingress NNI ports and terminate locally              | Supported                                                                                                                      | Not supported   |
| Flow that ingress NNI ports and egress NNI ports                | Not supported                                                                                                                  | Not supported   |
| Flows on DvR Controllers or DvR Leafs                           | Supported                                                                                                                      | Supported       |

**Table 41: Application Telemetry collector/server reachability**

| Attribute                     | 5420 Series, 5520 Series, VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series                                                                                                                                                                                                                                                                                                                                                                                               | VSP 8600 Series                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Table 49: Host monitoring**

| Attribute                                                                  | 5420 Series, 5520 Series, VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series | VSP 8600 Series |
|----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Supported using Extreme Management Center or ExtremeCloud IQ - Site Engine | Yes                                                                                                                            | Yes             |

## Configuration Overview

After the optional step of uploading the `apptelemetry.p01` file to flash memory using Extreme Management Center or ExtremeCloud IQ - Site Engine, activate Application Telemetry by configuring the following:

1. Configure the IP address of the egress interface for the GRE tunnel with the `sFlow agent-ip` command.
2. Enable sFlow with the `sflow enable` command.
3. Configure the IP address of the Analytics Engine with the `sFlow collector 1` command.
4. Enable Application Telemetry with the `app-telemetry enable` command.

The following figure shows the Application Telemetry agent on various routers and switches with packets being sent to the Analytics Engine.

**Figure 16: Application Telemetry Overview**

**Table 50: Application Telemetry Legend**

| Number | Description                  |
|--------|------------------------------|
| 1      | Analytics Engine             |
| 2      | GRE tunnels                  |
| 3      | Application Telemetry agents |

## Host Monitoring

---

You can use Application Telemetry to get better visibility for a selected host by performing a timed packet capture for both incoming and outgoing traffic specific to that host. Initiate the packet capture (PCAP) from Extreme Management Center or ExtremeCloud IQ - Site Engine and specify a source or destination IP address to match. Extreme Management Center or ExtremeCloud IQ - Site Engine pushes an additional rule to the Application Telemetry agent on the switch, which captures packets that match this rule and uses the existing ERSPAN GRE session to mirror these packets to Analytics Engine for analysis.

To use this feature, all configuration occurs in Extreme Management Center or ExtremeCloud IQ - Site Engine. The following prerequisites for configuration must be met:

- Application Telemetry is active.
- The Analytics Engine records application flows.
- You can see the flows in Extreme Management Center or ExtremeCloud IQ - Site Engine.

In Extreme Management Center or ExtremeCloud IQ - Site Engine, select a flow and configure packet capture. You can specify the host, either the originating or destination host for the flow, and a monitoring interval. For more information about how to configure packet capture in Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation.

The following list identifies restrictions specific to host monitoring:

- You cannot configure monitoring of the same host twice.
- Host monitoring shares resources with the filter ACL application. The maximum number of hosts that can be monitored depends on the number of ACEs you configure. If no resources are available, the Resource Manager generates an error for both applications.
- You cannot configure monitoring of the sFlow agent IP address or collector IP address.

Although you use Extreme Management Center or ExtremeCloud IQ - Site Engine to configure the packet capture, the switch logs a message when this feature is activated or deactivated. Configuration of host monitoring is not saved; the monitoring is time-based.

### Note

Host monitoring is supported beginning with Extreme Management Center or ExtremeCloud IQ - Site Engine version 8.2.4.

## Application Telemetry Configuration Using CLI

---

Use Application Telemetry to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure this feature using CLI.

### Configuring the Agent IP Address

Use this procedure to configure the source of the Application Telemetry packets.

**Procedure**

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Enable the agent IPv4 address:  
sflow agent-ip {A.B.C.D}

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow agent-ip 192.0.2.27
```

*Variable Definitions*

Use the data in the following table to use the **sflow agent-ip** command.

| Variable    | Definition                             |
|-------------|----------------------------------------|
| {A.B.C.D. } | Specifies the agent-ip address (IPv4). |

**Configuring an Analytics Engine and Enabling Application Telemetry Globally**

Use this procedure to enable Application Telemetry and configure the device used as either an sFlow Collector or an Application Telemetry Analytics Engine. This device is where the agent sends sFlow datagrams and Application Telemetry packets for analysis.

sFlow supports up to two collectors for each interface slot in the chassis. However, Application Telemetry supports Collector 1 only.

**Note**

- You can configure two Collectors, but Application Telemetry uses Collector 1 only. You must configure Collector 1 before you enable Application Telemetry.
- Before you change or remove Collector 1, you must disable Application Telemetry.
- By default, Application Telemetry is globally disabled.

**Before You Begin**

- You must configure the sFlow agent IP address.
- You must enable sFlow before you can enable Application Telemetry.

**Procedure**

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Configure the Analytics Engine information using Collector 1:  
sflow collector 1 address {A.B.C.D} [owner WORD<1-20>] [vrf WORD<1-16>]

3. Verify the Analytics Engine configuration:

```
show sflow collector 1
```

4. Enable Application Telemetry:

```
app-telemetry enable
```

5. Verify the global configuration:

```
show app-telemetry status
```

#### Note

The output of this command shows whether Application Telemetry is enabled or not and if the collector is reachable.

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow collector 1 address 192.0.2.26 owner sflow1 port 6343 timeout 497
Switch:1(config)#show sflow collector 1
```

#### sFlow Collector Configuration Info

| Id | Owner  | Collector-IP | Port | Timeout(secs) | Reachable via |
|----|--------|--------------|------|---------------|---------------|
| 1  | sflow1 | 192.0.2.26   | 6343 | 497           | 192.0.2.15    |

```
All 1 out of 1 Total Num of sflow collector entries displayed
Switch:1(config)#app-telemetry enable
Switch:1(config)#show app-telemetry status
Application Telemetry is enabled
Collector is reachable via 192.0.2.26
```

#### Variable Definitions

Use the data in the following table to use the **sflow collector** command.

| Variable                   | Value                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <1-2>                      | Specifies the ID of the collector where you want to send packets for analysis. Application Telemetry uses Collector 1 only.         |
| owner WORD<1-20>           | Specifies the name of the collector.                                                                                                |
| Collector-IP<br>{A.B.C.D.} | Specifies the IP address of the collector.                                                                                          |
| port <1-65535>             | Specifies the destination port. The default port is 6343.<br><br><b>Note:</b><br>Application Telemetry does not use this parameter. |

| Variable                             | Value                                                                                                                                                                                                                                                  |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>timeout &lt;1-65535&gt;</code> | Specifies the time remaining (in seconds) before the collector is released. The default timeout is 0, which means the timeout is not used and the switch sends data forever.<br><br><b>Note:</b><br>Application Telemetry does not use this parameter. |
| <code>vrf WORD&lt;1-16&gt;</code>    | Specifies the name of the VRF used to reach the collector.<br><br><b>Note:</b><br>This parameter is not supported on all hardware platforms.                                                                                                           |

## View Application Telemetry Counters

Use the following procedure to view the Application Telemetry status counters. The switch assigns an ID to each counter and displays information about each filter rule by name. The information includes how many packets were transmitted to the Analytics Engine that matched the specified pattern in the rule and the total number of bytes in the packets.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View Application Telemetry counters:  

```
show app-telemetry counter [name <WORD<1-32> | id <1-2000>]
```

### Example

```
Switch:1>show app-telemetry counter

=====
Application Telemetry Counters
=====
EntryId      Name      Packets    Bytes
-----
1            ssh      1258      72145
2            sslclient 457       27000
-----

All 2 out of 2 Total Num of Application Telemetry counters entries displayed
```

## Clearing Application Telemetry Counters

Use this procedure to clear the Application Telemetry status counters. You can clear all of the counters or specify just the counters you want to clear by name or ID.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Clear Application Telemetry counters:  

```
clear app-telemetry counter [name <WORD<1-32> | id <1-2000>]
```
3. Verify that the counters were cleared:  

```
show app-telemetry counter [name <WORD<1-32> | id <1-2000>]
```

## Example

Clear the counters.

```
Switch:1>enable
Switch:1#clear app-telemetry counter
Switch:1>show app-telemetry counter

=====
Application Telemetry Counters
=====
EntryId      Name           Packets      Bytes
-----
1            ssh            0            0
2            sslclient     0            0
-----
All 2 out of 2 Total Num of Application Telemetry counters entries displayed
```

## Application Telemetry Configuration Using EDM

Use Application Telemetry to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure this feature using EDM.

sFlow and Application Telemetry send mirrored packets from a common source to a common destination. sFlow sends samples directly to the destination, while Application Telemetry sends mirrored packets through a GRE tunnel, to the same destination.

Both sFlow and Application Telemetry use an agent to package either the sFlow streams or the Application Telemetry packets. To configure the agent, they both use the **Serviceability > Sflow > Globals** and **Serviceability > Sflow > Collector** tabs. For more information, see [sFlow Configuration Using EDM](#) on page 3084.

### Enabling Application Telemetry Globally

Use this procedure to globally enable Application Telemetry so it can send packets to an Analytics Engine. By default, Application Telemetry is globally disabled.

#### Before You Begin

You must complete the following:

- Configure an agent IP address.
- Enable sFlow.
- Configure Collector 1.

#### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Application Telemetry**.
3. Click the **Globals** tab.
4. Select the **AdminEnable** check box.
5. Click **Apply**.

*Globals Field Descriptions*

Use the data in the following table to use the **Globals** tab.

| Name                     | Description                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------|
| <b>AdminEnable</b>       | Shows whether Application Telemetry is enabled. By default, the check box is not enabled. |
| <b>ClearCounterStats</b> | Clears the Application Telemetry status counters.                                         |

## Viewing Application Telemetry Counters

Use the following procedure to view the Application Telemetry status counters. The switch assigns an ID to each counter and displays information about each filter rule by name. The information includes how many packets were transmitted to the Analytics Engine that matched the specified pattern in the rule and the total number of bytes in the packets.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Application Telemetry**.
3. Click the **Counter** tab.

*Counter field descriptions*

Use the data in the following table to use the **Counter** tab.

| Name                | Description                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>CounterId</b>    | Shows the Application Telemetry rule ID.                                                                        |
| <b>CounterName</b>  | Shows the rule name.                                                                                            |
| <b>CounterPkts</b>  | Shows the number of packets transmitted to the Analytics Engine that matched the specified pattern in the rule. |
| <b>CounterBytes</b> | Shows the total number of bytes in the packets.                                                                 |

## Clearing Application Telemetry Counters

Use this procedure to clear the Application Telemetry status counters. You can clear all of the counters or specify just the counters you want to clear by name or ID.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Application Telemetry**.
3. Perform one of the following actions:
  - To clear all the counters, click the **Globals** tab, and then select **ClearCounterStats**.
  - To clear specific counters, click the **Counter** tab, select the counter ID you want to clear, and then click **ClearStats**.
4. Click **Apply**.

## Viewing Application Telemetry Status

### About This Task

Use this procedure to view the status of the Application Telemetry collector.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Application Telemetry**.
3. Click the **Status** tab.

### *Status field descriptions*

Use the data in the following table to use the **Status** tab.

| Name                        | Description                                                                                                        |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Collector IP Address</b> | Shows the address of the Application Telemetry collector.                                                          |
| <b>IsReachable</b>          | Shows whether the Application Telemetry collector is reachable.                                                    |
| <b>NextHop</b>              | If the collector is reachable, shows the name or address of the next hop through which the collector is reachable. |

Use Bidirectional Forwarding Detection (BFD) to provide a failure detection mechanism between two systems.

The following sections provide information and procedures for BFD.

## BFD Fundamentals

The following sections provide fundamentals information about Bidirectional Forwarding Detection (BFD).

### BFD Overview

Bidirectional Forwarding Detection (BFD) is a simple Hello protocol used between two peers. In BFD, peer systems periodically transmit BFD packets to each other. If one of the systems does not receive a BFD packet after a certain period of time, the system assumes that the link or other system is not operating.

A path is considered operational when bidirectional communication is established between systems. However, this does not preclude the use of unidirectional links.

BFD provides low-overhead, short-duration failure detection between two systems. BFD also provides a single mechanism for connectivity detection over any media, at any protocol layer.

Because BFD sends rapid failure-detection notifications to the routing protocols that run on the local system, which initiates routing table recalculations, BFD helps reduce network convergence time.

BFD supports IPv4/IPv6 single hop detection for static routes, OSPFv2, OSPFv3, iBGP, iBGPv6. Forwarding path failure detection for Fabric Extend tunnels is supported over an IPv4 network only.

#### Note

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

**Note**

iBGPv6 is not supported in VRF.

## BFD Operation

VOSS uses one BFD session for all protocols with the same destination. For example, if a network runs OSPFv2 and BGP across the same link with the same peer, only one BFD session is established, and BFD shares session information with both routing protocols.

You can enable BFD over data paths with specified OSPFv2 and OSPFv3 neighbors, BGP neighbors, static routing next-hop addresses, and Fabric Extend tunnels.

VOSS supports BFD asynchronous mode, which sends BFD control packets between two systems to activate and maintain BFD neighbor sessions. To reach an agreement with its neighbor about how rapidly failure detection occurs, each system estimates how quickly it can send and receive BFD packets.

A session begins with the periodic, slow transmission of BFD control packets. When bidirectional communication is achieved, the BFD session comes up.

After the session is up, the transmission rate of Control packets can increase to achieve detection time requirements. If Control packets are not received within the calculated detection time, the session is declared down. After a session is down, Control packet transmission returns to the slow rate.

If a session is declared down, it cannot come back up until the remote end signals that it is down (three-way handshake). A session can be kept administratively down by configuring the state of AdminDown.

In asynchronous mode, detection time is equal to the value of DetectMult received from the remote system multiplied by the agreed transmit interval of the remote system (the greater of RequiredMinRxInterval and DesiredMinTxInterval.) DetectMult is approximately equal to the number of sequential packets that must be missed to declare a session down.

## BFD States

A session normally proceeds through three states; two states are used to establish a session (Init and Up) and one state is used to tear down a session (Down). This allows a three-way handshake for both session establishment and session teardown, assuring that both systems are aware of all session state changes. There is a fourth state (AdminDown) that you can use to administratively put a session down indefinitely.

- Down state: Indicates the session is down or has just been created. The session will remain in Down state until the remote system sends a BFD control packet indicating anything other than Up state. If the control packet signals Down state, the session advances to Init state. If the control packet signals Init state, the session advances to Up state.
- Init state: In this state, the host system establishes communications with the remote system and sends a request to move the session to the Up state, but the remote system has not yet recognized the request. A session remains in Init state until it receives a BFD control packet signaling Init or Up state, or until the connectivity timer expires, indicating communication with the remote system is lost.

- Up state: Indicates the BFD session is established and connectivity is working. A session remains in Up state until connectivity fails or until the session is taken down administratively.
- AdminDown state: Indicates the BFD session is being held down administratively. This causes the remote system to enter Down state and remain there until the local system exits AdminDown state.

## BFD Configuration

The following sections provide conceptual information about BFD configuration. For detailed procedural information about BFD configuration, see [BFD Configuration using CLI](#) on page 342 and [BFD Configuration using EDM](#) on page 357.

### *Enable BFD*

To enable Bidirectional Forwarding Detection (BFD) between 2 peers:

- Configure BFD globally.
- Configure BFD on the required interfaces of both peer systems.
- Enable BFD on the required routing protocols.
- Specify the next-hop device with which the switch initiates the BFD session.

### *Delete a BFD Session*

To delete a BFD session, disassociate all applications with the BFD session, then administratively bring down the BFD session.

#### **Note**

To successfully delete a BFD session, you must execute the commands in the following order:

1. Disassociate all applications from the BFD session.
2. Disable BFD at the global level or interface level, which transitions the BFD session to AdminDown state.

If you change the above order of operations, the BFD session is not deleted.

## BFD Considerations

The following considerations apply to Bidirectional Forwarding Detection (BFD):

- BFD is supported only in asynchronous mode. Demand mode and echo functionalities are not supported.
- You configure BFD parameters on a per session basis, not on a per next-hop basis.
- BFD creates multiple sessions even though a neighbor shares an IP address.
- The granularity of the fault detection interval in BFD is 100 ms, and the minimum multiplier is 2.

The minimum value for the transmit interval or the receive interval is 100 ms. If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

You can configure a total of 16 BFD sessions. Of the 16 possible BFD sessions, you can configure a maximum of 4 BFD sessions with the minimum value for transmit interval or receive interval. You

can configure the remaining BFD sessions with a transmit interval or a receive interval that is greater than or equal to the 200 ms default value.

- BFD is not supported over RSMILT links. This applies to BFD sessions over IPv4 interfaces and IPv6 interfaces.
- Inter-tunnel routing with 6in4 tunnels is not supported. This means that incoming IPv6 packets over a tunnel cannot be forwarded over another tunnel configured on the same VOSS switch.
- BFD for Interior Border Gateway Protocol (iBGP) and BGPv6 in VRF is not supported.
- Session dampening is not supported for BFD.
- BFD for eBGPv6 in VRF is not supported.
- VOSS supports BFD multihop only at the eBGP application level. For other applications, VOSS does not support BFD multihop, as defined by RFC 5883. However, there is no requirement for source and destination IP addresses to be in the same subnet.
- BFD over IPv6 Fabric Extend (FE) tunnels is not supported.
- The minimum value for the transmit interval or the receive interval is 1 second with a fault detection time of 3 seconds for BFD over IPv4 FE tunnels.
- BFD does not support a static route flag.
- BFD is not supported on a Virtual Router Redundancy Protocol (VRRP) interface.
- High Availability for BFD is not supported.
- You can configure a total of 256 BFD and Virtual Link Aggregation Control Protocol (VLACP) sessions.
- BFD packets cannot be mirrored when BFD is configured on the switch.

## BFD Configuration using CLI

---

Use the following procedures to configure Bidirectional Forwarding Detection (BFD) using CLI. BFD provides low-overhead, short-duration failure-detection between two systems.

### Enable BFD Globally

#### Note

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD globally.

#### Note

Enabling BFD globally does not establish a BFD session. To establish a BFD session, you must also configure BFD at the interface level and at the application level.

### Procedure

1. Enter BFD Router Configuration mode:

```
enable

configure terminal

router bfd
```

2. Enable BFD:

```
router bfd enable
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bfd
Switch:1(router-bfd)#router bfd enable
```

## Configure BFD on an IPv4 Interface

### About This Task

Use the following procedure to enable and to configure Bidirectional Forwarding Detection (BFD) on an IPv4 interface. All interface configuration is performed at the VLAN, GigabitEthernet, or Loopback level.

#### Note

Enabling BFD on an interface does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the application level.

### Procedure

1. Enter Interface Configuration mode:

```
enable

configure terminal
```

followed by one of the following:

- `interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`
- `interface loopback <1-256>`
- `interface vlan <1-4059>`

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable BFD on an interface:

```
ip bfd enable
```

3. (Optional) Configure the transmit interval:  

```
ip bfd interval <100-65335>
```
4. (Optional) Configure the minimum receive interval:  

```
ip bfd min-rx <100-65335>
```
5. (Optional) Configure the multiplier:  

```
ip bfd multiplier <1-20>
```
6. (Optional) In GigabitEthernet Interface Configuration mode, you can configure a value for port:  

```
ip bfd port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
7. (Optional) In VLAN Interface Configuration mode, you can configure a value for VLAN:  

```
ip bfd vlan <1-4094>
```
8. (Optional) In Loopback Interface Configuration mode, you can configure a value for loopback:  

```
ip bfd loopback <1-256>
```

### Variable Definitions

The following table defines parameters for the **ip bfd** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                              |
| enable                                                             | Enable BFD on a port, VLAN, or loopback.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| interval <100-65335>                                               | Specifies the transmit interval in milliseconds. The default is 200 ms.<br><br><b>Note:</b><br>For XA1400 Series, the default is 1000 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value. |
| min-rx <100-65335>                                                 | Specifies the receive interval in milliseconds. The default is 200 ms.<br><br><b>Note:</b><br>For XA1400 Series, the default is 1000 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.     |

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| multiplier <1-20>                                          | Specifies the multiplier used to calculate the amount of time BFD waits before declaring a receive timeout. The default is 3.<br><br><b>Note:</b><br>If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.                                                                 |
| port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| vlan <1-4094>                                              | Specifies the VLAN ID in the range of 1 to 4094.                                                                                                                                                                                                                                                                                                              |
| loopback <1-256>                                           | Specifies the Loopback ID in the range of 1 to 256.                                                                                                                                                                                                                                                                                                           |

## Configure BFD on an IPv6 Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

Use the following procedure to enable and to configure BFD on an IPv6 interface. All interface configuration is performed at the VLAN or GigabitEthernet level.

#### Note

Enabling BFD on an interface does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the application level.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable BFD on an interface:

```
ipv6 bfd enable
```
3. (Optional) Configure the transmit interval:

```
ipv6 bfd interval <100-65335>
```

4. (Optional) Configure the minimum receive interval:

```
ipv6 bfd min-rx <100-65335>
```

5. (Optional) Configure the multiplier:

```
ipv6 bfd multiplier <1-20>
```

6. (Optional) In GigabitEthernet Interface Configuration mode, you can configure a value for port:

```
ipv6 bfd port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. (Optional) In VLAN Interface Configuration mode, you can configure a value for VLAN:

```
ipv6 bfd vlan <1-4094>
```

### Variable Definitions

The following table defines parameters for the **ip bfd** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                              |
| enable                                                       | Enable BFD on a port, VLAN, or loopback.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| interval <100-65335>                                         | Specifies the transmit interval in milliseconds. The default is 200 ms.<br><br><b>Note:</b><br>For XA1400 Series, the default is 1000 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value. |
| min-rx <100-65335>                                           | Specifies the receive interval in milliseconds. The default is 200 ms.<br><br><b>Note:</b><br>For XA1400 Series, the default is 1000 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.     |

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| multiplier <1-20>                                          | Specifies the multiplier used to calculate the amount of time BFD waits before declaring a receive timeout. The default is 3.<br><br><b>Note:</b><br>If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.                                                                 |
| port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| vlan <1-4094>                                              | Specifies the VLAN ID in the range of 1 to 4094.                                                                                                                                                                                                                                                                                                              |
| loopback <1-256>                                           | Specifies the Loopback ID in the range of 1 to 256.                                                                                                                                                                                                                                                                                                           |

## Enable BFD at the BGP Application Level

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD supports internal Border Gateway Protocol (iBGP) and external Border Gateway Protocol (eBGP) on IPv4 interfaces. You configure BFD on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. BFD does not support BGPv6 for VRF on IPv6 interfaces.

#### Note

Enabling BFD at the BGP application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

- Enter BGP Router Configuration mode:
 

```
enable

configure terminal

router bgp
```
- Enable BFD for the BGP protocol:
 

```
neighbor WORD<0-1536> fall-over bfd
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bgp
Switch:1(router-bgp)#neighbor 192.0.2.15 fall-over bfd
```

### Variable Definitions

The following table defines parameters for the **neighbor** command.

| Variable     | Value                                                 |
|--------------|-------------------------------------------------------|
| WORD<0-1536> | Specifies the peer IP address or the peer group name. |

## Enable BFD at the OSPF Application Level

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD supports Open Shortest Path First (OSPF) for IPv4 interfaces and OSPFv3 for IPv6 interfaces.

Use the following procedure to enable BFD at the OSPF application level.

#### Note

Enabling BFD at the OSPF application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. (Optional) Enable BFD on an IPv4 interface under the OSPF protocol:

```
ip ospf bfd
```

3. Enable BFD on an IPv6 interface under the OSPF protocol:

```
ipv6 ospf bfd
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/3
Switch:1(config-if)#ip ospf bfd
```

### Variable Definitions

The following table defines parameters for the **ip ospf bfd** command.

| Variable                                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]<br/>[-slot/port[/sub-<br/>port]][,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <code>&lt;1-4059&gt;</code>                                                | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## Configure BFD on an IPv4 Static Route

### About This Task

Use the following procedure to configure BFD on an IPv4 static route.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure BFD on an IPv4 static route:
 

```
ip route bfd {A.B.C.D}
```

### Variable Definitions

The following table defines parameters for the **ip route bfd** command.

| Variable               | Value                                        |
|------------------------|----------------------------------------------|
| <code>{A.B.C.D}</code> | Specifies the BFD static route IPv4 address. |

## Configure BFD on an IPv6 Static Route

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

Use the following procedure to configure BFD on an IPv6 static route.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure BFD on an IPv6 static route:  

```
ipv6 route bfd WORD<0-128>
```
3. (Optional) Configure an IPv6 static route for a port:  

```
ipv6 route bfd WORD<0-128> port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
4. (Optional) Configure an IPv6 static route for a VLAN:  

```
ipv6 route bfd WORD<0-128> vlan <1-4094>
```

*Variable Definitions*

The following table defines parameters for the **ipv6 route bfd** command.

| Variable                                                   | Value                                                    |
|------------------------------------------------------------|----------------------------------------------------------|
| WORD<0-128>                                                | Specifies the BFD static route IPv6 address.             |
| port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Specifies the port number for the BFD IPv6 static route. |
| vlan <1-4094>                                              | Specifies the VLAN ID for the BFD IPv6 static route.     |

**Clear BFD Session Statistics**

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

**About This Task**

Use the following procedure to clear local and remote Bidirectional Forwarding Detection (BFD) session statistics for IPv4 or IPv6 interfaces.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```
2. (Optional) Clear BFD session statistics for an IPv4 interface:  

```
clear ip bfd stats
```
3. Clear BFD session statistics for an IPv6 interface:  

```
clear ipv6 bfd stats
```

*Variable Definitions*

The following table defines parameters for the **clear ip bfd stats** command.

| Variable           | Value                                   |
|--------------------|-----------------------------------------|
| vrf WORD<1-16>     | Specifies a VRF instance by VRF name.   |
| vrfids WORD<0-512> | Specifies a VRF or range of VRFs by ID. |

## Display BFD Global Configuration

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

Use this procedure to display global configuration information for BFD.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display global BFD configuration information:  

```
show ip bfd [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

The following example displays global configuration information for BFD on an IPv4 interface.

```
Switch:1>show ip bfd
=====
                        BFD information - GlobalRouter
=====
                        BFD Version : 1
                        Admin Status : TRUE
                        Trap Enable  : FALSE
=====
Total session number : 1

UP: 1, DOWN: 0, AdminDown: 0, Init: 0
=====
```

*Variable Definitions*

The following table defines parameters for the **show ip bfd** command.

| Variable           | Value                                   |
|--------------------|-----------------------------------------|
| vrf WORD<1-16>     | Specifies a VRF instance by VRF name.   |
| vrfids WORD<0-512> | Specifies a VRF or range of VRFs by ID. |

## Display BFD Configuration for an IPv4 Interface

### About This Task

Use the following procedure to display BFD configuration on an interface.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD on a Gigabit Ethernet interface:
 

```
show ip bfd interfaces GigabitEthernet [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
3. Display BFD on a VLAN interface:
 

```
show ip bfd interfaces vlan [<1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Examples

The following example displays VLAN interface configuration information for BFD.

```
Switch:1>show ip bfd interfaces vlan 11
=====
                        Vlan Bfd
=====
VLAN      STATUS    MIN_RX   INTERVAL  MULTIPLIER  VRF-ID
-----
11        enable    200      200       3           0
```

The following example displays Loopback interface configuration information for BFD:

```
Switch:1>enable
Switch:1#show ip bfd interfaces loopback
=====
                Circuitless IP Interface Bfd
=====
INTF ID   STATUS    MIN_RX   INTERVAL  MULTIPLIER  VRF-ID
-----
1         enable    200      200       3           0
2         enable    200      200       3           2
```

### Variable Definitions

The following table defines parameters for the **show ip bfd interfaces** command.

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <1-4059>                                                   | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

| Variable           | Value                                   |
|--------------------|-----------------------------------------|
| vrf WORD<1-16>     | Specifies a VRF instance by VRF name.   |
| vrfids WORD<0-512> | Specifies a VRF or range of VRFs by ID. |

## Display BFD Configuration for an IPv6 Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

Use the following procedure to display BFD configuration on an IPv6 interface.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD on a Gigabit Ethernet interface:

```
show ipv6 bfd interfaces GigabitEthernet [{slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]]
```

3. Display BFD on a VLAN interface:

```
show ipv6 bfd interfaces vlan <1-4059>
```

### Example

The following example displays port configuration information for BFD.

```
Switch:1>show ipv6 bfd interfaces gigabitEthernet 1/3

=====
Port Bfd
=====
PORT          STATUS    MIN_RX   INTERVAL  MULTIPLIER  VRF-ID
-----
1/3           enable    200      200        3            0
```

### Variable Definitions

The following table defines parameters for the **show ip bfd interfaces** command.

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <1-4059>                                                   | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

| Variable           | Value                                   |
|--------------------|-----------------------------------------|
| vrf WORD<1-16>     | Specifies a VRF instance by VRF name.   |
| vrfids WORD<0-512> | Specifies a VRF or range of VRFs by ID. |

## Display BFD IPv4 Neighbor Information

### About This Task

Use this procedure to display BFD session information for IPv4 neighbors.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD neighbor information:  

```
show ip bfd neighbors
```
3. (Optional) Display BFD neighbor next-hop information:  

```
show ip bfd neighbors next-hop {A.B.C.D}
```
4. (Optional) Display BFD neighbor information for a particular VRF:  

```
show ip bfd neighbors vrf WORD<1-16>
```
5. (Optional) Display BFD neighbor information for a VRF ID or a range of VRF IDs:  

```
show ip bfd neighbors vrfids WORD<0-512>
```

### Example

The following example displays BFD session information for an IPv4 neighbor.

```
Switch:1>show ip bfd neighbors
=====
                        BFD Session - GlobalRouter
=====
MY_DISC   YOUR_DISC  NEXT_HOP      STATE    MULTI  MIN_TX  MIN_RX  ACT_TX  DETECT_TIME  REMOTE_STATE  APP   RUN
-----
1         0         192.0.2.11   Down     3      200    200    1000   600          Down         O
-----
1 out of 1 BFD session displayed
=====
APP and RUN Legend:
      B=BGP, O=OSPF, S=Static Route
=====
```

### Variable Definitions

The following table defines parameters for the **show ip bfd neighbors** command.

| Variable           | Value                                                                             |
|--------------------|-----------------------------------------------------------------------------------|
| {A.B.C.D}          | Specifies the next-hop IP address in the format a.b.c.d.                          |
| vrf WORD<1-16>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters). |
| vrfids WORD<0-512> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                |

## Display BFD IPv6 Neighbor Information

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

Use this procedure to display information about BFD IPv6 neighbors.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD neighbor information:  

```
show ipv6 bfd neighbors
```
3. (Optional) Display BFD neighbor next-hop information:  

```
show ipv6 bfd neighbors next-hop WORD<0-128>
```
4. (Optional) Display BFD neighbor information for a particular VRF:  

```
show ipv6 bfd neighbors vrf WORD<1-16>
```
5. (Optional) Display BFD neighbor information for a range of VRFs:  

```
show ipv6 bfd neighbors vrfids WORD<0-512>
```

### Example

The following example displays BFD session information for an IPv6 neighbor.

```
Switch:1>show ipv6 bfd neighbors
=====
BFD Session - GlobalRouter
=====
MY_DISC  YOUR_DISC  NEXT_HOP          STATE  MULTI  MIN_TX  MIN_RX  ACT_TX  DETECT_TIME  REMOTE_STATE  APP  RUN
1         0          2001:DB8:0:0:25AB:0:0:1  Down   3      200    200    1000   0           Down         0    0
-----
1 out of 1 BFD session displayed
-----
APP and RUN Legend:
  B=BGP_IPv6, O=OSPFv3, S=IPv6 Static Route
-----
```

### Variable Definitions

The following table defines parameters for the **show ipv6 bfd neighbors** command.

| Variable           | Value                                                                             |
|--------------------|-----------------------------------------------------------------------------------|
| WORD<0-128>        | Specifies the next-hop IPv6 address in the format a:b:c:d:e:f:g:h.                |
| vrf WORD<1-16>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters). |
| vrfids WORD<0-512> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                |

## Display BFD Statistics

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

Use the following procedure to display BFD statistics for IPv4 or IPv6 interfaces.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD IPv4 statistics:  

```
show ip bfd stats [vrf] [vrfids]
```
3. Display BFD IPv6 statistics:  

```
show ipv6 bfd stats [vrf] [vrfids]
```

### Example

The following example displays BFD statistics for IPv4 interfaces.

```
Switch:1>show ip bfd stats
=====
BFD statistics - GlobalRouter
=====
MY_DISC    YOUR_DISC  NEXT_HOP    PACKET_IN    PACKET_OUT    LAST_UP    LAST_DOWN
-----
1          0          192.0.2.10  4661750     4620630     Mon Sep 6 15:31:15 2021  Mon Sep 6
15:28:08 2021
-----
```

The following example displays BFD statistics for IPv6 interfaces.

```
Switch:1>show ipv6 bfd stats
=====
BFD statistics - GlobalRouter
=====
MY_DISC    YOUR_DISC  NEXT_HOP    PACKET_IN    PACKET_OUT    LAST_UP    LAST_DOWN
-----
1          0          2001:DB8:0:0:0:0:ffff 4661750     4620630     Mon Sep 6 15:31:15 2021  Mon Sep
6 15:28:08 2021
-----
```

### Variable Definitions

The following table defines parameters for the **show ip bfd stats** command.

| Variable | Value                                   |
|----------|-----------------------------------------|
| vrf      | Specifies a VRF instance by VRF name.   |
| vrfids   | Specifies a VRF or range of VRFs by ID. |

## BFD Configuration using EDM

Use the following procedures to configure Bidirectional Forwarding Detection (BFD) using EDM. BFD provides low-overhead, short-duration failure-detection between two systems.

### Enable BFD Globally

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

#### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD globally.

#### Note

Enabling BFD globally does not establish a BFD session. To establish a BFD session, you must enable BFD at the interface level and at the application level.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **BFD**.
3. Select the **Globals** tab.
4. In the **AdminStatus** field, select **enabled**.
5. (Optional) Select **TrapEnabled** to send BFD traps.

#### *BFD Globals Field Descriptions*

Use the data in the following table to use the **Globals** tab.

| Name                 | Description                                               |
|----------------------|-----------------------------------------------------------|
| <b>AdminStatus</b>   | Specifies whether BFD is enabled.                         |
| <b>VersionNumber</b> | Specifies the current version number of the BFD protocol. |
| <b>TrapEnabled</b>   | Specifies whether BFD traps are sent.                     |

### Display BFD Sessions

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

#### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to display information about BFD sessions. You can optionally display BFD session information for IPv4 or IPv6 interfaces.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.

2. Select **BFD**.
3. Select the **Sessions** tab.
4. (Optional) Select **Filter**.
5. (Optional) Select **AddrType**.
6. (Optional) In the **AddrType** field, specify a value for address type.

### *BFD Sessions Field Descriptions*

Use the data in the following table to use the **Sessions** tab.

| Name                        | Description                                                                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Discriminator</b>        | Specifies the local discriminator that uniquely identifies the BFD session.                                                                                              |
| <b>RemoteDiscr</b>          | Specifies the discriminator of the remote system in the BFD session.                                                                                                     |
| <b>UdpPort</b>              | Specifies the UDP Port for the BFD session. The default value is the well-known value for the port.                                                                      |
| <b>State</b>                | Specifies the state of the BFD session. Possible values are Down, Up, Init, and AdminDown.                                                                               |
| <b>Addr</b>                 | Specifies the IP address of the interface associated with the BFD session. A value of unknown (0) indicates the BFD session is not associated with a specific interface. |
| <b>DesiredMinTxInterval</b> | Specifies the preferred minimum interval for transmitting BFD control packets by the local system.                                                                       |
| <b>ReqMinTxInterval</b>     | Specifies the minimum interval for transmitting BFD control packets that the local system can support.                                                                   |
| <b>DestAddr</b>             | Specifies the destination IP address of the interface associated with the BFD session.                                                                                   |
| <b>OldState</b>             | Specifies the old state of the BFD session.                                                                                                                              |
| <b>App</b>                  | Specifies the applications configured on the BFD session.                                                                                                                |
| <b>AppRun</b>               | Specifies the applications running on the BFD session.                                                                                                                   |
| <b>AddrType</b>             | Specifies the IP address type of the interface associated with this BFD session. Possible values are ipv4 and ipv6.                                                      |

## Configure BFD for an IPv4 Interface on a Port

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv4 interface on a port.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Port**.
2. Select **IP**.
3. Select the **BFD** tab.
4. Select **Enable**.

5. (Optional) In the **MinRxInterval** field, specify the minimum receive interval..
6. (Optional) In the **TxInterval** field, specify the transmit interval.
7. (Optional) In the **Multiplier** field, specify a value for the multiplier used to calculate a receive timeout.

### BFD Field Descriptions

Use the data in the following table to use the **BFD** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>        | Enable BFD on the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>MinRxInterval</b> | Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value. |
| <b>TxInterval</b>    | Specifies the transmit interval in milliseconds. The default is 200 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. | <b>Multiplier</b>    | Specifies a value for the multiplier used to calculate a receive timeout. The default is 3.<br><br><b>Note:</b><br>If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.                                                                                                                                                                                                                                |

## Configure BFD for an IPv6 Interface on a Port

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv6 interface on a port.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Port**.
2. Select **IPv6**.
3. Select the **IPv6 BFD Interface** tab.
4. (Optional) In the **MinRxInterval** column, double-click the field and type a value for **MinRxInterval**.

5. (Optional) In the **TxInterval** column, double-click the field and type a value for **TxInterval**.
6. (Optional) In the **Multiplier** column, double-click the field and type a value for **Multiplier**.

### BFD Field Descriptions

Use the data in the following table to use the **BFD** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>     | Specifies the BFD interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Configure BFD for an IPv4 Interface on a VLAN

### About This Task

BFD provides a failure detection-mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv4 interface on a VLAN.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to configure BFD.
5. Select **IP**.
6. Select **BFD**.
7. Select **Enable**.

8. (Optional) In the **MinRxInterval** field, specify the minimum receive interval..
9. (Optional) In the **TxInterval** field, specify the transmit interval.
10. (Optional) In the **Multiplier** field, specify a value for the multiplier used to calculate a receive timeout.

### IP BFD field descriptions

Use the data in the following table to use the **BFD** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>        | Enable BFD on the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Enable BFD for BGP Peers

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for Border Gateway Protocol (BGP) peers.

#### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

## Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Select **BfdEnable**.

### *Peers* Field Descriptions

Use the data in the following table to use the **Peers** tab.

| Name                         | Description                                                                                                                                       |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Instance</b>              | Specifies the BGP peer instance.                                                                                                                  |
| <b>LocalAddrType</b>         | Specifies the local IP address type of the entered BGP peer.                                                                                      |
| <b>LocalAddr</b>             | Specifies the local IP address of the entered BGP peer.                                                                                           |
| <b>RemoteAddrType</b>        | Specifies the remote IP address type of the entered BGP peer.                                                                                     |
| <b>RemoteAddr</b>            | Specifies the remote IP address of the entered BGP peer.                                                                                          |
| <b>AdminStatus</b>           | Specifies the administrative status of the BGP peer.                                                                                              |
| <b>GroupName</b>             | Specifies the peer group name to which the peer belongs (optional).                                                                               |
| <b>PeerState</b>             | Specifies the BGP peer connection state.                                                                                                          |
| <b>RemoteAs</b>              | Configures a remote AS number for the peer or peer-group in the range 0-65535.                                                                    |
| <b>Enable</b>                | Controls whether the peer connection is enabled or disabled. The default is disabled.                                                             |
| <b>EbgpMultiHop</b>          | Enables or disables a connection to a BGP peer that is more than one hop away from the local router. The default value is disable.                |
| <b>RoutePolicyIn</b>         | Specifies the policy (by name) that applies to all network routes learned from this peer.                                                         |
| <b>RoutePolicyOut</b>        | Specifies the policy (by name) that applies to all outgoing route updates.                                                                        |
| <b>RemovePrivateAs</b>       | Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.                                                  |
| <b>UpdateSourceInterface</b> | Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.                                             |
| <b>ConnectRetryInterval</b>  | Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535. |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HoldTimeConfigured</b>    | Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.                                                                                                                                                                                                                                                                            |
| <b>KeepAliveConfigured</b>   | Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.                                                                                                                                                                                                                                    |
| <b>MD5Authentication</b>     | Enables and disables MD5 authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGP neighbor. The default value is 30 seconds and the range is 5–120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained. |
| <b>DefaultOriginate</b>      | When enabled, specifies that the current route originated from the BGP peer. This parameter enables or disables sending the default route information to the specified neighbor or peer. The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DefaultOriginateIpv6</b>  | When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Weight</b>                | Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0–65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>MaxPrefix</b>             | Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0–2147483647. A value of 0 means no limit exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>NextHopSelf</b>           | Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RouteReflectorClient</b>  | Specifies that this peer is a route reflector client.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SoftReconfigurationIn</b> | When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable.<br>Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DebugMask</b>             | Displays the specified debug information for the BGP peer. The default value is none. <ul style="list-style-type: none"> <li>• None disables all debug messages.</li> <li>• Event enables the display of debug event messages.</li> <li>• State enables display of debug state transition messages.</li> <li>• Update enables display of debug messages related to updates transmission and reception.</li> <li>• Error enables the display of debug error messages.</li> <li>• Trace enables the display of debug trace messages.</li> <li>• Init enables the display of debug initialization messages.</li> <li>• All enables all debug messages.</li> <li>• Packet enables the display of debug packet messages.</li> <li>• Warning enables the display of debug warning messages.</li> <li>• Filter enables the display of debug messages related to filtering.</li> </ul> |
| <b>SendCommunity</b>         | Enables or disables sending the community attribute of the update message to the specified peer. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Vpnv4Address</b>          | Specifies the vpnv4 routes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>IppvnLiteCap</b>          | Enable or disable IP VPN-lite capability on the BGP neighbor peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Ipv6Cap</b>               | Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SooAddress</b>            | Specifies the site-of-origin (SoO) address of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SooAsNumber</b>           | Specifies the site-of-origin (SoO) Autonomous System (AS) number of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SooAssignedNum</b>        | Specifies the site-of-origin (SoO) assigned number of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SooType</b>               | Specifies the site-of-origin (SoO) type of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>RouteRefresh</b>          | Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Name                                                                                      | Description                                                                                                      |
|-------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>AsOverride</b><br><b>Note:</b><br>This field does not apply on all hardware platforms. | Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.    |
| <b>AllowAsIn</b><br><b>Note:</b><br>This field does not apply on all hardware platforms.  | Specifies the number of AS-in allowed for the BGP peer. The range is 1-10.                                       |
| <b>Ipv6RoutePolicyIn</b>                                                                  | Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.                   |
| <b>Ipv6RoutePolicyOut</b>                                                                 | Specifies the policy (by name) that applies to all outgoing IPv6 route updates.                                  |
| <b>Ipv6MaxPrefix</b>                                                                      | Configures a limit on the number of IPv6 routes accepted from a neighbor.<br>A value of 0 means no limit exists. |
| <b>BfdEnable</b>                                                                          | Enables Bidirectional Forwarding Detection (BFD) for this BGP peer.                                              |

## Enable BFD for BGP Peer Groups

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for Border Gateway Protocol (BGP) peer groups.

#### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Peer Groups** tab.
4. Select **Insert**.
5. Select **BfdEnable**.

**Peer Groups** field descriptions

Use the data in the following table to use the **Peer Groups** tab.

| Name                         | Description                                                                                                                                                    |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                 | Specifies the index of this peer group.                                                                                                                        |
| <b>GroupName</b>             | Specifies the peer group to which this neighbor belongs (optional).                                                                                            |
| <b>Enable</b>                | Enables or disables the peer group.                                                                                                                            |
| <b>RemoteAs</b>              | Configures a remote AS number for the peer-group in the range 0-65535.                                                                                         |
| <b>DefaultOriginate</b>      | When enabled, the BGP speaker (the local router) sends the default route 0.0.0.0 to a group of neighbors for use as a default route. The default is disabled.  |
| <b>DefaultOriginateIpv6</b>  | When enabled, the BGP speaker (the local router) sends the default route to a group of neighbors for use as a default route. The default is disabled.          |
| <b>EbgpMultiHop</b>          | When enabled, the switch accepts and attempts BGP connections to external peers that reside on networks that do not directly connect. The default is disabled. |
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, that elapses between BGP routing updates. The default value is 30 seconds.                                            |
| <b>KeepAlive</b>             | Specifies the time interval, in seconds, between sent BGP keep alive messages to remote peers. The default value is 60.                                        |
| <b>HoldTime</b>              | Configures the hold time for the group of peers in seconds. Use a value that is three times the value of the KeepAlive time. The default value is 180.         |
| <b>Weight</b>                | Assigns an absolute weight to a BGP network. The default value is 100.                                                                                         |
| <b>MaxPrefix</b>             | Limits the number of routes accepted from this group of neighbors. A value of zero indicates no limit. The default value is 12,000 routes.                     |
| <b>NextHopSelf</b>           | Specifies that the switch must set the NextHop attribute to the local router address before sending updates to remote peers.                                   |
| <b>RoutePolicyIn</b>         | Specifies the route policy that applies to all networks learned from this group of peers.                                                                      |
| <b>RoutePolicyOut</b>        | Specifies the route policy that applies to all outgoing updates to this group of peers.                                                                        |
| <b>RouteReflectorClient</b>  | Specifies that this peer group is a route reflector client.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                       |

| Name                               | Description                                                                                                                                                                                                                                                                                                  |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SoftReconfigurationIn</b>       | When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is enable.<br>Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes). |
| <b>MD5Authentication</b>           | Enables and disables MD5 authentication. The default is disable.                                                                                                                                                                                                                                             |
| <b>RemovePrivateAs</b>             | Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.                                                                                                                                                                                                             |
| <b>SendCommunity</b>               | Enables or disables sending the community attribute of the update message to the specified peer group. The default value is disable.                                                                                                                                                                         |
| <b>AfUpdateSourceInterfaceType</b> | Specifies the interface type.                                                                                                                                                                                                                                                                                |
| <b>AfUpdateSourceInterface</b>     | Specifies the IP address used for circuitless IP (CLIP) for this peer group.                                                                                                                                                                                                                                 |
| <b>Vpvn4Address</b>                | Enables BGP address families for IPv4 (BGP) and Layer 3 VPN (MP-BGP) support. Enable this parameter for VPN/VRF Lite routes.                                                                                                                                                                                 |
| <b>IppvnLiteCap</b>                | Specifies (when enabled) that IP VPN Lite capability can be enabled or disabled on the BGP neighbor peer. The default is disable.                                                                                                                                                                            |
| <b>RouteRefresh</b>                | Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.                                                |
| <b>AsOverride</b>                  | Specifies that the AS Override parameter can be enabled or disabled for the BGP peer group. The default is disable.                                                                                                                                                                                          |
| <b>AllowedASIn</b>                 | Specifies the number of AS-in allowed for the BGP peer group. The range is 1-10.                                                                                                                                                                                                                             |
| <b>IPv6Cap</b>                     | Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.                                                                                                                                                                                                                |
| <b>Ipv6RoutePolicyIn</b>           | Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.                                                                                                                                                                                                               |
| <b>Ipv6RoutePolicyOut</b>          | Specifies the policy (by name) that applies to all outgoing IPv6 route updates.                                                                                                                                                                                                                              |
| <b>Ipv6MaxPrefix</b>               | Configures a limit on the number of IPv6 routes accepted from a neighbor.<br>A value of 0 means no limit exists.                                                                                                                                                                                             |
| <b>BfdEnable</b>                   | Enables Bidirectional Forwarding Detection (BFD) for the BGP peer group.                                                                                                                                                                                                                                     |

## Enable BFD for BGPv6 Peers

## About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for BGPv6 peers.

### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Note

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

## Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **BGP+**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Select **BfdEnable**.

### *Peers* Field Descriptions

Use the data in the following table to use the **Peers** tab.

| Name                         | Description                                                                                                                          |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>RemoteAddr</b>            | Specifies the remote IPv6 address of the entered BGP+ peer.                                                                          |
| <b>GroupName</b>             | Specifies the peer group name to which the peer belongs (optional).                                                                  |
| <b>PeerState</b>             | Specifies the BGPv6 peer connection state.                                                                                           |
| <b>RemoteAs</b>              | Configures a remote AS number for the peer or peer-group in the range 0 to 65535.                                                    |
| <b>Enable</b>                | Controls whether the peer connection is enabled or disabled. The default is disabled.                                                |
| <b>EbgpMultiHop</b>          | Enables or disables a connection to a BGPv6 peer that is more than one hop away from the local router. The default value is disable. |
| <b>RoutePolicyIn</b>         | Specifies the policy (by name) that applies to all network routes learned from this peer.                                            |
| <b>RoutePolicyOut</b>        | Specifies the policy (by name) that applies to all outgoing route updates.                                                           |
| <b>RemovePrivateAs</b>       | Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.                                     |
| <b>UpdateSourceInterface</b> | Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.                                |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ConnectRetryInterval</b>  | Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>HoldTimeConfigured</b>    | Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.                                                                                                                                                                                                                                                                                 |
| <b>KeepAliveConfigured</b>   | Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.                                                                                                                                                                                                                                         |
| <b>MD5Authentication</b>     | Enables and disables MD5 authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGPv6 neighbor. The default value is 30 seconds and the range is 5 to 120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained. |
| <b>DefaultOriginatelpv6</b>  | When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Weight</b>                | Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>MaxPrefix</b>             | Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0 to 2147483647. A value of 0 means no limit exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>NextHopSelf</b>           | Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Name                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>RouteRefresh</b>                                                                           | <p>Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>AsOverride</b><br><br><b>Note:</b><br>This field does not apply on all hardware platforms. | <p>Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>AllowAsIn</b><br><br><b>Note:</b><br>This field does not apply on all hardware platforms.  | <p>Specifies the number of AS-in allowed for the BGP peer. The range is 1-10.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Name                      | Description                                                                                                      |
|---------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Ipv6RoutePolicyIn</b>  | Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.                   |
| <b>Ipv6RoutePolicyOut</b> | Specifies the policy (by name) that applies to all outgoing IPv6 route updates.                                  |
| <b>Ipv6MaxPrefix</b>      | Configures a limit on the number of IPv6 routes accepted from a neighbor.<br>A value of 0 means no limit exists. |
| <b>BfdEnable</b>          | Enables Bidirectional Forwarding Detection (BFD) for this peer.                                                  |

## Enable BFD for OSPF on an IPv4 Port Interface

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for the OSPF protocol on an IPv4 port interface.

#### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **IP**.
4. Select the **OSPF** tab.
5. Select **BfdEnable**.

### *OSPF* Field Descriptions

Use the data in the following table to use the **OSPF** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>        | Enables or disables OSPF routing on the specified port. The default is false.                                                                                                                                                                                                                                                                                                          |
| <b>HelloInterval</b> | Specifies the length of time, in seconds, between the transmission of hello packets. This value must be the same for all routers attached to a common network. The default is 10 seconds. After you change the hello interval values, you must save the configuration file, and then restart the switch. After the switch restarts, it restores the values and checks for consistency. |

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RtrDeadInterval</b>  | Specifies the interval used by adjacent routers to determine if the router was removed from the network. This interval must be identical on all routers on the subnet, and a minimum of four times the hello interval. To avoid interoperability issues, the RtrDeadInterval value for the OSPF interface needs to match with the RtrDeadInterval value for the OSPF virtual interface. The default is 40 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DesigRtrPriority</b> | Specifies the priority of this port in multiaccess networks to use in the designated router election algorithm. The value 0 indicates the router is not eligible to become the designated router on this particular network. If a tie occurs, routers use their router ID as a tie breaker. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Metric</b>           | Specifies the metric for the type of service (TOS) on this port. The value of the TOS metric is $(10^9 / \text{interface speed})$ . The default is 1. <ul style="list-style-type: none"> <li>• FFFF—No route exists for this TOS.</li> <li>• IPCP links—Defaults to 0.</li> <li>• 0—Use the interface speed as the metric value when the state of the interface is up.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>AuthType</b>         | Specifies the type of authentication required for the interface. <ul style="list-style-type: none"> <li>• none—Specifies that no authentication required.</li> <li>• simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter.</li> <li>• MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key.</li> <li>• sha1—Specifies secure hash algorithm (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long. You can only access and enable the SHA-1 authentication type after you enable enhanced secure mode.</li> <li>• sha-2—Specifies SHA-2, which offers the hash function SHA-256.</li> </ul> <p><b>Note:</b><br/>sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.</p> |
| <b>AuthKey</b>          | Specifies the key (up to 8 characters) when you specify simple password authentication in the port AuthType variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>AreaId</b>           | Specifies the OSPF area name in dotted-decimal format. The area name is not related to an IP address. You can use a suitable value for the OSPF area name (for example, 1.1.1.1 or 200.200.200.200).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertiseWhenDown</b> | Advertises the network on this port as up, even if the port is down. The default is false.<br>After you configure a port with no link and enable AdvertiseWhenDown, it does not advertise the route until the port is active. Then, OSPF advertises the route even if the link is down. To disable advertising based on link-states, disable AdvertiseWhenDown. |
| <b>IfType</b>            | Specifies the type of OSPF interface (broadcast, NBMA, or passive).<br>Before you change an OSPF interface type, you must first disable the interface. If the interface is an NBMA interface, you must also delete all configured neighbors.                                                                                                                    |
| <b>PollInterval</b>      | Specifies the length of time, in seconds, between hello packets sent to an inactive OSPF router. Neighbors must have the same poll interval.                                                                                                                                                                                                                    |
| <b>IfMtuIgnore</b>       | Specifies whether the interface ignores the global maximum transmission unit (MTU) configuration. To allow the switch to accept OSPF database description (DD) packets with a different MTU size, enable MtuIgnore. The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes.                                                       |
| <b>BfdEnable</b>         | Enable Bidirectional Forwarding Detection (BFD) for OSPF.                                                                                                                                                                                                                                                                                                       |

## Enable BFD for OSPF on an IPv4 VLAN Interface

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable OSPF BFD on an IPv4 VLAN interface.

#### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to enable BFD for OSPF.
5. Select **IP**.
6. Select **OSPF**.
7. Select **BfdEnable**.

**OSPF** Field Descriptions

Use the data in the following table to use the **OSPF** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>           | Enables or disables OSPF routing on the specified VLAN. The default is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>HelloInterval</b>    | Specifies the length of time, in seconds, between the transmission of hello packets. This value must be the same for all routers attached to a common network. The default is 10 seconds. After you change the hello interval values, you must save the configuration file, and then restart the switch. After the switch restarts, it restores the values and checks for consistency.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>RtrDeadInterval</b>  | Specifies the interval used by adjacent routers to determine if the router was removed from the network. This interval must be identical on all routers on the subnet and a minimum of four times the hello interval. To avoid interoperability issues, the RtrDeadInterval value for the OSPF interface needs to match with the RtrDeadInterval value for the OSPF virtual interface. The default is 40 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DesigRtrPriority</b> | Specifies the priority of this VLAN in multiaccess networks to use in the designated router election algorithm. The value 0 indicates the router is not eligible to become the designated router on this particular network. If a tie occurs, routers use their router ID as a tie breaker. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Metric</b>           | Specifies the metric for this TOS on this VLAN. The value of the TOS metric is $(10^9 / \text{interface speed})$ . The default is 1. <ul style="list-style-type: none"> <li>FFFF—No route exists for this TOS.</li> <li>IPCP links—Defaults to 0.</li> <li>0—Use the interface speed as the metric value when the state of the interface is up.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>AuthType</b>         | Specifies the type of authentication required for the interface. <ul style="list-style-type: none"> <li>none—Specifies that no authentication required.</li> <li>simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter.</li> <li>MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key.</li> <li>sha1—Specifies secure hash algorithm 1 (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long. You can only access and enable the SHA-1 authentication type after you enable enhanced secure mode.</li> <li>sha-2—Specifies SHA-2, which offers the hash function SHA-256.</li> </ul> <p><b>Note:</b><br/>sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.</p> |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AuthKey</b>           | Specifies the key (up to eight characters) when you specify simple password authentication in the VLAN AuthType variable.                                                                                                                                                                                                                                                                                                          |
| <b>Areald</b>            | Specifies the OSPF area name in dotted-decimal format. The area name is not related to an IP address. You can use a suitable value for the OSPF area name (for example, 1.1.1.1 or 200.200.200.200).                                                                                                                                                                                                                               |
| <b>AdvertiseWhenDown</b> | Advertises the network even if the port is down. If true, OSPF advertises the network on this VLAN as up, even if the port is down. The default is false.<br>After you configure a port without a link and enable AdvertiseWhenDown, it does not advertise the route until the port is active. Then, OSPF advertises the route even when the link is down. To disable advertising based on link states, disable AdvertiseWhenDown. |
| <b>IfType</b>            | Specifies the type of OSPF interface (broadcast, NBMA, or passive).<br>Before you change an OSPF interface type, you must first disable the interface. If the interface is an NBMA interface, you must also delete all configured neighbors.                                                                                                                                                                                       |
| <b>PollInterval</b>      | Specifies the length of time, in seconds, between hello packets sent to an inactive OSPF router. Neighbors must use the same poll interval.                                                                                                                                                                                                                                                                                        |
| <b>IfMtuIgnore</b>       | Specifies whether the VLAN ignores the MTU configuration. To allow the switch to accept OSPF DD packets with a different MTU size, enable MtuIgnore. The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes.                                                                                                                                                                                         |
| <b>BfdEnable</b>         | Enables Bidirectional Forwarding Detection (BFD) for OSPF.                                                                                                                                                                                                                                                                                                                                                                         |

## Enable BFD for OSPF on an IPv6 Port Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for the OSPF protocol on an IPv6 port interface.

#### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **IPv6**.
4. Select the **IPv6 OSPF Interface** tab.

5. Select **Insert**.
6. Select **BfdEnable**.

### **IPv6 OSPF Interface** Field Descriptions

Use the data in the following table to use the **IPv6 OSPF Interface** tab.

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>           | Shows the interface index for the IPv6 interface on which OSPFv3 is configured.                                                                                                                                                                                                                                                                                                                                                       |
| <b>AreaId</b>          | Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.                                                                                                                                                                                                                                                                                                                                      |
| <b>Type</b>            | Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> <li>• broadcast</li> <li>• NBMA</li> <li>• point-to-point</li> <li>• point-to-multipoint</li> <li>• passive</li> </ul>                                                                                                                                                                                                                |
| <b>AdminStat</b>       | Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an interal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.                                                                                                                                                                                                   |
| <b>RtrPriority</b>     | Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election.<br>A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router.<br>The default is 1. |
| <b>TransitDelay</b>    | Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.                                                                                                                                                                                                                                                                                                               |
| <b>RetransInterval</b> | Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.                                                                                                                                                                                                                 |
| <b>HelloInterval</b>   | Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.                                                                                                                                                                                                                   |

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RtrDeadInterval</b>        | Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.                                                                                                                                                    |
| <b>PollInterval</b>           | Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.                                                                                                                                                                                                                                                               |
| <b>State</b>                  | Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> <li>• down</li> <li>• loopback</li> <li>• waiting</li> <li>• pointToPoint</li> <li>• designatedRouter</li> <li>• backupDesignatedRouter</li> <li>• otherDesignatedRouter</li> </ul>                                                                                    |
| <b>DesignatedRouter</b>       | Shows the router ID for the designated router.                                                                                                                                                                                                                                                                                                                             |
| <b>BackupDesignatedRouter</b> | Shows the router ID for the backup designated router.                                                                                                                                                                                                                                                                                                                      |
| <b>MetricValue</b>            | Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100.<br><br><b>Note:</b><br>If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface. |
| <b>LinkLsaSuppression</b>     | Specifies whether Link LSA suppression is enabled.                                                                                                                                                                                                                                                                                                                         |
| <b>BfdEnable</b>              | Enable Bidirectional Forwarding Detection (BFD) for OSPF.                                                                                                                                                                                                                                                                                                                  |

## Enable BFD for OSPF on an IPv6 VLAN Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

## About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable OSPF BFD on an IPv6 VLAN interface.

### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

## Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to enable BFD for OSPF.
5. Select **IPV6**.
6. Select **IPv6 OSPF Interface**.
7. Select **Insert**.
8. Select **BfdEnable**.

### **IPv6 OSPF Interface** Field Descriptions

Use the data in the following table to use the **IPv6 OSPF Interface** tab.

| Name             | Description                                                                                                                                                                                                                          |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>     | Shows the interface index for the IPv6 interface on which OSPFv3 is configured.                                                                                                                                                      |
| <b>Areald</b>    | Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.                                                                                                                                     |
| <b>Type</b>      | Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> <li>• broadcast</li> <li>• NBMA</li> <li>• point-to-point</li> <li>• point-to-multipoint</li> <li>• passive</li> </ul>               |
| <b>AdminStat</b> | Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled. |

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RtrPriority</b>            | Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election.<br>A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router.<br>The default is 1. |
| <b>TransitDelay</b>           | Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.                                                                                                                                                                                                                                                                                                               |
| <b>RetransInterval</b>        | Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.                                                                                                                                                                                                                 |
| <b>HelloInterval</b>          | Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.                                                                                                                                                                                                                   |
| <b>RtrDeadInterval</b>        | Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.                                                                                                                                                                                                               |
| <b>PollInterval</b>           | Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.                                                                                                                                                                                                                                                                                                                          |
| <b>State</b>                  | Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> <li>• down</li> <li>• loopback</li> <li>• waiting</li> <li>• pointToPoint</li> <li>• designatedRouter</li> <li>• backupDesginatedRouter</li> <li>• otherDesignatedRouter</li> </ul>                                                                                                                                               |
| <b>DesignatedRouter</b>       | Shows the router ID for the designated router.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>BackupDesignatedRouter</b> | Shows the router ID for the backup designated router.                                                                                                                                                                                                                                                                                                                                                                                 |

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MetricValue</b>        | Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100.<br><br><b>Note:</b><br>If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface. |
| <b>LinkLsaSuppression</b> | Specifies whether Link LSA suppression is enabled.                                                                                                                                                                                                                                                                                                                         |
| <b>BfdEnable</b>          | Enables Bidirectional Forwarding Detection (BFD) for OSPF.                                                                                                                                                                                                                                                                                                                 |

## Configure BFD on an IPv4 Static Route

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BFD**.
3. Select **Insert**.
4. In the **NextHop** field, type the IPv4 address of the next hop of the BFD session.
5. (Optional) In the **Vrflid** field, type the ID of the VRF associated with the BFD session.

### BFD Static Route Field Descriptions

Use the data in the following table to use the **Static Route** tab.

| Name           | Description                                                    |
|----------------|----------------------------------------------------------------|
| <b>NextHop</b> | Specifies the IPv4 address of the next hop of the BFD session. |
| <b>Vrflid</b>  | Specifies the ID of the VRF associated with the BFD session.   |
| <b>VrfName</b> | Specifies the name of the VRF associated with the BFD session. |

## Configure BFD on an IPv6 Static Route

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **IPv6 BFD**.
3. Select **Insert**.
4. In the **Interface** field, select either **Port** or **Vlan** and select an interface.

5. In the **NextHop** field, type the IPv6 address of the next hop of the BFD session.
6. (Optional) In the **Vrfid** field, type the ID of the VRF associated with the BFD session.

#### *IPv6 BFD Static Route Field Descriptions*

Use the data in the following table to use the **Static Route** tab.

| Name             | Description                                                    |
|------------------|----------------------------------------------------------------|
| <b>Interface</b> | Specifies either a port or VLAN interface.                     |
| <b>NextHop</b>   | Specifies the IPv4 address of the next hop of the BFD session. |
| <b>Vrfid</b>     | Specifies the ID of the VRF associated with the BFD session.   |
| <b>VrfName</b>   | Specifies the name of the VRF associated with the BFD session. |

## Display BFD Performance Counters

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **BFD**.
3. Select the **Performance counters** tab.

#### *BFDPerformance Counters Field Descriptions*

Use the data in the following table to use the **Performance counters** tab.

| Name          | Description                                                               |
|---------------|---------------------------------------------------------------------------|
| <b>PktIn</b>  | Specifies the total number of BFD messages received for this BFD session. |
| <b>PktOut</b> | Specifies the total number of BFD messages sent for this BFD session.     |

# BGP

[BGP fundamentals on page 383](#)

[BGP configuration using CLI on page 420](#)

[BGP Verification Using CLI on page 447](#)

[BGP configuration using EDM on page 462](#)

[BGP Configuration Examples on page 488](#)

The following sections provide conceptual information and procedures that you can use to configure Border Gateway Protocol (BGP) services. The following operations are supported by BGP:

- IPv4
- 4-byte AS
- Peer groups
- Redistribution

Examples and network illustrations in these sections illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

## BGP fundamentals

**Table 52: Border Gateway Protocol product support**

| Feature                                  | Product         | Release introduced |
|------------------------------------------|-----------------|--------------------|
| Border Gateway Protocol for IPv4 (BGPv4) | 5420 Series     | VOSS 8.4           |
|                                          | 5520 Series     | VOSS 8.2.5         |
|                                          | VSP 4450 Series | VSP 4000 4.0       |
|                                          | VSP 4900 Series | VOSS 8.1           |
|                                          | VSP 7200 Series | VOSS 4.2.1         |
|                                          | VSP 7400 Series | VOSS 8.0           |
|                                          | VSP 8200 Series | VOSS 4.1           |
|                                          | VSP 8400 Series | VOSS 4.2           |
|                                          | VSP 8600 Series | VSP 8600 4.5       |
|                                          | XA1400 Series   | VOSS 8.0.50        |

**Table 52: Border Gateway Protocol product support (continued)**

| Feature                | Product         | Release introduced |
|------------------------|-----------------|--------------------|
| BGP+ (BGPv4 for IPv6). | 5420 Series     | VOSS 8.4           |
|                        | 5520 Series     | VOSS 8.2.5         |
|                        | VSP 4450 Series | VOSS 5.0           |
|                        | VSP 4900 Series | VOSS 8.1           |

Border Gateway Protocol (BGP) is an inter-domain routing protocol that provides loop-free routing between autonomous systems (AS) or within an AS. This section describes the major BGP features.

## Autonomous Systems

An Autonomous system (AS) is a group of routers and hosts run by a single technical administrator that has a single, clearly defined routing policy. Each AS uses a unique AS number assigned by the appropriate Internet Registry entity. LANs and WANs that interconnect by IP routers form a group of networks called an internetwork. For administrative purposes, internetworks divide into boundaries known as autonomous systems.

The following figure shows a sample internetwork segmented into three autonomous systems.

**Figure 17: Internetwork segmented into three autonomous systems**

BGP exchanges information between autonomous systems as well as between routers within the same AS. As shown in the preceding figure, routers that are members of the same AS and exchange BGP updates run internal BGP (iBGP), and routers that are members of different autonomous systems and exchange BGP updates run external BGP (eBGP).

### *Internal and external BGP routing*

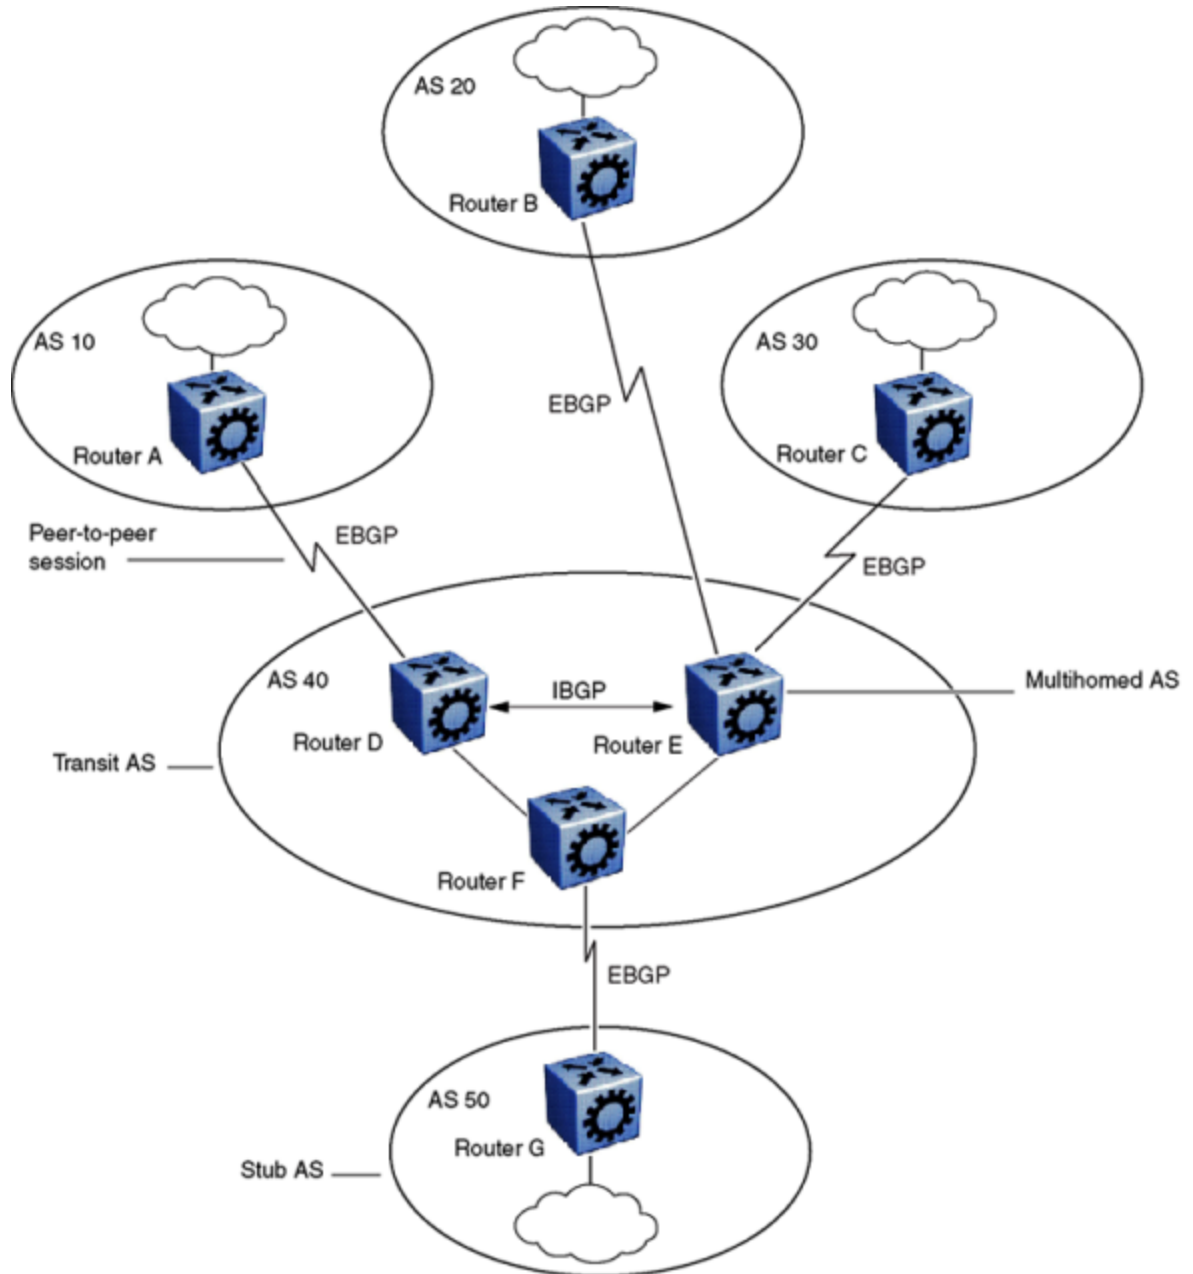

The switch supports both iBGP intra-AS routing and eBGP external-AS routing. With iBGP, each router within an AS runs an interior gateway protocol (IGP), such as Routing Information Protocol (RIP) or Open Shortest Path First (OSPF). The iBGP information, along with the IGP route to the originating BGP border router, determines the next hop to use to exchange information with an external AS. Each router uses iBGP exclusively to determine reachability to external autonomous systems. After a router receives an iBGP update destined for an external AS, it passes the update to IP for inclusion in the routing table only if a viable IGP route to the correct border gateway is available.

BGP speakers in different autonomous systems use eBGP to communicate routing information.

### *BGP speaker*

BGP routers employ an entity within the router, referred to as a BGP speaker, which transmits and receives BGP messages and acts upon them. BGP speakers establish a peer-to-peer session with other BGP speakers to communicate.

All BGP speakers within an AS must be fully meshed. The following figure shows a BGP network with fully-meshed BGP speakers.

10861FA

**Figure 18: BGP networks**

#### *Transit AS*

An AS with more than one BGP speaker can use iBGP to provide a transit service for networks located outside the AS. An AS that provides this service is a transit AS. As shown in the preceding figure, [BGP networks](#), AS 40 is the transit AS. AS 40 provides information about the internal networks, as well as transit networks, to the remaining autonomous systems. The iBGP connections between routers D, E, and F provide consistent routing information to the autonomous systems.

### *Stub and multihomed autonomous systems*

As shown in the preceding figure, [BGP networks](#), an AS can include one or more BGP speakers that establish peer-to-peer sessions with BGP speakers in other autonomous systems to provide external route information for the networks within the AS.

A stub AS has a single BGP speaker that establishes a peer-to-peer session with one external BGP speaker. In this case, the BGP speaker provides external route information only for the networks within its own AS.

A multihomed AS has multiple BGP speakers.

### *Peers*

BGP uses Transmission Control Protocol (TCP) as a transport protocol. When two routers open a TCP connection to each other for the purpose of exchanging routing information, they form a peer-to-peer relationship. In the preceding figure, [BGP networks](#), Routers A and D are BGP peers, as are Routers B and E, C and E, F and G, and Routers D, E, and F.

Although Routers A and D run eBGP, Routers D, E, and F within AS 40 run iBGP. The eBGP peers directly connect to each other, while the iBGP peers do not. As long as an IGP operates and allows two neighbors to logically communicate, the iBGP peers do not require a direct connection.

#### **Note**

You cannot create the same iBGP peers on two different VRFs, or the same eBGP peers on two different chassis. Only one local autonomous system (AS) can exist for each chassis or VRF.

Because all BGP speakers within an AS must be fully meshed logically, the iBGP mesh can grow to large proportions and become difficult to manage. You can reduce the number of peers within an AS by creating confederations and route reflectors.

BGP peers exchange complete routing information only after the peers establish a connection. Thereafter, BGP peers exchange routing updates. An update message consists of a network number, a list of autonomous systems that the routing information passed through (the AS path), and other path attributes that describe the route to a set of destination networks. When multiple paths exist, BGP compares the path attributes to choose the preferred path. Even if you disable BGP, the system logs all BGP peer connection requests. For more information about update messages, see [BGP Updates](#) on page 404.

### *Supernet advertisements*

BGP has no concept of address classes. Each network listed in the network layer reachability information (NLRI) portion of an update message contains a prefix length field, which describes the length of the mask associated with the network. The prefix length field allows for both supernet and subnet advertisement. The supernet advertisement is what makes classless interdomain routing (CIDR) possible (see [CIDR and aggregate addresses](#) on page 393).

### *Bandwidth and maintenance reduction*

BGP provides two features that reduce the high bandwidth and maintenance costs associated with a large full-mesh topology:

- confederations
- route reflectors

#### **Note**

Confederations and route reflectors are not supported on iBGP for non-default VRFs.

For information on confederations and route reflectors, see [Routing information consolidation](#) on page 393.

### *BGP 4 Byte AS Support*

Each Autonomous System (AS) must have its own unique number. Because the 2-byte AS numbering scheme is unable to meet the increasing demand, the switch supports 4-byte AS numbers. This feature is enabled by supporting RFC 4893, BGP Support for 4-octet AS Number Space.

The switch supports the following three types of peer relationships as a result of 4 byte AS support:

- Old peer to old peer
- Old peer to new peer
- New peer to new peer

An old peer is the one that supports 2-byte AS numbers only and new peer is the one that supports both 2-byte AS numbers and 4-byte AS numbers.

RFC4893 supports two new path attributes:

- AS4\_PATH contains the AS path encoded with a 4-octet AS number.
- AS4-AGGR is a new aggregator attribute that carries a 4-octet AS number.

**Figure 19: 2-byte and 4-byte Mixed Environment**

The preceding figure shows an example of how the switch uses the AS4\_PATH attribute in a mixed environment. The figure illustrates how a 2-byte BGP speaker interoperates with a 4-byte BGP speaker.

Router B is a 2-byte BGP speaker. Router A substitutes AS\_PATH with the AS\_TRANS, a 2-octet AS number defined by RFC4893 for backward compatibility, and encodes the 4-byte AS into AS4\_PATH in BGP updates it sends to router B.

Router B does not understand the AS4\_PATH but does preserve the information and sends it to router C.

Router C is a 4-byte BGP speaker. Router C merges the information received in AS\_PATH and AS4\_PATH, and encodes the 4-byte AS when it sends the AS\_PATH information to router D.

#### Old Peer to Old Peer

When the peer relationship between an old peer and another old peer is established, 4 byte AS numbers contained in the AS4\_PATH and AS4\_AGGREGATOR are transited to other peers.

#### Important

Do not assign 23456 as an AS number. The Internet Assigned Numbers Authority (IANA) reserved this number for the AS\_TRANS attribute and BGP uses it to facilitate communication between peer modes. AS\_TRANS uses a 2-byte AS format to represent a 4-byte AS number. The switch interprets the AS\_TRANS attribute and propagates it to other peers.

#### New Peer to New Peer

The new BGP speaker establishes its 4 byte AS support through BGP capability advertisement. A BGP speaker that announces such capability and receives it from its peer, uses 4 byte AS numbers in

AS\_PATH and AGGREGATOR attributes and assumes these attributes received from its peer are encoded in 4 byte AS numbers.

The new BGP attributes AS4\_PATH and AS4\_AGGREGATOR received from the new BGP speaker between the new BGP peers in the update message is discarded.

### Old Peer to New Peer

An old BGP speaker and a new BGP speaker can form peering relationship only if the new BGP speaker is assigned a 2 byte AS number. This 2 byte number can be any global unique AS number or AS\_TRANS.

New BGP speaker sends AS path information to the old BGP speaker in AS\_PATH attribute as well as AS4\_PATH attribute. If the entire AS\_PATH consists of only 2 byte AS numbers then the new BGP speaker does not send AS4\_PATH information.

The 4-byte AS number feature does not in any way restrict the use or change the way you configure 2-byte AS numbers. You can also configure 2-byte AS or 4 byte AS numbers in AS path lists, community lists, and route policies.

### BGP 4-byte AS Number Notation

BGP 4-byte AS numbers are represented in two ways: AS Plain and AS dot. The default form of representing the AS numbers is AS Plain while you have an option to configure AS dot. AS Plain form of representation is preferred over AS dot representation as a large amount of network providers find the AS dot notation incompatible with the regular expressions used by them. In case of any issues, troubleshooting and analyzing also gets difficult with AS dot notation.

### BGP AS Number Format - AS Plain

**Table 53: Default Asplain 4-Byte Autonomous System Number Format**

| Format  | Configuration Format                              | Show Command Output and Regular Expression Match Format |
|---------|---------------------------------------------------|---------------------------------------------------------|
| asplain | 2-byte: 1 to 65535<br>4-byte: 65536 to 4294967295 | 2-byte: 1 to 65535<br>4-byte: 65536 to 4294967295       |

## Routing information consolidation

Use the information in this section to understand how to reduce the size of routing tables.

### *CIDR and aggregate addresses*

Classless interdomain routing (CIDR) is an addressing scheme (also known as supernetting) that eliminates the concept of classifying networks into class types. Earlier addressing schemes identified five classes of networks: Class A, Class B, Class C, Class D, and Class E. This document does not discuss Classes D (used for multicast) and E (reserved and currently not used).

Network 195.215.0.0, an illegal Class C network number, becomes a legal supernet when represented in CIDR notation as 195.215.0.0/16. The /16 is the prefix length and expresses the explicit mask that CIDR requires. In this case, the addition of the prefix /16 indicates that the subnet mask consists of 16 bits (counting from the left).

Using this method, supernet 195.215.0.0/16 represents 195.215.0.0 255.255.0.0. The following table shows the conversion of prefix length to subnet mask.

**Table 55: CIDR conversion**

| Prefix | Dotted-decimal | Binary                                  | Network class            |
|--------|----------------|-----------------------------------------|--------------------------|
| /1     | 128.0.0.0      | 1000 0000 0000 0000 0000 0000 0000 0000 | 128 Class A              |
| /2     | 192.0.0.0      | 1100 0000 0000 0000 0000 0000 0000 0000 | 64 Class A               |
| /3     | 224.0.0.0      | 1110 0000 0000 0000 0000 0000 0000 0000 | 32 Class A               |
| /4     | 240.0.0.0      | 1111 0000 0000 0000 0000 0000 0000 0000 | 16 Class A               |
| /5     | 248.0.0.0      | 1111 1000 0000 0000 0000 0000 0000 0000 | 8 Class A                |
| /6     | 252.0.0.0      | 1111 1100 0000 0000 0000 0000 0000 0000 | 4 Class A                |
| /7     | 254.0.0.0      | 1111 1110 0000 0000 0000 0000 0000 0000 | 2 Class A                |
| /8     | 255.0.0.0      | 1111 1111 0000 0000 0000 0000 0000 0000 | 1 Class A or 256 Class B |
| /9     | 255.128.0.0    | 1111 1111 1000 0000 0000 0000 0000 0000 | 128 Class B              |
| /10    | 255.192.0.0    | 1111 1111 1100 0000 0000 0000 0000 0000 | 64 Class B               |
| /11    | 255.224.0.0    | 1111 1111 1110 0000 0000 0000 0000 0000 | 32 Class B               |
| /12    | 255.240.0.0    | 1111 1111 1111 0000 0000 0000 0000 0000 | 16 Class B               |
| /13    | 255.248.0.0    | 1111 1111 1111 1000 0000 0000 0000 0000 | 8 Class B                |
| /14    | 255.252.0.0    | 1111 1111 1111 1100 0000 0000 0000 0000 | 4 Class B                |
| /15    | 255.254.0.0    | 1111 1111 1111 1110 0000 0000 0000 0000 | 2 Class B                |
| /16    | 255.255.0.0    | 1111 1111 1111 1111 0000 0000 0000 0000 | 1 Class B or 256 Class C |
| /17    | 255.255.128.0  | 1111 1111 1111 1111 1000 0000 0000 0000 | 128 Class C              |

10863EA

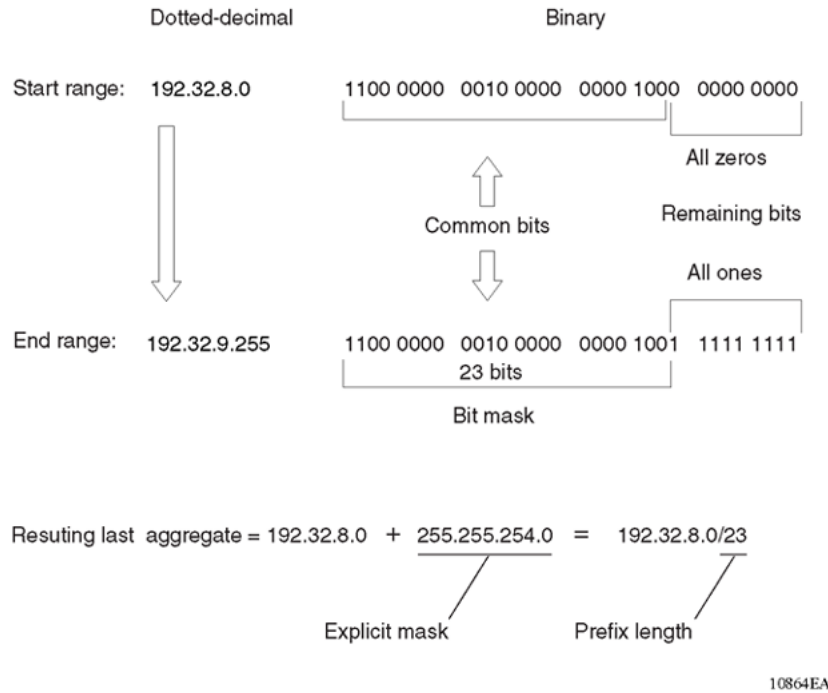

**Figure 21: First aggregate and prefix length**

5. The 21 bits that match the common bits form the prefix length. The prefix length is the number of binary bits that form the explicit mask (in dotted-decimal notation) for this IP prefix.
6. The remaining aggregate is formed from 192.32.8.0 to the end range, 192.32.9.255.

As shown in [Figure 21](#), the resulting first aggregate 192.32.0.0/21 represents all of the IP prefixes from 192.32.0.0 to 192.32.7.255.

The following figure shows the results after forming the remaining aggregate from 192.32.9.0 to the end range, 192.32.9.255.

The resulting aggregate 192.32.8.0/23 represents all of the IP prefixes from 192.32.8.0 to 192.32.9.255.

**Figure 22: Last aggregate and prefix length**

The final result of calculating the supernet address that ranges from 192.32.0.0 to 192.32.9.255 is as follows:

192.32.0.0 (with mask) 255.255.248.0 = 192.32.0.0/21

192.32.8.0 (with mask) 255.255.254.0 = 192.32.8.0/23

### Aggregate routes

Eliminating the idea of network classes provides an easy method to aggregate routes. Rather than advertise a separate route for each destination network in a supernet, BGP uses a supernet address to advertise a single route (called an aggregate route) that represents all the destinations. CIDR also reduces the size of the routing tables used to store advertised IP routes.

The following figure shows an example of route aggregation using CIDR. In this example, a single supernet address 195.215.0.0/16 advertises 256 separate Class C network numbers 195.215.0.0 through 195.215.255.0.

**Figure 23: Aggregating routes with CIDR**

### *Confederations*

A BGP router configured for iBGP establishes a peer-to-peer session with every other iBGP speaker in the AS. In an AS with a large number of iBGP speakers, this full-mesh topology can result in high bandwidth and maintenance costs.

#### **Note**

Confederations are not supported on iBGP for non-default VRFs.

As shown in the following example, a full-mesh topology for an AS with 50 iBGP speakers requires 1225 internal peer-to-peer connections:

Example:

$$n \times (n-1)/2 = n \text{ iBGP sessions}$$

where:

$$50 \times (50-1)/2 = 1225 \text{ number of unique iBGP sessions}$$

You can reduce the high bandwidth and maintenance costs associated with a large full-mesh topology by dividing the AS into multiple smaller autonomous systems (sub-autonomous systems), and then group them into a single confederation (see the following figure).

**Figure 24: Confederations**

As shown in the preceding figure, each sub-AS is fully meshed within itself and has eBGP sessions with other sub-autonomous systems in the same confederation.

Although the peers in different autonomous systems have eBGP sessions with the various sub-AS peers, they preserve the next-hop, Multi-Exit Discriminator (MED), and local preference information and exchange routing updates as if they were iBGP peers. All of the autonomous systems retain a single interior gateway protocol (IGP). When the confederation uses its own confederation identifier, the system displays the group of sub-autonomous systems as a single AS (with the confederation identifier as the AS number).

#### *Route reflectors*

Another way to reduce the iBGP mesh inherent in an AS with a large number of iBGP speakers is to configure a route reflector. Using this method, when an iBGP speaker needs to communicate with other

BGP speakers in the AS, the speaker establishes a single peer-to-peer route reflector client session with the iBGP route reflector.

#### Note

Route reflectors are not supported on iBGP for non-default VRFs.

In an AS, more than one route reflector cluster can exist and more than one route reflector in a cluster. When more than one reflector exists in a cluster, take care to prevent route loops.

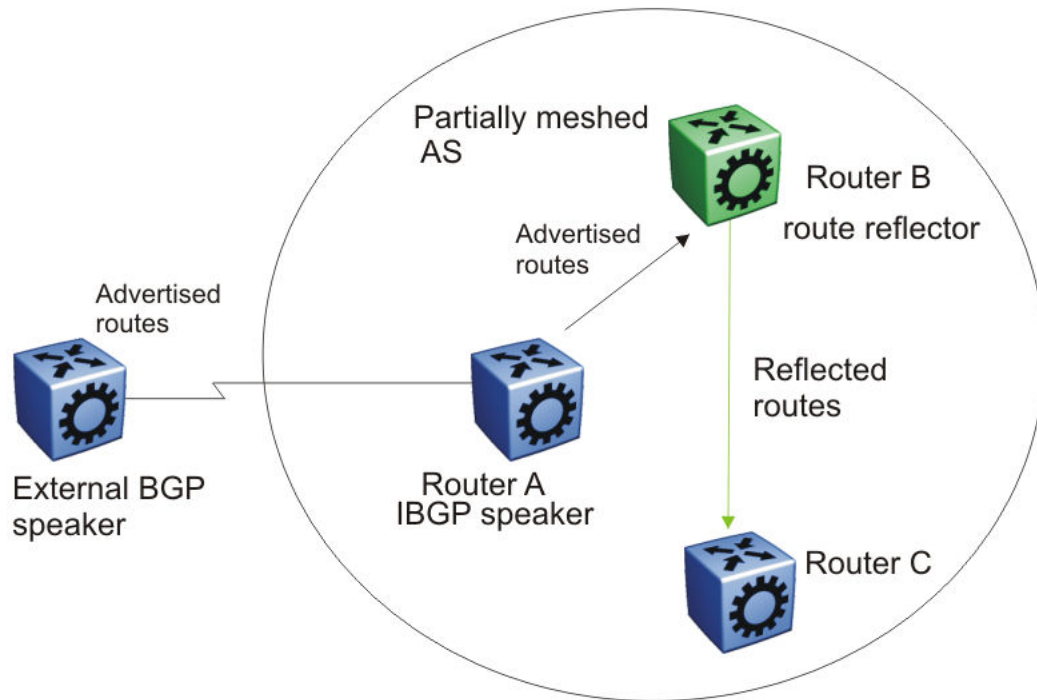

The following figure shows a simple iBGP configuration with three iBGP speakers (routers A, B, and C). Without route reflectors, after Router A receives an advertised route from an external neighbor, it must advertise the route to Routers B and C.

**Figure 25: Fully meshed AS with iBGP speakers**

Routers B and C do not readvertise the iBGP learned routes to other iBGP speakers. BGP does not allow routers to pass routes learned from internal neighbors on to other internal neighbors, which avoids routing information loops.

As shown in the following figure, when you configure an internal BGP peer (Router B) as a route reflector, all of the iBGP speakers do not need to be fully meshed. In this case, the assigned route reflector passes iBGP learned routes to a set of iBGP neighbors.

**Figure 26: AS with route reflector**

After Router B, the route reflector, receives routes from Router A (the iBGP speaker), it advertises them to router C. Conversely, after the route reflector receives routes from internal peers, it advertises those routes to Router A. Routers A and C do not need an iBGP session.

Route reflectors separate internal peers into two groups: client peers and nonclient peers. The route reflector and its clients form a cluster. The client peers in the cluster do not need to be fully meshed, and do not communicate with iBGP speakers outside their cluster. Nonclient peers must be fully meshed with each other.

The following figure shows a cluster, where Router A is the route reflector in a cluster with client routers B, C, and D. Routers E, F, and G are fully meshed, nonclient routers.

**Figure 27: Route reflector with client and nonclient peers**

## BGP Communities

You can group destinations into communities to simplify policy administration. A community is a group of destinations that share a common administrative property.

Use community control routing policies with respect to destinations. Create communities when you have more than one destination and want to share a common attribute.

The following list identifies specific community types:

- Internet—advertise this route to the Internet community
- no advertise—do not advertise to BGP peers including iBGP peers

You can use a community to control which routing information to accept, prefer, or distribute to other BGP neighbors. If you specify the append option in the route policy, the router adds the specified community value to the existing value of the community attribute. Otherwise, the specified community value replaces a previous community value.

## BGP path attributes

You can create policies that control routes, work with default routing, control specific and aggregated routes, and manipulate BGP path attributes.

Four categories of BGP path attributes exist:

- Well-known mandatory attributes must be in every BGP update message.
- Well-known discretionary attributes can be in a BGP update message.
- Optional transitive attributes are accepted and passed to other BGP peers.
- Optional non-transitive attributes can be either accepted or ignored, but must not pass along to other BGP peers.

Border routers that utilize built-in algorithms or manually configured policies to select paths use path attributes. BGP uses the following path attributes to control the path a BGP router chooses:

- origin (well-known mandatory)
- AS\_path (well-known mandatory)
- next hop (well-known mandatory)
- MED attribute (optional non-transitive)
- local preference (well-known discretionary)
- atomic aggregate (well-known discretionary)
- aggregator (optional transitive)
- community (optional transitive)

For more information about path attributes in BGP updates, see [Path Attributes](#) on page 405.

## BGP Route Selection

A BGP router determines the best path to a destination network. This path is then eligible for use in the IP forwarding table and the router also advertises the path to its eBGP peers. To choose the best of multiple BGP routes to a destination, the router executes a best path algorithm.

The algorithm chooses a route in the following order:

- highest weight

Weight is a locally significant parameter associated with each BGP peer. You can use the weight to influence which peer paths the router uses.

- highest local preference

The local preference has global significance within an AS. You can manipulate the preference using route policies to influence path selection.

- prefer locally originated paths

The router prefers a path locally originated using the network, redistribution, or aggregate command over a path learned through a BGP update. The router prefers local paths sourced by network or redistribute commands over local aggregates sourced by the aggregate address command.

- shortest AS path

The AS path parameter specifies the autonomous systems that the network prefix traversed. The AS path commonly determines the best path. For example, a router can choose a path based on whether the network passed through a specific AS. You can configure a route policy to match the AS, and then modify the local preference. Also, you can pad the AS path before the AS advertises it to a peer AS, so that downstream routers are less likely to prefer the advertised network path.

The AS\_CONFED\_SEQUENCE length will also be considered while picking the best path inside the confederation.

- lowest origin type

The order of preference is IGP, EGP, INC (incomplete).

- lowest MED

The MED parameter influences the preferred path from a remote AS to the advertising AS. This parameter applies when there are multiple exit points from the remote AS to the advertising AS. A lower MED value indicates a stronger path preference than a higher MED value. By default, the MED attribute is ignored as specified by the BGP global parameter Always Compare MED except when the routes come from the same AS. This parameter must be enabled for MEDs to be compared (and for this step of the best path algorithm to execute).

The router compares MEDs regardless of what the first (neighboring) AS specified in the AS\_PATH. Deterministic MED, when enabled, means that the first AS of the multiple paths must be the same. Paths received with no MED are assigned a MED of 0, unless the global BGP parameter Missing Is Worst is enabled. If so, received paths are assigned a MED of 4 294 967 294. Missing is Worst is enabled by default. The "no-med-path-is-worst" flag has an impact only when the "First AS" or the "Most Left AS" is the same for multiple routes received. The router changes paths received with a MED of 4 294 967 295 to 4 294 967 294 before insertion into the BGP table.

#### Note

You cannot enable or disable the MED selection process. BGP aggregation does not occur when routes have different MEDs or next hops.

When MED value is set in route-map configuration, the configured MED value is not applicable if it is already set in the associated Path Attribute.

1. When router A sets MED value of 100 by route-map, it will send Path Attribute with MED=100 to EBGP peer B.
2. Router B sends Path Attribute with MED=100 to IBGP peer C.
3. If the route-map is configured with "set MED 200", then router C does not apply MED=200 to the Path Attribute as it is already set to 100 when it is received from router B.
4. Router D will get Path Attribute with MED=100 so that router C does not influence router D when it selects the best route.

Example: If Prefix: X is set as MED=100 from router A, it will be received at B with MED=100, and will carry same MED=100 value to router C, as it is an IBGP peer. Router C will not propagate MED=100 value to D as MED is a non-transitive attribute, so MED can travel maximum of 1 AS.

- lowest IGP metric to the BGP next-hop

If multiple paths exist whose BGP next-hop is reachable through an IGP, the path with the lowest IGP metric to the BGP next-hop is chosen.

- prefer external paths (learned by eBGP) over internal paths (iBGP)

The system prefers external paths over internal paths.

- if Equal Cost Multipath (ECMP) is enabled, insert up to four paths in the routing table

If you enable ECMP, multiple BGP learned routes that use the same metric to different IP next-hops are installed in the IP forwarding table for traffic load-balancing purposes.

- lowest router ID

The lowest router ID, or Circuitless IP (CLIP) address, is preferred.

## BGP and dampened routes

The switch supports route dampening (route suppression). When you use route dampening, a route accumulates penalties each time the route fails. After the accumulated penalties exceed a threshold, the router no longer advertises the route. The router enters the suppressed routes into the routing table only after the accumulated penalty falls below the reuse threshold.

Route flap dampening suppresses the advertisement of the unstable route until the route becomes stable. For information about how to enable flap-dampening, see [Configure BGP](#) on page 420. For information about viewing flap dampening configurations, see [Viewing global flap-dampening configurations](#) on page 451.

Dampening applies only to routes that are learned through an eBGP. Route flap dampening prevents routing loops and protects iBGP peers from having higher penalties for routes external to the AS.

The following paragraph describes the algorithm that controls route flaps.

After the route flaps the first time

- the router creates a route history entry
- a timer starts (180 seconds)

If the route does not flap again, the router uses this timer to delete the history entry after the 180 seconds expires.

After the route flaps a second time

- The penalty is recalculated based on the decay function.

If the penalty is greater than the cut-off value (1536), the route is suppressed and the reuse time is calculated based on the reuse time function.

- The reuse timer starts.

After the reuse time expires, the suppressed route is announced again (the reuse time is recalculated if the route flaps again). The penalty decays slower for withdrawn routes than for update routes. The route history entry is kept longer if the route is withdrawn. For update history, the delete time is 90 seconds and the withdrawn history delete time is 180 seconds.

## BGP Updates

BGP uses update messages to communicate information between two BGP speakers. The update message can advertise a single feasible route to a peer, or withdraw multiple unfeasible routes from service.

The following figure shows the format of an update message.

### Figure 28: Update Message Format

This section describes how BGP uses the update message fields to communicate information between BGP speakers.

#### *Withdrawn Routes Length*

The withdrawn routes length parameter (referred to in RFC1771 as the Unfeasible Routes Length field) indicates the total length of the withdrawn routes field in octets. The withdrawn routes length field calculates the length of the NLRI field. For example, a value of 0 indicates that no routes are withdrawn from service, and that the withdrawn routes field is not present in this update message.

#### *Withdrawn Routes*

The withdrawn routes parameter is a variable-length parameter that contains a list of IP prefixes for routes that are withdrawn from service. The following figure shows the format of an IP prefix.

### Figure 29: IP Prefix Format

The length indicates the number of bits in the prefix (also called the network mask).

For example, 192.0.2.0/24 is equivalent to 192.0.2.0 255.255.255.0 (the /24 indicates the number of bits in the length parameter to represent the network mask 255.255.255.0).

The prefix parameter contains the IP address prefix itself, followed by enough trailing bits to make the length of the whole field an integer multiple of 8 bits (1 octet).

#### *Total Path Attributes Length*

The total path attributes length parameter indicates the total length of the path attributes parameter in octets.

The total path attributes length calculates the length of the NLRI parameter. For example, a value of 0 indicates that no NLRI field is present in this update message.

#### *Path Attributes*

The path attributes parameter is a variable-length sequence of path attributes that exists in every BGP update. The path attributes contain BGP attributes associated with the prefixes in the NLRI parameter.

For example, the attribute values allow you to specify the prefixes that the BGP session can exchange, or which of the multiple paths of a specified prefix to use.

The attributes carry the following information about the associated prefixes:

- the path origin
- the AS paths through which the prefix is advertised
- the metrics that display degrees of preference for this prefix

The following figure shows the encoding used with the path attribute parameter.

**Figure 30: Path Attribute Encoding**

#### *Attribute Type*

As shown in the following figure, the attribute type is a two-octet field that comprises two sub-fields: attribute flags and attribute type code.

**Figure 31: Attribute Type Fields**

The attribute flags parameter is a bit string that contains four binary values that describe the attribute, and four unused bits. The following list provides bit descriptions (from the high-order bit to the low-order bit):

- The high-order bit (bit 0) is the optional bit. When this bit is set (the value is 1), the attribute is optional. When this bit is clear (the value is 0), the attribute is well-known. Well-known attributes must be recognized by all BGP implementations and, when appropriate, passed on to BGP peers. Optional attributes are not required in all BGP implementations.
- The second high-order bit (bit 1) is the transitive bit. For well-known attributes, this bit must be set to 1. For optional attributes, it defines whether the attribute is transitive (when set to 1) or non-transitive (when set to 0).
- The third high-order bit (bit 2) is the partial bit. The partial bit defines whether the information in the optional transitive attribute is partial (when set to 1) or complete (when set to 0). For well-known attributes and for optional non-transitive attributes the partial bit must be set to 0.
- The fourth high-order bit (bit 3) is the extended length bit. The extended length bit defines whether the attribute length is one octet (when set to 0) or two octets (when set to 1). The attribute flag can use the extended length only if the length of the attribute value is greater than 255 octets.
  - If the extended length bit of the attribute flags octet is set to 0, the third octet of the path attribute contains the length of the attribute data in octets.
  - If the extended length bit of the attribute flags octet is set to 1, then the third and the fourth octets of the path attribute contain the length of the attribute data in octets.
- The lower-order four bits of the attribute flags octet are unused. The lower-order four bits must be zero (and must be ignored when received).

The attribute type code parameter contains the attribute type code, as defined by the Internet Assigned Numbers Authority (IANA). The attribute type code uniquely identifies the attribute from all others. The remaining octets of the path attribute represent the attribute value and are interpreted according to the attribute flags and the attribute type code parameters.

The following table shows the supported attribute type codes.

**Table 56: BGP Mandatory Path Attributes**

| Attribute              | Type code | Description                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Origin                 | 1         | Defines the origin of the path information: <ul style="list-style-type: none"> <li>Value = 0 --- IGP (the path is valid all the way to the IGP of the originating AS)</li> <li>Value = 1--- EGP (the last AS in the AS path uses an EGP to advertise the path)</li> <li>Value = 2--- Incomplete (the path is valid only to the last AS in the AS path)</li> </ul> |
| AS path                | 2         | Contains a list of the autonomous systems that packets must traverse to reach the destinations. This code represents each AS path segment as follows: <ul style="list-style-type: none"> <li>path segment type</li> <li>path segment length</li> <li>path segment value</li> </ul>                                                                                |
| Next hop               | 3         | Specifies the IP address of the border router to use as a next hop for the advertised destinations (destinations listed in the NLRI field of the update message).                                                                                                                                                                                                 |
| Multixit discriminator | 4         | Discriminates among multiple exit or entry points to the same neighboring AS on external (internal-AS) links.                                                                                                                                                                                                                                                     |
| Local preference       | 5         | Indicates the preference that AS border routers assign to a chosen route when they advertise it to iBGP peers                                                                                                                                                                                                                                                     |
| Atomic aggregate       | 6         | Ensures that certain NLRI is not deaggregated                                                                                                                                                                                                                                                                                                                     |
| Aggregator             | 7         | Identifies which AS performed the most recent route aggregation. This attribute contains the last AS number that formed the aggregate route followed by the IP address of the BGP speaker that formed the aggregate route.                                                                                                                                        |

#### *Attribute Length*

The attribute length can be one or two octets in length, depending on the value of the extended length parameter in the attributes flag field.

This parameter indicates the length of the attribute value field.

#### *Attribute Value*

The attribute value contains the actual value of the specific attribute. The system implements the attribute value according to the values in the attribute flags and the attribute type code parameters.

#### *NLRI*

The NLRI parameter is a variable length field that contains a list of prefixes. The packet size that BGP speakers can exchange limits the number of prefixes in the list.

## Equal Cost Multipath

Equal Cost Multipath (ECMP) support allows a BGP speaker to perform route or traffic balancing within an AS by using multiple equal-cost routes submitted to the routing table by OSPF, RIP, or static routes.

For more information about ECMP, see [Equal Cost Multipath](#) on page 1817.

## MD5 message authentication

Authenticate BGP messages by using Message Digest 5 (MD5) signatures. After you enable BGP authentication, the BGP speaker verifies that the BGP messages it receives from its peers are actually from a peer and not from a third party masquerading as a peer.

BGPv4 TCP MD5 message authentication provides the following features:

- A TCP MD5 signature can exist for BGP peers. You can configure authentication and secret keys for each peer. Peers configured with common secret keys can authenticate each other and exchange routing information.
- The switch can concurrently have BGP peers with authentication enabled and other BGP peers with authentication disabled.
- The switch always encrypts the secret keys.

After you enable BGPv4 TCP MD5 authentication, the router computes an MD5 signature for each TCP packet based on the TCP packet and an individual peer secret key. The router adds this MD5 signature to the TCP packet that contains a BGP message and sends it with the packet, but it does not send the secret key.

The receiver of the TCP packet also knows the secret key and can verify the MD5 signature. A third party that tries to masquerade as the sender, however, cannot generate an authentic signature because it does not know the secret key.

In commands, the term *password* refers to the secret key. The secret keys provide security. If the keys are compromised, then the authentication itself is compromised. To prevent this, the switch stores the secret keys in encrypted form.

### *MD5 signature generation*

BGP peers calculate MD5 signatures in BGP messages based on the following elements:

- TCP pseudo-header
- TCP header, excluding options
- TCP segment data
- TCP MD5 authentication key

If TCP receives an MD5 authentication key, it reduces its maximum segment size by 18 octets, which is the length of the TCP MD5 option. TCP adds an MD5 signature to each transmitted packet. The peer inserts the resulting 16-byte MD5 signature into the following TCP options: *kind*=19, *length*=18.

### MD5 signature verification

After the switch receives a packet, it performs three tests. The following table lists the tests and the event message that TCP logs if a test fails.

**Table 57: MD5 signature verification rules on BGP TCP packets**

| Condition tested                                                  | Action on success                                 | Failure event message           |
|-------------------------------------------------------------------|---------------------------------------------------|---------------------------------|
| Is the connection configured for MD5 authentication?              | Verify that the packet contains a kind=19 option. | TCP MD5 No Signature            |
| Is MD5 authentication enabled for this TCP connection?            | TCP computes the expected MD5 signature.          | TCP MD5 Authentication Disabled |
| Does the computed MD5 signature match the received MD5 signature? | TCP sends the packet to BGP.                      | TCP MD5 Invalid Signature       |

If a packet passes a test, it proceeds to the next test. After a packet passes all three tests, TCP accepts the packet and sends it to BGP.

If a packet fails a test, the switch logs an event, increments the count of TCP connection errors (wfTcpConnMd5Errors), and discards the packet. The TCP connection remains open.

## BGP and route redistribution

Redistribution imports routes from one protocol to another. Redistribution sends route updates for a protocol-based route through another protocol. For example, if OSPF routes exist in a router and they must travel through a BGP network, then configure redistribution of OSPF routes through BGP. This sends OSPF routes to a router that uses BGP.

The switch can redistribute routes:

- on an interface basis.
- on a global basis between protocols on a single VRF instance (intraVRF).
- between the same or different protocols on different VRF instances (interVRF).

Configure interface-based redistribution by configuring a route policy and apply it to the interface. Configure the match parameter to the protocol from which to learn the routes.

You can redistribute routes on a global basis, rather than on an interface basis. Use the **ip bgp redistribute** command to accomplish the (intraVRF) redistribution of routes through BGP, so that BGP redistribution occurs globally on all BGP-enabled interfaces. This redistribution does not require a route policy, but you can use one for more control.

If you configure redistribution globally and on an interface, redistribution through the route policy takes precedence.

You can redistribute routes from a protocol in one VRF to BGP in another VRF. You can use a route policy for redistribution control. If you enable route redistribution between VRF instances, ensure that IP addresses do not overlap.

Use caution when you configure redistribution. An improperly configured parameter can cause the router to advertise learned eBGP routes out of your local AS. If this happens, the local AS can route other networks.

Do not use redistribution if you peer to an Internet Service Provider (ISP) and do not want traffic to transit your local AS.

When you redistribute OSPF routes into BGP, route priorities can create routing loops. Because BGP has a higher route preference than OSPF external type 1 and 2 routes, if you redistribute OSPF external type 1 and 2 routes into BGP, the router uses the BGP routes, which can cause a routing loop.

#### *Route-maps and BGP neighbors*

BGP Routing Information Base (BGP RIB) stores routing information received from different peers. BGP RIB has two types of BGP routes, External and Internal (Local). The routes learned from BGP neighbors are External routes and all imported routes are considered as Internal (Local) routes.

In BGP RIB, the OSPF routes redistributed into BGP are considered as Internal (Local) and are matched by route-type only when the keyword is set to **local**. When match route-type is set to **external**, the route-maps applied on BGP neighbors are ignored and the set operation is not performed.

#### **Note**

This is applied only on the route-maps applied to BGP neighbors in BGP RIB, and not considered when applying a route-map to the redistribute command.

#### *BGP route redistribution and DvR*

DvR Controllers redistribute routes (direct routes, static routes and the default route) into the DvR domain. You can configure redistribution of DvR host routes into BGP.

For information on DvR, see [Distributed Virtual Routing](#) on page 680.

## BGP+

The switch extends the BGPv4 process to support the exchange of IPv6 routes using BGPv4 peering. BGP+ is an extension of BGPv4 for IPv6, which is indicated using the Address Family Identifier (AFI) in the BGP header.

The switch supports capabilities for AFI with the following values: 1 (IPv4) and 2 (IPv6). If the switch receives an OPEN message advertising an AFI with a different value, the connection is closed and a BGP notification message is sent to the peer mentioning unsupported capability.

BGP+ is only supported on the global VRF instance.

#### **Note**

Ensure you configure IPv6 forwarding for BGP+ to work.

Note that the BGP+ support on the switch is not an implementation of BGPv6. Native BGPv6 peering uses the IPv6 Transport layer (TCPv6) for establishing the BGPv6 peering, route exchanges, and data traffic.

The switch supports the exchange of IPv6 reachability information over IPv4 transport. To support BGP+, the switch supports two BGP protocol extensions, standards RFC 4760 (multi-protocol extensions to BGP) and RFC 2545 (MP-BGP for IPv6). These extensions allow BGPv4 peering to be enabled with IPv6 address family capabilities.

The implementation of BGP+ on the switch uses an existing TCPv4 stack to establish a BGPv4 connection. Optionally, nontransitive BGP properties are used to transfer IPv6 routes over the BGPv4 connection. Any BGP+ speaker has to maintain at least one IPv4 address to establish a BGPv4 connection.

Different from IPv4, IPv6 introduces scoped unicast addresses, identifying whether the address is global or link-local. When BGP+ is used to convey IPv6 reachability information for interdomain routing, it is sometimes necessary to announce a next hop attribute that consists of a global address and a link-local address. For BGP+, no distinction is made between global and site-local addresses.

The BGP+ implementation includes support for BGPv6 policies, including redistributing BGPv6 into OSPFv3, ISIS, RIPng, and advertising OSPFv3, ISIS, RIPng, IPv6 static and local routes into BGPv6 (through BGP+). It also supports the aggregation of global unicast IPv6 addresses.

When configuring BGP+ on the router that is enabled only for IPv6 (the router does not have an IPv4 address), then BGP router ID must be manually configured for the router.

BGP+ does not support confederations. You can configure confederations for IPv4 routes only.

The basic configuration of BGP+ is the same as BGPv4 with one additional parameter added and some existing commands altered to support IPv6 capabilities. You can enable and disable IPv6 route exchange by specifying the address family attribute as IPv6. Note that an IPv6 tunnel is required for the flow of IPv6 data traffic.

#### *BGP+ tunnel*

When you use BGP+ you must configure an IPv6 tunnel and static routes at BGP+ peers.

When BGP+ peers advertise route information, they use Update messages to advertise route information.

These RTM routes contain next-hop addresses from the BGP peer that the route was learned from.

The static routes correlate the next-hop addresses represented by the IPv4-mapped IPv6 address to a specific outgoing interface.

Following is one way to express a static route in an IPv6-configured tunnel for BGP+:

```
ipv6 route 2001:DB8:0:0:0:ffff:192.0.2.0/24 cost 1 tunnel 10 where  
2001:DB8:0:0:0:ffff:192.0.2.0 is the IPv4-mapped IPv6 address of the BGP peer at 192.0.2.0
```

## ECMP with BGP+

The ECMP feature supports and complements BGP+ protocol.

The number of equal-cost-paths supported can differ by hardware platform. For more information, see [VOSS Release Notes](#).

You can use multiple paths for load sharing of traffic. These multiple paths allow faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use your links between routers more efficiently when sending IP and IPv6 traffic. Equal Cost Multipath is formed using routes from the same protocol.

#### Note

To add BGP+ equal cost paths in the routing table, you must enable the following:

- IPv6 ECMP feature globally
- BGP multiple-paths attribute

## BGPv6

BGP peering over IPv6 transport uses a BGPv6 peer to exchange IPv6 routes over an IPv6 transport layer. This is different than BGP+, which enables exchange of IPv6 routes over a BGPv4 peer. Also with BGP+, you must use an IPv6 tunnel to install and configure IPv6 routes in an IPv6 Routing Table Manager (RTM). BGP+ uses an IPv4 mapped IPv6 address for the next hop address and requires you to configure IPv6 static routes and install IPv6 routes in an IPv6 RTM where the next hop for the static route is an IPv6 tunnel interface.

BGPv6 supports the following:

- Input/Output policies.
- Redistribution of OSPFv3, IS-IS, IPv6 static route, and IPv6 direct routes into BGPv6.
- Aggregation of global unicast IPv6 addresses.

#### Note

BGP+ also supports the preceding features.

#### *RFC*

The switch supports the BGP multiprotocol extension, as described in RFC 4760. Also supports RFC 2545 (MP-BGP for IPv6).

The BGP protocol extensions ensure peering can be enabled with IPv6 address family capabilities.

#### *Route exchange*

BGPv6 does not exchange any IPv4 routes. BGPv6 advertises or learns only IPv6 routes.

The following table shows the differences between BGPv4 and BGPv6 for route exchange.

|       | GRT/VRF | IPv4 Routes Exchange | IPv6 Routes Exchange                                                                |
|-------|---------|----------------------|-------------------------------------------------------------------------------------|
| BGPv4 | GRT     | Supported            | Supported (BGP+)                                                                    |
|       | VRF     | Supported            | Not supported<br><br><b>Note:</b><br>IPv6 over IPv4 tunnels is not yet virtualized. |

|       | GRT/VRF | IPv4 Routes Exchange | IPv6 Routes Exchange |
|-------|---------|----------------------|----------------------|
| BGPv6 | GRT     | Not supported        | Supported            |
|       | VRF     | Not supported        | Supported            |

Specify the address family attribute as IPv6 to enable IPv6 route exchange.

You can enable IPv6 route exchange by specifying the address family attribute as IPv6. Optionally, you can use non-transitive BGP properties to exchange IPv6 routes between the BGPv6 peering. Any BGPv6 speaker must maintain at least one IPv6 address to establish a BGPv6 connection. The IPv6 scoped unicast addresses can identify the address as global or link-local. If you use BGPv6 to convey IPv6 reachability information for interdomain routing, you can also announce a next hop attribute that consists of a global address and a link-local address.

#### Note

BGPv6 does not support adjacency on link-local.

### Authentication

BGPv6 uses IPsec for security. MD-5 authentication is supported for BGPv4 and is not supported for BGPv6.

The following table shows the differences between BGPv4 and BGPv6 for authentication.

|       | MD5           | IPsec                                                                                                                                       | SHA1/SHA2     |
|-------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| BGPv4 | Supported     | Not supported                                                                                                                               | Not supported |
| BGPv6 | Not supported | Supported<br><b>Note:</b><br>IP Sec is not virtualized, hence BGPv6 is supported only in Global Router mode, and not supported in VRF mode. | Not supported |

### MD5 authentication

MD5 authentication is not supported in BGPv6 so it is not necessary to enable MD5 authentication.

### IPsec

Only IPsec is supported. Therefore, MD5 authentication cannot be configured.

### Consistency checking

Includes consistency checking for MD5 authentication. BGP peer and BGP peer group configuration for IPv6 addresses include a rule to block MD5 authentication. If you attempt to configure MD5 authentication, you will receive an error message.

### IPv6 tunneling

With BGPv6, IPv6 tunneling is not required for IPv6 data traffic flow. An IPv6 tunnel is required for BGP +.

## Circuitless IP

Circuitless IP (CLIP) is a virtual (or loopback) interface that you do not associate with a physical port. You can use a CLIP interface to provide uninterrupted connectivity to your switch as long as an actual path exists to reach the device. For example, as shown in the following figure, a physical point-to-point link exists between R1 and R2 along with the associated addresses (195.39.1.1/30 and 195.39.1.2/30). Note also that an iBGP session exists between two additional addresses 195.39.128.1/32 (CLIP 1) and 195.39.128.2/32 (CLIP 2).

**Figure 32: Routers with iBGP connections**

The system treats the CLIP interface like an IP interface and treats the network associated with the CLIP as a local network attached to the device. This route always exists and the circuit is always up because no physical attachment exists.

The router advertises routes to other routers in the domain either as external routes using the route-redistribution process or after you enable OSPF in a passive mode to advertise an OSPF internal route. You can configure only the OSPF protocol on the CLIP interface. After you create a CLIP interface, the system software programs a local route with the CPU as the destination ID. The CPU processes all packets destined to the CLIP interface address. The system treats other packets with destination addresses associated with this network (but not to the interface address) as if they are from an unknown host.

A circuitless IP or CLIP address is a logical IP address for network management, as well as other purposes. The CLIP is typically a host address (with a 32 bit subnet mask). Configure the OSPF router ID to the configured CLIP address. By default, the BGP router ID is automatically equivalent to the OSPF router ID.

For information about how to configure CLIP interfaces, see [Configure a CLIP Interface](#) on page 1844 and [Configure a Circuitless IPv4 Interface](#) on page 1868.

## BGP Configuration Considerations and Limitations

Use the information in this section to help you configure BGP on your switch, which supports BGPv4 as described in RFC 1771.

### *BGP Implementation Guidelines*

The following list provides guidelines to successfully implement BGP:

- BGP does not operate with an IP router in nonforwarding (host-only) mode. Make sure that the routers you want BGP to operate with are in forwarding mode.
- If you use BGP for a multihomed AS (one that contains more than a single exit point), use OSPF for your IGP and BGP for your sole exterior gateway protocol, or use intra-AS iBGP routing.
- If OSPF is the IGP, use the default OSPF tag construction. Using EGP or modifying the OSPF tags makes network administration and proper configuration of BGP path attributes difficult.
- For routers that support both BGP and OSPF, the OSPF router ID and the BGP identifier must be the same IP address. The BGP router ID automatically uses the OSPF router ID.
- In configurations where BGP speakers reside on routers that have multiple network connections over multiple IP interfaces (the typical case for iBGP speakers), consider using the address of the circuitless (virtual) IP interface as the local peer address. In this configuration, you ensure that BGP is reachable as long as an active circuit exists on the router.
- By default, BGP speakers do not advertise or inject routes into the IGP. You must configure route policies to enable route advertisement.
- Coordinate routing policies among all BGP speakers within an AS so that every BGP border router within an AS constructs the same path attributes for an external path.
- Configure accept and announce policies on all iBGP connections to accept and propagate all routes. Make consistent routing policy decisions on external BGP connections.

### *Minimum Requirements*

You must configure the following minimum parameters:

- router ID
- local AS number
- enable BGP globally
- BGP neighbor peer session: remote IP addresses
- enable BGP peers
- When you use both BGP and OSPF, the OSPF and BGP router ID must be the same.

The router ID must be a valid IP address of an IP interface on the router or a CLIP address. BGP update messages use this IP address. By default, the BGP router ID automatically uses the OSPF router ID.

You cannot configure the BGP router ID if you configure BGP before you configured the OSPF router ID. You must first disable BGP, configure the OSPF route ID, and then enable BGP globally.

You can add BGP policies to the BGP peer configuration to influence route decisions. BGP policies apply to the peer through the soft-reconfiguration commands.

After you configure the switch for BGP, some parameter changes can require you to enable or disable the BGP global state or the neighbor admin-state.

You can dynamically modify BGP policies. On the global level, the BGP redistribution command has an apply parameter that causes the policy to take effect after you issue the command.

### *BGP Neighbor Maximum Prefix Configuration*

By default, the maximum prefix parameter limits 12 000 NLRI messages for each neighbor. The maximum prefix parameter limits the number of routes that the switch can accept.

The maximum prefix parameter prevents large numbers of BGP routes from flooding the network if you implement an incorrect configuration. You can assign a value to the maximum prefix limit, including 0 (0 means unlimited routes). When you configure the maximum prefix value, consider the maximum number of active routes that your equipment configuration can support.

### *BGP and OSPF Interaction*

RFC1745 defines the interaction between BGP and OSPF when OSPF is the IGP within an autonomous system. For routers that use both protocols, the OSPF router ID and the BGP ID must be the same IP address. You must configure a BGP route policy to allow BGP advertisement of OSPF routes.

Interaction between BGPv4 and OSPF can advertise supernets to support CIDR. BGPv4 supports interdomain supernet advertisements; OSPF can carry supernet advertisements within a routing domain.

### *BGP and Internet Peering*

By using BGP, you can perform Internet peering directly between the switch and another edge router. In such a scenario, you can use each switch for aggregation and link it with a Layer 3 edge router, as shown in the following figure.

**Figure 33: BGP and Internet peering**

In cases where the Internet connection is single-homed, to reduce the size of the routing table, as a best practice, advertise Internet routes as the default route to the IGP.

For route scaling information, see [VOSS Release Notes](#).

### *Routing Domain Interconnection with BGP*

You can implement BGP so that autonomous routing domains, such as OSPF routing domains, connect. This connection allows the two different networks to begin communicating quickly over a common

infrastructure, thus providing additional time to plan the IGP merger. Such a scenario is particularly effective when you need to merge two OSPF area 0.0.0.0s, as shown in the following figure.

**Figure 34: Routing Domain Interconnection with BGP**

#### *BGP and Edge Aggregation*

You can perform edge aggregation with multiple point of presence or edge concentrations. The switch supports 12 pairs (peering services). You can use BGP to inject dynamic routes rather than using static routes or RIP (see the following figure).

**Figure 35: BGP and Edge Aggregation**

#### *BGP and ISP Segmentation*

You can use the platform as a peering point between different regions or autonomous systems (AS) that belong to the same ISP. In such cases, you can define a region as an OSPF area, an AS, or a part of an AS.

You can divide the AS into multiple regions that each run different IGPs. Interconnect regions logically by using a full iBGP mesh. Each region then injects its IGP routes into iBGP and also injects a default route inside the region. For destinations that do not belong to the region, each region defaults to the BGP border router.

Use the community parameter to differentiate between regions. To provide Internet connectivity, this scenario requires you to make your Internet connections part of the central iBGP mesh (see the following figure).

**Figure 36: Multiple Regions Separated by iBGP**

In the preceding figure, consider the following:

- The AS is divided into three regions that each run different and independent IGPs.
- Regions logically interconnect by using a full-mesh iBGP, which also provides Internet connectivity.
- Internal non-BGP routers in each region default to the BGP border router, which contains all routes.
- If the destination belongs to another region, the traffic is directed to that region; otherwise, the traffic is sent to the Internet connections according to BGP policies.

To configure multiple policies between regions, represent each region as a separate AS. Implement eBGP between autonomous systems, and implement iBGP within each AS. In such instances, each AS injects its IGP routes into BGP, where they are propagated to all other regions and the Internet.

The following figure shows the use of eBGP to join several autonomous systems.

**Figure 37: Multiple regions Separated by eBGP**

You can obtain AS numbers from the Inter-Network Information Center (NIC) or use private AS numbers. If you use private AS numbers, be sure to design your Internet connectivity carefully. For example, you can introduce a central, well-known AS to provide interconnections between all private autonomous systems and the Internet. Before it propagates the BGP updates, this central AS strips the private AS numbers to prevent them from leaking to providers.

The following figure illustrates a design scenario in which you use multiple OSPF regions to enable peering with the Internet.

**Figure 38: Multiple OSPF Regions Peering with the Internet**

*BGP Peers*

The following list provides rules related to BGP peers:

- Only metric (=MED) attribute is applied to the output policy if its BGP peer is IBGP
- metric (=MED) and community attributes are applied to output policy if its BGP peer is EBGP

- To influence EBGP and IBGP peers with all applicable BGP attributes, configure **route-map** as an option to **neighbor** command, for example, `neighbor 192.0.2.2 out-route-map policy1`

### *BGP and Route Aggregation*

When you configure the attribute-map with the aggregate command, community, metric, AS Path, and next-hop attributes are set, while the origin attribute is not set.

### *BGP Session Flapping when IPv6 Forwarding is Enabled or Disabled*

In a BGP session that is established with IPv4 and IPv6 capability, disabling or enabling IPv6 forwarding results in BGP session flapping due to capability negotiation. The flapping session in turn affects the IPv4 routing through BGP and the BGP session gets terminated. Ultimately, a capability negotiation takes place to re-establish the IPv4 and IPv6 capable session.

## BGP configuration using CLI

---

Configure the Border Gateway Protocol (BGP) to create and maintain an interdomain routing system that guarantees loop-free routing information between autonomous systems (AS).

For information about how to configure route policies for BGP, see [Configure IP Route Policies](#) on page 2888.

## Configure BGP

Configure BGP globally to enable BGP on the switch and determine how BGP operates.

### **Before You Begin**

- To configure the suppress-map, advertise-map, or attribute-map options, the route policy for those options must exist.
- For initial BGP configuration, you must know the AS number.
- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

#### **Note**

Route refresh is not currently supported on non-default VRFs.

### **Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Specify the AS number and enable BGP:

```
router bgp [WORD <0-11>] [enable]
```

#### Note

- This command applies only on VRF 0. To enable BGP globally on other VRFs, use the **ip bgp enable** command. You must configure BGP locally before you configure it globally.
- You can also configure AS number on non-default VRFs. For more information, see [Configure an AS Number for a Non-default VRF](#) on page 446.

- Access Router BGP Configuration mode:

```
router bgp
```

- Configure BGP variables or accept the default values.

### Example

Specify the AS number and enable BGP:

```
Switch(config)#router bgp 3 enable
```

Access Router BGP Configuration mode:

```
Switch(config)#router bgp
```

```
Switch(router-bgp)#
```

### Variable Definitions

The following table defines parameters for the **router bgp** command.

| Variable           | Value                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <0-11> | Specifies the AS number. You cannot enable BGP until you change the local AS to a value other than 0. |
| <i>enable</i>      | Enables BGP on the router.                                                                            |

Use the data in the following table to use the BGP variables in BGP and VRF Router Configuration mode.

| Variable                                        | Value                                                                                                                              |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>aggregate-address</i><br><i>WORD</i> <1-256> | Specifies an IP address and its length in the form {a.b.c.d/len}, or an IPv6 address and its length in the form {ipv6addr/len}.    |
| <i>auto-peer-restart enable</i>                 | Enables the process that automatically restarts a connection to a BGP neighbor. The default value is enable.                       |
| <i>auto-summary</i>                             | When enabled, BGP summarizes networks based on class limits, for example, Class A, B, and C networks. The default value is enable. |

| Variable                                                                                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bgp always-compare-med</code>                                                      | Enables the comparison of the multi-exit discriminator (MED) parameter for paths from neighbors in different autonomous systems. The system prefers a path with a lower MED over a path with a higher MED. The default value is disable.                                                                                                                                                                                                                                                                                                                        |
| <code>bgp aggregation</code>                                                             | Enables the aggregation feature on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>bgp client-to-client reflection</code>                                             | Enables or disables route reflection between two route reflector clients. This variable applies only if the route reflection value is enable. The default value is disable. You can enable route reflection even when clients are fully meshed.<br>This variable only applies to VRF 0.<br>Example: <code>Switch(router-bgp) # bgp client-to-client reflection</code><br>System Response: Restart or soft-restart BGP for the change to take effect.                                                                                                            |
| <code>bgp cluster-id {A.B.C.D}</code>                                                    | Configures a cluster ID. This variable applies only if the route reflection value is enable, and if multiple route reflectors are in a cluster. {A.B.C.D} is the IP address of the reflector router.<br>This variable only applies to VRF 0.<br>Example: <code>Switch(router-bgp) # bgp cluster-id 0.0.0.0</code>                                                                                                                                                                                                                                               |
| <code>bgp confederation identifier &lt;0-4294967295&gt; [peers WORD&lt;0-255&gt;]</code> | Configures a BGP confederation.<br><code>identifier&lt;0-4294967295&gt;</code> specifies the confederation identifier. Use 0-65535 for 2-byte AS and <0-4294967295> for 4-byte AS.<br><code>peers WORD&lt;0-255&gt;</code> lists adjoining autonomous systems that are part of the confederation in the format (5500,65535,0,10,.....). Use quotation marks (") around the list of autonomous systems.<br><br><b>Note:</b><br>Use this command only on VRF 0.<br><br>Example: <code>Switch(router-bgp) # bgp confederation identifier 1 peers "20 30 40"</code> |
| <code>bgp default local-preference &lt;0-2147483647&gt;</code>                           | Specifies the default value of the local preference attribute. The default value is 0. You must disable BGP before you can change the default value.<br>Example: <code>Switch(router-bgp) # bgp default local-preference 2-12</code>                                                                                                                                                                                                                                                                                                                            |
| <code>bgp deterministic-med enable</code>                                                | Enables deterministic MED.<br>Example: <code>Switch(router-bgp) # bgp deterministic-med enable</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Variable                                          | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bgp multiple-paths &lt;1-8&gt;</code>       | <p>Configures the maximum number of equal-cost-paths that are available to a BGP router by limiting the number of equal-cost-paths the routing table can store. The default value is 1.</p> <p>Example: <code>Switch(router-bgp) # bgp multiple-paths 4</code></p> <p><b>Note:</b><br/>Configuring the <code>bgp multiple-paths</code> variable does not affect existing routes. The routing table does not show ECMP routes; instead only one route is shown in the routing table.</p> <p>To view Equal-Cost Multipath (ECMP) routes, receive the routes after executing the <code>bgp multiple-paths</code> variable, or toggle the BGP state.</p> <p>The number of equal-cost-paths supported can differ by hardware platform. For more information, see <a href="#">VOSS Release Notes</a>.</p> |
| <code>comp-bestpath-med-confed enable</code>      | <p>When enabled, compares MED attributes within a confederation. The default value is disable.</p> <p>This variable only applies to VRF 0.</p> <p>Example: <code>Switch(router-bgp) # comp-bestpath-med-confed enable Restart or soft-restart BGP for the change to take effect</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>debug-screen &lt;off on&gt;</code>          | <p>Displays debug messages on the console, or saves them in a log file. Disable BGP screen logging (off) or enable BGP screen logging (on).</p> <p>Example: <code>Switch(router-bgp) # debug-screen on</code><br/>System Response: BGP Screen Logging is On</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>default-information originate</code>        | <p>Enables the advertisement of a default route to peers, if the route exists in the routing table. The default value is disable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>default-information ipv6-originate</code>   | <p>Enables the advertisement of an IPv6 default route to peers, if the route exists in the routing table. | <code>default-metric &lt;-1-2147483647&gt;</code> | <p>Configures a value to send to a BGP neighbor to determine the cost of a route a neighbor uses. A default metric value solves the problems associated with redistributing routes that use incompatible metrics. For example, whenever metrics do not convert, using a default metric provides a reasonable substitute and redistribution proceeds. Use this option in conjunction with the redistribute commands so the current routing protocol uses the same metric for all redistributed routes. The default value is 0.</p>                                                                                                                                                                                                                                                                   |
| <code>flap-dampening enable</code>                | <p>Enables route suppression for routes that flap on and off. The default value is disable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

For mask options, see the <code>global-debug mask WORD&lt;1-100&gt;</code> variable.</p> <p>Example: <code>Switch(router-bgp)# neighbor-debug-all mask error, packet, event.trace, state, filter</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>no-med-path-is-worst enable</code>                               | <p>Enables BGP to treat an update without a MED attribute as the worst path. The default value is disable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>quick-start enable</code>                                        | <p>Enables the quick-start flag for exponential backoff.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>route-reflector enable</code>                                    | <p>Enables the reflection of routes from iBGP neighbors. The default value is disable.</p> <p>This variable only applies to VRF 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>route-refresh</code>                                             | <p>Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request.</p> <p>This variable only applies to VRF 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Variable                             | Value                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>router-id {A.B.C.D}</code>     | Specifies the BGP router ID in IP address format. This variable only applies to VRF 0.                                                                                                                                                                                                                                                                  |
| <code>synchronization</code>         | Enables the router to accept routes from BGP peers without waiting for an update from the IGP. The default value is enable.                                                                                                                                                                                                                             |
| <code>traps enable</code>            | Enables BGP traps.                                                                                                                                                                                                                                                                                                                                      |
| <code>vrf-as WORD&lt;0-11&gt;</code> | Configures an AS number on a specific VRF instance. Use 0-65535 for a 2-byte AS and <0-4294967295> for a 4-byte AS.<br>The default value of 0, or configuring the local-as in the VRF to 0, is equivalent to deleting the local-as configured on user-defined VRFs, and in both cases the local-as on the VRF becomes the local-as on the GlobalRouter. |

### Job Aid

Use debug command values to control debug messages for global BGP message types, and for message types associated with a specified BGP peer or peer group.

#### Tip

The following tips can help you use the debug commands:

- Display debug commands for multiple mask choices by entering the mask choices separated by commas, with no space between choices.
- To end (disable) the display of debug messages, use the mask choice of none.
- You can save debug messages in a log file, or you can display the messages on your console using the debug-screen command.

For more information about the logged debug messages, see [VOSS Alarms and Logs Reference](#).

## Configure 4-byte AS numbers

Configure Autonomous System (AS) numbers using the 4-byte format and represent the numbers in octets.

### Before You Begin

- You cannot modify the global BGP configuration unless BGP is disabled.
- Configure the local AS number at Global Router (VRF0) only.
- Make sure that you define AS numbers in policies the same way that you configure them for the router. The AS list for the route policies accepts AS number only in the **asplain** format. If you create policies using **asplain** and configure the switch with **asdot**, the match will not occur.

### About This Task

Use BGP 4-byte AS numbers to ensure the continuity of loop-free inter-domain routing information between autonomous systems and to control the flow of BGP updates as 2-byte AS numbers will deplete soon. AS Plain notation format is the default and the preferred form of representing 4-byte AS numbers over the AS dot notation format.

You have an option to configure AS dot notation format as well. With AS dot notation, analyzing and troubleshooting any issues encountered becomes difficult as it is incompatible with the regular expressions used by most of the network providers.

If you enable 4-byte AS numbers, or the dotted octet notation, for the Global Router (VRF0), the configuration is inherited by user-defined VRFs. You cannot enable 4-byte AS numbers on individual user-defined VRFs.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Disable BGP to change the AS number format.  
`no router bgp enable`
3. Enable the 4-byte AS numbering format.  
`router bgp as-4-byte enable`
4. To use the dotted octet notation, enable as-dot.  
`router bgp as-dot enable`
5. Configure the 4-byte AS number and enable BGP. If you have enabled as-dot, enter the AS number in octet.  
`router bgp WORD<0-11> enable`
6. Access Router BGP Configuration mode:  
`router bgp`
7. (Optional) Configure BGP confederation identifier.  
`bgp confederation identifier <0-4294967295>`
8. (Optional) Configure BGP confederation peers.  
`bgp confederation peers WORD<0-255>`

### Example

Disable BGP to change the AS number format.

```
Switch(config)# no router bgp enable
```

Enable the 4-byte AS numbering format.

```
Switch(config)# router bgp as-4-byte enable
```

To use the dotted octet notation, enable as-dot.

```
Switch(config)# router bgp as-dot enable
```

Configure the 4-byte AS number and enable BGP.

```
Switch(config)# router bgp 65536 enable
```

### Variable Definitions

The following table defines parameters for the **router bgp** command.

| Variable                                         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-4-byte</i><br><i>&lt;enable&gt;</i>        | Enables the switch for using 4 byte numbers for an autonomous system (AS). The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>as-dot</i> <i>&lt;enable&gt;</i>              | Enables or disables representing AS numbers in octets. The default is disable so the switch uses the plain notation format. If you enable the 4-byte-as and as-dot parameters, enter numbers in the range of 1.0 to 65535.65535. The default value is disable.<br><br><b>Note:</b><br>This parameter is not supported with BGP+.                                                                                                                                                                                                                                                                                                                                                     |
| <i>WORD</i> <i>&lt;0-11&gt;</i><br><i>enable</i> | Sets the local autonomous system (AS) number. You cannot change local-as when BGP is set to enable. <ul style="list-style-type: none"> <li>To set a 2-byte local AS number, enter a local-as number in the range of 0 to 65535.</li> <li>To set a 4-byte local-as number, enable the 4-byte as variable and enter a number in the range of 0 to 4294967295.</li> </ul> <b>Note:</b><br>If as-4-byte is set to false, the range for AS number is 0-65535 and if as-4-byte is set to true, the range is 0-4294967295.<br><br>If you enable as-dot, enter the AS number in octets in the range of 1.0 to 65535.65535.<br><br><b>Note:</b><br>This parameter is not supported with BGP+. |

## Configure Aggregate Routes

Configure aggregate routes so that the router advertises a single route (aggregate route) that represents all destinations. Aggregate routes also reduce the size of routing tables.

### Before You Begin

- Disable BGP before you enable aggregation.
- You need the appropriate aggregate address and mask.
- If required, policies exist.
- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

#### Note

Route refresh is not currently supported on non-default VRFs.

## Procedure

1. Enter BGP Router Configuration mode:
 

```
enable

configure terminal

router bgp
```
2. Enable BGP aggregation:
 

```
bgp aggregation enable
```
3. Add an aggregate route to the routing table:
 

```
aggregate-address WORD<1-256> {advertise-map WORD<0-1536>} [as-set]
[attribute-map WORD<0-1536>] [summary-only] [suppress-map WORD<0-1536>]
```
4. Exit to Global Configuration mode:
 

```
exit
```
5. Enable BGP:
 

```
router bgp [<0-65535>] [enable]
```

## Example

Add an aggregate route to the routing table:

```
Switch(router-bgp)# aggregate-address 2001:DB8::/32 advertise-map map1
attribute-map map2
```

Enable BGP:

```
Switch(router-bgp)# router bgp 4 enable
```

### Variable Definitions

The following table defines parameters for the **aggregate-address** command.

| Variable                          | Value                                                                                                                                |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <i>advertise-map</i> WORD<0-1536> | Specifies the route map name for route advertisements.                                                                               |
| <i>as-set</i>                     | Enables autonomous system information. The default value is disable.                                                                 |
| <i>attribute-map</i> WORD<0-1536> | Specifies the route map name.                                                                                                        |
| WORD <1-256>                      | Specifies an IP address and its length in the appropriate form. The value must be entered in the format a.b.c.d/len or ipv6addr/len. |

| Variable                               | Value                                                                                                                                                                                                                |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>summary-only</i>                    | Enables the summarization of routes not included in routing updates. This variable creates the aggregate route and suppresses advertisements of more specific routes to all neighbors. The default value is disable. |
| <i>suppress-map WORD&lt;0-1536&gt;</i> | Specifies the route map name for the suppressed route list.                                                                                                                                                          |

The following table defines parameters for the **router bgp** command.

| Variable      | Value                                                                                                 |
|---------------|-------------------------------------------------------------------------------------------------------|
| <0-65535>     | Specifies the AS number. You cannot enable BGP until you change the local AS to a value other than 0. |
| <i>enable</i> | Enables BGP on the router.                                                                            |

## Configure Allowed Networks

Configure network addresses to determine the network addresses that BGP advertises. The allowed addresses determine the BGP networks that originate from the switch.

### Before You Begin

- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

### Procedure

- Enter BGP Router Configuration mode:
 

```
enable

configure terminal

router bgp
```
- Specify IGP network prefixes for BGP to advertise:
 

```
network <WORD 1-256> [metric <0-65535>]
```

### Example

Specify IGP network prefixes for BGP to advertise:

```
Switch(router-bgp)# network 2001:DB8::/32 metric 32
```

### Variable Definitions

The following table defines parameters for the **network** command.

| Variable                | Value                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-256>     | Specifies an IP address and its length in the appropriate form.                                                                                                                               |
| <i>metric</i> <0-65535> | Specifies the metric to use when the system sends an update for the routes in the network table. The metric configures the MED for the routes advertised to eBGP peers. The range is 0-65535. |

## Configure BGP Peers or Peer Groups

Configure peers and peer groups to simplify BGP configuration and make updates more efficient.

BGP speakers can have many neighbors configured with similar update policies. For example, many neighbors use the same distribute lists, filter lists, outbound route maps, and update source. Group the neighbors that use the same update policies into peer groups and peer associations.

### Note

- If required, route policies exist.
- You configure BGPv4 on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.
- Route refresh is not currently supported on non-default VRFs.
- Not all parameters are supported on non-default VRFs.

### About This Task

Many of the command variables in this procedure use default values. You can accept the default values or change them to customize the configuration.

### Procedure

1. Enter BGP Router Configuration mode:
 

```
enable

configure terminal

router bgp
```
2. Create a peer or peer group:
 

```
neighbor WORD<0-1536>
```
3. Apply a route policy to all incoming routes:
 

```
For BGPv4: neighbor WORD<0-1536> in-route-map WORD<0-256>

For BGPv6: neighbor WORD<0-1536> ipv6-in-route-map WORD<0-256>
```

4. Apply a route policy to all outgoing routes:  
For BGPv4: `neighbor WORD<0-1536> out-route-map WORD<0-256>`  
  
For BGPv6: `neighbor WORD<0-1536> ipv6-out-route-map WORD<0-256>`
5. (Optional) Configure the source IP address:  
`neighbor WORD<0-1536> update-source WORD<1-256>`
6. Enable MD5 authentication (for BGPv4):  
`neighbor WORD<0-1536> MD5-authentication enable`
7. Specify an MD5 authentication password (for BGPv4):  
`neighbor password <nbr_ipaddr|peer-group-name> WORD<0-1536>`
8. Change the default values for other command variables as required.
9. Enable the configuration:  
`neighbor WORD<0-1536> enable`

### Example

Create a peer or a peer group:

```
Switch(router-bgp)# neighbor peergroupa
```

Apply a route policy (in-route-map or out-route-map) to all incoming or outgoing routes:

```
Switch(router-bgp)# neighbor peergroupa in-route-map map1 out-route-map map2
```

Configure the source IP address:

```
Switch(router-bgp)# neighbor peergroupa update-source 192.0.2.1
```

Enable MD5 authentication:

```
Switch(router-bgp)# neighbor peergroupa MD5-authentication enable
```

Specify an MD5 authentication password:

```
Switch(router-bgp)# neighbor password peergroupa password
```

Enable the configuration:

```
Switch(router-bgp)# neighbor peergroupa enable
```

## Variable Definitions

The following table defines parameters for the **neighbor** command.

| Variable                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>address-family</i> <ipv6>          | Enables the IPv6 address family on BGP neighbor.<br>Switch(router-bgp)# neighbor peergroupa<br>address-family ipv6                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>advertisement-interval</i> <5-120> | Specifies the time interval, in seconds, that transpires between each transmission of an advertisement from a BGP neighbor. The default value is 5 seconds.<br>Switch(router-bgp)# neighbor peergroupa<br>advertisement-interval 26 enable<br>The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or it should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained. |
| <i>allow-as-in</i>                    | Allows BGP to inject updates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>default-ipv6-originate</i>         | Enables IPv6 BGP neighbor default originate.<br>Switch(router-bgp)# neighbor peergroupa<br>default-ipv6-originate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>default-originate</i>              | Enables the switch to send a default route advertisement to the specified neighbor. A default route does not need to be in the routing table. The default value is disable.<br>Do not use this command if <b>default-information originate</b> is globally enabled.<br>Switch(router-bgp)# neighbor peergroupa<br>default-originate enable peer-group test                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>ebgp-multihop</i>                  | Enables a connection to a BGP peer that is more than one hop away from the local router. The default value is disable.<br>Switch(router-bgp)# neighbor peergroupa<br>ebgp-multihop retry-interval 3 timers 4 5                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>enable</i>                         | Enables the BGP neighbor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>fall-over bfd</i>                  | Enable fall-over Bidirectional Forwarding Detection (BFD).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>in-route-map</i> WORD<0-256>       | Applies a route policy rule to all incoming routes that are learned from, or sent to, the peers or peer groups of the local router. The local BGP router is the BGP router that allows or disallows routes and configures attributes in incoming or outgoing updates.<br>WORD<0-256> is an alphanumeric string length (0-256 characters) that indicates the name of the route map or policy.<br>Switch(router-bgp)# neighbor peergroupa<br>in-route-map map1 address-family ipv6                                                                                                                                                                                                                                                                                                                                                                      |

| Variable                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>out-route-map WORD&lt;0-256&gt;</code> | Applies a route policy rule to all outgoing routes that are learned from, or sent to, the peers or peer groups of the local router. The local BGP router is the BGP router that allows or disallows routes and configures attributes in incoming or outgoing updates.<br><code>WORD&lt;0-256&gt;</code> is an alphanumeric string length (0-256 characters) that indicates the name of the route map or policy. |
| <code>peer-group &lt;WORD 0-1536&gt;</code>  | Adds a BGP peer to the specified subscriber group. You must create the specified subscriber group before you use this command.                                                                                                                                                                                                                                                                                  |
| <code>remote-as &lt;WORD 0-11&gt;</code>     | Configures the remote AS number of a BGP peer or a peer-group. You must disable the admin-state before you can configure this variable.<br><code>Switch(router-bgp) # neighbor peergroupa remote-as As-number &lt;WORD 0-11&gt;</code> is an alphanumeric string length (0-11 characters) that indicates the AS number.                                                                                         |
| <code>remove-private-as enable</code>        | Strips private AS numbers when an update is sent. The default value is enable.                                                                                                                                                                                                                                                                                                                                  |
| <code>retry-interval &lt;1-65535&gt;</code>  | Configures the time interval, in seconds, for the ConnectRetry timer. The default value is 120 seconds.<br><code>Switch(router-bgp) # neighbor 198.51.100.2 retry-interval 34</code><br>You can configure the retry interval for BGP neighbors only; you cannot configure the retry interval for BGP peer groups.                                                                                               |
| <code>route-reflector-client</code>          | Configures the specified neighbor or group of neighbors as a route reflector client. The default value is disable. All configured neighbors become members of the client group and the remaining iBGP peers become members of the nonclient group for the local route reflector.<br><br><b>Note:</b><br>This variable only applies to VRF 0.<br><br><code>Switch(router-bgp) # neighbor</code>                  |
| <code>route-refresh</code>                   | Enables route refresh for the BGP peer. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request.<br><br><b>Note:</b><br>This variable only applies to VRF 0.                                                                                                            |
| <code>send-community</code>                  | Enables the switch to send the update message community attribute to the specified peer. The default value is disable.                                                                                                                                                                                                                                                                                          |
| <code>site-of-origin</code>                  | Specifies a site of origin that is added to the extended communities list in each route from a specific peer.                                                                                                                                                                                                                                                                                                   |

| Variable                                            | Value                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>soft-reconfiguration-in enable</code>         | Enables the router to relearn routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable.                                                                                                |
| <code>timers &lt;0-21845&gt; &lt;0-65535&gt;</code> | Configures timers, in seconds, for the BGP speaker for this peer.<br><0-21845> is the keepalive time. The default is 60. As a best practice, configure a value of 30 seconds.<br><0-65535> is the hold time. The default is 180.<br>Switch(router-bgp)# neighbor peergroupa<br>timers 4 6                |
| <code>update-source WORD&lt;1-256&gt;</code>        | Specifies the source IPv4 address {A.B.C.D.} or IPv6 address to use when the system sends BGP packets to this peer or peer group. You must disable the admin-state before you can configure this variable.<br>Switch(router-bgp)# neighbor peergroupa<br>update-source 192.0.2.2 weight 560              |
| <code>weight &lt;0-65535&gt;</code>                 | Specifies the weight of a BGP peer or peer group, or the priority of updates the router can receive from that BGP peer. The default value is 0. If you have particular neighbors that you want to use for most of your traffic, you can assign a higher weight to all routes learned from that neighbor. |
| <code>WORD&lt;0-1536&gt;</code>                     | Specifies the peer IP address or the peer group name.                                                                                                                                                                                                                                                    |

## Configure a BGP Peer or Peer Group Password

Use this procedure to configure a BGP peer or peer group password for Transmission Control Protocol (TCP) MD5 authentication between two peers.

### Note

You configure BGP peer on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix `ip bgp`. The VRF must have an RP Trigger of BGP. Route refresh is not currently supported on non-default VRFs.

### Procedure

1. Enter BGP Router Configuration mode:
 

```
enable

configure terminal

router bgp
```
2. Assign a BGP peer or peer group password:
 

```
neighbor password <nbr_ipaddr|peer-group=name> WORD <0-1536>
```

### Example

Assign a BGP peer or peer group password:

```
Switch(router-bgp)# neighbor password peergroupa password1
```

### Variable Definitions

The following table defines parameters for the **neighbor password <nbr\_ipaddr|peer-group-name>** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>password &lt;nbr_ipaddr peer-group-name&gt; WORD &lt;0-1536&gt;</code> | Specifies a password for TCP MD5 authentication between two peers.<br>WORD <0-1536> is an alphanumeric string length from 0 to 1536 characters.<br>To disable this option, use <b>no</b> operator with the command.<br>To configure this option to the default value, use <b>default</b> operator with the command. |

## Configure Redistribution to BGP

Configure a redistribution entry to announce routes of a certain source protocol type into the BGP domain such as: DvR routes, static routes, Routing Information Protocol (RIP) routes, or direct routes. Use a route policy to control the redistribution of routes.

### Note

When a route map with attributes set to `origin` and `local-pref` is applied to the BGP redistribute command, the attributes are not applied to the redistributed routes.

### Before You Begin

- If required, a route policy exists.
- You can configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

### Note

Route refresh is not currently supported on non-default VRFs.

- Before you redistribute DvR host routes to BGP, you must disable BGP aggregation and BGP auto-summarization of networks, using the commands **no ip bgp aggregation enable** and **no ip bgp auto-summary** respectively.

Disabling these settings ensures that all the DvR host routes are correctly advertised into BGP and are not summarized.

### Note

When applying a route map to an inter-vrf redistribution, the route map and any associated IP prefix lists must be configured first on the source VRF before configuring the redistribute policy on the destination VRF.

Inter-vrf redistribution is not supported on IPv6 routes.

## Procedure

1. Enter BGP Router Configuration mode:

```
enable

configure terminal

router bgp
```

2. Create a redistribution instance:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static>
```

### Note

Redistribution of ripng routes into BGP is supported only on VRF 0.

3. If required, specify a route policy to govern redistribution:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> route-map WORD<0-64> [vrf-src WORD<1-16>]
```

4. If required, configure the route metric:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> metric <0-65535> [vrf-src WORD<1-16>]
```

5. If required, configure the route metric-type:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> metric-type live-metric [vrf-src WORD<1-16>]
```

6. Enable the instance:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> enable [vrf-src WORD<1-16>]
```

7. Exit BGP Router Configuration mode:

```
exit
```

8. Apply the redistribution instance configuration:

```
For IPv4: ip bgp apply redistribute <direct|dvr|isis|ospf|rip|static>
[vrf WORD<1-16>] [vrf-src <WORD 1-16>]
```

```
For IPv6: ipv6 bgp apply redistribute <direct|dvr|isis|ospf|rip|static>
[vrf <WORD 1-16>]
```

9. Apply BGP redistribution to a specific VRF:

```
ip bgp apply redistribute vrf WORD<1-16>
```

Changes do not take effect until you apply them.

10. View all routes (including DvR host routes) that are redistributed into BGP:

View routes redistributed from GRT to BGP:

For IPv4: `show ip bgp imported-routes`

For IPv6: `show bgp ipv6 imported-routes`

View routes redistributed to BGP for a specific VRF instance:

For IPv4: `show ip bgp imported-routes [vrf WORD<1-64>] [vrfids WORD<0-512>]`

For IPv6: `show bgp ipv6 imported-routes [WORD<1-256>] [vrf WORD<1-16>] [vrfids WORD<0-255>]`

### Examples

Redistribute direct routes from the VRF instance `source1` into BGP, in the GRT context.

Create a redistribution instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bgp
Switch(router-bgp)#redistribute direct vrf-src source1
```

If required, specify a route policy to govern redistribution:

```
Switch(router-bgp)# redistribute direct route-map policy1 vrf-src source1
```

If required, configure the route metric:

```
Switch:1(router-bgp)# redistribute direct metric 4 vrf-src source1
```

Enable the instance:

```
Switch:1(router-bgp)# redistribute direct enable vrf-src source1
```

Exit BGP Router Configuration mode:

```
Switch:1(router-bgp)# exit
```

Apply the redistribution instance configuration:

```
Switch:1(config)# ip bgp apply redistribute direct vrf-src source1
```

Redistribute DvR routes from the GRT to BGP:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bgp
Switch:1(router-bgp)#redistribute dvr
Switch:1(router-bgp)#redistribute dvr enable
Switch:1(router-bgp)#exit
Switch:1(config)#ip bgp apply redistribute dvr
```

View the host routes (including DvR host routes) that are redistributed from the GRT to BGP:

```
Switch:1(config)#show ip bgp imported-routes vrf vrf1

=====
                        BGP Imported Routes - VRF vrf1

```

Redistribute DvR routes to BGP for the specific VRF instance vrf1:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router vrf vrf1
Switch:1(router-vrf)#ip bgp redistribute dvr
Switch:1(router-vrf)#ip bgp redistribute dvr enable
Switch:1(router-vrf)#exit
Switch:1(config)#ip bgp apply redistribute dvr vrf vrf1
```

View the DvR host routes that are redistributed to BGP for vrf vrf1:

```
Switch:1(config)#show ip bgp imported-routes vrf vrf1

This example demonstrates redistribution of inter-VRF routes (both direct and DvR routes) to BGP, with a route policy configured.

Redistribute inter-VRF DvR routes between VRFs (with VRF IDs 10 and 30), to BGP.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf 10
Switch:1(router-vrf)#ip prefix-list "test10" 192.0.2.0/24 ge 25 le 32
Switch:1(router-vrf)#route-map "test10" 1
Switch:1(router-vrf)#permit
Switch:1(router-vrf)#enable
Switch:1(router-vrf)#match network "test10"
Switch:1(router-vrf)#set metric 99
Switch:1(router-vrf)#exit
```

```

Switch:1(config)#router vrf 30
Switch:1(router-vrf)#ip bgp redistribute direct vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute direct enable vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute dvr vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute dvr route-map "test10" vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute dvr enable vrf-src 10
Switch:1(router-vrf)#exit

Switch:1(config)#ip bgp apply redistribute direct vrf 30 vrf-src 10
Switch:1(config)#ip bgp apply redistribute dvr vrf 30 vrf-src 10

```

### Variable Definitions

The following table defines parameters for the **redistribute** and **ip bgp apply redistribute** commands.

| Variable                                                                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;direct   dvr   ipv6-direct   ipv6-isis   ipv6-static   isis   ospf   ospfv3   rip   ripng  static &gt;</code> | Specifies the type of routes to redistribute (the protocol source).                                                                                                                                                                                                                                                                                                                             |
| <code>enable</code>                                                                                                     | Enables the BGP route redistribution instance.                                                                                                                                                                                                                                                                                                                                                  |
| <code>metric &lt;0-65535&gt;</code>                                                                                     | Configures the metric to apply to redistributed routes.                                                                                                                                                                                                                                                                                                                                         |
| <code>metric-type live-metric</code>                                                                                    | Configures the metric type to apply to redistributed routes. When you enable the live-metric option, when BGP redistributes static, RIP, OSPF, IS-IS, or DvR routes, the metric value is taken from the routing table and is set to the Path attributes as a MED value. By default, this option is disabled, which means the BGP MED value is not derived from the metric in the routing table. |
| <code>route-map WORD&lt;0-64&gt;</code>                                                                                 | Configures the route policy to apply to redistributed routes.                                                                                                                                                                                                                                                                                                                                   |

| <code>vrf-src WORD&lt;1-16&gt;</code>                                                                                   | Specifies the source VRF instance by name for route redistribution.                                                                                                                                                                                                                                                                                                                             |

## Configure redistribution to BGP+ for VRF 0

Configure an IPv6 redistribute entry to announce IPv6 routes of a certain source protocol type into the BGP domain, for example, static, OSPF, IS-IS, RIPng, or direct routes. Use a route policy to control the redistribution of routes.

### Note

When a route map with attributes set to `origin` and `local-pref` is applied to the BGP redistribute command, the attributes are not applied to the redistributed routes.

### Before You Begin

- If required, a route policy exists.

## Procedure

1. Enter BGP Router Configuration mode:

```
enable

configure terminal

router bgp
```

2. Create a redistribution instance:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
ospfv3|rip|ripng|static>
```

3. If required, specify a route policy to govern redistribution:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
ospfv3|rip|ripng|static> route-map WORD <0-64>
```

4. If required, configure a route metric:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
ospfv3|rip|ripng|static> metric <0-65535>
```

5. Enable the instance:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
ospfv3|rip|ripng|static> enable
```

Unlike IPv4 redistribution, you do not need to manually apply the IPv6 redistribution instance. Once you enable the IPv6 redistribution instance, it is automatically applied.

## Example

Specify a route policy to govern redistribution by using the following command:

```
Switch:1(router-bgp)#redistribute ipv6-direct route-map policy2
```

### Variable Definitions

The following table defines parameters for the **redistribute <ipv6-direct|ipv6-static|ospfv3|ipv6-isis|ripng>** command.

| Variable                           | Value                                                                                                                                                                                                                                         |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>                      | Enables the BGP route redistribution instance. The default value is none.<br>To configure this option to the default value, use <b>default</b> operator with the command.<br>To disable this option, use <b>no</b> operator with the command. |
| <i>metric&lt;0-65535&gt;</i>       | Configures the metric to apply to redistributed routes. The default value is 0.<br>To configure this option to the default value, use <b>default</b> operator with the command.                                                               |
| <i>route-map &lt;Word 0-64&gt;</i> | Configures the route policy to apply to redistributed routes. The default value is none.<br>To configure this option to the default value, use <b>default</b> operator with the command.                                                      |

## Job Aid

Use the data in the following table to know how route policies are used for BGP from IPv6 perspective.

**Table 58: BGP for IPv6 Route Policy Support**

|                  | REDISTRIBUTE |             |        |            |       | ACCEPT | ANNOUNCE |
|------------------|--------------|-------------|--------|------------|-------|--------|----------|
|                  | IPv6 Direct  | IPv6 Static | OSPFv3 | IPv6 IS-IS | RIPng | BGP    | BGP      |
| MATCH            |              |             |        |            |       |        |          |
| as-path          |              |             |        |            |       | Yes    | Yes      |

## Configure AS Path Lists

Configure an AS path list to restrict the routing information a router learns or advertises to and from a neighbor. The AS path list acts as a filter that matches AS paths.

### Before You Begin

- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

#### Note

Route refresh is not currently supported on non-default VRFs.

### Procedure

- Enter BGP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router bgp
```

- Create the path list:

```
ip as-list <1-1024> memberid <0-65535> <permit|deny> as-path WORD<0-1536>
```

Use this command for each member by specifying different member IDs.

### Example

Create the path list:

```
Switch(config)# ip as-list 234 memberid 3456 permit as-path "5"
```

### Variable Definitions

The following table defines parameters for the **ip as-list** command.

| Variable      | Value                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------|
| <0-65535>     | Specifies an integer value between 0-65535 that represents the regular expression entry in the AS path list.      |
| <1-1024>      | Specifies an integer value from 1-1024 that represents the AS-path list ID you want to create or modify.          |
| <permit deny> | Permits or denies access for matching conditions.                                                                 |
| WORD<0-1536>  | Specifies the AS number as an integer value between 0-1536. Place multiple AS numbers within quotation marks ("). |

## Configure Community Lists

Configure community lists to specify permitted routes by using their BGP community. This list acts as a filter that matches communities or AS numbers.

### Before You Begin

- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

#### Note

Route refresh is not currently supported on non-default VRFs.

### Procedure

- Enter BGP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router bgp
```

- Create a community list:

```
ip community-list <1-1024> memberid <0-65535> <permit|deny> community-string WORD<0-256>
```

### Example

Create a community list:

```
Switch(config)# ip community-list 1 memberid 4551 permit community-string internet
```

### Variable Definitions

The following table defines parameters for the **ip community-list** command.

| Variable      | Value                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0-65535>     | Specifies an integer value from 0-65535 that represents the member ID in the community list.                                                                                                                                                                                                                                                                                               |
| <1-1024>      | Specifies an integer value from 1-1024 that represents the community list ID.                                                                                                                                                                                                                                                                                                              |
| <permit deny> | Configures the access mode, which permits or denies access for matching conditions.                                                                                                                                                                                                                                                                                                        |
| WORD<0-256>   | Specifies the community as an alphanumeric string value with a string length from 0-256 characters. Enter this value in one of the following formats: <ul style="list-style-type: none"> <li>(AS num:community-value)</li> <li>(well-known community string)</li> </ul> <p>Well known communities include: internet, no-export, no-advertise, local-as (known as NO_EXPORT_SUBCONFED).</p> |

## Configure Extended Community Lists

Configure community lists to specify permitted routes by BGP extended community attributes, including route targets and sites of origin (SOO). This list acts as a filter that matches route targets and SOO.

### Before You Begin

- Configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

#### Note

Route refresh is not currently supported on non-default VRFs.

### Procedure

- Enter BGP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router bgp
```

- Create an extended community list based on the route target attribute:

```
ip extcommunity-list <1-1024> memberId <0-65535> rt {<0-65535>
<0-2147483647>|<A.B.C.D> <0-65535>} [soo {<0-65535> <0-2147483647>|
<A.B.C.D> <0-65535>}]
```

You can optionally configure the SOO attributes at the end of the same command or you can configure the SOO separately using the syntax in the following step.

3. Create an extended community list based on the SOO attribute:

```
ip extcommunity-list <1-1024> memberId <0-65535> soo {<0-65535>
<0-2147483647>|<A.B.C.D> <0-65535>}
```

### Example

Create an extended community list based on the route target attribute:

```
Switch(config)# ip extcommunity-list 1 memberid 234 rt 192.0.2.1 5 soo
32 45
```

### Variable Definitions

The following table defines parameters for the **ip extcommunity-list** command.

| Variable                                                              | Value                                                                                                                                                                     |
|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-1024>                                                              | Specifies an integer value from 1-1024 that represents the community list ID you want to create or modify.                                                                |
| <i>memberId</i> <0-65535>                                             | Specifies an integer value from 0-65535 that represents the member ID in the community list.                                                                              |
| <i>rt</i> <0-65536> <0-2147483647><br><i>rt</i> <A.B.C.D> <0-65535>   | Specifies the route target in the format {AS number:assigned number} (that is, {0-65535}:{0-2147483647}) or {ipaddress:assigned number} (that is, {a.b.c.d}:{0-65535}).   |
| <i>soo</i> <0-65535> <0-2147483647><br><i>soo</i> <A.B.C.D> <0-65535> | Specifies the site of origin in the format {AS number:assigned number} (that is, {0-65535}:{0-2147483647}) or {ipaddress:assigned number} (that is, {a.b.c.d}:{0-65535}). |

## Configure an AS Number for a Non-default VRF

The Autonomous System (AS) number configured on the global Virtual Routing Forwarding (VRF) instance, called the GlobalRouter (GRT), is inherited by all user-created VRFs by default, however, you can override the AS number for the specific VRF instance using the following procedure.

### Before You Begin

- Disable BGP synchronization.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Set the AS number:

```
ip bgp vrf-as WORD<0-11>
```

### Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
Switch:1(config)#router vrf vrfred
Switch:1(router-vrf)#ip bgp vrf-as 3
```

### Variable Definitions

The following table defines parameters for the **ip bgp vrf-as** command.

| Variable                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;0-11&gt;</code> | <p>Configures the local autonomous system (AS) number for the specific VRF instance. You cannot change local-as when BGP is set to enable.</p> <ul style="list-style-type: none"> <li>To configure a 2-byte local AS number, enter a local-as number in the range of 0 to 65535.</li> <li>To configure a 4-byte local-as number, enable the 4-byte as variable and enter a number in the range of 0 to 4294967295.</li> </ul> <p><b>Note:</b><br/>If as-4-byte is configured to false, the range for AS number is 0-65535 and if as-4-byte is configured to true, the range is 0-4294967295.</p> <p>If you enable as-dot, enter the AS number in octets in the range of 1.0 to 65535.65535.<br/>The AS number in a specific VRF instance inherits the AS number in the GlobalRouter in the following instances:</p> <ul style="list-style-type: none"> <li>Configuring the AS number in a specific VRF instance to 0 (<b>ip bgp vrf-as 0</b>).</li> <li>Deleting the AS number in a specific VRF instance (<b>no ip bgp vrf-as</b> or <b>default ip bgp vrf-as</b>).</li> </ul> |

## BGP Verification Using CLI

Use **show** commands to verify Border Gateway Protocol (BGP) configuration and to monitor or troubleshoot BGP operation.

### Note

If the next hop of a BGP route is resolved using an IS-IS route, show commands can display the IS-IS internal next hop from the 127.1.x.y class rather than the IS-IS sys name.

### Viewing BGP aggregate information

Display information about current aggregate addresses.

#### Procedure

- To enter User EXEC mode, log on to the switch.
- Display information about current aggregates:

```
show ip bgp aggregates [<prefix/len>] [vrf WORD <1-16>] [vrfids
WORD<0-255>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp aggregates** command.

| Variable                              | Value                                         |
|---------------------------------------|-----------------------------------------------|
| <code>&lt;prefix/len&gt;</code>       | Specifies the IP address and the mask length. |
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF instance by name.             |
| <code>vrfids WORD&lt;0-255&gt;</code> | Specifies a range of VRFs by ID number.       |

## Viewing IPv6 BGP+ aggregate information

Display information about current IPv6 aggregate addresses.

### About This Task

Use BGP 4 byte AS numbers to ensure the continuity of loop-free inter-domain routing information between ASs and to control the flow of BGP updates as 2 byte AS numbers will deplete soon.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about current IPv6 aggregates:

```
show bgp ipv6 aggregates [<WORD 1-256>] [vrf <WORD 1-16>] [vrfids
<0-255>]
```

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 aggregates** command.

| Variable                           | Value                                                                             |
|------------------------------------|-----------------------------------------------------------------------------------|
| <code>WORD &lt;1-256&gt;</code>    | Specifies the IPv6 prefix and the prefix length (the length can be 0 to 128).     |
| <code>vrf WORD &lt;1-16&gt;</code> | Specifies a VRF instance by name (the string length ranges from 1-16 characters). |
| <code>vrfids &lt;0-255&gt;</code>  | Specifies a range of VRFs by ID number (the ID ranges from 0-255).                |

## Viewing CIDR routes

Display information about classless interdomain routing (CIDR) routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about CIDR routes:

```
show ip bgp cidr-only [<prefix/len>] [vrf WORD<1-16>] [vrfids WORD<0-
512>]
```

## Variable Definitions

The following table defines parameters for the **show ip bgp cidr-only** command.

| Variable           | Value                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <prefix/len>       | Specifies an exact match of the prefix. This variable is an IP address and an integer value from 0-32 in the format a.b.c.d/xx. |
| vrf WORD<1-16>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters).                                               |
| vrfids WORD<0-512> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                                                              |

## View BGP Configuration

View information about the BGP configuration.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about the current BGP configuration:  

```
show ip bgp conf [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

```

=====
                        BGP Configuration - VRF vrf1
=====

                        BGP version - 4
                          local-as - 22610
                          Identifier - 27.82.217.1
                          BGP on/off - ON
                          as-4-byte - disable
                          as-dot - disable
                          aggregation - enable
                          always-cmp-med - disable
                          auto-peer-restart - enable
                          auto-summary - enable
                          comp-bestpath-med-confed - disable
                          default-local-preference - 100
                          default-metric - -1
                          deterministic-med - disable
                          flap-dampening - disable
                          debug-screen - Off
                          global-debug - none
                          ibgp-report-import-rt - enable
                          ignore-illegal-rtrid - enable
                          max-equalcost-routes - 1
                          no-med-path-is-worst - enable
                          route-refresh - disable
                          orig-def-route - disable
                          orig-v6-def-route - disable
                          quick-start - disable
                          synchronization - enable

--More-- (q = quit)

```

### Variable Definitions

The following table defines parameters for the **show ip bgp conf** command.

| Variable                        | Value                                                                             |
|---------------------------------|-----------------------------------------------------------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters). |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                |

## Viewing BGP confederation

Display information about BGP confederations.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about current BGP confederations:

```
show ip bgp confederation
```

### Example

```
Switch(config)#show ip bgp confederation
confederation identifier 0
confederation peer as
```

## Viewing flap-dampened routes

Display information about flap-dampened routes to determine unreliable routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about flap-dampened routes:

```
show ip bgp dampened-paths {A.B.C.D} [<prefix/len>] [longer-prefixes]
[vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp dampened-paths** command.

| Variable                  | Value                                                                                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D}</i>          | Specifies the source IP address in the format a.b.c.d.                                                                                                    |
| <i>longer-prefixes</i>    | Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32). |
| <i>&lt;prefix/len&gt;</i> | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32).                                    |

| Variable                              | Value                                                                             |
|---------------------------------------|-----------------------------------------------------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters). |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                |

## Viewing global flap-dampening configurations

Display global information about flap-dampening.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display global information about flap-dampening:

```
show ip bgp flap-damp-config [prefix/len] [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

### Example

```
Switch(config)# show ip bgp flap-damp-config vrf vrf1
```

```
=====
                        BGP Flap Dampening - VRF vrf1
=====
                                Status - enable
                                PolicyName - N/A
                                CutoffThreshold - 1536
                                ReuseThreshold - 512
                                Decay - 2
                                MaxHoldDown - 180
```

### Variable Definitions

The following table defines parameters for the **show ip bgp flap-damp-config** command.

| Variable                              | Value                                                                                                                  |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;prefix/len&gt;</code>       | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32). |
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters).                                      |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                                                     |

## Viewing imported routes

Display information about BGP imported routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display information about BGP imported routes:

```
show ip bgp imported-routes [<prefix/len>] [longer-prefixes] [vrf
WORD<1-16>] [vrfids WORD<0-512>]
```

#### Variable Definitions

The following table defines parameters for the **show ip bgp imported-routes** command.

| Variable                        | Value                                                                                                                                                     |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>longer-prefixes</i>          | Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32). |
| <i>&lt;prefix/len&gt;</i>       | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).                                    |
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies a VRF instance by name (the string length ranges from 1–16 characters).                                                                         |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies a range of VRFs by ID number (the ID ranges from 0–512).                                                                                        |

## Viewing BGPv6 imported routes

Display information about BGPv6 imported routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGPv6 imported routes:

```
show bgp ipv6 imported-routes [<prefix/len>] [longer-prefixes] [vrf
WORD<1-16>] [vrfids WORD<0-255>]
```

#### Variable Definitions

The following table defines parameters for the **show bgp ipv6 imported-routes** command.

| Variable                        | Value                                                                                                                                                     |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>longer-prefixes</i>          | Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32). |
| <i>&lt;prefix/len&gt;</i>       | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).                                    |
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies a VRF instance by name (the string length ranges from 1–16 characters).                                                                         |
| <i>vrfids WORD&lt;0-255&gt;</i> | Specifies a range of VRFs by ID number (the ID ranges from 0–255).                                                                                        |

## View BGP Neighbors Information

Display information about BGP neighbors.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP neighbors:
 

```
show ip bgp neighbors [{A.B.C.D}] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
3. Display information about BGP peer advertised routes:
 

```
show ip bgp neighbors {A.B.C.D} advertised-routes [<prefix/len>] [longer-prefixes] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
4. Display information about BGP peer routes:
 

```
show ip bgp neighbors {A.B.C.D} routes [<prefix/len>] [community <enable|disable>] [longer-prefixes] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
5. Display statistics for BGP peers:
 

```
show ip bgp neighbors {A.B.C.D} stats [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

## Example

```
Switch:#show ip bgp neighbors vrf vrf1

=====

### Variable Definitions

The following table defines parameters for the **show ip bgp neighbors** command.

| Variable                                | Value                                                                                                                                                     |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D}</i>                        | Specifies the IP address.                                                                                                                                 |
| <i>community &lt;enable disable&gt;</i> | Enables or disables the display of community attributes.                                                                                                  |
| <i>longer-prefixes</i>                  | Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32). |
| <i>prefix/len</i>                       | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32).                                    |
| <i>vrf WORD&lt;1-16&gt;</i>             | Specifies a VRF instance by name.                                                                                                                         |
| <i>vrfids WORD&lt;0-512&gt;</i>         | Specifies a range of VRFs by ID number.                                                                                                                   |

## Viewing BGPv6 neighbors information

View information about BGPv6 neighbors.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View information about BGPv6 neighbors:  

```
show bgp ipv6 neighbors [WORD<1-256>] [vrf <WORD 1-16>] [vrfids <0-255>]
```
3. View information about BGPv6 peer advertised routes:  

```
show bgp ipv6 neighbors WORD<1-256> advertised-routes [WORD<1-256>] [longer-prefixes] [vrf <WORD 1-16>] [vrfids <0-255>]
```
4. View information about BGPv6 peer routes:  

```
show bgp ipv6 neighbors WORD<1-256> routes [WORD<1-256>] [community <enable|disable>] [vrf <WORD 1-16>] [vrfids <0-255>]
```

### Example

The following examples shows the summary output for **show bgp ipv6 neighbors** command, and the *advertised-routes* and *routes* variable options.

```
Switch:1>show bgp ipv6 neighbors vrf vrf1

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 neighbors** command.

| Variable                 | Value                                          |
|--------------------------|------------------------------------------------|
| <i>WORD</i> <1-256>      | Specifies the IPv6 address.                    |
| <i>advertised-routes</i> | Specifies an IPv6 neighbors advertised routes. |
| <i>routes</i>            | Specifies an IPv6 neighbors routes.            |
| <i>WORD</i> <1-256>      | Specifies an IPv6 address/length.              |

| Variable                                | Value                                                                                                                                                           |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>longer-prefixes</i>                  | Shows long prefixes. The longer-prefixes indicate the mask length from any specified prefix to 128. For example, show from prefix :X::X:X/len to X:X::X/X/ 128. |
| <i>community &lt;enable disable&gt;</i> | Enables or disables the display of community attributes.                                                                                                        |
| <i>vrf</i>                              | Specifies a VRF instance by name (the string length ranges from 1-16 characters).                                                                               |
| <i>vrfids</i>                           | Specifies a range of VRFs by ID number (the ID ranges from 0-255).                                                                                              |

## Viewing BGP network configurations

Display information about BGP network configurations.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP network configurations:

```
show ip bgp networks [<prefix/len>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp networks** command.

| Variable                        | Value                                                                                                                  |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <prefix/len>                    | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32). |
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters).                                      |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                                                     |

## Viewing IPv6 BGP+ network configurations

Display information about BGP+ network configurations.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP+ network configurations:

```
show bgp ipv6 networks <WORD 1-256> [vrf <WORD 1-16>] [vrfids <0-255>]
```

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 networks** command.

| Variable     | Value                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------|
| <WORD 1-256> | Specifies the IPv6 prefix and the prefix length (must be an integer value between 0 and 128). |
| vrf          | Specifies a VRF instance by name (the string length ranges from 1-16 characters).             |
| vrfids       | Specifies a range of VRFs by ID number (the ID ranges from 0-255).                            |

## Viewing BGP peer group information

Display information about BGP peer groups.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP peer groups:

```
show ip bgp peer-group [WORD<0-1536>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp peer-group** command.

| Variable           | Value                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------|
| vrf WORD<1-16>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters).       |
| vrfids WORD<0-512> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                      |
| WORD<0-1536>       | Specifies the name of the peer group (the string length ranges from 0-1536 characters). |

## Viewing BGP redistributed routes

Display information about BGP redistributed routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP redistributed routes:

```
show ip bgp redistributed-routes [<prefix/len>] [vrf WORD<1-16>]
[vrfids WORD<0-512>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp redistributed-routes** command.

| Variable                              | Value                                                                                                                  |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;prefix/len&gt;</code>       | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32). |
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF instance by name (the string length ranges from 1–16 characters).                                      |
| <code>vrfids WORD&lt;0-255&gt;</code> | Specifies a range of VRFs by ID number (the ID ranges from 0–255).                                                     |

## Viewing BGPv6 redistributed routes

Display information about BGPv6 redistributed routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGPv6 redistributed routes:

```
show bgp ipv6 redistributed-routes [vrf <WORD 1-16>] [vrfids <0-255>]
```

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 redistributed-routes** command.

| Variable            | Value                                                                             |
|---------------------|-----------------------------------------------------------------------------------|
| <code>vrf</code>    | Specifies a VRF instance by name (the string length ranges from 1–16 characters). |
| <code>vrfids</code> | Specifies a range of VRFs by ID number (the ID ranges from 0–255).                |

## View a Summary of BGP Configurations

Display summarized information about BGP.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display summarized information about BGP:

```
show ip bgp summary [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

The following example shows partial output for the **show ip bgp summary** command.

```
Switch:1>show ip bgp summary vrf vrf1
```

```
=====
BGP Summary - VRF vrf1
```

```

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 summary** command.

| Variable | Value                                                                             |
|----------|-----------------------------------------------------------------------------------|
| vrf      | Specifies a VRF instance by name (the string length ranges from 1-16 characters). |
| vrfids   | Specifies a range of VRFs by ID number (the ID ranges from 0-255).                |

## Viewing BGP routes

Display information about BGP routes.

### Note

BGP stores route information on the AVL tree and this command retrieves that information. Information in the AVL tree is not sorted. The information returned by this command will not be displayed in any particular order.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP routes:

```

show ip bgp route [<prefix/len>] [community <enable|disable>] [ip
{A.B.C.D}] [longer-prefixes] [vrf WORD<1-16>] [vrfids WORD<0-512>]

```

### Variable Definitions

The following table defines parameters for the **show ip bgp route** command.

| Variable                          | Value                                                                                                                                                  |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>community</i> <enable disable> | Enables or disables the display of community attributes.                                                                                               |
| <i>ip</i> {A.B.C.D}               | Specifies an IP address.                                                                                                                               |
| <i>longer-prefixes</i>            | Shows long prefixes. Longer-prefixes indicates the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32). |
| <prefix/len>                      | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32).                                 |
| <i>vrf</i> WORD<1-16>             | Specifies a VRF instance by name.                                                                                                                      |
| <i>vrfids</i> WORD<0-512>         | Specifies a range of VRFs by ID number.                                                                                                                |

## Viewing BGPv6 routes

Display information about BGPv6 routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Enter Privileged EXEC mode:  
enable
3. Display information about BGP routes:

```
show bgp ipv6 route [<WORD 1-256> [longer-prefixes]] [community
<enable|disable>] [ipv6 <WORD 1-256>] [vrf <WORD 1-16>] [vrfids
<0-255>]
```

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 route** command.

| Variable                          | Value                                                                                                                                                            |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [<WORD 1-256>]                    | Specifies the IPv6 prefix and the prefix length (must be an integer value between 0 and 128).                                                                    |
| <i>community</i> <enable disable> | Enables or disables the display of community attributes.                                                                                                         |
| <i>ipv6</i> <WORD 1-256>]         | Specifies an IPv6 address.                                                                                                                                       |
| <i>longer-prefixes</i>            | Shows long prefixes. The longer-prefixes indicate the mask length from any specified prefix to 128 (for example, show from prefix X:X::X:X/len to X:X::X/X/128). |
| <i>vrf</i>                        | Specifies a VRF instance by name (the string length ranges from 1-16 characters).                                                                                |
| <i>vrfids</i>                     | Specifies a range of VRFs by ID number (the ID ranges from 0-255).                                                                                               |

## BGP configuration using EDM

Configure Border Gateway Protocol (BGP) to create an inter-domain routing system that guarantees loop-free routing information between autonomous systems.

For information about how to configure route policies, see [Configure a Route Policy](#) on page 2900.

### Configure BGP

Enable BGP so that BGP runs on the router. Configure general BGP parameters to define how BGP operates on the system.

#### Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Generals** tab.
4. In AdminStatus, select **enable**.
5. Configure the local autonomous system (AS) ID.
6. In the **Aggregate** area, enable or disable route aggregation as required.
7. Configure the BGP options as required.
8. In the **DebugMask** area, select the check box for the type of information to show for BGP debugging purposes.
9. Configure BGP confederations as required.
10. Configure BGP route reflectors as required.
11. Click **Apply**.

#### *Generals Field Descriptions*

Use the data in the following table to use the **Generals** tab.

| Name               | Description                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bgpVersion</b>  | Specifies the version of BGP that operates on the router.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                              |
| <b>Identifier</b>  | Specifies the BGP router ID number.                                                                                                                 |
| <b>AdminStatus</b> | Enables or disables BGP on the router. The default is disable. You cannot enable AdminStatus until you change the LocalAS value to a nonzero value. |

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>4ByteAs</b>                | <p>Enables or disables 4-byte AS numbers. The default is disable.</p> <p><b>Note:</b><br/>This parameter only applies to VRF 0.</p>                                                                                                                                                                                                                                                                                       |
| <b>LocalAs</b>                | <p>Configures the local AS number in the range of 0–65535. You cannot change the LocalAs value if AdminStatus is enable.</p> <p><b>Note:</b><br/>If the inserted LocalAs is 0, then the LocalAs in that VRFcontext loses its significance and it becomes the LocalAs configured in GlobalRouter (the equivalence to CLI commands <b>ip bgp vrf-as 0</b> and <b>no ip bgp vrf-as</b> or <b>default ip bgp vrf-as</b>).</p> |
| <b>AsDot</b>                  | <p>Enables or disable the AS dot notation format for the 4-byte AS number. The default is disable.</p> <p>The AS dot notation is easier to read and remember than the AS plain notation, but it can be difficult to convert from AS plain to AS dot. The IETF prefers the AS plain notation.</p> <p><b>Note:</b><br/>This parameter only applies to VRF 0.</p>                                                            |
| <b>Aggregate</b>              | Enables or disables aggregation. The default is enable.                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DefaultMetric</b>          | <p>Configures the metric sent to BGP neighbors. The default metric determines the cost of a route a neighbor uses. Use this parameter in conjunction with the redistribute parameters so that BGP uses the same metric for all redistributed routes.</p> <p>The default is -1. The range is -1-2147483647.</p>                                                                                                            |
| <b>DefaultLocalPreference</b> | <p>Specifies the default local preference. The local preference indicates the preference that AS border routers assign to a chosen route when they advertise it to iBGP peers. The default is 100. The range is 0–2147483647.</p>                                                                                                                                                                                         |
| <b>AlwaysCompareMed</b>       | <p>Enables or disables the comparison of the multi-exit discriminator (MED) parameter for paths from neighbors in different autonomous systems. The system prefers a path with a lower MED over a path with a higher MED. The default is disable.</p>                                                                                                                                                                     |
| <b>DeterministicMed</b>       | <p>Enables or disables deterministic MED. Deterministic MED compares the MEDs after routes advertised by different peers in the same AS are chosen. The default is disable.</p>                                                                                                                                                                                                                                           |
| <b>AutoPeerRestart</b>        | <p>Enables or disables the process that automatically restarts a connection to a BGP neighbor. The default is enable.</p>                                                                                                                                                                                                                                                                                                 |
| <b>AutoSummary</b>            | <p>Enables or disables automatic summarization. If you enable this variable, BGP summarizes networks based on class limits (for example, Class A, B, or C networks). The default is enable.</p>                                                                                                                                                                                                                           |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NoMedPathsWorst</b>       | Enables or disables NoMedPathsWorst. If you enable this variable, BGP treats an update without a MED attribute as the worst path. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>BestPathMedConfed</b>     | Enables or disables the comparison of MED attributes within a confederation. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DebugMask</b>             | Displays the specified debug information for BGP global configurations. The default value is none. Other options are <ul style="list-style-type: none"> <li>• none disables all debug messages.</li> <li>• event enables the display of debug event messages.</li> <li>• state enables display of debug state transition messages.</li> <li>• update enables display of debug messages related to updates transmission and reception.</li> <li>• error enables the display of debug error messages.</li> <li>• trace enables the display of debug trace messages.</li> <li>• init enables the display of debug initialization messages.</li> <li>• all enables all debug messages.</li> <li>• packet enables the display of debug packet messages.</li> <li>• warning enables the display of debug warning messages.</li> <li>• filter enables the display of debug messages related to filtering.</li> </ul> |
| <b>IgnoreIllegalRouterId</b> | Enables BGP to overlook an illegal router ID. For example, this variable enables the acceptance of a connection from a peer that sends an open message using a router ID of 0. The default is enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Synchronization</b>       | Enables or disables the router to accept routes from BGP peers without waiting for an update from the IGP. The default is enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>MaxEqualcostRoutes</b>    | Configures the maximum number of equal-cost-paths that are available to a BGP router by limiting the number of equal-cost-paths the routing table can store. The default value is 1; the range is 1-8.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>IbgpReportImportRoute</b> | Configures BGP to report imported routes to an interior BGP (iBGP) peer. This variable also enables or disables reporting of non-BGP imported routes to other iBGP neighbors. The default is enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>FlapDampEnable</b>        | Enables or disables route suppression for routes that go up and down (flap). The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>QuickStart</b>            | Enables or disables the Quick Start feature, which forces the BGP speaker to begin establishing peers immediately, instead of waiting for the auto-restart timer to expire. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>TrapEnable</b>            | Enables or disables the BGP traps. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Name                                     | Description                                                                                                                                                                                                                                                                                      |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ConfederationASIdentifier</b>         | Specifies a BGP confederation identifier in the range of 0-65535.<br><br><b>Note:</b><br>This parameter applies only to VRF 0.                                                                                                                                                                   |
| <b>ConfederationPeers</b>                | Lists adjoining autonomous systems that are part of the confederation in the format (5500,65535,0,10,...).. This value can use 0-255 characters.<br><br><b>Note:</b><br>This parameter applies only to VRF 0.                                                                                    |
| <b>RouteReflectionEnable</b>             | Enables or disables the reflection of routes from iBGP neighbors. The default is enable.<br><br><b>Note:</b><br>This parameter applies only to VRF 0.                                                                                                                                            |
| <b>RouteReflectorClusterId</b>           | Configures a reflector cluster ID IP address. This variable applies only if you enable RouteReflectionEnable, and if multiple route reflectors are in a cluster.<br><br><b>Note:</b><br>This parameter applies only to VRF 0.                                                                    |
| <b>ReflectorClientToClientReflection</b> | Enables or disables route reflection between two route reflector clients. This variable applies only if RouteReflectionEnable is enable. The default is enable.<br><br><b>Note:</b><br>This parameter applies only to VRF 0.                                                                     |
| <b>RouteRefresh</b>                      | Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request.<br><br><b>Note:</b><br>This parameter only applies to VRF 0. |

## Configure 4-byte AS numbers

Configure AS numbers using the 4-byte format and represent the numbers in octets.

### Before You Begin

- You cannot modify the global BGP configuration unless BGP is disabled.
- Make sure that you define AS numbers in policies the same way that you configure them for the router. The choices are asplain (regular expression) or asdot (dot notation). If you create policies using asplain and configure the switch with asdot, the match will not occur.

## About This Task

Use BGP 4-byte AS numbers to ensure the continuity of loop-free inter-domain routing information between autonomous systems and to control the flow of BGP updates as 2 byte AS numbers will deplete soon. AS Plain notation format is the default and the preferred form of representing 4-byte AS numbers over the AS dot notation format.

You have an option to configure AS dot notation format as well. With AS dot notation, analyzing and troubleshooting any issues encountered becomes difficult as it is incompatible with the regular expressions used by most of the network providers.

If you enable 4-byte AS numbers, or the dotted octet notation, for the Global Router (VRF0), the configuration is inherited by user-defined VRFs. You cannot enable 4-byte AS numbers on individual user-defined VRFs.

## Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Generals** tab.
4. To change the AS number format, select **disable** for **AdminStatus**.
5. Select **Apply**.
6. In **4-byteAs**, select **enable**.
7. In **AsDot**, select **enable**.
8. In **LocalAs**, type the 4-byte AS number in octets.
9. In **AdminStatus**, select **enable**.
10. Select **Apply**.

### 4-byte AS Field Descriptions

Use the data in the following table to use the 4-byte AS related fields on the **Generals** tab.

| Name           | Description                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LocalAs</b> | Configures the local autonomous system (AS) number. You cannot change this field when AdminStatus is set to enable. This field sets a 2-byte local AS number in the range from 0 to 65535. To set a 4-byte local AS number, click enable in the 4ByteAs field and enter a number in the LocalAs field.<br>Attention: The switch does not support this parameter with BGP +. |
| <b>4byteAs</b> | Enables or disables the switch from using 4 byte numbers for autonomous systems.                                                                                                                                                                                                                                                                                            |
| <b>AsDot</b>   | Enables or disables representing AS numbers in octets. The default is disable so the switch uses the plain notation format. If you enable this field and the 4ByteAs field, enter the AS number in the LocalAs field.<br>Attention: The switch does not support this parameter with BGP +.                                                                                  |

## Viewing BGP Global Stats

View BGP global stats.

### Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **BGP**.
3. Click the **Global Stats** tab.

### Global Stats Field Descriptions

Use the data in the following table to use the BGP Global Stats tab.

| Name                 | Description                                                  |
|----------------------|--------------------------------------------------------------|
| <b>AbsoluteValue</b> | Displays the counter value.                                  |
| <b>Cumulative</b>    | Displays the total value since you opened the Stats tab.     |
| <b>Average/sec</b>   | Displays the average value for each second.                  |
| <b>Minimum/sec</b>   | Displays the minimum value for each second.                  |
| <b>Maximum/sec</b>   | Displays the maximum value for each second.                  |
| <b>LastVal/sec</b>   | Displays the last value for each second.                     |
| <b>Starts</b>        | Displays the number of times the BGP connection started.     |
| <b>Stops</b>         | Displays the number of times the BGP connection stopped.     |
| <b>Opens</b>         | Displays the number of times BGP opens TCP.                  |
| <b>Closes</b>        | Displays the number of times BGP closes TCP.                 |
| <b>Fails</b>         | Displays the number of times TCP attempts failed.            |
| <b>Fatals</b>        | Displays the number of times TCP crashes due to fatal error. |
| <b>ConnExps</b>      | Displays the number of times the TCP retry timer expired.    |
| <b>HoldExps</b>      | Displays the number of times the hold timer expired.         |
| <b>KeepExps</b>      | Displays the number of times the keepalive timer expired.    |
| <b>RxOpens</b>       | Displays the number of open instances BGP receives.          |
| <b>RxKeeps</b>       | Displays the number of keepalive instances BGP receives.     |
| <b>RxUpdates</b>     | Displays the number of update instances BGP receives.        |
| <b>RxNotifys</b>     | Displays the number of notification instances BGP receives.  |
| <b>TxOpens</b>       | Displays the number of open instances BGP transmitted.       |
| <b>TxKeeps</b>       | Displays the number of keepalive instances BGP transmitted.  |
| <b>TxUpdates</b>     | Displays the number of updates instances BGP transmits.      |
| <b>TxNotifys</b>     | Displays the number of notification instances BGP transmits. |
| <b>BadEvents</b>     | Displays the number of invalid events FSM received.          |
| <b>SyncFails</b>     | Displays the number of times FDB sync failed.                |
| <b>TrEvent</b>       | Displays the trace event.                                    |

| Name                                | Description                                                    |
|-------------------------------------|----------------------------------------------------------------|
| <b>RxECodeHeader</b>                | Displays the total header errors received.                     |
| <b>RxECodeOpen</b>                  | Displays the total open errors received.                       |
| <b>RxECodeUpdate</b>                | Displays the total update errors received.                     |
| <b>RxECodeHoldtimer</b>             | Displays the total hold timer errors received.                 |
| <b>RxECodeFSM</b>                   | Displays the total FSM errors received.                        |
| <b>RxECodeCease</b>                 | Displays the total cease errors received.                      |
| <b>RxHdrCodeNoSync</b>              | Displays the header not synchronized errors received.          |
| <b>RxHdrCodeInvalidMsgLen</b>       | Displays the header invalid message length errors received.    |
| <b>RxHdrCodeInvalidMsgType</b>      | Displays the header invalid message type errors received.      |
| <b>RxOpCodeBadVer</b>               | Displays the open errors received for Bad Version.             |
| <b>RxOpCodeBadAs</b>                | Displays the open errors received for le Bad AS Number.        |
| <b>RxOpCodeBadRtID</b>              | Displays the open errors received for Bad BGP Rtr ID.          |
| <b>RxOpCodeUnsuppOption</b>         | Displays the open errors received for Unsupported Option.      |
| <b>RxOpCodeAuthFail</b>             | Displays the open errors received for Auth Failures.           |
| <b>RxOpCodeBadHold</b>              | Displays the open errors received for Bad Hold Value.          |
| <b>RxUpdCodeMalformedAttrList</b>   | Displays the update errors received for Malformed Attr List.   |
| <b>RxUpdCodeWelKnownAttrUnrecog</b> | Displays the update errors received for Welknown Attr Unrecog. |
| <b>RxUpdCodeWelknownAttrMiss</b>    | Displays the update errors received for Welknown Attr Missing. |
| <b>RxUpdCodeAttrFlagError</b>       | Displays the update errors received for Attr Flag Error.       |
| <b>RxUpdCodeAttrLenError</b>        | Displays the update errors received for Attr Len Error.        |
| <b>RxUpdCodeBadORIGINAttr</b>       | Displays the update errors received for Bad ORIGIN Attr.       |
| <b>RxUpdCodeASRoutingLoop</b>       | Displays the update errors received for AS Routing Loop.       |
| <b>RxUpdCodeBadNHAttr</b>           | Displays the update errors received for Bad NEXT-HOP Attr.     |
| <b>RxUpdCodeOptionalAttrError</b>   | Displays the update errors received for Optional Attr Error.   |
| <b>RxUpdCodeBadNetworkField</b>     | Displays the update errors received for Bad Network Field.     |
| <b>RxUpdCodeMalformedASPath</b>     | Displays the update errors received for Malformed AS Path.     |
| <b>TxECodeHeader</b>                | Displays the total Header errors transmitted.                  |
| <b>TxECodeOpen</b>                  | Displays the total Open errors transmitted.                    |
| <b>TxECodeUpdate</b>                | Displays the total Update errors transmitted.                  |
| <b>TxECodeHoldtimer</b>             | Displays the total Hold timer errors transmitted.              |
| <b>TxECodeFSM</b>                   | Displays the total FSM errors transmitted.                     |
| <b>TxECodeCease</b>                 | Displays the total Cease errors transmitted.                   |
| <b>TxHdrCodeNoSync</b>              | Displays the header Not Synchronized errors transmitted.       |
| <b>TxHdrCodeInvalidMsgLen</b>       | Displays the header Invalid msg len errors transmitted.        |
| <b>TxHdrCodeInvalidMsgType</b>      | Displays the header Invalid msg type errors transmitted.       |

| Name                                | Description                                                       |
|-------------------------------------|-------------------------------------------------------------------|
| <b>TxOpCodeBadVer</b>               | Displays the open errors transmitted for Bad Version.             |
| <b>TxOpCodeBadAs</b>                | Displays the open errors transmitted for Bad AS Number.           |
| <b>TxOpCodeBadRtrID</b>             | Displays the open errors transmitted for Bad BGP Rtr ID.          |
| <b>TxOpCodeUnsuppOption</b>         | Displays the open errors transmitted for Unsupported Option.      |
| <b>TxOpCodeAuthFail</b>             | Displays the open errors transmitted for Auth Failures.           |
| <b>TxOpCodeBadHold</b>              | Displays the open errors transmitted for Bad Hold Value.          |
| <b>TxUpdCodeMalformedAttrList</b>   | Displays the update errors transmitted for Malformed Attr List.   |
| <b>TxUpdCodeWelknownAttrUnrecog</b> | Displays the update errors transmitted for Welknown Attr Unrecog. |
| <b>TxUpdCodeWelknownAttrMiss</b>    | Displays the update errors transmitted for Welknown Attr Missing. |
| <b>TxUpdCodeAttrFlagError</b>       | Displays the update errors transmitted for Attr Flag Error.       |
| <b>TxUpdCodeAttrLenError</b>        | Displays the update errors transmitted for Attr Len Error.        |
| <b>TxUpdCodeBadORIGINAttr</b>       | Displays the update errors transmitted for Bad ORIGIN Attr.       |
| <b>TxUpdCodeASRoutingLoop</b>       | Displays the update errors transmitted for AS Routing Loop        |
| <b>TxUpdCodeBadNHAttr</b>           | Displays the update errors transmitted for Bad NEXT-HOP Attr      |
| <b>TxUpdCodeOptionalAttrError</b>   | Displays the update errors transmitted for Optional Attr Error.   |
| <b>TxUpdCodeBadNetworkField</b>     | Displays the update errors transmitted for Bad Network Field.     |
| <b>TxUpdCodeMalformedASPath</b>     | Displays the update errors transmitted for Malformed AS Path.     |

## Configure Aggregate Routes

Configure aggregate routes so that the router advertises a single route (aggregate route) that represents all destinations. Aggregate routes also reduce the size of routing tables.

### Before You Begin

- Enable aggregate routes globally.
- You need the appropriate aggregate address and mask.
- If required, policies exist.
- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Aggregates** tab.
4. Click **Insert**.
5. Configure the aggregate **Address** and **PrefixLen**.
6. Select **AsSetGenerate** or **SummaryOnly** as required.
7. Configure policies for the aggregate route.

8. Click **Insert**.

### **Aggregates** field descriptions

Use the data in the following table to use the **Aggregates** tab.

| Name                   | Description                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Address</b>         | Specifies the aggregate IP address.                                                                                                                                                                                   |
| <b>PrefixLen</b>       | Specifies the aggregate PrefixLen.                                                                                                                                                                                    |
| <b>AsSetGenerate</b>   | Enables or disables AS-set path information generation. The default is disable.                                                                                                                                       |
| <b>SummaryOnly</b>     | Enables or disables the summarization of routes in routing updates. Enable this parameter to create the aggregate route and suppress advertisements of more-specific routes to all neighbors. The default is disable. |
| <b>SuppressPolicy</b>  | Specifies the route policy (by name) used for the suppressed route list. Enable this parameter to create the aggregate route and suppress advertisements of the specified routes.                                     |
| <b>AdvertisePolicy</b> | Specifies the route policy (by name) used for route advertisements. The route policy selects the routes that create AS-set origin communities.                                                                        |
| <b>AttributePolicy</b> | Specifies the route policy (by name) used to determine aggregate route attributes.                                                                                                                                    |

## Configuring Aggregate IPv6 Routes

Configure IPv6 aggregate routes so that the router advertises a single route (aggregate route) that represents all destinations. Aggregate routes also reduce the size of routing tables.

To configure aggregate routes for IPv4, see [Configure Aggregate Routes](#) on page 469.

### Before You Begin

- Aggregate routes are enabled.
- You have determined the appropriate aggregate prefix and length.
- If required, policies exist.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **BGP+**.
3. Click the **Aggregates** tab.
4. Click **Insert**.
5. Specify the **aggregate Address** and **PrefixLen**
6. Configure **AsSetGenerate** and **SummaryOnly** as required.
7. Configure policies for the aggregate route.
8. Click **Insert**.

**Aggregates** field descriptions

Use the data in the following table to use the **Aggregates** tab.

| Name                   | Description                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Address</b>         | Specifies the aggregate address. The default is none.                                                                                                                                                                 |
| <b>PrefixLen</b>       | Specifies the length of the prefix (in bits).                                                                                                                                                                         |
| <b>AsSetGenerate</b>   | Enables or disables AS-set path information generation. The default is disable.                                                                                                                                       |
| <b>SummaryOnly</b>     | Enables or disables the summarization of routes in routing updates. Enable this parameter to create the aggregate route and suppress advertisements of more-specific routes to all neighbors. The default is disable. |
| <b>SuppressPolicy</b>  | Specifies the route policy (by name) used for the suppressed route list. Enable this parameter to create the aggregate route and suppress advertisements of the specified routes.                                     |
| <b>AdvertisePolicy</b> | Specifies the route policy (by name) used for route advertisements. The route policy selects the routes that create AS-set origin communities.                                                                        |
| <b>AttributePolicy</b> | Specifies the route policy (by name) used to determine aggregate route attributes.                                                                                                                                    |

## Configure Allowed Networks

Configure network addresses to determine the network addresses that BGP advertises. The allowed addresses determine the BGP networks that originate from the switch.

### Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Network** tab.
4. Click **Insert**.
5. Configure the network address, mask, and metric.
6. Click **Insert**.

**Network** field descriptions

Use the data in the following table to use the **Network** tab.

| Name                      | Description                                                                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NetworkAfAddr</b>      | Specifies the network prefix that BGP advertises.                                                                                                                                             |
| <b>NetworkAfPrefixLen</b> | Specifies the prefix length of the network address.                                                                                                                                           |
| <b>NetworkAfMetric</b>    | Specifies the metric to use when the system sends an update for the routes in the network table. The metric configures the MED for the routes advertised to eBGP peers. The range is 0–65535. |

## Configuring Allowed IPv6 Networks

Configure IPv6 network addresses to determine the network addresses that BGP advertises. The allowed addresses determine the BGP networks that originate from the switch.

To configure allowed IPv4 networks, see [Configure Allowed Networks](#) on page 471.

**Procedure**

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **BGP+**.
3. Click the **Network** tab.
4. Click **Insert**.
5. Configure the **network address, prefix length** and **metric**.
6. Click **Insert**.

**Network** field descriptions

Use the data in the following table to use the **Network** tab.

| Name                      | Description                                                                                                                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NetworkAfAddr</b>      | Specifies the network prefix that BGP advertises. The default is none.                                                                                                                                  |
| <b>NetworkAfPrefixLen</b> | Specifies the network prefix length. The default is none.                                                                                                                                               |
| <b>NetworkAfMetric</b>    | Specifies the metric used when an update is sent for the routes in the network table. The metric configures the MED for the routes advertised to EBGP peers. The range is 0 to 65535. The default is 0. |

## Configure BGP Peers

Configure BGP peers to connect two routers to each other for the purpose of exchanging routing information. BGP peers exchange complete routing information only after they establish the peer connection.

### Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Configure the peer as required.
6. Select **Insert**.
7. In the **Enable** column, double-click the value, and then select **true**.  
By default, new peer configuration parameters are disabled.
8. Select **Apply**.
9. To modify a peer configuration, double-click the value, and then select a new value.

### Peers Field Descriptions

Use the data in the following table to use the **Peers** tab.

| Name                         | Description                                                                                                                        |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Instance</b>              | Specifies the BGP peer instance.                                                                                                   |
| <b>LocalAddrType</b>         | Specifies the local IP address type of the entered BGP peer.                                                                       |
| <b>LocalAddr</b>             | Specifies the local IP address of the entered BGP peer.                                                                            |
| <b>RemoteAddrType</b>        | Specifies the remote IP address type of the entered BGP peer.                                                                      |
| <b>RemoteAddr</b>            | Specifies the remote IP address of the entered BGP peer.                                                                           |
| <b>AdminStatus</b>           | Specifies the administrative status of the BGP peer.                                                                               |
| <b>GroupName</b>             | Specifies the peer group name to which the peer belongs (optional).                                                                |
| <b>PeerState</b>             | Specifies the BGP peer connection state.                                                                                           |
| <b>RemoteAs</b>              | Configures a remote AS number for the peer or peer-group in the range 0–65535.                                                     |
| <b>Enable</b>                | Controls whether the peer connection is enabled or disabled. The default is disabled.                                              |
| <b>EbgpMultiHop</b>          | Enables or disables a connection to a BGP peer that is more than one hop away from the local router. The default value is disable. |
| <b>RoutePolicyIn</b>         | Specifies the policy (by name) that applies to all network routes learned from this peer.                                          |
| <b>RoutePolicyOut</b>        | Specifies the policy (by name) that applies to all outgoing route updates.                                                         |
| <b>RemovePrivateAs</b>       | Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.                                   |
| <b>UpdateSourceInterface</b> | Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.                              |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ConnectRetryInterval</b>  | Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>HoldTimeConfigured</b>    | Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.                                                                                                                                                                                                                                                                            |
| <b>KeepAliveConfigured</b>   | Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.                                                                                                                                                                                                                                    |
| <b>MD5Authentication</b>     | Enables and disables MD5 authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGP neighbor. The default value is 30 seconds and the range is 5–120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained. |
| <b>DefaultOriginate</b>      | When enabled, specifies that the current route originated from the BGP peer. This parameter enables or disables sending the default route information to the specified neighbor or peer. The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DefaultOriginateIpv6</b>  | When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Weight</b>                | Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0–65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>MaxPrefix</b>             | Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0–2147483647. A value of 0 means no limit exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NextHopSelf</b>           | Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>RouteReflectorClient</b>  | Specifies that this peer is a route reflector client.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SoftReconfigurationIn</b> | When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable.<br>Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DebugMask</b>             | Displays the specified debug information for the BGP peer. The default value is none. <ul style="list-style-type: none"> <li>• None disables all debug messages.</li> <li>• Event enables the display of debug event messages.</li> <li>• State enables display of debug state transition messages.</li> <li>• Update enables display of debug messages related to updates transmission and reception.</li> <li>• Error enables the display of debug error messages.</li> <li>• Trace enables the display of debug trace messages.</li> <li>• Init enables the display of debug initialization messages.</li> <li>• All enables all debug messages.</li> <li>• Packet enables the display of debug packet messages.</li> <li>• Warning enables the display of debug warning messages.</li> <li>• Filter enables the display of debug messages related to filtering.</li> </ul> |
| <b>SendCommunity</b>         | Enables or disables sending the community attribute of the update message to the specified peer. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Vpnv4Address</b>          | Specifies the vpnv4 routes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>IpvpnLiteCap</b>          | Enable or disable IP VPN-lite capability on the BGP neighbor peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Ipv6Cap</b>               | Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SooAddress</b>            | Specifies the site-of-origin (SoO) address of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SooAsNumber</b>           | Specifies the site-of-origin (SoO) Autonomous System (AS) number of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SooAssignedNum</b>        | Specifies the site-of-origin (SoO) assigned number of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SooType</b>               | Specifies the site-of-origin (SoO) type of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>RouteRefresh</b>          | Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Name                                                                                      | Description                                                                                                      |
|-------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>AsOverride</b><br><b>Note:</b><br>This field does not apply on all hardware platforms. | Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.    |
| <b>AllowAsIn</b><br><b>Note:</b><br>This field does not apply on all hardware platforms.  | Specifies the number of AS-in allowed for the BGP peer. The range is 1-10.                                       |
| <b>Ipv6RoutePolicyIn</b>                                                                  | Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.                   |
| <b>Ipv6RoutePolicyOut</b>                                                                 | Specifies the policy (by name) that applies to all outgoing IPv6 route updates.                                  |
| <b>Ipv6MaxPrefix</b>                                                                      | Configures a limit on the number of IPv6 routes accepted from a neighbor.<br>A value of 0 means no limit exists. |
| <b>BfdEnable</b>                                                                          | Enables Bidirectional Forwarding Detection (BFD) for this BGP peer.                                              |

## Configure BGPv6 Peers

Configure BGPv6 peers to connect two routers to each other for the purpose of exchanging routing information. BGPv6 peers exchange complete routing information only after they establish the peer connection.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **BGP+**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Configure the peer, as required.
6. Select **Insert**.
7. In the **Enable** column, double-click the value, and then select **enable**.  
By default, new peer configuration parameters are disabled.
8. Select **Apply**.
9. To modify a peer configuration, double-click the value, and then select a new value.

**Peers** Field Descriptions

Use the data in the following table to use the **Peers** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RemoteAddr</b>            | Specifies the remote IPv6 address of the entered BGP+ peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>GroupName</b>             | Specifies the peer group name to which the peer belongs (optional).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>PeerState</b>             | Specifies the BGPv6 peer connection state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>RemoteAs</b>              | Configures a remote AS number for the peer or peer-group in the range 0 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Enable</b>                | Controls whether the peer connection is enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>EbgpMultiHop</b>          | Enables or disables a connection to a BGPv6 peer that is more than one hop away from the local router. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>RoutePolicyIn</b>         | Specifies the policy (by name) that applies to all network routes learned from this peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>RoutePolicyOut</b>        | Specifies the policy (by name) that applies to all outgoing route updates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>RemovePrivateAs</b>       | Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>UpdateSourceInterface</b> | Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ConnectRetryInterval</b>  | Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>HoldTimeConfigured</b>    | Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.                                         |
| <b>KeepAliveConfigured</b>   | Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845. |
| <b>MD5Authentication</b>     | Enables and disables MD5 authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGPv6 neighbor. The default value is 30 seconds and the range is 5 to 120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained. |
| <b>DefaultOriginatelpv6</b>  | When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Weight</b>                | Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>MaxPrefix</b>             | Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0 to 2147483647. A value of 0 means no limit exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>NextHopSelf</b>           | Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>RouteReflectorClient</b>  | Specifies that this peer is a route reflector client.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SoftReconfigurationIn</b> | When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Name                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Ipv6MaxPrefix</b>                                                                          | Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>BfdEnable</b>                                                                              | Enables Bidirectional Forwarding Detection (BFD) for this peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Configure Peer Groups

Configure or edit peer groups to create update policies for neighbors in the same group.

### Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Peer Groups** tab.

You can modify an existing parameter by double-clicking the value.

4. Select **Insert**.
5. Configure the peer group as required.
6. Select **Insert**.

### *Peer Groups* field descriptions

Use the data in the following table to use the **Peer Groups** tab.

| Name                         | Description                                                                                                                                                    |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                 | Specifies the index of this peer group.                                                                                                                        |
| <b>GroupName</b>             | Specifies the peer group to which this neighbor belongs (optional).                                                                                            |
| <b>Enable</b>                | Enables or disables the peer group.                                                                                                                            |
| <b>RemoteAs</b>              | Configures a remote AS number for the peer-group in the range 0-65535.                                                                                         |
| <b>DefaultOriginate</b>      | When enabled, the BGP speaker (the local router) sends the default route 0.0.0.0 to a group of neighbors for use as a default route. The default is disabled.  |
| <b>DefaultOriginateIpv6</b>  | When enabled, the BGP speaker (the local router) sends the default route to a group of neighbors for use as a default route. The default is disabled.          |
| <b>EbgpMultiHop</b>          | When enabled, the switch accepts and attempts BGP connections to external peers that reside on networks that do not directly connect. The default is disabled. |
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, that elapses between BGP routing updates. The default value is 30 seconds.                                            |
| <b>KeepAlive</b>             | Specifies the time interval, in seconds, between sent BGP keep alive messages to remote peers. The default value is 60.                                        |
| <b>HoldTime</b>              | Configures the hold time for the group of peers in seconds. Use a value that is three times the value of the KeepAlive time. The default value is 180.         |
| <b>Weight</b>                | Assigns an absolute weight to a BGP network. The default value is 100.                                                                                         |

| Name                               | Description                                                                                                                                                                                                                                                                                                  |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MaxPrefix</b>                   | Limits the number of routes accepted from this group of neighbors. A value of zero indicates no limit. The default value is 12,000 routes.                                                                                                                                                                   |
| <b>NextHopSelf</b>                 | Specifies that the switch must set the NextHop attribute to the local router address before sending updates to remote peers.                                                                                                                                                                                 |
| <b>RoutePolicyIn</b>               | Specifies the route policy that applies to all networks learned from this group of peers.                                                                                                                                                                                                                    |
| <b>RoutePolicyOut</b>              | Specifies the route policy that applies to all outgoing updates to this group of peers.                                                                                                                                                                                                                      |
| <b>RouteReflectorClient</b>        | Specifies that this peer group is a route reflector client.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                                                                                                                                     |
| <b>SoftReconfigurationIn</b>       | When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is enable.<br>Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes). |
| <b>MD5Authentication</b>           | Enables and disables MD5 authentication. The default is disable.                                                                                                                                                                                                                                             |
| <b>RemovePrivateAs</b>             | Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.                                                                                                                                                                                                             |
| <b>SendCommunity</b>               | Enables or disables sending the community attribute of the update message to the specified peer group. The default value is disable.                                                                                                                                                                         |
| <b>AfUpdateSourceInterfaceType</b> | Specifies the interface type.                                                                                                                                                                                                                                                                                |
| <b>AfUpdateSourceInterface</b>     | Specifies the IP address used for circuitless IP (CLIP) for this peer group.                                                                                                                                                                                                                                 |
| <b>Vpvn4Address</b>                | Enables BGP address families for IPv4 (BGP) and Layer 3 VPN (MP-BGP) support. Enable this parameter for VPN/VRF Lite routes.                                                                                                                                                                                 |
| <b>IpvpnLiteCap</b>                | Specifies (when enabled) that IP VPN Lite capability can be enabled or disabled on the BGP neighbor peer. The default is disable.                                                                                                                                                                            |
| <b>RouteRefresh</b>                | Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.                                                |
| <b>AsOverride</b>                  | Specifies that the AS Override parameter can be enabled or disabled for the BGP peer group. The default is disable.                                                                                                                                                                                          |
| <b>AllowedAsIn</b>                 | Specifies the number of AS-in allowed for the BGP peer group. The range is 1-10.                                                                                                                                                                                                                             |
| <b>IPv6Cap</b>                     | Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.                                                                                                                                                                                                                |

| Name                      | Description                                                                                                      |
|---------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Ipv6RoutePolicyIn</b>  | Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.                   |
| <b>Ipv6RoutePolicyOut</b> | Specifies the policy (by name) that applies to all outgoing IPv6 route updates.                                  |
| <b>Ipv6MaxPrefix</b>      | Configures a limit on the number of IPv6 routes accepted from a neighbor.<br>A value of 0 means no limit exists. |
| <b>BfdEnable</b>          | Enables Bidirectional Forwarding Detection (BFD) for the BGP peer group.                                         |

## View IPv6 Community Attributes

View IPv6 community attributes for specific routes to utilize the update message fields to communicate information between BGP speakers. Use the Path Attribute values to specify the prefixes that the BGP session can exchanged, or which of the multiple paths of a specified prefix to use.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **BGP+**.
3. Select the **Bgp Route Summary** tab.
4. Select a route for which you want to view the route summary information.
5. Select the **Route Comm Attr** option on the menu.

The **BGP Path Attributes** tab opens with the BGP IPv6 community attribute information.

### **BGP Path Attributes** field descriptions

Use the data in the following table to use the **Community List** tab.

| Name                | Description                                                                                                                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Origin</b>       | Specifies the ultimate origin of the path information.                                                                                                                                                             |
| <b>NextHopAddr</b>  | Specifies the address of the border router that is used to access the destination network. This address is the nexthop address received in the UPDATE packet associated with this prefix.                          |
| <b>Med</b>          | This metric is used to discriminate between multiple exit points to an adjacent autonomous system. When the MED value is absent but has a calculated default value, this object will contain the calculated value. |
| <b>LocalPref</b>    | Specifies the value used during route decision process in the BGP protocol. Applicable to BGP only.                                                                                                                |
| <b>AggregatorAS</b> | Specifies the AS number of the last BGP4 speaker that performed route aggregation. If the AGGREGATOR path attribute is absent, this object will not be present in the conceptual row.                              |

| Name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AggregatorAddr</b> | Specifies the IP address of the last BGP4 speaker that performed route aggregation. If the AGGREGATOR path attribute is absent, this object will not be present in the conceptual row.                                                                                                                                                                                                                            |
| <b>String</b>         | This is a string representing the autonomous system path to the network which was received from the peer which advertised it. The format of the string is implementation-dependent, and is designed for operator readability.<br><br><b>Note:</b><br>SnmpAdminString is only capable of representing a maximum of 255 characters. This may lead to the string being truncated in the presence of a large AS Path. |

## Display Dampened Routes Information

Display dampened path information to see which routes are suppressed.

### Before You Begin

- Change the VRF instance as required to view BGP information about a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.
- Enable dampened routes.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Dampened Routes** tab.

### *Dampened Routes* field descriptions

Use the data in the following table to use the **Dampened Routes** tab.

| Name                   | Description                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddrPrefix</b>    | Specifies the IP address prefix in the NLRI field. This variable is an IP address that contains the prefix with a length specified by IpAddrPrefixLen. Bits beyond the length specified by IpAddrPrefixLen are set to zero. |
| <b>IpAddrPrefixLen</b> | Specifies the length, in bits, of the IP address prefix in the NLRI field.                                                                                                                                                  |
| <b>Peer</b>            | Specifies the IP address of the peer from which the router learns the path information.                                                                                                                                     |
| <b>FlapPenalty</b>     | Specifies the penalty based on number of route flaps.                                                                                                                                                                       |
| <b>FlapCount</b>       | Specifies the number of times a route flapped (went down and up) since the last time the penalty was reset to zero.                                                                                                         |
| <b>RouteDampened</b>   | Indicates whether this route is suppressed or announced.                                                                                                                                                                    |
| <b>ReuseTime</b>       | Specifies the system-configured time for route reuse.                                                                                                                                                                       |

## Configure Redistribution to BGP

Configure redistribute entries for BGP to announce routes of a certain source type to BGP, for example, DvR, direct, static, Routing Information Protocol (RIP), and Open Shortest Path First (OSPF). If you do not configure a route policy, then the switch uses the default action based on metric, metric type, and subnet. Use a route policy to perform detailed redistribution.

### Before You Begin

- If required, configure a route policy.
- When you configure BGP on a specific VRF instance, the VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.
- Before you redistribute DvR host routes to BGP, ensure that you disable BGP aggregation and BGP auto-summarization of networks. Disabling these settings ensures that all the DvR host routes are advertised into BGP correctly, and are not summarized.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Configure the source protocol.
6. If required, choose a route policy.
7. Configure the metric to apply to redistributed routes.
8. Enable the redistribution instance.
9. Click **Insert**.

### **Redistribute** field descriptions

Use the data in the following table to use the **Redistribute** tab.

| Name               | Description                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DstVrflid</b>   | Specifies the destination VRF instance (read-only).                                                                                                                                |
| <b>Protocol</b>    | Specifies the protocols that receive the redistributed routes.                                                                                                                     |
| <b>SrcVrflid</b>   | Specifies the source VRF instance (read-only).                                                                                                                                     |
| <b>RouteSource</b> | Specifies the source protocol for the route redistribution entry.                                                                                                                  |
| <b>Enable</b>      | Enables (or disables) a BGP redistribute entry for a specified source type.                                                                                                        |
| <b>RoutePolicy</b> | Configures the route policy to use for the detailed redistribution of external routes from a specified source into the BGP domain.                                                 |
| <b>Metric</b>      | Configures the metric for the redistributed route. The value can be a range between 0–65535. The default value is 0. Use a value that is consistent with the destination protocol. |

## Configure Redistribution to BGPv6

Configure redistribute entries for BGPv6 to announce routes of a certain source type to BGPv6, for example, DvR, direct, static, Routing Information Protocol (RIP), and Open Shortest Path First (OSPF). If

you do not configure a route policy, then the switch uses the default action based on metric, metric type, and subnet. Use a route policy to perform detailed redistribution.

### Before You Begin

- If required, configure a route policy.
- Before you redistribute DvR host routes to BGPv6, ensure that you disable BGPv6 aggregation and BGPv6 autosummarization of networks. Disabling these settings ensures that all the DvR host routes are advertised into BGPv6 correctly, and are not summarized.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **BGP+**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Configure the source protocol.
6. If required, choose a route policy.
7. Configure the metric to apply to redistributed routes.
8. Enable the redistribution instance.
9. Click **Insert**.

### **Redistribute** field descriptions

Use the data in the following table to use the **Redistribute** tab.

| Name                                                                                        | Description                                                                                                                                                                                                                                                                                           |
|---------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DstVrfId</b>                                                                             | Specifies the destination VRF instance (read-only).                                                                                                                                                                                                                                                   |
| <b>Protocol</b><br><br><b>Note:</b><br>This field does not apply on all hardware platforms. | Specifies the protocols that receive the redistributed routes.                                                                                                                                                                                                                                        |
| <b>SrcVrfId</b>                                                                             | Specifies the source VRF instance (read-only).                                                                                                                                                                                                                                                        |
| <b>RouteSource</b>                                                                          | Specifies the source protocol for the route redistribution entry.                                                                                                                                                                                                                                     |
| <b>Enable</b>                                                                               | Enables (or disables) a BGPv6 redistribute entry for a specified source type.                                                                                                                                                                                                                         |
| <b>RoutePolicy</b>                                                                          | Configures the route policy to use for the detailed redistribution of external routes from a specified source into the BGPv6 domain.                                                                                                                                                                  |
| <b>Metric</b>                                                                               | Configures the metric for the redistributed route. The default value is 0. Use a value that is consistent with the destination protocol.                                                                                                                                                              |
| <b>MetricType</b>                                                                           | Specifies the metric type.<br>Specifies a type1 or a type2 metric. For metric type1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type2, the cost of the external routes is equal to the external cost alone.<br>The default is type2. |

## View BGP+ or BGPv6 Route Summary Information

You can display current IPv6 BGP+ route information.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.  
Use the **IP** folder in the navigation pane to view the IPv4 route summary.
2. Click **BGP+**.
3. Click the **Bgp Route Summary** tab to view the BGP route summary information

### *Bgp Route Summary field descriptions*

Use the data in the following table to use the **Bgp Route Summary** tab.

| Name              | Description                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Prefix</b>     | Specifies the IP address prefix in the Network Layer Reachability Information (NLRI) field. This is an IP address that contains the prefix with a length specified by IpAddrPrefixLen. Any bits beyond the length specified by IpAddrPrefixLen are set to zero. |
| <b>PrefixLen</b>  | Specifies the length, in bits, of the IP address prefix in the NLRI field.                                                                                                                                                                                      |
| <b>LocalAddr</b>  | The local address of this entry's BGP connection.                                                                                                                                                                                                               |
| <b>RemoteAddr</b> | Specifies the IP address of the peer from which path information was learned.                                                                                                                                                                                   |

## Viewing BGP Route Summary

Display BGP route summary.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Bgp Route Summary** tab.

### *Bgp Route Summary field descriptions*

Use the data in the following table to use the Bgp Route Summary tab.

| Name              | Description                                                            |
|-------------------|------------------------------------------------------------------------|
| <b>Prefix</b>     | Configures the IP address of the route.                                |
| <b>PrefixLen</b>  | Specifies the IP address and the mask length (the length can be 0–32). |
| <b>LocalAddr</b>  | Specifies the local IP address of the entered BGP route.               |
| <b>RemoteAddr</b> | Specifies the remote IP address of the entered BGP route.              |

## Configure an AS Path List

Configure an AS path list to restrict the routing information a router learns or advertises to and from a neighbor. The AS path list acts as a filter that matches AS paths.

### Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **Policy**.
3. Click the **As Path List** tab.
4. Click **Insert**.
5. Enter the appropriate information for your configuration.
6. Click **Insert**.

### *As Path List* field descriptions

Use the data in the following table to use the **As Path List** tab.

| Name                       | Description                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                  | Specifies the AS path list.                                                                                                                   |
| <b>MemberId</b>            | Specifies the AS path access list member ID.                                                                                                  |
| <b>Mode</b>                | Specifies the action to take if the system selects a policy for a specific route. Select permit (allow the route) or deny (ignore the route). |
| <b>AsRegularExpression</b> | Specifies the expression to use for the AS path.                                                                                              |

## Configure a Community Access List

Configure community lists to specify permitted routes by using their BGP community. This list acts as a filter that matches communities or AS numbers.

### Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **Policy**.
3. Click the **Community List** tab.
4. Click **Insert**.
5. Configure the list as required.
6. Click **Insert**.

**Community List** field descriptions

Use the data in the following table to use the **Community List** tab.

| Name             | Description                                                                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>        | Specifies the community list. The range is 0-1024.                                                                                            |
| <b>MemberId</b>  | Specifies the community list member ID. The range is 0-65535.                                                                                 |
| <b>Mode</b>      | Specifies the action to take if the system selects a policy for a specific route. Select permit (allow the route) or deny (ignore the route). |
| <b>Community</b> | Specifies the community access list community string.                                                                                         |

## BGP Configuration Examples

### IPv6 Tunnel Configurations for BGP+

You must configure an IPv6 tunnel and static routes at BGP+ peers when you use BGP+.

When BGP+ peers advertise route information, they use Update messages to advertise route information. And, when route information is encapsulated in Update messages, BGP+ peers convert their own IPv4 peer addresses to IPv4-mapped IPv6 addresses and insert them into the next-hop field in the Update message.

When the BGP+ software module receives Update messages, it adds route information to the IPv6 Routing Manager (RTM). These RTM routes contain next-hop addresses from the BGP peer that the route was learned from. The next-hop addresses are represented as IPv4-mapped IPv6 addresses.

But, because the IPv6 RTM cannot correlate the IPv4-mapped IPv6 address to a specific outgoing interface, you must create a manually-configured static route to make the link between the BGP peer and the IPv6 tunnel interface so that traffic can reach networks advertised by the peer.

Following is one way to express a static route in an IPv6-configured tunnel for BGP+:

```
ipv6 route 0:0:0:0:0:ffff:192.0.2.0/24 cost 1 tunnel 10
```

Configure the IPv6 tunnel endpoint and the BGP peer to reside on the same switch.

If the IPv6 tunnel endpoint and the BGP peer must reside on different switches you can terminate the tunnel on a different switch, but you must consider the following:

- Because the IPv6 tunnel endpoint does not reside on the same switch as the BGP peer, the BGP device cannot use the tunnel as the outgoing interface. That is, to reach the IPv6-configured tunnel endpoint, if the BGP peer resides on a different switch from the IPv6 tunnel endpoint, the next-hop for the manually-configured IPv4-mapped IPv6 static route is the native IPv6 interface next-hop address.

- The node where the tunnel terminates must contain all of the information needed to route the packets between the remote IPv6 network clouds.

**Note**

In order for the tunnel endpoint switch to be aware of all of the necessary IPv6 routes, you may need to redistribute the BGP routes into OSPFv3.

*IPv4-mapped IPv6 address*

IPv4-mapped IPv6 addresses are IPv4 addresses that the system has mapped into the IPv6 address space.

The system uses these IPv4-mapped IPv6 addresses for devices that are only IPv4-capable.

These IPv4-mapped address have the first 80 bits set to zeros, followed by the next 16 bits set to ones, and the last 32 bits have IPv4 addresses.

When converted to an IPv4-mapped IPv6 address, an IPv4 device address of 192.0.2.1 would be represented as one of the following:

- 0:0:0:0:FFFF:192.0.2.1
- ::FFFF:192.0.2.1

The following figure illustrates the components in an IPv4-mapped IPv6 address.

**Figure 39: IPv4-mapped IPv6 address components**

*eBGP+ peership between two switches with IPv6 Tunneling*

The following figure shows a sample network that contains eBGP+ peers using IPv6 tunneling.

**Figure 40: eBGP+ peers with IPv6 tunneling**

The configuration in the figure, *eBGP+ peers with IPv6 tunneling*, assumes that the BGP peer IP address is the next hop.

When you configure the static route for the BGP+ tunnel, you must designate the BGP peer IP address as the next hop in most cases.

You can configure multiple static routes, using the same tunnel, but you must ensure reachability when you create the static routes.

## R1 configuration

```
interface GigabitEthernet 3/2
brouter port 3/2 vlan 2090 subnet 192.0.2.1/255.255.255.0 mac-offset 2
exit
# BGP CONFIGURATION - GlobalRouter
#

router bgp as-dot enable

```

### *iBGP+ peership on CLIP between two switches with IPv6 Tunneling*

The following figure shows a sample network that contains iBGP+ peers using IPv6 tunneling.

**Figure 41: iBGP+ peers on CLIP interfaces with IPv6 tunneling**

You must enable OSPF on the interface and globally as well.

If you cannot enable OSPF, you must configure static routes to provide reachability to the BGP+ peer.

The static route must point to the next hop for the routes to be installed in the IPv6 RTM.

The next hop must be the BGP peer IP address.

The IPv4 interfaces do not need to connect directly, but the routing table on each switch must include the IPv4 interface of the other switch.

iBGP between the CLIP interfaces needs to run OSPF as a routing protocol so that the BGP neighbor can remain reachable.

eBGP connections cannot use a CLIP interface as an end point.

### **R1 configuration**

```

## Native IPv6 eBGP peership between two switches on VRF

The following figure shows a sample network that contains native IPv6 eBGP peers on VRFs.

**Figure 42: Native IPv6 eBGP peers on VRFs**

Configure the local AS first on GRT (and it is inherited by all VRFs), and then enable BGP on GRT/VRF.

You must configure the **address-family ipv6** option for IPv6 peers, otherwise, peer-ship is formed, but no routing updates between them will take place.

You must configure the **ebgp-multihop** option for the given eBGP peer that is not on one of local subnets (remote peers), otherwise, peer-ship will not be formed.

**Note**

The switch does not accept any configuration command for BGP in router-vrf configuration mode unless a BGP instance associated to the VRF context is created. You can use `ip bgp` command in router-vrf configuration mode to create a BGP instance on VRF.

*R1 configuration*

```

## iBGP over User-created VRFs Configuration Example

This section shows examples of configured internal Border Gateway Protocol (iBGP) IPv4 and IPv6 peers over user-created Virtual Routing and Forwarding (VRF) instances.

### Note

The Autonomous System (AS) number configured on the global VRF is inherited by all user-created VRFs, however, you can override the AS number for a specific user-created VRF. For more information, see [Configure an AS Number for a Non-default VRF](#) on page 446.

### IPv4 iBGP Peers Configuration

Configuration on switch 1:

```

#
# VRF CONFIGURATION
#

# Chassis Operations

---

[Chassis operations fundamentals](#) on page 506

[Chassis operations configuration using the CLI](#) on page 537

[Chassis operations configuration using EDM](#) on page 567

The following sections provide information for chassis operations such as hardware and software compatibility.

## Chassis operations fundamentals

---

This section provides conceptual information for chassis operations such as hardware and software compatibility and power management. Read this section before you configure the chassis operations.

### Management Port

#### Note

The Management Router for management port configuration is only supported on VSP 8600 Series. For all other platforms, see [Segmented Management](#) on page 60.

The management port is a 10/100/1000 Mbps Ethernet port that you can use for an Out-of-Band (OOB) management connection to the switch. To remotely access the switch using the management port, you must configure an IP address for the OOB management port.

#### *Management Router VRF*

A separate VRF called Management Router (MgmtRouter) is reserved for the OAM (mgmt) port. The configured IP subnet must be globally unique because the management protocols, for example, SNMP, Telnet, and FTP, can go through in-band or out-of-band ports. The VRF ID for the Management Router is 512.

The switch never switches or routes transit packets between the Management Router VRF port and the Global Router VRF, or between the Management Router VRF and other VRF ports.

The switch honors the VRF of the ingress packet; however, in no circumstance does the switch enable routing between the Management VRF and Global Router VRF. The switch does not support the

configuration if you have an out-of-band management network with access to the same networks present in the GRT routing table.

**Note**

IPv6 is not supported on MgmtRouter.

*Non-virtualized client management applications*

Do not define a default route in the Management Router VRF. A route originating from the switch and used for non-virtualized client management applications, such as Telnet, Secure Shell (SSH), and FTP will always match a default route defined in the Management Router VRF.

If you want out-of-band management, define a specific static route in the Management Router VRF to the IP subnet where your management application resides. When you specify a static route in the Management Router VRF, it enables the client management applications originating from the switch to perform out-of-band management without affecting in-band management. This enables in-band management applications to operate in the Global Router VRF.

Non-virtualized client management applications originating from the switch, such as Telnet, SSH, and FTP, follow the behavior listed below:

1. Look at the Management Router VRF route table
2. If no route is found, the applications will proceed to look in the Global Router VRF table

Non-virtualized client management applications include:

- DNS
- FTP client with the **copy** command
- NTP
- rlogin
- RADIUS authentication and accounting
- SSH
- SNMP clients in the form of traps
- SYSLOG
- TACACS+
- Telnet
- TFTP client

For management applications that originate outside the switch, the initial incoming packets establish a VRF context that limits the return path to the same VRF context.

*Virtualized management applications*

Virtualized management applications, such as ping and traceroute, operate using the specified VRF context. To operate ping or traceroute you must specify the desired VRF context. If not specified, ping

defaults to the Global Router VRF. For example, if you want to ping a device through the out-of-band management port you must select the Management Router VRF.

#### Note

IPv6 is not supported on MgmtRouter.

```
Switch:1(config)#ping 192.0.2.1 vrf MgmtRouter
192.0.2.1 is alive
```

Ping test for IPv6:

```
Switch:1(config)#ping 2001:db8::1 vrf vrfRED
2001:db8::1 is alive
```

Traceroute test for IPv4:

```
Switch:1#traceroute 192.0.2.1 vrf MgmtRouter
```

Traceroute test for IPv6:

```
Switch:1#traceroute 2001:db8::1 vrf vrfRED
```

## Entity MIB - Physical Table

**Table 59: Entity MIB product support**

|                                                                                                                                                                                                                                                                             | XA1400 Series   | VOSS 8.4           |

The Entity MIB – Physical Table assists in the discovery of functional components on the switch. The Entity MIB – Physical Table supports a physical interface table that includes information about the chassis, power supply, fan, I/O cards, console, and management port.

Some hardware platforms support removable interface modules while others offer a fixed configuration. The names used for these modules can vary depending on the hardware platform.

The following table identifies the entity index range for the switch components.

| Component                   | Entity index range |
|-----------------------------|--------------------|
| Chassis                     | 1                  |
| Power supply slot           | 3 to 8             |
| Fan tray and fan slot       | 9 to 16            |
| I/O slot                    | 17 to 30           |
| SF Slot                     | 31 to 36           |
| I/O card or module          | 37 to 50           |
| SF Card                     | 51 to 56           |
| Console port                | 57                 |
| Console port 2              | 58                 |
| Management port             | 64                 |
| Management port 2           | 65                 |
| Power supply                | 68 to 73           |
| Fan tray                    | 74 to 81           |
| Fan module                  | 82 to 105          |
| Port                        | 192 to 1023        |
| Pluggable Module and Sensor | 19201 to 102314    |

For more information about Entity MIB – Physical Table, see [View Physical Entities](#) on page 571.

## High Availability-CPU (HA-CPU)

**Table 60: High-Availability product support**

| Feature                                                         | Product         | Release introduced |
|-----------------------------------------------------------------|-----------------|--------------------|
| High Availability-CPU (HA-CPU) for a standalone switch          | 5420 Series     | Not Applicable     |
|                                                                 | 5520 Series     | Not Applicable     |
|                                                                 | VSP 4450 Series | Not Applicable     |
|                                                                 | VSP 4900 Series | Not Applicable     |

|                                                                 | VSP 8200 Series | Not Applicable     |
|                                                                 | VSP 8400 Series | Not Applicable     |
|                                                                 | VSP 8600 Series | VSP 8600 6.3       |
|                                                                 | XA1400 Series   | Not Applicable     |

The High Availability-CPU (HA-CPU) framework supports redundancy at the hardware and application levels. The CP software runs on an Input/Output control (IOC) module in both slots 1 and 2, and the HA-CPU feature activates two CPUs simultaneously in master or standby role. These CPUs exchange topology data so that, if a failure occurs, one of the CPUs can take over the operations of the other. You can configure the CPUs to operate in either HA mode or non-HA mode. In HA mode, the two CPUs synchronize configuration, protocol states, and tables. In non-HA mode, the two CPUs do not synchronize.

The default mode is HA disabled. To activate HA-CPU mode, use the **boot config flags ha-cpu** command. To deactivate HA-CPU mode, use the **no boot config flags ha-cpu** command.

If you switch from one mode to the other, the standby CP restarts in the specified HA mode (hot standby) or non-HA mode (warm standby). This does not impact the Input/Output process and there is no traffic loss on the physical slot of the card.

If a failure occurs and the chassis is configured for either HA mode (hot standby) or non-HA mode (warm standby), the CP software restarts and runs as standby. The system generates a trap to indicate the change from hot-standby mode to warm-standby mode.

#### Note

- The HA-CPU feature provides node-level redundancy. Hot standby mode is not supported with fabric functionality, which provides network-level redundancy.
- If your switch is in hot standby mode (ha-cpu boot flag is set to true), you must disable boot config flag to configure SPBM or vIST on the switch. When the switch is in warm standby mode (ha-cpu boot flag is set to false), you must disable SPBM and vIST to move to hot standby mode.
- When you try to switch-over from warm standby mode to hot standby mode using EDM, the system displays the following error message when you enable the boot config flag for ha-cpu:

```
Hot-standby mode cannot be enabled while SPB/VIST features are still configured.
```

#### *HA mode*

In HA mode, also called hot standby, the platform synchronizes the master (primary) CPU information to the standby (secondary) CPU. The platform adds any configuration changes or application table changes to the master CPU by using bulk synchronization or incremental synchronization. Once synchronization is complete, both the CPUs contain the same configuration and application tables information. Application in HA mode support either full HA implementation or partial HA implementation. In full HA implementation, both the configuration and runtime application data tables exist on the master CPU and the standby CPU.

If the master CPU fails, the standby CPU takes over the master responsibility quickly and you do not see an impact on your network. Also, the IOC and SF modules as well as the full HA applications continue to operate and the full HA applications run consistency checks to verify the tables.

The following applications support full HA mode:

| Feature                                                         | Supported                    |
|-----------------------------------------------------------------|------------------------------|
| Layer 1                                                         |                              |
| Port configuration parameters                                   | Yes                          |
| Layer 2                                                         |                              |
| Media Access Control security (MACsec)                          | Yes                          |
| Multiple Spanning Tree Protocol parameters                      | Yes                          |
| Quality of Service (QoS) parameters                             | Yes                          |
| Rapid Spanning Tree Protocol parameters                         | Yes                          |
| VLAN parameters                                                 | Yes                          |
| Layer 3                                                         |                              |
| ARP entries                                                     | Yes                          |
| Border Gateway Protocol (BGP)                                   | Partial (configuration only) |
| Dynamic Host Configuration Protocol (DHCP) Relay                | Partial (configuration only) |
| Internet Group Management Protocol (IGMP)                       | Yes                          |
| IPv6                                                            | Partial (configuration only) |
| Access Control Lists                                            | Yes                          |
| Open Shortest Path First (OSPF)                                 | Yes                          |
| Protocol Independent Multicast (PIM)                            | Partial (configuration only) |
| Prefix lists and route policies                                 | Yes                          |
| Routing Information Protocol                                    | Yes                          |
| Router Discovery                                                | Yes                          |
| Static and default routes                                       | Yes                          |
| Virtual IP (VLANs)                                              | Yes                          |
| Virtual Router Redundancy Protocol                              | Yes                          |
| Transport Layer                                                 |                              |
| Network Load Balancing (NLB)                                    | Yes                          |
| Remote Access Dial-In User Services (RADIUS)                    | Yes                          |
| Terminal Access Controller Access-Control System plus (TACACS+) | Partial (configuration only) |
| UDP forwarding                                                  | Yes                          |

#### *Partial HA*

A few applications in HA mode have partial HA implementation, where the system synchronizes user configuration data (including interfaces, IPv6 addresses and static routes) from the master CPU to the standby CPU. However, for partial HA implementation, the platform does not synchronize dynamic data learned by protocols. After failure, those applications restart and rebuild their tables, which causes an interruption to traffic that is dependent on a protocol or application with partial HA support.

The following applications support Partial HA:

- Layer 3
  - Border Gateway Protocol (BGP)
  - Dynamic Host Configuration Protocol (DHCP) Relay
  - IPv6
  - Protocol Independent Multicast-Sparse Mode (PIM-SM)
  - Protocol Independent Multicast-Source Specific Mode (PIM-SSM)
- Transport Layer
  - Terminal Access Controller Access Control System plus (TACACS+)

### *Non-HA mode*

In non-HA mode, also called warm standby, the platform does not synchronize the configuration between the master CPU and the standby CPU. When failover happens, the standby CPU switches to master role, and all the IOCs (except the new master CPU) are restarted. The new master CPU loads the configuration when all the cards are ready. These operations cause an interruption to traffic on all ports on the chassis.

#### Note

- When there is a switch-over to warm standby mode, only the RWA access level user can log in to the new master CPU console screen.

The remaining users can log in to the CPU console screen only after the master CP module reloads the configuration and displays the new login prompt.

- When the platform switches from standby CPU to master CPU in warm standby mode, the platform always uses the previously-saved primary configuration file to boot the chassis on the switch.
- The runtime config file must be present on the flash drive during the boot-up of both the master CPU and the standby CPU. If the config file that is used by the master CPU for booting is not available on the standby CPU, the standby CPU loads the default config file. You can run the **save config** command to synchronize the configuration settings or copy the boot config file from the master CPU to the standby CPU. The standby CPU must be rebooted to load the desired config file.

When the master CPU is physically removed in warm-standby mode, all cards are rebooted and the standby CPU switches to the master role and loads the saved configuration. If the old master CPU is physically not plugged in during this time, the respective slot configuration is not loaded to memory even though the configuration exists in the config file. When the old master CPU is re-inserted later, the system considers this as a first time insertion and loads the default configuration on the inserted CP card. This is expected behavior in warm-standby mode. To load the configuration for the re-inserted standby CPU, ensure that the **savetostandby** boot-flag is set to true after re-inserting the removed CPU, and run the CLI command **source <config-file>** on the active CPU.

*HA-CPU support in Simplified vIST*

HA-CPU in Simplified vIST configurations enables synchronization of data for Layer 2 and Layer 3 applications between the master CPU and standby CPU, to provide hot standby capability.

## Power Manager

**Table 61: Power Manager product support**

| Feature          | Product         | Release introduced |
|------------------|-----------------|--------------------|
| Power Management | 5420 Series     | VOSS 8.4           |
|                  | 5520 Series     | VOSS 8.2.5         |
|                  | VSP 4450 Series | Not Supported      |
|                  | VSP 4900 Series | Not Supported      |
|                  | VSP 7200 Series | Not Supported      |
|                  | VSP 7400 Series | Not Supported      |
|                  | VSP 8200 Series | Not Supported      |
|                  | VSP 8400 Series | VOSS 4.2           |
|                  | VSP 8600 Series | VSP 8600 4.5       |
|                  | XA1400 Series   | Not Supported      |

Power Manager identifies the available power in the chassis (called the power budget), and determines if enough power is available to operate the installed components. Power Manager also gives you control over which module slots to supply power to and enables you to prioritize the slots that should shut down first if there isn't enough power available.

If the power usage exceeds the power budget, the system powers off the module with the lowest priority. After a power over-usage occurs, the system uses a Simple Network Management Protocol (SNMP) trap to send a message to the network administrator configured to receive the trap.

The system compares the total chassis power consumed against the total chassis power available, and verifies that if one power supply fails, enough power still remains to operate the chassis and components. If enough power is available to keep all modules powered on in the case of a single failed power supply, then the system is considered to have redundant power.

**Note**

In a redundant power supply configuration, that is, a +1 configuration where the system has one or more power supplies above the actual requirement, the power management logic automatically employs load-sharing across all active power supplies. This load-sharing ensures that the switch draws power equally from all available power supplies to support the system requirements in a fully active model.

If the system does not have redundant power, then the system sends an SNMP trap to the receiver and a message to CLI to inform you that the device no longer operates in redundant power mode.

For information on configuring Power Manager, see the following:

- If using the CLI, see [Configuring power on module slots](#) on page 555 and [Configuring Slot Priority](#) on page 556.
- If using EDM, see [Configure Slot Priority](#) on page 607.

## Software Lock-up Detection

The software lock-up detect feature monitors processes on the CPU to limit situations where the device stops functioning because of a software process issue. Monitored issues include

- software that enters a dead-lock state
- a software process that enters an infinite loop

The software lock-up detect feature monitors processes to ensure that the software functions within expected time limit.

The CPU logs detail about suspended tasks in the log file.

## Jumbo frames

Jumbo packets and large packets are particularly useful in server and storage over Ethernet applications. If the payload to header relation increases in a packet, the bandwidth can be used more efficiently. For this reason, increasing Ethernet frame size is a logical option. The switch supports Ethernet frames as large as 9600 bytes, compared to the standard 1518 bytes, to transmit large amounts of data efficiently and minimize the task load on a server CPU.

### *Tagged VLAN support*

A port with VLAN tagging activated can send tagged frames. If you plan to use Jumbo frames in a VLAN, ensure that you configure the ports in the VLAN to accept Jumbo frames and that the server or hosts in the VLAN do not send frames that exceed 9600 bytes. For more information about how to configure VLANs, see [VLAN Configuration](#) on page 3727.

## Multi-speed Ports

If a port supports multiple speeds, the software configures the speed automatically based on the optic type it detects in the port; you do not need to configure the port speed. For multi-speed copper ports, Auto-Negotiation detects the speed.

### Note

Some VIMs must operate with all ports at the same speed, while others can operate with ports at different speeds. For more information, see [VOSS Release Notes](#). The **sys vim-speed** command is supported only on VIMs that must operate with all ports at the same speed. An error message displays if you run the command on an unsupported VIM.

In addition to the documented maximum port speed, and in cases where the hardware supports it:

- SFP ports are for 1 Gbps but can also support 100 Mbps.
- SFP+ ports are for 10 Gbps but can also support 1 Gbps or 100 Mbps.

- SFP28 ports are for 25 Gbps but can also support 10 Gbps or 1 Gbps.
- QSFP+ ports are for 40 Gbps but can also support 4x10 Gbps if channelization is supported and enabled.
- QSFP28 ports are for 100 Gbps but also can support 40 Gbps, or 4x25 Gbps or 4x10 Gbps if channelization is supported and enabled.

**Note**

A 100 Gbps DAC in a 100 Gbps port can negotiate down to 40 Gbps depending on the hardware and peer connection.

SFP28, SFP+ and SFP ports have the same physical size.

QSFP28 and QSFP+ ports have the same physical size.

To know if a port supports multiple speeds or channelization, see the applicable hardware documentation.

## Auto-Negotiation

**Table 62: Auto-Negotiation product support**

| Feature          | Product         | Release introduced                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

The Auto-Negotiation feature enables the devices to switch between the various operational modes in an ordered fashion and enables you to select a specific operational mode. The Auto-Negotiation feature also provides a parallel detection (called autosensing) function to recognize compatible devices, even if they do not support Auto-Negotiation and helps the device sense the link speed only; not the duplex mode.

You can use the **show interfaces gigabitEthernet 11-config** command to see the Auto-Negotiation operational state on a port. The operational state uses the configuration and transceiver type present in the port. If you enable Auto-Negotiation for the port but the transceiver type does not support Auto-Negotiation, the operational state is disabled (false).

#### *Default Auto-Negotiation Behavior*

The default Auto-Negotiation behavior depends on the switch model, port type, and transceiver type. The following table provides the default combinations.

**Table 63: 5420 Series default behavior**

| Port type                | Model                                                                                                                                                                                                                                                   | Transceiver type | Auto-Negotiation | FEC |

*10/100/1000 Mbps Port Considerations*

Auto-Negotiation lets devices share a link, and automatically configures both devices so that they take maximum advantage of their abilities. Auto-Negotiation uses a modified 10BASE-T link integrity test pulse sequence to determine device ability.

**Important**

Product-specific considerations for Auto-Negotiation include:

- If Auto-Negotiation is disabled, the following hardware does not support half-duplex:
  - 8424GT ESM
  - 8424XT ESM
  - VSP 7254XTQ

Configure Auto-Negotiation as shown in the following table, where A and B are two Ethernet devices.

**Table 66: Auto-Negotiation configuration on 10/100/1000BASE-TX ports**

| Port on A                | Port on B                | Remarks                                                  | Best practice                                                                                               |
|--------------------------|--------------------------|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Auto-Negotiation enabled | Auto-Negotiation enabled | Ports negotiate on highest supported mode on both sides. | Use this configuration if both ports support Auto-Negotiation mode.                                         |
| Full-duplex              | Full-duplex              | Both sides require the same mode.                        | Use this configuration if you require full-duplex, but the configuration does not support Auto-Negotiation. |

Auto-Negotiation cannot detect the identities of neighbors and cannot shut down misconnected ports. Upper-layer protocols perform these functions.

#### Note

The 10 GigabitEthernet (GbE) fiber-based I/O module ports can operate at either 1 Gigabit per second (Gbps) or 10 Gbps, depending upon the capabilities of the optical transceiver that you install.

This presents an ambiguity with respect to the Auto-Negotiation settings of the port, while 1 GbE ports require Auto-Negotiation; Auto-Negotiation is not defined and is non-existent for 10 GbE ports.

For a 10-GbE fiber-based I/O module, you can swap between 1 GbE and 10 GbE operation by simply swapping transceivers. To help with the swap, you can configure Auto-Negotiation when you install a 10 GbE transceiver, even though Auto-Negotiation is not defined for 10 GbE.

You can do this in anticipation of a port changeover from 10 GbE to 1 GbE. In this manner, you can pre-configure a port in 1 GbE mode while the 10 GbE transceiver is still installed. The port is ready to go upon the changeover to the 1 GbE transceiver.

You can use a saved configuration file with Auto-Negotiation enabled, to boot a system with either 10 GbE or 1 GbE transceivers installed. If you install a 1 GbE transceiver, the system applies Auto-Negotiation. If you install a 10 GbE transceiver, the system does not remove the Auto-Negotiation settings from the configuration, but the system simply ignores the configuration because Auto-Negotiation settings are irrelevant to a 10 GbE transceiver. The system preserves the saved configuration for Auto-Negotiation when re-saved no matter which speed of transceiver you install.

### 25 GbE Port Considerations

The 25 GbE ports typically support 25 Gbps, 10 Gbps, and 1 Gbps operational speeds. Auto-Negotiation support varies depending on the pluggable type and speed.

The following table provides a summary of Auto-Negotiation support for 25 Gbps ports.

**Table 67: 25 Gbps Port Auto-Negotiation**

| Transceiver Type    | Auto-Negotiation                                                                                            |
|---------------------|-------------------------------------------------------------------------------------------------------------|
| 25 Gbps DAC         | Supported<br><br><b>Note:</b><br>Exception: VIM5-2Y and VIM5-4Y do not support Auto-Negotiation at 25 Gbps. |
| 25 Gbps SR, LR, AOC | Not Supported                                                                                               |
| 10 Gbps             | Not Supported                                                                                               |
| 1 Gbps              | <b>Note:</b><br>Not Supported for VSP 7400-48Y.                                                             |

Forward Error Correction (FEC) is a negotiated port attribute for 25 GbE connections that support Auto-Negotiation. For more information, see [Forward Error Correction](#) on page 531.

### 40 GbE Port Considerations

Auto-Negotiation must be enabled in 40 GbE ports when using 40GbCR4 (copper Direct Attached Cables - DACs) pluggable modules as Clause 73 of the 40 GbE standard lists it as mandatory. Though the links may come up in 40 GbE ports even without Auto-Negotiation, the best practice is to always enable Auto-Negotiation. Otherwise, there might be link instability or FCS errors.

### 100 GbE Port Considerations

Ensure that you enable Auto-Negotiation for ports with 100GbCR4 modules plugged in.

Although Auto-Negotiation is mandatory as per the 100GbCR4 standard, and this is the default software configuration, you can disable Auto-Negotiation to connect with older systems that do not support it. The system does not support FEC on 100GbCR4 links with Auto-Negotiation disabled.

For more information about FEC, see [Forward Error Correction](#) on page 531.

## Auto-Negotiation Advertisements

Auto-Negotiation advertisements use Custom Auto-Negotiation Advertisement (CANA) to control the speed and duplex settings that the interface modules advertise during Auto-Negotiation sessions between Ethernet devices. Modules can only establish links using these advertised settings, rather than at the highest common supported operating mode and data rate.

Use CANA to provide smooth migration from 10 Mbps to 10000 Mbps on host and server connections. Using Auto-Negotiation only, the switch always uses the fastest possible data rates. In limited-uplink-bandwidth scenarios, CANA provides control over negotiated access speeds, and improves control over traffic load patterns.

Use the **auto-negotiation-advertisements** command to configure CANA.

To use CANA, you must enable Auto-Negotiation.

#### Important

If a port belongs to a MultiLink Trunking (MLT) group and you configure CANA on the port (that is, you configure an advertisement other than the default), you must apply the same configuration to all other ports of the MLT group if they support CANA.

The following platforms (switches and removable modules) support full duplex and half duplex modes for CANA:

| Platform                                                    | Full duplex                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Half duplex                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## SynOptics Network Management Protocol

**Table 68: SONMP product support**

| Feature | Product         | Release introduced |
|---------|-----------------|--------------------|
| SONMP   | 5420 Series     | VOSS 8.4           |
|         | 5520 Series     | VOSS 8.2.5         |
|         | VSP 4450 Series | VSP 4000 4.0       |
|         | VSP 4900 Series | VOSS 8.1           |
|         | VSP 7200 Series | VOSS 4.2.1         |
|         | VSP 7400 Series | VOSS 8.0           |
|         | VSP 8200 Series | VSP 8200 4.0       |
|         | VSP 8400 Series | VOSS 4.2           |
|         | VSP 8600 Series | VSP 8600 4.5       |
|         | XA1400 Series   | VOSS 8.0.50        |

The switch supports an auto-discovery protocol known as the SynOptics Network Management Protocol (SONMP). SONMP allows a network management station (NMS) to formulate a map that shows the interconnections between Layer 2 devices in a network. SONMP is also called Topology Discovery Protocol (TDP).

All devices in a network that are SONMP-enabled send hello packets to their immediate neighbors, that is, to interconnecting Layer 2 devices. A hello packet advertises the existence of the sending device and provides basic information about the device, such as the IP address and MAC address. The hello packets allow each device to construct a topology table of its immediate neighbors. A network management station periodically polls devices in its network for these topology tables, and then uses the data to formulate a topology map.

If you disable SONMP, the system stops transmitting and acknowledging SONMP hello packets. In addition, the system removes all entries in the topology table except its own entry. If you enable SONMP, the system transmits a hello packet every 12 seconds. The default status is enabled.

### *SONMP for the Segmented Management Instance*

SONMP and LLDP both advertise the same topology IP address for the Segmented Management Instance management interface. SONMP supports IPv4 advertisement only. If all three management interfaces are configured, the advertised default topology IP priority is management CLIP, then management VLAN, then management OOB. You can change the default topology IP using CLI or EDM. If multiple IPv4 addresses are configured on an OOB or VLAN management interface, the advertised IP priority is static IP address, then DHCP IP address, then link-local IP address.

## Channelization

**Table 69: Channelization product support**

| Feature                          | Product         | Release introduced          |
|----------------------------------|-----------------|-----------------------------|
| Channelization of 40 Gbps ports  | 5420 Series     | Not Applicable              |
|                                  | 5520 Series     | VOSS 8.2.5                  |

|                                  | VSP 8600 Series | VSP 8600 6.2                |
|                                  | XA1400 Series   | Not Applicable              |

Use the channelization feature to configure a single port to operate as four individual ports. Channelization can apply to the following port speeds:

- 40 Gbps (Quad Small Form-factor Pluggable) (QSFP+) – when channelized, operates as four 10 Gbps ports

- 100 Gbps (QSFP28) — when channelized, operates as four 25 Gbps ports

**Note**

In cases where the hardware supports it, you can insert a 40 Gbps QSFP+ transceiver in a 100 Gbps port, and use the 100 Gbps port as a 40 Gbps port. If you enable channelization on a 100 Gbps port and the switch detects a 40 Gbps QSFP+ transceiver in the port, the port operates as four individual 10 Gbps ports.

If the switch detects a 100 Gbps QSFP28 transceiver and you enable channelization, the port operates as four 25 Gbps ports.

To know if you can use a 100 Gbps port as a 40 Gbps port and support the channelization of that port, see the applicable hardware documentation.

You can use breakout direct attach cables (DAC) or transceivers with fiber breakout cables to connect the channelized ports to other servers, storage, and switches.

By default, the ports are not channelized, which means that the ports operate as one single port at the fully supported speed. You can enable or disable channelization on a port.

For the number of ports on the switch that support channelization, see the applicable hardware documentation.

If the product supports channelization and you enable or disable channelization on a port, the port QoS configuration resets to default values. For information about configuring QoS values, see [Quality of Service](#) on page 2626.

**Note**

When you use channelized ports in an Split Multi-Link Trunking (SMLT) configuration, the system does not display the channelized ports properly when you show MLT information for the remote port member if the remote switch runs a release that does not support channelization.

When a port is channelized, use only break out cables (copper or active optical DAC) in it. Using other cables in either a channelized port or a non-channelized port results in mismatched link status between link partners, which can lead to network issues.

*SFP-DD Ports***Note**

Product Notice: SFP-DD ports are specific to 5420 Series.

Advanced Feature Bandwidth is enabled by default on the SFP-DD ports. When Advanced Feature Bandwidth is disabled, SFP-DD ports can operate as 1 Gbps ports with an SFP and as 10 Gbps ports with an SFP+. When the SFP-DD split DAC is used, SFP-DD ports can accept two SFP+ with 10 Gbps port speed.

**Note**

SFP-DD split DAC applies to certain 5420 Series models.

For more information about SFP-DD ports, see [5420 Series](#) on page 3934.

### Feature Interaction with Channelization

Software features operate on channelized ports. When an interface is dechannelized, the interface cleans up all the channels.

If a feature operates on channel 1/1/1 and 1/1/2, and the circuit is dechannelized, the 1/1/1 configuration is saved and the commands are configured on 1/1. The configuration on 1/1/2 is deleted.

## Forward Error Correction

Forward Error Correction (FEC) is a method of obtaining error control in data transmission over an unreliable or noisy channel in which the source (transmitter) encodes the data in a redundant way by using an error correcting code (ECC). This redundancy enables a destination (receiver) to detect a limited number of errors and correct them without requiring a re-transmission.

FEC is useful where re-transmitting data is either expensive or impossible, for example, when transmitting to multiple receivers in multicast. However, although FEC provides more error control, it introduces a latency in data transmission.

### FEC Configuration Options

You typically configure FEC on a port. The supported options are:

- cl91 (Clause 91 RS-FEC)
- cl108 (Clause 108 RS-FEC):
- cl74 (Clause 74 Firecode R-FEC):
- auto:

FEC is not supported on:

- Out-of-band (OOB) management ports.
- 100 GbE ports that are changed to 40 GbE ports by dynamically swapping 100 Gb modules with 40 Gb modules. FEC does not support the 40 Gbps speed.

#### Important

- On ports that support FEC configuration, ensure that you configure the same option at both end-points. Otherwise, the link does not come up.
- You must enable FEC to achieve proper functionality when using interconnects such as the 25Gb SR, 25 Gb SR-lite, 25 Gb ESR optics or the 25 Gb AOC and 25 Gb DAC.
- FEC is not required on 100 Gb or 25 Gb long-range optics because these optics do error checking internally.

#### *Clause 91 RS-FEC*

This option supports both the 25 Gbps and 100 Gbps speeds. You can configure this option on ports with either the 100GbSR4 or 100GbCR4 modules plugged in, or on 100 GbE channelized ports operating at 25Gbps speed.

#### Note

Ensure that you enable Auto-Negotiation for ports with the 100GbCR4 modules plugged in; it is mandatory.

#### *Clause 108 RS-FEC*

This option also supports both the 25 Gbps and 100 Gbps speeds. It is similar to Clause 91 but provides extra latency.

#### *Clause 74 Firecode R-FEC*

This option supports only the 25 Gbps speed and is used in applications that require reduced latency.

#### *Auto*

This option automatically configures FEC based on port speed and pluggable module type.

- For 25 Gbps speeds, FEC CL108 is enabled for all transceiver types.
- For 100Gbps speeds:
  - FEC is disabled for 100GbE LR4 and ER4 transceivers.
  - FEC CL91 is enabled for all other transceiver types (for example, 100GbE SR4, CR4, AOC, CWDM4, SWDM4).

#### *FEC and Auto-Negotiation*

FEC is a negotiated port attribute for 25 Gb and 100 Gb connections that support Auto-Negotiation. If you enable Auto-Negotiation on a port for a supported transceiver type, the switch uses the configured FEC value in the negotiation advertisement. Peers can advertise different values, which means the resulting FEC operational state can be different than the one advertised.

The following table lists the 25 Gb end-point advertisements and the resulting FEC operational state:

**Table 71: 25 Gb end-point advertisements**

| Peer A | Peer B | Result |
|--------|--------|--------|
| CL108  | CL108  | CL108  |
| CL74   | CL74   | CL74   |
| No FEC | No FEC | No FEC |
| No FEC | CL108  | CL108  |
| No FEC | CL74   | CL74   |
| CL74   | CL108  | CL108  |

The following table lists the 100 Gb end-point advertisements and the resulting FEC operational state:

**Table 72: 100 Gb end-point advertisements**

| Peer A | Peer B | Result                                                                                                                                   |
|--------|--------|------------------------------------------------------------------------------------------------------------------------------------------|
| CL91   | CL91   | CL91                                                                                                                                     |
| No FEC | No FEC | CL91<br><b>Note:</b><br>Even when both peers advertise no FEC, negotiation results in clause 91 FEC per IEEE standard mandatory setting. |
| No FEC | CL91   | CL91                                                                                                                                     |

You can use the **show interfaces gigabitEthernet config** command to see the FEC operational state for a port.

For additional details about support, see [Default Auto-Negotiation Behavior](#) on page 518.

## IEEE 802.3X Pause Frame Transmit

**Table 73: IEEE 802.3X Pause Frame Transmit product support**

| Feature                          | Product         | Release introduced |
|----------------------------------|-----------------|--------------------|
| IEEE 802.3X Pause frame transmit | 5420 Series     | VOSS 8.4           |
|                                  | 5520 Series     | VOSS 8.2.5         |
|                                  | VSP 4450 Series | VOSS 6.0           |
|                                  | VSP 4900 Series | VOSS 8.1           |
|                                  | VSP 7200 Series | VOSS 6.0           |
|                                  | VSP 7400 Series | VOSS 8.0           |
|                                  | VSP 8200 Series | VOSS 6.0           |
|                                  | VSP 8400 Series | VOSS 6.0           |
|                                  | VSP 8600 Series | Not Supported      |
|                                  | XA1400 Series   | VOSS 8.1.50        |

The switch uses MAC pause frames to provide congestion relief on full-duplex interfaces.

### *Overview*

When congestion occurs on a port, the system can send or receive pause frames, also known as flow control, to temporarily pause the packet flow. The system uses flow control if the rate at which one or more ports receives or sends packets is greater than the rate the switch can process or accept the packets.

The switch can generate pause frames to tell the sending device to stop sending additional packets for a specified time period. After the time period expires, the sending device can resume sending packets. During the specified time period, if the switch determines the congestion is reduced, it can send pause frames to the sending device to instruct it to begin sending packets immediately.

### *Flow control mode and pause frames*

If you enable flow control mode, the switch drops packets on ingress when congestion occurs. If the switch is not in flow control mode, it drops packets at egress when congestion occurs.

Configure an interface to send pause frames when congestion occurs to alleviate packet drops due to flow control mode.

### *Auto-Negotiation*

Interfaces that support auto-negotiation advertise and exchange their flow control capability to agree on a pause frame configuration. IEEE 802.3 annex 28b defines the auto-negotiation ability fields and the

pause resolution. The switch advertises only two capabilities. The following table shows the software bit settings based on the flow control configuration.

**Note**

Not all interfaces support Auto-Negotiation. For more information, see your hardware documentation.

**Table 74: Advertised abilities**

| Interface configuration | Pause | ASM | Capability advertised                     |
|-------------------------|-------|-----|-------------------------------------------|
| Flow control enabled    | 1     | 0   | Symmetric pause                           |
| Flow control disabled   | 1     | 1   | Both Symmetric pause and asymmetric pause |

The following tables identifies the pause resolution.

**Table 75: Pause resolution**

| Local device pause | Local device ASM | Peer device pause | Peer device ASM | Local device resolution                       | Peer device resolution                        |
|--------------------|------------------|-------------------|-----------------|-----------------------------------------------|-----------------------------------------------|
| 0                  | 0                | Do not care       | Do not care     | Disable pause transmit and receive.           | Disable pause transmit and receive.           |
| 0                  | 1                | 0                 | Do not care     | Disable pause transmit and receive.           | Disable pause transmit and receive.           |
| 0                  | 1                | 1                 | 0               | Disable pause transmit and receive.           | Disable pause transmit and receive.           |
| 0                  | 1                | 1                 | 1               | Enable pause transmit. Disable pause receive. | Disable pause transmit. Enable pause receive. |
| 1                  | 0                | 0                 | Do not care     | Disable pause transmit and receive.           | Disable pause transmit and receive.           |
| 1                  | Do not care      | 1                 | Do not care     | Enable pause transmit and receive.            | Enable pause transmit and receive.            |
| 1                  | 1                | 0                 | 0               | Disable pause transmit and receive.           | Disable pause transmit and receive.           |
| 1                  | 1                | 0                 | 1               | Disable pause transmit. Enable pause receive. | Enable pause transmit. Disable pause receive. |

The following list identifies the type of interfaces that support auto-negotiated flow control:

- 10 Mbps/100 Mbps/1 Gbps copper
- 100 Mbps/1 Gbps/10 Gbps copper
- 1 Gbps fiber (in both SFP and SFP+ ports)

## Auto MDIX

Automatic medium-dependent interface crossover (Auto-MDIX) automatically detects the need for a straight-through or crossover cable connection and configures the connection appropriately. This removes the need for crossover cables to interconnect switches and ensures either type of cable can be used. The speed and duplex setting of an interface must be set to Auto for Auto-MDIX to operate correctly.

Auto MDIX is supported on all platforms with fixed copper ports. All fixed copper ports are supported.

## IOC Module Preconfiguration

**Table 76: IOC Module Preconfiguration**

| Feature                     | Product         | Release introduced |
|-----------------------------|-----------------|--------------------|
| IOC Module Preconfiguration | 5420 Series     | Not Applicable     |
|                             | 5520 Series     | Not Applicable     |
|                             | VSP 4450 Series | Not Applicable     |
|                             | VSP 4900 Series | Not Applicable     |
|                             | VSP 4900 Series | Not Applicable     |
|                             | VSP 7200 Series | Not Applicable     |
|                             | VSP 7400 Series | Not Applicable     |
|                             | VSP 8200 Series | Not Applicable     |
|                             | VSP 8600 Series | VSP 8600 8.0       |
|                             | XA1400 Series   | Not Applicable     |

Using IOC Module Pre-Configuration, you can configure a slot for an IOC Module before you insert the module in the chassis. By specifying the slot and module type, all configuration at the slot or port level become available for that slot. You can issue configuration commands for a specific slot before you insert an IOC Module in that slot.

When you insert the IOC Module that matches the pre-configured module type in the specified slot, all configuration related to that slot is applied, and pre-configuration loads on the IOC Module automatically. However, if the module type of the inserted IOC Module does not match the module type of the IOC Module Pre-Configuration, then the IOC module functionality depends on the following card lock configurations:

- If the card lock option is enabled, the inserted IOC Module is rejected and does not boot up. Only modules that are of same type as the IOC Module Pre-Configuration type for the slot are able to boot up on that slot. The output of the **show sys-info** command displays the operational status of the inserted module as `down-Mismatch`.
- If the card lock option is disabled, existing configuration is removed on that slot and a new IOC Module is accepted and boots up with default configuration.

When you remove an IOC Module from the chassis, all configuration on that slot is still available because the module was automatically pre-configured on that slot. You can view the configuration for the module by using the **show sys-info card** command. You can also change the configuration for an

IOC Module that has been removed from the chassis. When you save the configuration, the configuration for all slots is saved regardless of which modules are plugged into the chassis.

### *Hotswapping IOC Modules*

If a preconfigured IOC Module is replaced with a model that does not match the preconfigured IOC Module type and the card lock is enabled, then the IOC Module does not boot up. Either a module of the same type as the preconfigured IOC Module must be reinserted in the slot or the pre-configured IOC Module type must be removed from the configuration.

#### **Important**

Removing the preconfigured IOC Module type from the configuration also removes the configuration for the slot.

When a new IOC Module is inserted in the slot, the module boots with default configuration. If a module is inserted into a running system and the module type is not configured for the slot, the system automatically creates a preconfiguration with the module type of the IOC Module that was inserted. Then the module boots with default configuration.

## Chassis operations configuration using the CLI

---

This section provides the details to configure basic hardware and system settings.

### Enabling the High Availability-CPU (HA-CPU) mode

#### **About This Task**

Enable High Availability-CPU (HA-CPU) mode to enable devices with two CPUs to recover quickly from a failure of the master CPU.

#### **Procedure**

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure the following boot flag:  
`boot config flags ha-cpu`

The configuration file is saved on both the CPUs. After you disable HA mode on the master CPU, the secondary CPU software automatically resets and loads the settings from the previously-saved configuration file.

3. Type `y` after displaying the following prompt:

```
Do you want to continue (y/n) ?
```

Responding to the user prompt with a `y` causes the secondary CPU to reset itself automatically, and that secondary CPU restarts with HA mode enabled.

4. Save the configuration.

**Example**

```
Switch:1>enable
Switch:1#configure terminal
```

Enable HA mode:

```
Switch:1(config)#boot config flags ha-cpu
The config files on the Master and Slave will be overwritten with the current active
configuration.
-Layer 2/3 features will be enabled in L2/L3 redundancy mode.
Do you want to continue (y/n)?y
Boot configuration is being saved.
CP-1: Save config to file /intflash/config.cfg successful.
CP-2: Save /intflash/config.cfg to standby successful.
Runtime configuration is being saved.
Resetting Slave CPU from Master CPU.
CP1 [01/07/17 15:21:50.605:UTC] 0x000045e3 00000000 GlobalRouter SNMP INFO Save config
successful.
CP2 [01/07/17 15:22:16.890:UTC] 0x000105e3 00000000 GlobalRouter HW INFO HA-CPU: Table
Sync is complete (Standby CPU)
CP1 [01/07/17 15:22:17.407:UTC] 0x000105c8 00000000 GlobalRouter HW INFO HA-CPU: Table
Sync Completed on Secondary CPU
```

Verify the configuration:

```
Switch:1(config)#show ha-state
Current CPU State : Synchronized State.
Last Event : Table synchronization completed.
Mode : Warm Standby

Card Info :
      Slot#      CardType      Oper      Admin      Power
              Status      Status      State
          1      8624XS      up-Master      up      on
          2      8624XS      up-Warmstandby      up      on

Current Boot Config State: master 1
```

Save the configuration:

```
Switch:1(config)#save config
```

**What to Do Next****Note**

In HA-CPU mode, whenever there is a mismatch of boot config flags between the master CPU and the standby CPU, the standby CPU follows the master CPU. The mismatch could be due to different runtime config files or primary config files at standby CPU. Once the chassis boots up successfully on the switch, ensure that both the CPUs run the same primary config file and the running config file.

## Disabling the High Availability-CPU (HA-CPU) Mode

**About This Task**

Perform this procedure to disable HA mode.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enter the following boot flag command:  

```
no boot config flags ha-cpu
```

The configuration file is saved on both the CPUs. After you enable HA mode on the master CPU, the secondary CPU software automatically synchronizes the configuration from the master CPU.

**Example**

```
Switch:1>enable
Switch:1#configure terminal
```

Disable HA mode:

```
Switch:1(config)#no boot config flags ha-cpu
The config files on the Master and Slave will be overwritten with the current active
configuration.
-No longer Layer 2/3 features run in L2/L3 redundancy mode.
Do you want to continue (y/n) ? y
Boot configuration is being saved.
CP-1: Save config to file /intflash/config.cfg successful.
CP-2: Save /intflash/config.cfg to standby successful.
Resetting Slave CPU from Master CPU.
```

Verify the configuration:

```
Switch:1(config)#show ha-state
Current CPU State : Disabled State.
Last Event : No event.
Mode : Warm Standby

Card Info :
      Slot#      CardType      Oper      Admin      Power
              Status      Status      State
          1      8624XS      up-Master      up      on
          2      8624XS      up-Warmstandby      up      on

Current Boot Config State: master 1
```

## Removing an IOC Module with HA Mode Activated

**About This Task**

Perform this procedure to properly remove the IOC module that is in the master CP slot, when the system operates in HA mode.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```

2. Use the `sys action cpu-switch-over` command to fail over to another CP.
3. Remove the IOC module.

**Important**

Do not reinsert an IOC module until at least 15 seconds has elapsed, which is long enough for another CP slot to become master.

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys action cpu-switch-over
```

## Enabling jumbo frames

**About This Task**

Enable jumbo frames to increase the size of Ethernet frames the chassis supports.

**Procedure**

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable jumbo frames:  
`sys mtu <1522-9600>`

**Example**

```
Switch:1> enable

Switch:1# configure terminal

Enable jumbo frames to 9600 bytes:

Switch:1#(config)# sys mtu 9600
```

*Variable Definitions*

The following table defines parameters for the **sys mtu** command.

| Variable    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1522-9600> | <p>Configures the frame size support for the data path.<br/>Possible sizes are 1522, 1950, or 9600 bytes.<br/>The default varies depending on the platform:</p> <ul style="list-style-type: none"> <li>• 5420 Series - 9600 bytes</li> <li>• 5520 Series - 1950 bytes</li> <li>• VSP 4450 Series - 1950 bytes</li> <li>• VSP 4900 Series - 1950 bytes</li> <li>• VSP 7200 Series - 1950 bytes</li> <li>• VSP 7400 Series - 1950 bytes</li> <li>• VSP 8200 Series - 1950 bytes</li> <li>• VSP 8400 Series - 1950 bytes</li> <li>• VSP 8600 Series - 1950 bytes</li> <li>• XA1400 Series - 1950 bytes</li> </ul> |

## Configuring port lock

### About This Task

Configure port lock to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify a locked port until you unlock the port.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable port lock globally:
 

```
portlock enable
```
3. Log on to GigabitEthernet Interface Configuration mode:
 

```
interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```
4. Lock a port:
 

```
lock port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} enable
```

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Log on to GigabitEthernet Interface Configuration mode:
```

```
Switch:1(config)# interface GigabitEthernet 1/1
```

Unlock port 1/14:

```
Switch:1(config-if)# no lock port 1/14 enable
```

### Variable Definitions

The following table defines parameters for the **interface gigabitethernet** and **lock port** commands.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.<br>For the <code>lock port</code> command, use the <code>no</code> form of this command to unlock a port: <code>no lock port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> |

## Configuring SONMP

### About This Task

Configure the SynOptics Network Management Protocol (SONMP) to allow a network management station (NMS) formulate a map that shows the interconnections between Layer 2 devices in a network. The default status is enabled.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Disable SONMP:  
no autotopology
3. Enable SONMP:  
autotopology

### Example

```
Switch:1> enable

Switch:1 configure terminal

Disable SONMP:

Switch:1(config)# no autotopology
```

## View the Topology Message Status

### About This Task

View topology message status to view the interconnections between Layer 2 devices in a network.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the contents of the topology table:

```
show autotopology nmm-table
```

Unless the switch is physically connected to other devices in the network, this topology will be blank.

### Example

#### Note

In the following example, the column “ChassisType” uses a generic name. When you use the **show autotopology nmm-table**, your switch displays the actual chassis type.

```
Switch:1(config)#show autotopology nmm-table
```

| Topology Table |            |           |              |               |  |    |     |      |          |
|----------------|------------|-----------|--------------|---------------|--|----|-----|------|----------|
| Local Port     | IpAddress  | SegmentId | MacAddress   | ChassisType   |  | BT | LS  | CS   | Rem Port |
| 0/0            | 192.0.2.81 | 0x000000  | 0030ab707a00 | ChassisType 1 |  | 12 | Yes | HtBt | 0/0      |
| 1/1            | 192.0.2.81 | 0x000000  | 0050ea268800 | ChassisType 2 |  | 12 | Yes | HtBt | 1/50     |
| 1/42           | 192.0.2.81 | 0x000000  | 070ab307aa00 | ChassisType 3 |  | 12 | Yes | HtBt | 1/1      |
| 2/1            | 192.0.2.81 | 0x000000  | 0030ab57ab00 | ChassisType 4 |  | 12 | Yes | HtBt | 1/49     |
| 2/2            | 192.0.2.81 | 0x000000  | 0030ab307af0 | ChassisType 5 |  | 12 | Yes | HtBt | 1/50     |
| 2/41           | 192.0.2.81 | 0x000000  | 00e0ba327c00 | ChassisType 6 |  | 12 | Yes | HtBt | 2/1      |
| 2/42/1         | 192.0.2.81 | 0x000000  | 0050eb127400 | ChassisType 7 |  | 12 | Yes | HtBt | 1/2      |

#### Note

When a peer switch is running an older software version that does not include support for SONMP hello messages with channelization information, it can only show the slot/port. It cannot show the sub-port.

## Associating a port to a VRF instance

Associate a port to a Virtual Router Forwarding (VRF) instance so that the port becomes a member of the VRF instance.

### Before You Begin

- The VRF instance must exist. For more information about the creation of VRFs, see [Create a VRF Instance](#) on page 3815.

### About This Task

You can assign a VRF instance to a port after you configure the VRF. The system assigns ports to the Global Router, VRF 0, by default.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Associate a VRF instance with a port:

```
vrf <WORD 1-16>
```

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# interface gigabitethernet 1/12
```

```
Switch:1(config-if)# vrf red
```

## Configure an IP Address for the Management Port

#### Note

This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management](#) on page 60.

Configure an IP address for the management port so that you can remotely access the device using the out-of-band (OOB) management port. The management port runs on a dedicated VRF.

The configured IP subnet has to be globally unique because the management protocols can go through in-band (Global Router) or out-of-band ports (Management VRF).

### Before You Begin

- Do not configure a default route in the Management VRF.
- If you want out-of-band management, define a specific static route in the Management Router VRF to the IP subnet where your management application resides.
- If you initiate an FTP session from a client device behind a firewall, you should set FTP to passive mode.
- The switch gives priority to out-of-band management when there is reachability from both in-band and out-of-band. To avoid a potential conflict, do not configure an overlap between in-band and out-of-band networks.

## Procedure

1. Enter mgmtEthernet Interface Configuration mode:  

```
enable

configure terminal

interface mgmtEthernet <mgmt | mgmt2>
```
2. Configure the IP address and mask for the management port:  

```
ip address {<A.B.C.D/X> | <A.B.C.D> <A.B.C.D>}
```
3. Configure an IPv6 address and prefix length for the management port:  

```
ipv6 interface address WORD<0-255>
```
4. Show the complete network management information:  

```
show interface mgmtEthernet
```
5. Show the management interface packet/link errors:  

```
show interface mgmtEthernet error
```
6. Show the management interface statistics information:  

```
show interface mgmtEthernet statistics
```

## Example

Configure the IP address for the management port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface mgmte ethernet mgmt
Switch:1(config-if)#ip address 192.0.2.24 255.255.255.0
```

### Variable Definitions

The following table defines parameters for the **ip address** command.

| Variable                            | Value                                                 |
|-------------------------------------|-------------------------------------------------------|
| {<A.B.C.D/X>   <A.B.C.D> <A.B.C.D>} | Specifies the IP address followed by the subnet mask. |

The following table defines parameters for the **ipv6 interface address** command.

| Variable    | Value                                         |
|-------------|-----------------------------------------------|
| WORD<0-255> | Specifies the IPv6 address and prefix length. |

## Configure Ethernet Ports with Auto-Negotiation

Configure Ethernet ports so they operate optimally for your network conditions.

### About This Task

When you use 1 Gigabit Ethernet SFP transceivers, the software disables Auto-Negotiation on the port. If you use 1 Gbps SFP transceivers, the remote end must also have Auto-Negotiation disabled.

All ports that belong to the same MLT or Link Aggregation Control Protocol (LACP) group must use the same port speed. In the case of MLTs, the software does not enforce this.

The software requires the same Auto-Negotiation settings on link partners to avoid incorrect declaration of link status. Mismatched settings can cause the links to stay down. Ensure the Auto-Negotiation settings between local ports and their remote link partners match before you upgrade the software.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Auto-Negotiation:

```
auto-negotiate [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] enable
```

3. Verify the configuration:

```
show interfaces gigabitEthernet l1-config [{slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]]
```

## Example

```
Switch:>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/8
Switch:1(config-if)#auto-negotiate enable
Switch:1(config-if)#show interfaces gigabitEthernet l1-config 1/8
=====
Port Config L1
=====
PORT      AUTO  OPERATE  CUSTOM AUTO NEGOTIATION CANA  ADMIN  OPERATE  ADMIN  OPERATE
NUM      NEG.  AUTO-NEG ADVERTISEMENTS          ORIGIN DPLX SPD  DPLX SPD  TX-FLW-CTRL  TX-FLW-CTRL
-----
1/8      true  true    Not Configured          RADIUS full 10000  0          enable  enable
```

### Variable Definitions

The following table defines parameters for the **auto-negotiate** command.

| Variable                                                           | Value                                                                                                                                                          |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Specifies the port or ports that you want to configure.                                                                                                        |
| <code>enable</code>                                                | Enables auto-negotiation for the port or other ports of the module.<br>The default Auto-Negotiation behavior depends on the switch model and transceiver type. |

## Configure Auto-Negotiation Advertisements

Configure local port Auto-Negotiation advertisements to specify the speed and duplex mode for traffic between local ports and remote link partners. Supported speeds and duplex modes vary, depending on your hardware.

### Before You Begin

You must enable Auto-Negotiation before you perform this procedure.

### About This Task

Configure local port Auto-Negotiation advertisements.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Auto-Negotiation advertisements on one or more ports:

```
auto-negotiation-advertisements {10000-full|2500-full|5000-full|1000-
full|100-full|100-half|10-full|10-half}
```

or

```
auto-negotiation-advertisements port {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]} {10000-full|2500-full|5000-full|1000-full|
100-full|100-half|10-full|10-half}
```

3. Verify the configuration:

```
show interfaces gigabitEthernet ll-config [{slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]}
```

### Variable Definitions

The following table defines parameters for the **auto-negotiation-advertisements** command.

| Variable                                                     | Value                                                   |
|--------------------------------------------------------------|---------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Specifies the port or ports that you want to configure. |
| <i>10000-full</i>                                            | Advertises 10000 Mbps full duplex.                      |
| <i>5000-full</i>                                             | Advertises 5000 Mbps full duplex.                       |
| <i>2500-full</i>                                             | Advertises 2500 Mbps full duplex.                       |
| <i>1000-full</i>                                             | Advertises 1000 Mbps full duplex.                       |
| <i>100-full</i>                                              | Advertises 10000 Mbps full duplex.                      |
| <i>100-half</i>                                              | Advertises 10000 Mbps half duplex.                      |
| <i>10-full</i>                                               | Advertises 10 Mbps full duplex.                         |
| <i>10-half</i>                                               | Advertises 10 Mbps half duplex.                         |
| <i>none</i>                                                  | Configures the Auto-Negotiate value to none.            |

## Configure IEEE 802.3X Pause Frame Transmit

Configure IEEE 802.3X Pause frame transmit to eliminate or minimize packet loss.

### About This Task

By default, flow control mode is disabled. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.

By default, an interface does not send pause frames.

#### Note

If you enable MACsec on an interface and you send small packet size traffic near line rate, the **In FlowCtrl** frame might increment in the output of the **show interface gigabitEthernet statistics** command because of the processing overhead caused by adding the MACsec header of 32 bytes. This is part of the expected over-subscription footprint.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable flow control mode:
 

```
boot config flags flow-control-mode
```
3. Save the configuration.
4. Exit Privileged EXEC mode:
 

```
exit
```

5. Reboot the chassis.

```
boot
```

6. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

7. Configure the interface to generate pause frames:

```
tx-flow-control [enable]
```

8. (Optional) Configure other interfaces to generate pause frames:

```
tx-flow-control port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} enable
```

9. Verify the boot flag configuration:

```
show boot config flags
```

10. Verify the interface configuration:

```
show interfaces gigabitEthernet ll-config {slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]}
```

11. View the pause-frame packet count:

```
show interfaces gigabitEthernet statistics {slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]}
```

### Example

Enable flow control on the system and configure slot 1, port 10 to send pause frames. Verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags flow-control-mode
Warning: Please save the configuration and reboot the switch
        for this configuration to take effect.
Switch:1<config>#save config
CP-1: Save config to file /intflash/config.cfg successful.
CP-1: Save license to file /intflash/license.xml successful.
Switch:1<config>#exit
Switch:1#boot
Are you sure you want to re-boot the switch (y/n) ?y
```

#### Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
```

```

### Variable Definitions

The following table defines parameters for the **tx-flow-control** command.

| Variable                                                                | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enable</code>                                                     | Configures the interface to send pause frames. By default, flow control is disabled.<br><br><b>Note:</b><br><b>tx-flow-control</b> is enabled by default on XA1400 Series.                                                                                                                                                                                    |
| <code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

Use the data in the following table to use the **show interfaces gigabitEthernet l1-config** and **show interfaces gigabitEthernet statistics** commands.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Enable Channelization

Enable channelization on a port to configure it to operate as four channels, or ports.

### Important

Enabling or disabling channelization resets the port QoS configuration to default values.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable channelization on a port:

```
channelize [port {slot/port[-slot/port]} [,...]] enable
```

3. Display the status of the ports:

```
show interfaces gigabitEthernet channelize [{slot/port[-slot/port]
[,...]]}
```

To display the details of the sub-ports, use:

```
show interfaces gigabitEthernet channelize detail [{slot/port/sub-
port[-slot/port/sub-port][,...]]}
```

4. (Optional) To disable channelization on a port, enter:

```
no channelize [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] enable
```

**Example**

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitEthernet 2/1
Switch:1(config-if)# channelize enable
Enabling channelization on port 2/1. Subport 2/1/1 will inherit port 2/1 configuration.
Subports 2,3,4 will use default config. QSFP will be reset as removal and re-insert.
NOTE: Modify QOS configurations on all subports as required.
Do you wish to continue (y/n) ? y
```

Display the port status:

```
Switch:1(config)# show interfaces gigabitEthernet channelize 2/2-2/4

=====
Port Channelization
=====
-----
PORT          ADMIN MODE    CHANNEL TYPE
-----
2/2           true          40G
2/3           false         40G
2/4           false         40G
```

The following is an example of how to disable channelization on a port:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitEthernet 2/2/1
Switch:1(config-if)# no channelize enable
```

*Variable Definitions*

The following table defines parameters for the **channelization** command.

| Variable                                             | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {slot/port[/sub-port] [-slot/port[/sub-port]][,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Configure FEC on a Port

### About This Task

Use this procedure to configure Forward Error Correction (FEC) on supported ports.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. (Optional) Specify the port or ports to configure for FEC:

```
fec port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

3. Configure FEC on a port:

```
fec {auto | c1108 | c174 | c191}
```

4. Verify the configuration:

```
show interfaces gigabitEthernet config {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

### Examples

Configure Clause 108 FEC on a 25 Gbps port 1/1:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#fec c1108
```

Verify the configuration when a 25 Gbps optic is present:

```
Switch:1(config-if)#show interfaces gigabitEthernet config 1/1
=====
Port Config
=====
PORT          DIFF-SERV  QOS  MLT  VENDOR
NUM    TYPE          EN    TYPE  LVL  ID    NAME
-----
1/1     25GbCX         true core  1    0    Extreme
=====
Port Config
=====
PORT  ADMIN  OPERATE AUTO  ACCESS-SERV  RMON  FLEX-UNI  ADMIN  APPLICABLE  OPERATE

-----
1/1  Enable  Disable Disable false          Disable  Disable  Auto  CL108  CL108
```

Verify the configuration when a 10 Gb optic is present in a 25 Gb port:

```
Switch:1(config-if)#show interfaces gigabitEthernet config 1/1
=====
Port Config
=====
PORT          DIFF-SERV  QOS  MLT  VENDOR
NUM          TYPE      EN   TYPE LVL  ID   NAME
-----
1/1          10GbSR   true core  1   0   Extreme

PORT  ADMIN  OPERATE AUTO  ACCESS-SERV  RMON  FLEX-UNI  ADMIN  APPLICABLE  OPERATE
NUM   ROUTING ROUTING RECOVER  EN          ID        FEC     FEC          FEC
-----
1/1   Enable  Disable Disable false          Disable  Disable  Auto  Not Applicable  Off
```

Variable Definitions

The following table defines parameters for the **fec** command.

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                                                                                                                                                                           |
| {auto   c1108   c174   c191}                               | Configures one of the following options for FEC on the port: <ul style="list-style-type: none"> <li>• auto</li> <li>• Clause 91</li> <li>• Clause 108</li> <li>• Clause 74</li> </ul> <p><b>Note:</b><br/>On a 100 GbE port, only the Clause 91 and Clause 108 options are supported. On 100 GbE channelized ports (operating at 25 Gbps speed), you can configure Clause 108 for extra latency or Clause 74 for reduced latency.<br/>Configuration of FEC is not supported on a management port or on 100 GbE ports operating at 40 Gbps speed.</p> <p><b>Important:</b><br/>On ports that support FEC, always configure the same option on both end-points. Otherwise, the link does not come up.</p> |

## Configuring Serial Management Port Dropping

Configure the serial management ports to drop a connection that is interrupted for any reason. If you enable serial port dropping, the serial management ports drop the connection for the following reasons:

- modem power failure
- link disconnection
- loss of the carrier

Serial ports interrupted due to link disconnection, power failure, or other reasons force out the user and end the user session. Ending the user session ensures a maintenance port is not available with an active session that can allow unauthorized use by someone other than the authenticated user, and prevents the physical hijacking of an active session by unplugging the connected cable and plugging in another.

By default, the feature is disabled with enhanced secure mode disabled. If enhanced secure mode is enabled, the default is enabled.

For more information on enhanced secure mode, see [Enabling enhanced secure mode](#) on page 3322.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Configure the serial port to drop if a connection is interrupted:  
`sys security-console`

### Example

Configure the serial port to drop if a connection is interrupted:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys security-console
```

## Configuring power on module slots

### About This Task

Use this procedure to control whether or not to supply power to specific slots that contain either switch fabric modules or input/output modules. By default, power is available to all slots.

After enabling power to specific input/output module slots, you can also configure the priority in which they are powered on. For more information, see [Configuring Slot Priority](#) on page 556.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable power to one or more slots:  
`sys power slot <1-4 | 1-8 | SF1-SF3>`

3. Disable power to one or more slots:

```
no sys power slot <1-4 | 1-8 | SF1-SF3>
```

### Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Enable power to Slot 1:

```
Switch:1 (config)#sys power slot 1
```

Disable power to Slot 1:

```
Switch:1 (config)#no sys power slot 1
```

Enable power to Slots 3 and 5:

```
Switch:1(config)#sys power slot 3,5
```

Disable power to Slots 3 and 5:

```
Switch:1(config)#no sys power slot 3,5
```

### Variable Definitions

The following table defines parameters for the **sys power slot** command.

| Variable              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4   1-8   SF1-SF3> | Identifies the slot to provide power in one of the following formats: a single slot (1), a range of slots (1-3), or a series of slots (1,2,4). The default is to provide power to all slots.<br>Use the <code>no</code> operator to disable power to a slot.<br>Use the <code>default</code> operator to enable power to a slot.<br>Different hardware platforms support different slot ranges. Use the CLI Help to see the available range. |

## Configuring Slot Priority

### Note

This procedure only applies to VSP 8600 Series.

### About This Task

Configure slot priority to specify which slots you want to shut down if there is insufficient power available in the chassis. By default, power is available to all slots, and the slots have the following priority:

- Slots 1, 2, SF1, SF2, and SF3 must always be *Critical* so you cannot configure them.

- Slots 3-8 are *High* by default, but you can configure any of them to *Low*.

**Note**

Power is always supplied to critical slots first which are the CP modules, SF modules, and fan trays.

The slot with the lowest priority shuts down first. Slots with the same priority shut down in descending order (highest slot number first) and interface slots shut down before CP, SF modules, and fan tray slots.

For example, if slot 3 has a *low* priority and slots 4 and 5 have a *high* priority, the slot shutdown priority is as follows: 4, 5, 3. Slot 3 has the lowest priority because it was configured as *low* so it would be shut down first. Slots 4 and 5 have the same priority, but slot 5 shuts down before slot 4 because slot 4 has a higher slot number.

**Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure slot priority:

```
sys power slot-priority <3-8> {high|low}
```

**Example**

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Configure slot priority to determine that slot 3 has a low priority if insufficient power is available for all modules:

```
Switch:1(config)#sys power slot-priority 3 low
```

*Variable Definitions*

The following table defines parameters for the **sys power slot-priority** command.

| Variable                 | Value                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <3-8>                    | Identifies the module slot.                                                                                                                                    |
| <i>high</i>   <i>low</i> | Specifies whether the module should have a high or low priority setting if there is insufficient power available for all modules. The default is <i>high</i> . |

**Enable the Locator LED****Note**

This procedure only applies to 5420 Series, 5520 Series, and VSP 4900 Series.

### About This Task

Perform this procedure to turn the system Locator LED on to provide a visual identification of a specific switch.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable the system Locator LED:  
`sys locator-led`
3. Display the system Locator LED status:  
`show sys locator-led`

## Enable or Disable the USB Port

Perform this procedure to control USB access. For security reasons, you may want to disable this port to prevent individuals from using it. By default, the port is automatically mounted when a USB device is inserted.

### Before You Begin

- The switch must be in Enhanced Secure mode.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Disable the USB port:  
`sys usb disable`
3. Enable a previously disabled USB port:  
`no sys usb disable`

## Configure Port Speed

### About This Task

Manually configure the port speed.

#### Important

If Auto-Negotiation is disabled and you change the speed on a port that results in a configuration mismatch in speed between two ports, VSP 4450 Series and VSP 4900 Series switches may show an incorrect operational status of "up" for the mismatched ports.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the speed for one or more ports:

```
speed {10|100|1000|10000|2500|25000|5000}
```

or

```
speed port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} {10|
100|1000|10000|2500|25000|5000}
```

### Variable Definitions

The following table defines parameters for the **speed** command.

| Variable                                                     | Value                                                   |
|--------------------------------------------------------------|---------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Specifies the port or ports that you want to configure. |
| <i>10</i>                                                    | Configures the port speed to 10 Mbps.                   |
| <i>100</i>                                                   | Configures the port speed to 100 Mbps.                  |
| <i>1000</i>                                                  | Configures the port speed to 1 Gbps.                    |
| <i>10000</i>                                                 | Configures the port speed to 10 Gbps.                   |
| <i>2500</i>                                                  | Configures the port speed to 2.5 Gbps.                  |
| <i>25000</i>                                                 | Configures the port speed to 25 Gbps.                   |
| <i>5000</i>                                                  | Configures the port speed to 5 Gbps.                    |

## Configure Ports Speeds for All VIM Ports

### Note

This procedure only applies to 5520 Series and VSP 4900 Series.

Configure all of the ports on an installed Versatile Interface Module (VIM) to operate at the same speed.

#### Note

Some VIMs must operate with all ports at the same speed, while others can operate with ports at different speeds. For more information, see [VOSS Release Notes](#). The **sys vim-speed** command is supported only on VIMs that must operate with all ports at the same speed. An error message displays if you run the command on an unsupported VIM.

### Before You Begin

Install the VIM before performing this procedure.

### About This Task

Use this procedure to configure the speed of all ports in a multi-port VIM to operate at either 10 Gbps or 25 Gbps.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the speed for all of the VIM ports:
 

```
sys vim-speed {10000 | 25000}
```

#### Variable Definitions

The following table defines parameters for the **sys vim-speed** command.

| Variable                   | Value                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>10000   25000</code> | Configures all ports in a multi-port VIM to operate at either 10 Gbps or 25 Gbps. The default is 25 Gbps. |

## Display Ports Speeds for All VIM Ports

#### Note

This procedure only applies to 5520 Series and VSP 4900 Series.

Display the configured speed on all VIM ports.

#### Note

Some VIMs must operate with all ports at the same speed, while others can operate with ports at different speeds. For more information, see [VOSS Release Notes](#). The **show sys vim-speed** command is supported only on VIMs that must operate with all ports at the same speed. An error message displays if you run the command with an unsupported VIM installed.

### Before You Begin

Install the VIM before performing this procedure.

### About This Task

Use this procedure to display the configured speed of all ports in a multi-port VIM.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the speed for all of the VIM ports:

```
show sys vim-speed
```

## Prepare a slot for IOC Module Preconfiguration using CLI

### About This Task

Use this procedure to designate a slot in the switch for IOC module preconfiguration. You can designate a slot for only one module type at a time.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
3. Designate a slot for IOC module preconfiguration:  

```
preconfig slot <1-8> WORD<1-20> [lock]
```
4. Verify IOC module preconfiguration:  

```
show sys-info card
```

### Example

The following examples prepare a slot for IOC module preconfiguration:

Prepare a slot for IOC module preconfiguration, with card lock enabled on the slot.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#preconfig slot 5 8624XT lock
```

Verify the configuration:

```
Switch:1(config)#show sys-info card

Card Info :
  Slot 5 :

      CardType       : 8624XT
      CardDescription : 8624XT
```

```
CardSerial#      : SDNI86XSD282
CardPart#        : EC8604002-E6
CardAssemblyDate : 20161125
CardHWRevision   : D2
CardHWConfig     : 0
AdminStatus      : up
OperStatus       : up
PowerStatus      : on
Preconfigured    : yes
Preconfig CardType: 8624XT
Preconfig Lock   : yes
```

If card lock is enabled on the slot, and the module type of the inserted IOC module does not match the preconfigured IOC module type (for example, if the inserted module is type 8624XT but the preconfigured module type is 8624XS), then the operational status of the inserted IOC module displays as down-Mismatch.

```
Switch:1(config)show sys-info card

Card Info :
  Slot 5 :

      CardType      : 8624XS
      CardDescription : 8624XS
      CardSerial#    : SDNI86XSD282
      CardPart#      : EC8604002-E6
      CardAssemblyDate : 20161125
      CardHWRevision  : D2
      CardHWConfig    : 0
      AdminStatus     : down
      OperStatus      : down-Mismatch
      PowerStatus     : down
      Preconfigured   : yes
      Preconfig CardType: 8624XT
      Preconfig Lock  : yes
```

Prepare another slot for IOC module preconfiguration, with no card lock enabled on the slot.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.

Switch:1(config)#preconfig slot 6 8624XS
```

Verify the configuration:

```
Switch:1(config)show sys-info card

Card Info :
  Slot 6 :

      CardType      : 8624XS
      CardDescription : 8624XS
      CardSerial#    : SDNI86XSD282
      CardPart#      : EC8604002-E6
      CardAssemblyDate : 20161125
      CardHWRevision  : D2
      CardHWConfig    : 0
      AdminStatus     : up
      OperStatus      : up
```

```

PowerStatus      : on
Preconfigured    : yes
Preconfig CardType: 8624XS
Preconfig Lock   : no

```

If card lock is disabled on the slot, and the IOC module type of the inserted card does not match the preconfigured module type, the existing configuration is deleted and the slot is automatically preconfigured with the module type of the inserted IOC module. The inserted module then boots up with default configuration.

In the following example, when the 8624XT module is inserted in a slot preconfigured for the 8624XS, the pre-configuration for the 8624XS is deleted because it is not locked. The slot is then automatically preconfigured for 8624XT when the IOC module is physically inserted in that slot.

```

Switch:1(config)#show sys-info card

Card Info :
  Slot 6 :

      CardType      : 8624XT
      CardDescription : 8624XT
      CardSerial#    : SDNI86XSD282
      CardPart#      : EC8604002-E6
      CardAssemblyDate : 20161125
      CardHWRevision  : D2
      CardHWConfig    : 0
      AdminStatus     : up
      OperStatus      : up
      PowerStatus     : on
      Preconfigured   : yes
      Preconfig CardType: 8624XT
      Preconfig Lock   : no

```

### Variable Definitions

The following table defines parameters for the **preconfig slot** command.

| Variable                 | Value                                                                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&lt;1-8&gt;</b>       | Specifies the slot number designated for pre-configuration.                                                                                                         |
| <b>WORD &lt;1-20&gt;</b> | Specifies the card type that can be assigned to the pre-configured slot.                                                                                            |
| <b>lock</b>              | Specifies that the IO card will be locked to the pre-configured slot. Only the IO card that matches the card type assigned to the pre-configured slot will operate. |

## View the Management Port Statistics

Use this procedure to view the management port statistics.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
configure terminal
```

2. View the management port statistics:

```
show interfaces mgmtethernet statistics
```

### Example

View management port statistics:

```
Switch:1#show interfaces mgmtethernet statistics
```

| Port Stats Interface |                |                 |              |               |                    |
|----------------------|----------------|-----------------|--------------|---------------|--------------------|
| PORT<br>NUM          | IN<br>OCTETS   | OUT<br>OCTETS   | IN<br>PACKET | OUT<br>PACKET |                    |
| mgmt                 | 7222116        | 44282           | 81789        | 586           |                    |
| PORT<br>NUM          | IN<br>FLOWCTRL | OUT<br>FLOWCTRL | IN<br>PFC    | OUT<br>PFC    | OUTLOSS<br>PACKETS |
| mgmt                 | 0              | 0               | 0            | 0             | 0                  |

## Viewing Port Routing Statistics

### About This Task

View port routing statistics to manage network performance.

#### Note

This command is not available on all hardware platforms.

### Procedure

View port routing statistics:

```
show routing statistics interface [gigabitethernet] [{slot/port[-slot/  
port] [, ...]}
```

### Example

```
Switch:1#show routing statistics interface gigabitethernet 1/7-1/9
```

| Port Stats Routing |                     |                       |               |                      |                        |
|--------------------|---------------------|-----------------------|---------------|----------------------|------------------------|
| PORT<br>NUM        | IN_FRAME<br>UNICAST | IN_FRAME<br>MULTICAST | IN<br>DISCARD | OUT_FRAME<br>UNICAST | OUT_FRAME<br>MULTICAST |
| 1/7                | 1386                | 0                     | 0             | 1344                 | 0                      |
| 1/8                | 1302                | 0                     | 0             | 1344                 | 0                      |
| 1/9                | 0                   | 0                     | 0             | 0                    | 0                      |

### Variable Definitions

Use the data in the following table to use the **show routing statistics interface** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i>                                       | Specifies the interface type.                                                                                                                                                                                                                                                                                                                                 |
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Displaying Bridging Statistics for Specific Ports

### About This Task

Display individual bridging statistics for specific ports to manage network performance.

#### Note

This command is not available on all hardware platforms.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View bridging statistics for a specific port:  
show interfaces GigabitEthernet statistics bridging [{slot/port[-slot/port] [,...]}]

### Example

```
Switch:1#show interfaces gigabitEthernet statistics bridging
```

```
=====
                        Port Stats Bridge
=====
```

| PORT<br>NUM | IN_FRAME<br>UNICAST | IN_FRAME<br>MULTICAST | IN_FRAME<br>BROADCAST | OUT_FRAME | IN_FRAME<br>xSTP BPDU | OUT_FRAME<br>xSTP BPDU | IN_DISCARD |
|-------------|---------------------|-----------------------|-----------------------|-----------|-----------------------|------------------------|------------|
| 1/1         | 179325              | 0                     | 0                     | 119310    | 179325                | 0                      | 0          |
| 1/2         | 187951              | 26078                 | 42                    | 689486    | 179324                | 0                      | 25617      |
| 1/3         | 0                   | 0                     | 0                     | 0         | 0                     | 0                      | 0          |
| 1/4         | 0                   | 0                     | 0                     | 0         | 0                     | 0                      | 0          |
| 1/5         | 0                   | 0                     | 0                     | 0         | 0                     | 0                      | 0          |
| 1/6         | 394                 | 0                     | 0                     | 948942    | 360                   | 0                      | 0          |
| 1/7         | 4689                | 0                     | 0                     | 863403    | 360                   | 0                      | 0          |
| 1/8         | 4369                | 3206                  | 116                   | 958752    | 360                   | 0                      | 3995       |
| 1/9         | 0                   | 0                     | 0                     | 0         | 0                     | 0                      | 0          |
| 1/10        | 0                   | 0                     | 0                     | 0         | 0                     | 0                      | 0          |

Variable Definitions

Use the data in the following table to use the **show interfaces GigabitEthernet statistics bridging** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Displaying Detailed Statistics for Ports

Display detailed statistics for specific ports to manage network performance.

**Note**

Slot and port information can differ depending on hardware platform.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. View statistics for specific ports:  
show interfaces GigabitEthernet statistics verbose {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}

**Example**

View statistics for various ports:

```
Switch:1>enable
Switch:1#show interfaces gigabitethernet statistics verbose

Please widen the terminal for optimal viewing of data.

### Variable Definitions

Use the data in the following table to use the **show interfaces GigabitEthernet statistics verbose** command.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Chassis operations configuration using EDM

This section provides the details to configure basic hardware and system settings using Enterprise Device Manager (EDM).

### Edit System Information

#### About This Task

Edit system identification information, configuration file information, and perform system actions.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Chassis**.
3. Click the **System** tab.
4. Enter or edit the information as required.
5. Click **Apply**.

**System** Field Descriptions

Use the data in the following table to use the **System** tab.

| Name                                                                                                                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Edit Chassis Information

### About This Task

Edit the chassis information to make changes to chassis-wide settings.

### Procedure

1. In the Device Physical View tab, select the device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Chassis**.
4. Select the **Chassis** tab.
5. Edit the necessary options.
6. Select **Apply**.

**Chassis** Field Descriptions

Use the data in the following table to use the **Chassis** tab.

| Name                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>PartNumber</b>                                                           | Specifies the device part number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SerialNumber</b>                                                         | Specifies a unique chassis serial number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>HardwareRevision</b>                                                     | Specifies the current hardware revision of the device chassis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>NumSlots</b>                                                             | Specifies the number of slots available in the chassis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>NumPorts</b>                                                             | Specifies the number of ports currently installed in the chassis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>BaseMacAddr</b>                                                          | Specifies the starting point of the block of MAC addresses used by the switch for logical and physical interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>MacAddrCapacity</b>                                                      | Specifies the number of routable MAC addresses based on the BaseMacAddr.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Temperature</b><br>This parameter does not apply for all platforms.      | Specifies the temperature of the device measured in degrees Celsius.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>MacFlapLimitTime</b><br>This parameter does not apply for all platforms. | Configures the time limit for the loop-detect feature, in milliseconds, for MAC flapping. The value ranges from 10–5000. The default value is 500.                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>AutoRecoverDelay</b>                                                     | Specifies the time interval, in seconds, after which auto-recovery runs on ports to clear actions taken by CP Limit or link flap. The default is 30.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>MTUSize</b>                                                              | Configures the maximum transmission unit size. The default varies depending on the platform: <ul style="list-style-type: none"> <li>• 5420 Series - 1950 bytes</li> <li>• 5520 Series - 1950 bytes</li> <li>• VSP 4450 Series - 1950 bytes</li> <li>• VSP 4900 Series - 1950 bytes</li> <li>• VSP 7200 Series - 1950 bytes</li> <li>• VSP 7400 Series - 1950 bytes</li> <li>• VSP 8200 Series - 1950 bytes</li> <li>• VSP 8400 Series - 1950 bytes</li> <li>• VSP 8600 Series - 1950 bytes</li> <li>• XA1400 Series - 1950 bytes</li> </ul> |
| <b>MgidUsageVlanCurrent</b>                                                 | Number of MGIDs for VLANs currently in use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>MgidUsageVlanRemaining</b>                                               | Number of remaining MGIDs for VLANs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Name                                                                     | Description                                                                                                                                                                                                     |
|--------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MgidUsageMulticastCurrent</b>                                         | Number of MGIDs for multicast currently in use.                                                                                                                                                                 |
| <b>MgidUsageMulticastRemaining</b>                                       | Number of remaining MGIDs for multicast.                                                                                                                                                                        |
| <b>DdmMonitor</b>                                                        | Enables or disables the monitoring of the DDM. When enabled, the user gets the internal performance condition (temperature, voltage, bias, Tx power and Rx power) of the SFP/XFP. The default is disable.       |
| <b>DdmMonitorInterval</b>                                                | Configures the DDM monitor interval in the range of 5 to 60 in seconds. If any alarm occurs, the user gets the log message before the specific interval configured by the user. The default value is 5 seconds. |
| <b>DdmTrapSend</b>                                                       | Enables or disables the sending of trap messages. When enabled, the trap message is sent to the Device manager, any time the alarm occurs. The default is enable.                                               |
| <b>DdmAlarmPortdown</b>                                                  | Sets the port down when an alarm occurs. When enabled, the port goes down when any alarm occurs. The default is disable.                                                                                        |
| <b>PowerUsage</b><br>This parameter does not apply on all platforms.     | Specifies the amount of power the CPU uses.                                                                                                                                                                     |
| <b>PowerAvailable</b><br>This parameter does not apply on all platforms. | Specifies the amount of power available to the CPU.                                                                                                                                                             |

## View Physical Entities

Perform this procedure to view information about the functional components of the switch.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Entity**.

### *Physical Entities Field Descriptions*

The following table defines the use the Physical Entities tab.

| Name               | Description                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>       | Indicates the index of the entry.                                                                                                                                                         |
| <b>Descr</b>       | Indicates the name of the manufacturer for the physical entity.                                                                                                                           |
| <b>VendorType</b>  | Indicates the vendor-specific hardware type for the physical entity. Because there is no vendor-specifier registration for this device, the value is 0.                                   |
| <b>ContainedIn</b> | Indicates the index value for the physical entity which contains this physical entity. A value of zero indicates that this physical entity is not contained in any other physical entity. |

| Name                | Description                                                                                                                                                                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Class</b>        | Indicates the general hardware type of the physical entity. The value is configured to the standard enumeration value that indicates the general class of the physical entity.                                                                                                                                                                                            |
| <b>ParentRelPos</b> | Indicates the relative position of the child component among the sibling components.                                                                                                                                                                                                                                                                                      |
| <b>Name</b>         | Indicates the name of the component, as assigned by the local device, and that is suitable to use in commands you enter on the console of the device. Depending on the physical component naming syntax of the device, the name can be a text name such as console, or a component number such as port or module number.<br>If there is no local name, there is no value. |
| <b>HardwareRev</b>  | Indicates the vendor-specific hardware revision string for the physical entity.<br>If no specific hardware revision string is associated with the physical component, or if this information is unknown, then this object contains a zero-length string, or there is no value.<br>If there is no information available, there is no value.                                |
| <b>FirmwareRev</b>  | Indicates the vendor-specific firmware revision string for the physical entity.<br>If no specific firmware programs are associated with the physical component, or if this information is unknown, then this object contains a zero-length string, or there is no value.<br>If there is no information available, there is no value.                                      |
| <b>SoftwareRev</b>  | Indicates the vendor-specific software revision string for the physical entity.<br>If no specific software programs are associated with the physical component, or if this information is unknown, then this object contains a zero-length string, or there is no value.<br>If there is no information available, there is no value.                                      |
| <b>SerialNum</b>    | Indicates the vendor-specific serial number string for the physical entity. The value is the serial number string printed on the component, if present.<br>If there is no information available, there is no value.                                                                                                                                                       |

| Name             | Description                                                                                                                                                                                                                                                                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MfgName</b>   | Indicates the name of the manufacturer of the physical component. The value is the manufacturer name string printed on the component, if present.<br>If the manufacturer name string associated with the physical component is unknown, then this object contains a zero-length string.<br>If there is no information available, there is no value.             |
| <b>ModelName</b> | Indicates the vendor-specific model name identifier string associated with the physical component. The value is the part number which is printed on the component.<br>If the model name string associated with the physical component is unknown, then this object contains a zero-length string.                                                               |
| <b>Alias</b>     | Indicates an alias name for the physical entity that is specified by a network manager, and provides a nonvolatile handle for the physical entity.<br>The software supports read-only and provides values for the port interface only.                                                                                                                          |
| <b>AssetID</b>   | Indicates a user-assigned asset tracking identifier for the physical entity. This value is specified by a network manager, and provides nonvolatile storage of this information.<br>Because this object is not supported, there is no value.                                                                                                                    |
| <b>IsFRU</b>     | Indicates whether or not the physical entity is considered a field replaceable unit. <ul style="list-style-type: none"> <li>• If the value is <code>true (1)</code>, then the component is a field replaceable unit.</li> <li>• If the value is <code>false (2)</code>, then the component is permanently contained within a field replaceable unit.</li> </ul> |
| <b>MfgDate</b>   | Indicates the manufacturing date of the managed entity. If the manufacturing date is unknown, then the value is '0000000000000000'.                                                                                                                                                                                                                             |
| <b>Uris</b>      | Indicates additional identification information about the physical entity.<br><b>Uris</b> is not supported, therefore there is no value.                                                                                                                                                                                                                        |

## View Entity Aliases

### About This Task

Perform this procedure to view the entity aliases on the switch.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.

2. Click **Entity**.
3. Click the **Alias** tab.

### Alias Field Descriptions

Use the data in the following table to use the **Alias** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>              | The index of the entry                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>LogicalIndexOrZero</b> | The index of the entry. The value of this object identifies the logical entity that defines the naming scope for the associated instance of the Mapping Identifier object. This is always 0.                                                                                                                                                                                                                     |
| <b>MappingIdentifier</b>  | The value of this object identifies a particular conceptual row associated with the indicated Physical Index and Logical Index pair. Because only physical ports are modeled in this table, only entries that represent interfaces or ports are allowed. If an ifEntry exists on behalf of a particular physical port, then this object should identify the associated ifEntry. This is the OID of ifIndex.Port. |

## Viewing Entity Child Indexes

### About This Task

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Entity**.
3. Click the **Child Index** tab.

### Child Index field descriptions

Use the data in the following table to use the **Child Index** tab.

| Name              | Description                                                                            |
|-------------------|----------------------------------------------------------------------------------------|
| <b>Index</b>      | Indicates the index of the entry.                                                      |
| <b>ChildIndex</b> | The index of the entry. The value of Physical Index for the contained physical entity. |

## Configure System Flags

### About This Task

Configure the system flags to enable or disable flags for specific configuration settings.

## Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Chassis**.
3. Click the **System Flags** tab.
4. Select the system flags you want to activate.
5. Clear the system flags you want to deactivate.
6. Click **Apply**.

### Important

After you change certain configuration parameters, you must save the changes to the configuration file.

## **System Flags** Field Descriptions

Use the data in the following table to use the **System Flags** tab.

| Name                                                                                                 | Description                                                                                                                                                                                                                  |
|------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EnableAccessPolicy</b>                                                                            | Activates access policies. The default is disabled.                                                                                                                                                                          |
| <b>ForceTrapSender</b>                                                                               | Configures circuitless IP as a trap originator. The default is disabled.                                                                                                                                                     |
| <b>ForceIphdrSender</b>                                                                              | If you enable Force IP Header Sender, the system matches the IP header source address with SNMP header sender networks. The default is disabled.                                                                             |
| <b>AuthSuccessTrapEnable</b>                                                                         | Enables the system to send the authentication success trap, rcnAuthenticationSuccess. The default is disabled.                                                                                                               |
| <b>MrouteStrLimit</b>                                                                                | Enable or disable Mroute stream limit in system. The default is disabled.                                                                                                                                                    |
| <b>DataPathFaultShutdownEnable</b>                                                                   | Enable or disable data path fault shutdown. The default is enabled.                                                                                                                                                          |
| <b>PingTracerouteContextType</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series. | Configures the default context for executing ping commands and traceroute commands. The default is grt.                                                                                                                      |

| <b>MasterCPUSlot</b>       | Specifies the slot number, either 1 or 2, for the master CPU. The default value is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>EnableSavetoStandby</b> | Enables or disables automatic save of the configuration file to the standby CPU. The default value is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>HaCpuState</b>          | Indicates the CPU High Availability state. <ul style="list-style-type: none"> <li>initialization—Indicates the CPU is in this state.</li> <li>oneWayActive—Specifies modules that need to synchronize register with the framework (either locally or a message received from a remote CPU).</li> <li>twoWayActive—Specifies modules that need to synchronize register with the framework (either locally or a message received from a remote CPU).</li> <li>synchronized—Specifies table-based synchronization is complete on the current CPU.</li> <li>remoteIncompatible—Specifies CPU framework version is incompatible with the remote CPU.</li> <li>error—Specifies if an invalid event is generated in a specific state the CPU enters Error state.</li> <li>disabled—Specifies High Availability is not activated.</li> <li>peerNotConnected—Specifies no established peer connection.</li> <li>peerConnected—Specifies peer connection is established.</li> <li>lostPeerConnection—Specifies a lost connection to peer or standby CPU.</li> <li>notSynchronized—Specifies table-based synchronization is not complete.</li> </ul> |
| <b>HaEvent</b>             | Indicates the High Availability event status. <ul style="list-style-type: none"> <li>restart—Causes the state machine to restart.</li> <li>systemRegistrationDone—Causes the CPU to transfer to One Way or Two Way Active state.</li> <li>tableSynchronizationDone—Causes the CPU to transfer to synchronized state.</li> <li>versionIncompatible—Causes the CPU to go to remote incompatible state</li> <li>noEvent—Means no event occurred to date.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>StandbyCpu</b>          | Indicates the state of the standby CPU.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Configure Channelization

Use this procedure to enable or disable channelization on a port. Channelization configures the port to operate as four channels, or ports.

### Important

Enabling or disabling channelization resets the port QoS configuration to default values.

### Procedure

1. In the Device Physical View tab, select a port that supports channelization.

2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Channelization** tab.
5. To enable channelization on the port, select **enable**.
6. Select **Apply**. Alternatively, you can right-click the port on the Device Physical View tab, and then select **Channelization Enable**.
7. To disable channelization on a port, select the first sub-port for the corresponding port, slot/port/1.
8. In the navigation pane, expand **Configuration > Edit > Port**.
9. Select **General**.
10. Select the **Channelization** tab.
11. To disable channelization on the port, select **disable**. This action will disable the four sub-ports.
12. Select **Apply**. Alternatively, you can right-click the port on the Device Physical View tab, and then select **Channelization Disable**.

### Channelization Field Descriptions

Use the data in the following table to use the **Channelization** tab.

| Name                  | Description                                                                                                                                                                      |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Channelization</b> | This field determines whether channelization is enabled or disabled on the selected port. The two options are <b>enable</b> and <b>disable</b> . The default is <b>disable</b> . |

## Configure Basic Port Parameters

Configure options for port operations.

### About This Task

If you select more than one port, the format of the tab changes to a table-based tab.

When you use 1 Gigabit Ethernet SFP transceivers, the software disables Auto-Negotiation on the port. If you use 1 Gbps SFP transceivers, the remote end must also have Auto-Negotiation disabled.

### Procedure

1. In the Device Physical View tab, select one or more ports.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. Configure the fields as required.
 

10/100BASE-TX ports do not consistently auto-negotiate with older 10/100BASE-TX equipment. You can sometimes upgrade the older devices with new firmware or driver revisions. If an upgrade does not enable auto-negotiation to correctly identify the link speed and duplex settings, you can manually configure the settings for the link in question.

Check the Extreme Networks website for the latest compatibility information.
6. Select **Apply**.

**Interface** Field Descriptions

Use the data in the following table to use the **Interface** tab.

| Name                                                                                      | Description                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                                                                              | Displays the index of the port, written in the slot/port[/sub-port] format.                                                                                                                                                                                                                                           |
| <b>Name</b>                                                                               | Configures the name of the port.                                                                                                                                                                                                                                                                                      |
| <b>Descr</b>                                                                              | Displays the description of the port. A textual string containing information about the interface.                                                                                                                                                                                                                    |
| <b>Type</b>                                                                               | Displays the type of connector plugged in the port.                                                                                                                                                                                                                                                                   |
| <b>Mtu</b>                                                                                | Displays the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface. |
| <b>PhysAddress</b>                                                                        | Displays the physical address of the port. The address of the interface at the protocol layer immediately `below' the network layer in the protocol stack. For interfaces which do not have such an address (e.g., a serial line), this object should contain an octet string of zero length.                         |
| <b>VendorDescr</b>                                                                        | Displays the vendor of the connector plugged in the port.                                                                                                                                                                                                                                                             |
| <b>DisplayFormat</b>                                                                      | Identifies the slot and port numbers (slot/port). If the port is channelized, the format also includes the sub-port in the format slot/port/sub-port                                                                                                                                                                  |
| <b>AdminStatus</b>                                                                        | Configures the port as enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.                                                                                                                                                                             |
| <b>OperStatus</b>                                                                         | Displays the current status of the port. The status includes enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.                                                                                                                                       |
| <b>LicenseControlStatus</b><br><br>Note:<br>Exception: only supported on VSP 7200 Series. | Shows the port license status.                                                                                                                                                                                                                                                                                        |

| <b>AutoNegAd</b>           | <p>Specifies the port speed and duplex abilities to advertise during link negotiation. Supported speeds and duplex modes vary, depending on your hardware.</p> <p>The abilities specified in this object are only used when auto-negotiation is enabled on the port. If all bits in this object are disabled, and auto-negotiation is enabled on the port, then the physical link process on the port will be disabled (if hardware supports this ability).</p> <p>Any change to this configuration restarts the auto-negotiation process, which has the same effect as physically unplugging and reattaching the cable attached to the port.</p> <p>If you select <b>default</b>, all capabilities supported by the hardware are advertised.</p> |
| <b>AdminDuplex</b>         | Configures the administrative duplex setting for the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OperDuplex</b>          | Indicates the operational duplex setting for the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>AdminSpeed</b>          | <p>Configures the administrative speed for the port.</p> <p><b>Important:</b><br/>If Auto-Negotiation is disabled and you change the administrative speed on a port that results in a configuration mismatch in speed between two ports, VSP 4450 Series and VSP 4900 Series switches can show an incorrect operational status of "up" for the mismatched ports.</p>                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OperSpeed</b>           | Indicates the operational speed for the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>QoSLevel</b>            | Selects the Quality of Service (QoS) level for this port. The default is level1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DiffServ</b>            | Enables the Differentiated Service feature for this port. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Layer3Trust</b>         | Configures if the system should trust Layer 3 packets coming from access links or core links only. The default is core.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Layer2Override8021p</b> | Specifies whether Layer 2 802.1p override is enabled (selected) or disabled (cleared) on the port. The default is disabled (clear).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>MltId</b>               | Shows the MLT ID associated with this port. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Locked</b>              | Shows if the port is locked. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>UnknownMacDiscard</b>   | Discards packets that have an unknown source MAC address, and prevents other ports from sending packets with that same MAC address as the destination MAC address. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Configure Basic Parameters on an Extreme Integrated Application Hosting Port

### About This Task

Perform this procedure to configure basic parameters on Extreme Integrated Application Hosting (IAH) ports, for example, auto negotiation, QoS level, and remote monitoring.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **Interface** tab.
4. In the **Name** field, type a name for the IAH port.
5. Configure the fields as required.
6. Select **Apply**.

**Interface** Field Descriptions

Use data in the following table to use the **Interface** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                            |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                | Specifies the index of the Extreme Integrated Application Hosting (IAH) port, written in the slot/port[/sub-port] format.                                                                                                                                                                                              |
| <b>Name</b>                 | Specifies the name of the IAH port.                                                                                                                                                                                                                                                                                    |
| <b>Descr</b>                | Specifies the information about the interface.                                                                                                                                                                                                                                                                         |
| <b>Type</b>                 | Specifies the type of connector plugged in the IAH port.                                                                                                                                                                                                                                                               |
| <b>Mtu</b>                  | Specifies the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface. |
| <b>PhysAddress</b>          | Specifies the physical address of the IAH port. The address of the interface at the protocol layer immediately below the network layer in the protocol stack. For interfaces which do not have such an address (like a serial line), this object should contain an octet string of zero length.                        |
| <b>VendorDescr</b>          | Specifies the vendor of the connector plugged in the IAH port.                                                                                                                                                                                                                                                         |
| <b>DisplayFormat</b>        | Specifies the slot and port numbers (slot/port).                                                                                                                                                                                                                                                                       |
| <b>AdminStatus</b>          | Specifies the operational status of the IAH port. The testing state indicates that no operational packets can be passed.                                                                                                                                                                                               |
| <b>OperStatus</b>           | Specifies the current status of the IAH port. The testing state indicates that no operational packets can be passed.                                                                                                                                                                                                   |
| <b>LicenseControlStatus</b> | Specifies the IAH port license status.                                                                                                                                                                                                                                                                                 |
| <b>ShutdownReason</b>       | Specifies the reason for the IAH port state change.                                                                                                                                                                                                                                                                    |
| <b>LastChange</b>           | Specifies the timestamp of the last change.                                                                                                                                                                                                                                                                            |
| <b>LinkTrap</b>             | Enables or disables link trapping. The default is enabled.                                                                                                                                                                                                                                                             |
| <b>AutoNegotiate</b>        | Enables or disables auto-negotiation for the IAH port. The default is true (enabled).                                                                                                                                                                                                                                  |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AutoNegAd</b>             | Specifies the port speed and duplex abilities to be advertised during link negotiation. The abilities specified in this object are only used when auto-negotiation is enabled on the IAH port. If all bits in this object are disabled, and auto-negotiation is enabled on the IAH port, then the physical link process on the IAH port will be disabled (if hardware supports this ability). Any change in the value of this bit map will force the switch to restart the auto-negotiation process. The capabilities being advertised are either all the capabilities supported by the hardware or the user-configured capabilities, which is a subset of all the capability supported by hardware. By default, all capabilities supported by the hardware are enabled. |
| <b>AdminDuplex</b>           | Specifies the administrative duplex setting for the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OperDuplex</b>            | Specifies the operational duplex setting for the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>AdminSpeed</b>            | Specifies the administrative speed for the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OperSpeed</b>             | Specifies the operational speed for the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>QoSLevel</b>              | Specifies the Quality of Service (QoS) level for the IAH port. The default is level1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DiffServ</b>              | Enables the Differentiated Service feature for the IAH port. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Layer3Trust</b>           | Specifies if the system should trust Layer 3 packets coming from access links or core links only. The default is core.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Layer2Override8021p</b>   | Specifies whether Layer 2 802.1p override is enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>MlId</b>                  | Specifies the MLT ID associated with the IAH port. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Locked</b>                | Specifies if the IAH port is locked. The default is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>UnknownMacDiscard</b>     | Enables the functionality to discard packets with an unknown source MAC address, and prevents the other IAH port from sending packets with the same MAC address as the destination MAC address. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DirectBroadcastEnable</b> | Specifies if the IAH port forwards direct broadcast traffic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OperRouting</b>           | Specifies the routing status of the IAH port. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>HighSecureEnable</b>      | Enables or disables the high secure feature for the IAH port. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Name                                       | Description                                                                                                                                                                                                                                                                             |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RmonEnable</b>                          | Enables or disables Remote Monitoring (RMON) on the IAH port. The default is disabled.                                                                                                                                                                                                  |
| <b>FlexUniEnable</b>                       | Enables or disables Flex UNI on the IAH port. The default is disabled.                                                                                                                                                                                                                  |
| <b>EgressRateLimitState</b>                | Enables or disables egress port-based shaping to bind the maximum rate at which traffic leaves the IAH port. The default is disabled.                                                                                                                                                   |
| <b>EgressRateLimit</b>                     | Specifies the egress rate limit in Kbps. Different hardware platforms provide different port speeds. The default is 0.                                                                                                                                                                  |
| <b>TxFlowControl</b>                       | Specifies if the IAH port is sending pause frames. The default is disabled.<br><br><b>Note:</b><br>You must enable the flow control feature globally.                                                                                                                                   |
| <b>TxFlowControlOperState</b>              | Specifies the operational state of flow control.                                                                                                                                                                                                                                        |
| <b>BpduGuardTimerCount</b>                 | Specifies the duration since when the IAH port is disabled. When the BpduGuardTimerCount reaches the BpduGuardTimeout value, the IAH port is enabled.                                                                                                                                   |
| <b>BpduGuardTimeout</b>                    | Specifies the time (in seconds) for the IAH port-state recovery. After the IAH port is disabled by the BPDU guard, the IAH port remains in the disabled state until this timer expires. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.            |
| <b>BpduGuardAdminEnabled</b>               | Enables or disables BPDU Guard on the IAH port. The default is disabled.                                                                                                                                                                                                                |
| <b>ForwardErrorCorrection</b>              | Configures one of the following options for Forward Error Correction (FEC) on the IAH port: <ul style="list-style-type: none"> <li>• CL 91</li> <li>• CL 108</li> <li>• CL 74</li> <li>• disable</li> <li>• auto</li> </ul> The disable option disables this configuration on the port. |
| <b>ForwardErrorCorrectionApplicability</b> | Displays whether FEC is applicable on the interface.                                                                                                                                                                                                                                    |
| <b>OperAutoNegotiate</b>                   | Shows the operational state of Auto-Negotiation.                                                                                                                                                                                                                                        |
| <b>OperForwardErrorCorrection</b>          | Shows the negotiated operational FEC clause. If the value is off, the port supports FEC and is up but not configured for FEC. If the value is notApplicable, the port does not support FEC. If the value is unknown, the port supports FEC but is down.                                 |

| Name                                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Action</b>                                                                                                    | Specifies the following actions on the IAH port: <ul style="list-style-type: none"> <li>• none - no action.</li> <li>• flushMacFdb - flush the MAC forwarding table.</li> <li>• flushArp - flush the ARP table.</li> <li>• flushIp - flush the IP route table.</li> <li>• flushAll - flush all tables.</li> <li>• triggerRipUpdate - manually triggers a RIP update.</li> <li>• clearLoopDetectAlarm - clears the loop detection alarm on the IAH port.</li> </ul> The default is none. |
| <b>Result</b>                                                                                                    | Specifies the result of the selected action. The default is none.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>AutoSense</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series and XA1400 Series.               | Enables or disables Auto-sense on the specific port. The default value is disabled for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.                                                                                                                                                                                                                                                                                                         |
| <b>AutoSenseKeepAutoConfig</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series and XA1400 Series. | Retains the Auto-sense configuration if you disable Auto-sense on the port. The dynamic configuration becomes a manual configuration and is visible in the <b>show running-config</b> output.                                                                                                                                                                                                                                                                                           |

## Configure IEEE 802.3X Pause Frame Transmit

Configure IEEE 802.3X Pause frame transmit to eliminate or minimize packet loss.

### About This Task

By default, flow control mode is disabled. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.

By default, an interface does not send pause frames.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **Boot Config** tab.
4. For EnableFlowControlMode, select **enable**.
5. Select **Apply**.
6. Save the switch configuration.
7. Reboot the chassis, and log in again.
8. In the Device Physical View, select a port or ports.
9. In the navigation pane, expand **Configuration > Edit > Port**.
10. Select **General**.
11. Select the **Interface** tab.
12. For TxFlowControl, select **enable** to enable the interface to generate pause frames.
13. Select **Apply**.

## View the Boot Configuration

### About This Task

View the boot configuration to determine the software version, as well as view the source from which the switch last started.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **Boot Config** tab.

### **Boot Config** Field Descriptions

Use the data in the following table to use the **Boot Config** tab.

| Name                           | Description                                                        |
|--------------------------------|--------------------------------------------------------------------|
| <b>SwVersion</b>               | Specifies the software version that currently runs on the chassis. |
| <b>LastRuntimeConfigSource</b> | Specifies the last source for the run-time image.                  |
| <b>PrimaryConfigSource</b>     | Specifies the primary configuration source.                        |

| Name                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PrimaryBackupConfigSource</b>                                      | Specifies the backup configuration source to use if the primary does not exist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EnableFactoryDefaultsMode</b>                                      | <p>Specifies whether the switch uses the factory default settings at startup.</p> <ul style="list-style-type: none"> <li>• <b>false</b>: The node does not use factory default settings at startup.</li> <li>• <b>fabric</b>: The node uses the factory default fabric mode settings at startup. Zero Touch Fabric Configuration is enabled.</li> <li>• <b>noFabric</b>: The node uses the factory default mode settings at startup.</li> </ul> <p>The default value is false. This flag is automatically reset to the default setting after the switch restarts. If you change this parameter, you must restart the switch for the change to take effect.</p> |
| <b>EnableDebugMode</b>                                                | <p>Enabling the debugmode allows a user to enable TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. It only works on console connection. The default value is disabled.</p> <p><b>Important:</b><br/>Do not change this parameter.</p>                                                                                                                                                                                                                                                                                                                     |
| <b>EnableRebootOnError</b>                                            | <p>Activates or disables automatic reboot on a fatal error. The default value is activated.</p> <p><b>Important:</b><br/>Do not change this parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>EnableTelnetServer</b>                                             | Activates or disables the Telnet server service. The default value is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EnableRloginServer</b>                                             | Activates or disables the rlogin and rsh server. The default value is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <p><b>Note:</b><br/>Exception: only supported on VSP 8600 Series.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EnableFtpServer</b>                                                | Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the TFTP flag is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>EnableTftpServer</b>                                               | Activates or disables Trivial File Transfer Protocol server service. The default value is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>EnableSshServer</b>                                                | Activates or disables the SSH server service. The default value is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>EnableSpbmConfigMode</b>                                           | Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. The boot flag is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Configure Boot Flags

### About This Task

Change the boot configuration to determine the services available after the system starts.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Chassis**.
2. Select the **Boot Config** tab.
3. Select the services you want to enable.
4. Select **Apply**.

**Boot Config** Field Descriptions

Use the data in the following table to use the **Boot Config** tab.

| Name                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SwVersion</b>                                              | Specifies the software version that currently runs on the chassis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>LastRuntimeConfigSource</b>                                | Specifies the last source for the run-time image.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>PrimaryConfigSource</b>                                    | Specifies the primary configuration source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>PrimaryBackupConfigSource</b>                              | Specifies the backup configuration source to use if the primary does not exist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EnableFactoryDefaultsMode</b>                              | <p>Specifies whether the switch uses the factory default settings at startup.</p> <ul style="list-style-type: none"> <li>• <b>false</b>: The node does not use factory default settings at startup.</li> <li>• <b>fabric</b>: The node uses the factory default fabric mode settings at startup. Zero Touch Fabric Configuration is enabled.</li> <li>• <b>noFabric</b>: The node uses the factory default mode settings at startup.</li> </ul> <p>The default value is false. This flag is automatically reset to the default setting after the switch restarts. If you change this parameter, you must restart the switch for the change to take effect.</p> |
| <b>EnableDebugMode</b>                                        | <p>Enabling the debugmode allows a user to enable TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. It only works on console connection. The default value is disabled.</p> <p><b>Important:</b><br/>Do not change this parameter.</p>                                                                                                                                                                                                                                                                                                                     |
| <b>EnableRebootOnError</b>                                    | <p>Activates or disables automatic reboot on a fatal error. The default value is activated.</p> <p><b>Important:</b><br/>Do not change this parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>EnableTelnetServer</b>                                     | Activates or disables the Telnet server service. The default value is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EnableRloginServer</b>                                     | Activates or disables the rlogin and rsh server. The default value is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Note:</b><br>Exception: only supported on VSP 8600 Series. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EnableFtpServer</b>                                        | Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the TFTPD flag is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>TftpRetransmit</b>                                                                       | Set TFTP retransmit timeout counter.                                                                                                                                                                                   |
| <b>TftpTimeout</b>                                                                          | Set TFTP timeout counter.                                                                                                                                                                                              |
| <b>User</b>                                                                                 | Configure host user.                                                                                                                                                                                                   |
| <b>Password</b>                                                                             | Configure host password.                                                                                                                                                                                               |

## Reserve Bandwidth for Advanced Features

Use this procedure if you want the switch to support advanced features. When you enable the boot flag, you need to save and reboot with the new configuration.

### Before You Begin

Product Notice: For 5420 Series, 5520 Series, and VSP 7400 Series, you must ensure your configuration does not include reserved ports before you enable this feature. If the configuration includes reserved ports after you enable this feature and restart the switch, the switch stops loading the configuration.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Chassis**.
2. Select the **Boot Config** tab.
3. In the **AdvancedFeatureBWReservation** field, select **high** or **low** or **vim** to enable the boot flag.
4. Select **Apply**.

A message displays to remind you that the configuration cannot include reserved ports, and that you must save the configuration and reboot the switch for changes to take effect.

5. Select **Yes** to continue or select **No** to cancel the change because the configuration includes reserved ports.

If you selected No, you can modify your switch configuration to remove the reserved ports and then return to this tab to change the **AdvancedFeatureBWReservation** configuration.

6. Save the configuration, and then reboot the switch.

## Enable Jumbo Frames

### About This Task

Enable Jumbo frames to increase the size of Ethernet frames supported on the chassis.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **Chassis** tab.
5. In **MTU size**, select either 1950, 9600 or 1522.
6. Click **Apply**.

## Configure the Date and Time

Configure the date and time to correctly identify when events occur on the system.

### About This Task

#### Note

According to a bill passed by the government of Russia, from October 2014 Moscow has moved from UTC+4 into UTC+3 time zone with no daylight savings. The software includes this change.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **User Set Time** tab.
5. Type and select the correct details.
6. Click **Apply**.

**User Set Time** field descriptions

Use the data in the following table to use the **User Set Time** tab.

| Name             | Description                                                   |
|------------------|---------------------------------------------------------------|
| <b>Year</b>      | Configures the year (integer 1998–2097). The default is 1998. |
| <b>Month</b>     | Configures the month. The default is 1.                       |
| <b>Date</b>      | Configures the day (integer 1–31). The default is 1.          |
| <b>Hour</b>      | Configures the hour (12am–11pm). The default is 0.            |
| <b>Minute</b>    | Configures the minute (integer 0–59). The default is 0.       |
| <b>Second</b>    | Configures the second (integer 0–59). The default is 0.       |
| <b>Time Zone</b> | Configures the time zone.                                     |

## Configure CP Limit

Configure CP Limit functionality to protect the switch from becoming congested by an excess of data flowing through one or more ports.

**Procedure**

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **CP Limit** tab.
5. Select the **AutoRecoverPort** check box.
6. Click **Apply**.

**CP Limit** field descriptions

Use the data in the following table to use the **CP Limit** tab.

| Name                   | Description                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>AutoRecoverPort</b> | Activates or disables auto recovery of the port from action taken by CP Limit or link flap features. The default value is disabled. |

## Configure CP Limit on an Extreme Integrated Application Hosting Port

**About This Task**

Perform this procedure to configure CP Limit functionality to protect the switch from becoming congested by excess data flow through Extreme Integrated Application Hosting (IAH) ports.

## Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **CP Limit** tab.
4. Select **AutoRecoverPort**.
5. Select **Apply**.

### **CP Limit** Field Descriptions

Use data in the following table to use the **CP Limit** tab.

| Name                   | Description                                                                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AutoRecoverPort</b> | Enables or disables auto recovery of the Extreme Integrated Application Hosting port from action taken by CP Limit or the link flap features. The default is disabled. |

## Configure an IP Address for the Management Port

### Note

This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management Instance Configuration for VOSS using EDM](#) on page 100.

Configure an IP address for the management port so that you can remotely access the device using the out-of-band (OOB) management port. The management port runs on a dedicated VRF.

The configured IP subnet must be globally unique because the management protocols can go through in-band (Global Router) or out-of-band ports (Management VRF).

This procedure only applies to hardware with a dedicated, physical management interface.

### Before You Begin

- You must make a direct connection through the console port to configure a new IP address. If you connect remotely, you can view or delete the existing IP address configuration. If you delete the IP address remotely, you lose the EDM connection to the device.
- Do not configure a default route in the Management VRF.
- If you want out-of-band management, define a specific static route in the Management Router VRF to the IP subnet where your management application resides.
- If you initiate an FTP session from a client device behind a firewall, you should set FTP to passive mode.
- The switch gives priority to out-of-band management when there is reachability from both in-band and out-of-band. To avoid a potential conflict, do not configure any overlapping between in-band and out-of-band networks.

## About This Task

Configure an IP address for the management port so that you can remotely access the device using the out-of-band (OOB) management port. The management port runs on a dedicated VRF. Redirect all commands that are run on the management port to its VRF.

The configured IP subnet has to be globally unique because the management protocols can go through in-band or out-of-band ports.

### Note

Do not configure a default route in the Management VRF and instead use a static route. Inbound FTP does not work when a default route is configured at the Management VRF. When you initiate FTP, you should also set FTP to passive mode.

## Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Select **Set VRF Context View**.
3. Select **MgmtRouter**, VRF 512.
4. Select **Launch VRF Context View**.

A new EDM webpage displays for the VRF context. Parameters that you cannot configure for this context appear dim.

5. In the Device Physical view, select the management port.
6. In the navigation pane, expand **Configuration > Edit**.
7. Select **Mgmt Port**.
8. Select the **IP Address** tab.
9. Select **Insert**.
10. Configure the IP address and mask.
11. Select **Insert**.
12. Collapse the VRF context view.

### **IP Address** field descriptions

Use the data in the following table to use the **IP Address** tab.

| Name                   | Description                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>       | Specifies the slot and port for the management port.                                                                                |
| <b>Ip Address</b>      | Specifies the IP address for the management port.                                                                                   |
| <b>Net Mask</b>        | Specifies the subnet mask for the IP address.                                                                                       |
| <b>BcastAddrFormat</b> | Specifies the broadcast address format for the management port.                                                                     |
| <b>ReasmMaxSize</b>    | Specifies the size of the largest IP datagram that can be reassembled from IP fragmented datagrams received on the management port. |

| Name               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>      | Specifies the VLAN ID to which the management port belongs.<br>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>BrouterPort</b> | Specifies if the management port is a brouter port rather than a routeable VLAN. You cannot change this value after the row is created.                                                                                                                                                                                                                                                                                                                                                   |
| <b>MacOffset</b>   | Translates the IP address into a MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Edit the Management Port Parameters

### About This Task

The management port on the switch is a 10/100/1000 Mb/s Ethernet port that you can use for an out-of-band management connection to the switch.

#### Note

This procedure only applies to hardware with a dedicated physical management interface.

If you use EDM to configure the static routes of the management port, you do not receive a warning if you configure a non-natural mask. After you save the changes, the system deletes those static routes after the next restart, possibly causing the loss of IP connectivity to the management port.

If you are uncertain whether the mask you configure is non-natural, use the CLI to configure static routes.

### Procedure

1. In the Device Physical View tab, select the management port.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Mgmt Port**.
4. Click the **General tab**.
5. Modify the appropriate settings.
6. Click **Apply**.

**General** Field Descriptions

Use the data in the following table to use the **General** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                | Specifies the slot and port number of the management port.                                                                                                                                                                                                                                                                                                                                                                            |
| <b>AdminStatus</b>          | Configures the administrative status of the device as up (ready to pass packets) or down. The testing state indicates that no operational packets can be passed.                                                                                                                                                                                                                                                                      |
| <b>OperStatus</b>           | Specifies the operational status of the device.                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>LicenseControlStatus</b> | Shows the license status of the port: <ul style="list-style-type: none"> <li>Locked means the port requires a Port License but one is not present on the switch.</li> <li>Unlocked means the port requires a Port License and one is present on the switch.</li> <li>notApplicable means the port does not require a Port License.</li> </ul>                                                                                         |
| <b>Mtu</b>                  | Shows the configuration for the maximum transmission unit. The size of the largest packet which can be sent/received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.                                                                                                                      |
| <b>LinkTrap</b>             | Enables or disables traps for the link status.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>IpsecEnable</b>          | Enables IPsec on the management port. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>PhysAddress</b>          | Shows the MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>AutoNegotiate</b>        | Enables or disables Auto-Negotiation for the management port. The default varies depending on the platform: <ul style="list-style-type: none"> <li>5420 Series - enabled</li> <li>5520 Series - enabled</li> <li>VSP 4900 Series - enabled</li> <li>VSP 7200 Series - disabled</li> <li>VSP 7400 Series - enabled</li> <li>VSP 8200 Series - enabled</li> <li>VSP 8400 Series - enabled</li> <li>VSP 8600 Series - enabled</li> </ul> |
| <b>AdminDuplex</b>          | Specifies the administrative duplex mode for the management port. The default is full.                                                                                                                                                                                                                                                                                                                                                |
| <b>OperDuplex</b>           | Specifies the operational duplex configuration for this port.                                                                                                                                                                                                                                                                                                                                                                         |
| <b>AdminSpeed</b>           | Specifies the administrative speed for this port. The default is 100 Mb/s.                                                                                                                                                                                                                                                                                                                                                            |
| <b>OperSpeed</b>            | Shows the current operating data rate of the port.                                                                                                                                                                                                                                                                                                                                                                                    |

## Configure the Management Port IPv6 Interface Parameters

**Note**

This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management Instance Configuration for VOSS using EDM](#) on page 100.

### About This Task

Configure IPv6 management port parameters to use IPv6 routing on the port.

This procedure only applies to hardware with a dedicated, physical management interface.

### Procedure

1. In the Device Physical View tab, select the management port.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Mgmt Port**.
4. Select the **IPv6 Interface** tab.
5. Select **Insert**.
6. Edit the fields as required.
7. Select **Insert**.
8. Select **Apply**.

#### **IPv6 Interface** field descriptions

Use the data in the following table to use the **IPv6 Interface** tab.

| Name                     | Description                                                                                                                                                                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>         | Identifies the unique IPv6 interface.                                                                                                                                                                                                     |
| <b>Descr</b>             | Specifies a textual string containing information about the interface. The network management system also configures the <b>Descr</b> string.                                                                                             |
| <b>Type</b>              | Specifies the type of interface.                                                                                                                                                                                                          |
| <b>ReasmMaxSize(MTU)</b> | Configures the MTU for this IPv6 interface. This value must be the same for all the IP addresses defined on this interface. The default value is 1500.                                                                                    |
| <b>PhysAddress</b>       | Specifies the physical address for the interface. For example, for an IPv6 interface attached to an 802.x link, this value is a MAC address.                                                                                              |
| <b>AdminStatus</b>       | Configures the indication of whether IPv6 is activated (up) or disabled (down) on this interface. This object does not affect the state of the interface, only the interface connection to an IPv6 stack. The default is false (cleared). |
| <b>ReachableTime</b>     | Configures the time, in milliseconds, that the system considers a neighbor reachable after it receives a reachability confirmation. The value is in a range from 0-3600000. The default value is 30000.                                   |

| Name                   | Description                                                                                                                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RetransmitTimer</b> | Configures the time between retransmissions of neighbor solicitation messages to a neighbor; during address resolution or neighbor reachability discovery. The value is expressed in milliseconds in a range from 0–3600000. The default value is 1000.                  |
| <b>CurHopLimit</b>     | Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for the current hop limit. The default is 64. |

## Configure Management Port IPv6 Addresses

### Note

This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management Instance Configuration for VOSS using EDM](#) on page 100.

### About This Task

Configure management port IPv6 addresses to add or remove IPv6 addresses from the port.

The switch supports IPv6 addressing with Ping, Telnet, and SNMP.

### Procedure

1. In the Device Physical View tab, select the management port.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Mgmt Port**.
4. Select the **IPv6 Addresses** tab.
5. Select **Insert**.
6. In the **Addr** box, type the required IPv6 address for the management port.
7. In the **AddrLen** box, type the number of bits from the IPv6 address you want to advertise.
8. Select **Insert**.
9. Select **Apply**.

### *IPv6 Addresses* field descriptions

Use the data in the following table to use the **IPv6 Addresses** tab.

| Name             | Description                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b> | Specifies an index value that uniquely identifies the interface.                                                                                                                                                                                                                           |
| <b>Addr</b>      | Specifies the IPv6 address to which this entry addressing information pertains.<br>If the IPv6 address exceeds 116 octets, the object identifiers (OIDs) of instances of columns in this row is more than 128 subidentifiers and you cannot use SNMPv1, SNMPv2c, or SNMPv3 to access them. |

| Name               | Description                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AddrLen</b>     | Specifies the prefix length value for this address. You cannot change the address length after creation. You must provide this field to create an entry in this table.                                                |
| <b>Type</b>        | Specifies unicast, the only supported type.                                                                                                                                                                           |
| <b>Origin</b>      | Specifies the origin of the address. The origin of the address can be one of the following: other, manual, dhcp, linklayer, or random.                                                                                |
| <b>Status</b>      | Specifies the status of the address, describing if the address can be used for communication. The status can be one of the following: preferred, deprecated, invalid, inaccessible, unknown, tentative, or duplicate. |
| <b>Created</b>     | Specifies the time this entry was created. If this entry was created prior to the last initialization of the local network management subsystem, then this option contains a zero value.                              |
| <b>LastChanged</b> | Specifies the time this entry was last updated. If this entry was updated prior to the last initialization of the local network management subsystem, then this option contains a zero value.                         |

## Automatically Reactivating the Port of the SLPP Shutdown

### About This Task

Use the following procedure to automatically reactivate the port that is shut down by the SLPP.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **CP Limit** tab.
5. Select **AutoRecoverPort** to activate auto recovery of the port from the action taken by SLPP shutdown features. The default value is disabled.
6. Click **Apply**.

## Edit Serial Port Parameters

### About This Task

Perform this procedure to specify serial port communication settings. The serial port on the device is the console port. Depending on the hardware platform, the console port displays as console or 10101.

### Procedure

1. In the Device Physical View tab, select the console port on the device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Serial Port**.
4. Edit the port parameters as required.
5. Click **Apply**.

**Serial Port** Field Descriptions

Use the data in the following table to use the **Serial Port** tab.

| Name            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>  | Identifies the port as a serial port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>BaudRate</b> | <p>Specifies the baud rate of this port. Different hardware platforms support different baud rates, which also impacts the default value for each hardware platform:</p> <ul style="list-style-type: none"> <li>• 5420 Series — 115200</li> <li>• 5520 Series — 115200</li> <li>• VSP 4450 Series — 9600</li> <li>• VSP 4900 Series — 115200</li> <li>• VSP 7200 Series — 9600</li> <li>• VSP 7400 Series — 115200</li> <li>• VSP 8200 Series — 9600</li> <li>• VSP 8400 Series — 9600</li> <li>• VSP 8600 Series — 115200</li> <li>• XA1400 Series — 115200</li> </ul> |
| <b>DataBits</b> | Specifies the number of data bits, for each byte of data, this port sends and receives. The default is eight.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Enable Port Lock

**About This Task**

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

**Procedure**

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Port Lock** tab.
4. To enable port lock, select the **Enable** check box.
5. Click **Apply**.

**Port Lock** field descriptions

Use the data in the following table to use the **Port Lock** tab.

| Name               | Description                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Enable</b>      | Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.         |
| <b>LockedPorts</b> | Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock. |

## Lock a Port

### Before You Begin

- You must enable port lock before you lock or unlock a port.

### About This Task

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

### Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **General**.
- Click the **Port Lock** tab.
- In the **LockedPorts** box, click the ellipsis (...) button.
- Click the desired port or ports.
- Click **Ok**.
- In the **Port Lock** tab, click **Apply**.

### **Port Lock** field descriptions

Use the data in the following table to use the **Port Lock** tab.

| Name               | Description                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Enable</b>      | Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.         |
| <b>LockedPorts</b> | Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock. |

## Configure Power on Module Slots

### About This Task

Use this procedure to control whether or not to supply power to specific slots that contain either switch fabric modules or input/output modules. By default, power is available to all slots.

After enabling power to specific input/output module slots, you can also configure the priority in which they are powered on. For more information, see [Configure Slot Priority](#) on page 607.

#### Note

This feature is not available for hardware platforms with fixed configurations. It is only available for platforms where the user can install modules in slots.

### Procedure

- In the Device Physical View tab, select a module.
- In the navigation pane, expand **Configuration > Edit**.
- Click **Card**.

4. Click the **Card** tab.
5. In the **SlotPower** field, select the priority level: *on* or *off*.
6. Click **Apply**.

## Configure Slot Priority

### Note

This procedure only applies to VSP 8600 Series.

### About This Task

Configure slot priority to specify which slots you want to shut down if there is insufficient power available in the chassis. By default, power is available to all slots, and the slots have the following priority:

- Slots 1, 2, SF1, SF2, and SF3 must always be *Critical* so you cannot configure them.
- Slots 3-8 are *High* by default, but you can configure any of them to *Low*.

### Note

Power is always supplied to critical slots first which are the CP modules, SF modules, and fan trays.

The slot with the lowest priority shuts down first. Slots with the same priority shut down in descending order (highest slot number first) and interface slots shut down before CP, SF modules, and fan tray slots.

For example, if slot 3 has a *low* priority and slots 4 and 5 have a *high* priority, the slot shutdown priority is as follows: 4, 5, 3. Slot 3 has the lowest priority because it was configured as *low* so it would be shut down first. Slots 4 and 5 have the same priority, but slot 5 shuts down before slot 4 because slot 4 has a higher slot number.

### Procedure

1. In the Device Physical View tab, select a module.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Card**.
4. Click the **Card** tab.
5. In the **PowerManagementPriority** field, select the priority level: *high* or *low*.
6. Click **Apply**.

## View Power Information

### About This Task

View power information to see the amount of power available and used by the chassis and all components.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Chassis**.
4. Select the **Power Info** tab.

#### *Power Info field descriptions*

Use the data in the following table to use the **Power Info** tab.

| Name                  | Description                                             |
|-----------------------|---------------------------------------------------------|
| <b>TotalPower</b>     | Shows the total power for the chassis.                  |
| <b>RedundantPower</b> | Shows the redundant power for the chassis.              |
| <b>PowerUsage</b>     | Shows the power currently used by the complete chassis. |
| <b>PowerAvailable</b> | Shows the unused power.                                 |

## View Power Status

### About This Task

Perform the following procedure to view the power consumption of the modules in the chassis.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Chassis**.
3. Click the **Power Consumption** tab.

#### *Power consumption field descriptions*

Use the data in the following table to use the **Power Consumption** tab.

| Name                   | Description                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------|
| <b>Index</b>           | Displays an index value that identifies the component.                                       |
| <b>PowerStatus</b>     | Displays the power status: on or off.                                                        |
| <b>BasePower</b>       | Displays the base power required for the slot.                                               |
| <b>ConsumedPower</b>   | Displays the actual consumed power for the slot. This value is 0 if the power status is off. |
| <b>PowerPriority</b>   | Displays the priority of the slot for power management.                                      |
| <b>SlotDescription</b> | Displays the slot number.                                                                    |
| <b>CardDescription</b> | Identifies the type of module in the slot.                                                   |

## View Fan Tray Information

View fan tray information to see manufacturing information about the fans.

### Note

Not all fields are supported on all hardware platforms.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **Fan Tray Info** tab.

### *Fan Tray Info* field descriptions

Use the data in the following table to use the **Fan Tray Info** tab.

| Name                | Description                                                       |
|---------------------|-------------------------------------------------------------------|
| <b>TrayId</b>       | Specifies the fan tray ID.                                        |
| <b>Description</b>  | Shows a description of the fan tray.                              |
| <b>SerialNumber</b> | Shows the serial number for the fan tray.                         |
| <b>PartNumber</b>   | Shows the part number for the fan tray.                           |
| <b>FlowType</b>     | Specifies whether the air flow is front-to-back or back-to-front. |

## View USB Port Information

### About This Task

Perform this procedure to view information about the USB port on the switch.

### Note

This information may not apply to your hardware model. For more information about your model features, see your hardware documentation.

### Procedure

1. In the Device Physical View, select the USB port.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **USB Port**.
4. Click the **General** tab.

*General field descriptions*

Use the data in the following table to use the **General** tab.

| Name                  | Description                                                               |
|-----------------------|---------------------------------------------------------------------------|
| <b>UsbStatus</b>      | Displays the current status of USB storage: either present or notPresent. |
| <b>UsbDescription</b> | Displays a description of the USB storage.                                |

## View USB Device Information

### About This Task

Perform this procedure to view information about an inserted USB device.

#### Note

This information may not apply to your hardware model. For more information about your model features, see your hardware documentation.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **USB** tab.

*USB field descriptions*

Use the data in the following table to use the USB tab.

| Name                   | Description                                                                                                                      |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>SlotDescription</b> | Specifies the slot type information.                                                                                             |
| <b>VendorId</b>        | Specifies the vendor ID for the inserted USB device.                                                                             |
| <b>Manufacturer</b>    | Specifies the manufacturer of the inserted USB device.                                                                           |
| <b>ProductId</b>       | Specifies the product ID of the inserted USB device.                                                                             |
| <b>ProductName</b>     | Specifies the product name of the inserted USB device.                                                                           |
| <b>SerialNumber</b>    | Specifies the serial number of the inserted USB device.                                                                          |
| <b>Revision</b>        | Specifies the release number of the inserted USB device.                                                                         |
| <b>MaxCurrent</b>      | Specifies the maximum power as defined by the specification for the inserted USB device. The units of measurement are milliamps. |

## View Topology Status Information

### About This Task

View topology status information (which includes MIB status information) to view the configuration status of the SynOptics Network Management Protocol (SONMP) on the system.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics**.
2. Click **Topology**.
3. Click the **Topology** tab.

### *Topology* field descriptions

Use the data in the following table to use the **Topology** tab.

| Name             | Description                                                                                                                                                                                                              |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddr</b>    | Specifies the IP address of the device.                                                                                                                                                                                  |
| <b>Status</b>    | Indicates whether topology (SONMP) is on or off for the device.                                                                                                                                                          |
| <b>NmmLstChg</b> | Specifies the value of sysUpTime, the last time an entry in the network management MIB (NMM) topology table was added, deleted, or modified, if the table did not change since the last cold or warm start of the agent. |
| <b>NmmMaxNum</b> | Specifies the maximum number of entries in the NMM topology table.                                                                                                                                                       |
| <b>NmmCurNum</b> | Specifies the current number of entries in the NMM topology table.                                                                                                                                                       |

## View the Topology Message Status

### About This Task

View topology message status to view the interconnections between Layer 2 devices in a network.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics**.
2. Click **Topology**.
3. Click the **Topology Table** tab.

### *Topology Table* Field Descriptions

Use the data in the following table to use the **Topology Table** tab.

| Name           | Description                                                                             |
|----------------|-----------------------------------------------------------------------------------------|
| <b>Slot</b>    | Specifies the slot number in the chassis that received the topology message.            |
| <b>Port</b>    | Specifies the port that received the topology message.                                  |
| <b>SubPort</b> | Specifies the channel of a channelized 40 Gbps port that received the topology message. |

| Name                   | Description                                                                                                                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddr</b>          | Specifies the IP address of the sender of the topology message.                                                                                                                                                                                                                                      |
| <b>SegId (RemPort)</b> | Specifies the segment identifier of the segment from which the remote agent sent the topology message. This value is extracted from the message.                                                                                                                                                     |
| <b>MacAddr</b>         | Specifies the MAC address of the sender of the topology message.                                                                                                                                                                                                                                     |
| <b>ChassisType</b>     | Specifies the chassis type of the device that sent the topology message.                                                                                                                                                                                                                             |
| <b>BkplType</b>        | Specifies the backplane type of the device that sent the topology message.                                                                                                                                                                                                                           |
| <b>LocalSeg</b>        | Indicates if the sender of the topology message is on the same Ethernet segment as the reporting agent.                                                                                                                                                                                              |
| <b>CurState</b>        | Specifies the current state of the sender of the topology message. The choices are <ul style="list-style-type: none"> <li>• topChanged—Topology information recently changed.</li> <li>• heartbeat—Topology information is unchanged.</li> <li>• new—The sending agent is in a new state.</li> </ul> |

## Configure a Forced Message Control Pattern

### About This Task

Configure a forced message control pattern to enforce configured message control actions.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Chassis**.
2. Click the **Force Msg Patterns** tab.
3. Click **Insert**.
4. In the **PatternId** field, enter a pattern ID number.
5. In the **Pattern** field, enter a message control pattern.
6. Click **Insert**.

*Force Msg Patterns Field Descriptions*

Use the data in the following table to use the **Force Msg Patterns** tab.

| Name             | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PatternId</b> | Specifies a pattern identification number in the range 1-32.                                                                                                                                                                                                                                                                                                                                                                |
| <b>Pattern</b>   | Specifies a forced message control pattern of 4 characters. The software and the hardware log messages that use the first four bytes matching one of the patterns in the force-msg table undergo the configured message control action. You can specify up to 32 different patterns in the force-msg table, including a wildcard pattern (****). If you specify the wildcard pattern, all messages undergo message control. |

**View Fan Information**

View fan information to monitor the alarm status of the cooling ports in the chassis.

**Note**

This tab does not apply on the VSP 8600 Series switch.

**About This Task**

For platforms that support both back-to-front and front-to-back airflow, the airflow direction must be the same for both the power supply fans and the chassis fan.

**Procedure**

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Chassis**.
4. Select the **Fan Info** tab.

*Fan Info field descriptions*

Use the data in the following tables to use the **Fan Info** tab.

| Name               | Description                                  |
|--------------------|----------------------------------------------|
| <b>Description</b> | Specifies a description of the fan location. |
| <b>OperStatus</b>  | Specifies the operation status of the fan.   |
| <b>OperSpeed</b>   | Specifies the actual fan speed.              |

## Configure Ports Speeds for All VIM Ports

### Note

This procedure only applies to 5520 Series and VSP 4900 Series.

Configure all of the ports on an installed Versatile Interface Module (VIM) to operate at the same speed.

### Note

Some VIMs must operate with all ports at the same speed, while others can operate with ports at different speeds. For more information, see [VOSS Release Notes](#). You can configure VIM ports speed only on VIMs that must operate with all ports at the same speed.

### Before You Begin

Install the VIM before performing this procedure.

### About This Task

Use this procedure to configure the speed of all ports in a multi-port VIM to operate at either 10 Gbps or 25 Gbps.

### Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **VIM** tab.
4. Select **mbps10000** or **mbps25000**.
5. Select **Apply**.

### VIM Field Descriptions

Use the data in the following table to use the VIM tab.

| Name              | Description                                                                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminSpeed</b> | <ul style="list-style-type: none"> <li>• <b>mbps10000</b>: Configures all ports in a multi-port VIM to operate at 10 Gbps.</li> <li>• <b>mbps25000</b>: Configures all ports in a multi-port VIM to operate at 25 Gbps.</li> </ul> <p>The default is 25 Gbps.</p> |

## View Modular SSD Information

### About This Task

Perform this procedure to display information about an installed Solid State Drive (SSD) on a switch.

### Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **SSD** tab.

**SSD Field Descriptions**

Use the data in the following table to use the SSD tab.

| Name                   | Description                                           |
|------------------------|-------------------------------------------------------|
| <b>ProductName</b>     | Specifies Solid State Drive (SSD) product name.       |
| <b>VendorName</b>      | Specifies the SSD vendor.                             |
| <b>ManufactureDate</b> | Specifies the date on which the SSD was manufactured. |
| <b>SerialNum</b>       | Specifies the SSD serial number.                      |
| <b>PartNum</b>         | Specifies the SSD part number.                        |
| <b>DeviceVersion</b>   | Specifies the version of the SSD.                     |
| <b>TotalSize</b>       | Specifies the total memory size of the SSD.           |

**Prepare a slot for IOC Module Preconfiguration using EDM****About This Task**

Use this procedure to designate a slot in the switch for IOC Module Preconfiguration. A slot can be designated for only one module type at a time.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit > Card Preconfig**.
2. Click **Insert**.
3. Enter the slot number in the **Slot** field.
4. Select the IOC Module type in the **CardType** field.
5. Select the **Lock** field to lock the slot to the specified IOC Module type.
6. Click **Insert**.

**Card Preconfig Field Descriptions**

Use the data in the following table to use the **Card Preconfig** tab.

| Field           | Description                                                                       |
|-----------------|-----------------------------------------------------------------------------------|
| <b>Slot</b>     | Specifies the slot number designated for pre-configuration.                       |
| <b>CardType</b> | Specifies the type of the IOC Module designated for the slot.                     |
| <b>Lock</b>     | If selected, the slot is locked to only accept the type of IOC Module designated. |

**Graphing Chassis Statistics**

Create graphs of chassis statistics to generate a visual representation of your data.

### Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. On the Graph Chassis tab, select the tab with the data you want to graph:
  - System
  - SNMP
  - IP
  - ICMP In
  - ICMP Out
  - TCP
  - UDP
5. Select the statistic you want to graph.
6. Select the graph type:
  - line chart
  - area chart
  - bar chart
  - pie chart

## Graphing Port Statistics

You can create a graph of the port statistics to generate a visual representation of your data.

### Procedure

1. In the Device Physical View, select the port or ports for which you want to create a graph.
2. In the navigation pane, expand the **Configuration > Graph** folders, and then click **Port**.  
OR, use the following shortcut:  
  
Right-click the selected port or ports from Step 1, and choose **Graph**.
3. On the **Graph Port** tab for the selected port or ports, select the item you want to graph.
4. Click an icon to select the type of graph you require. The following list provides the graph types available:
  - Line Chart
  - Area Chart
  - Bar Chart
  - Pie Chart

## Viewing Chassis System Statistics

Use the following procedure to create graphs for chassis statistics.

### Procedure

1. In the Device Physical View, select the chassis.

2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **System** tab.

### **System** Field Descriptions

The following table describes the fields on the **System** tab.

| Name           | Description                                                                                                                                                                                     |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MemUsed</b> | The percentage of memory space used.<br>Only the AbsoluteValue column is valid in the System tab. All other columns display as N/A because they are percentages and not actual memory counters. |
| <b>MemFree</b> | The amount in kilobytes of free memory.                                                                                                                                                         |
| <b>CpuUtil</b> | Percentage of CPU utilization.                                                                                                                                                                  |

## Viewing Chassis SNMP Statistics

View chassis SNMP statistics to monitor network performance.

### **Procedure**

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **SNMP** tab.

### **SNMP** Field Descriptions

The following table describes parameters on the **SNMP** tab.

| Name                  | Description                                                                                                                                       |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InPkts</b>         | The number of messages delivered to the SNMP entity from the transport service.                                                                   |
| <b>OutPkts</b>        | The number of SNMP messages passed from the SNMP protocol entity to the transport service.                                                        |
| <b>InTotalReqVars</b> | The number of MIB objects retrieved successfully by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs. |
| <b>InTotalSetVars</b> | The number of MIB objects altered successfully by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs.                |
| <b>InGetRequests</b>  | The number of SNMP Get-Request PDUs the SNMP protocol accepts and processes.                                                                      |
| <b>OutGetRequests</b> | The number of SNMP Get-Request PDUs that are generated by the SNMP protocol entity.                                                               |
| <b>InGetNexts</b>     | The number of SNMP Get-Next PDUs the SNMP protocol accepts and processes.                                                                         |

| Name                       | Description                                                                                                                                                                                                                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OutGetNexts</b>         | The number of SNMP Get-Next PDUs that are generated by the SNMP protocol entity.                                                                                                                                                                                                                            |
| <b>InSetRequests</b>       | The number of SNMP Set-Request PDUs the SNMP protocol accepts and processes.                                                                                                                                                                                                                                |
| <b>OutSetRequests</b>      | The number of SNMP Set-Request PDUs that are generated by the SNMP protocol entity.                                                                                                                                                                                                                         |
| <b>InGetResponses</b>      | The number of SNMP Get-Response PDUs the SNMP protocol accepts and processes.                                                                                                                                                                                                                               |
| <b>OutGetResponses</b>     | The number of SNMP Get-Response PDUs that are generated by the SNMP protocol entity.                                                                                                                                                                                                                        |
| <b>InTraps</b>             | The number of SNMP Trap PDUs the SNMP protocol accepts.                                                                                                                                                                                                                                                     |
| <b>OutTraps</b>            | The number of SNMP Trap PDUs the SNMP protocol generates.                                                                                                                                                                                                                                                   |
| <b>OutTooBig</b>           | The number of SNMP PDUs the SNMP protocol generates for which the value of the error-status field is tooBig.                                                                                                                                                                                                |
| <b>OutNoSuchNames</b>      | The number of SNMP PDUs the SNMP protocol generates for which the value of the error-status field is noSuchName.                                                                                                                                                                                            |
| <b>OutBadValues</b>        | The number of SNMP PDUs the SNMP protocol generates for which the value of the error-status field is badValue.                                                                                                                                                                                              |
| <b>OutGenErrs</b>          | The number of SNMP PDUs the SNMP protocol generates for which the value of the error-status field is genErr.                                                                                                                                                                                                |
| <b>InBadVersions</b>       | The number of SNMP messages delivered to the SNMP protocol entity for an unsupported SNMP version.                                                                                                                                                                                                          |
| <b>InBadCommunityNames</b> | The number of SNMP messages delivered to the SNMP protocol entity that used an SNMP community name not known to said entity.                                                                                                                                                                                |
| <b>InBadCommunityUses</b>  | The number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation not allowed by the SNMP community named in the message.                                                                                                                                                |
| <b>InASNParseErrs</b>      | The number of ASN.1 or BER errors the SNMP protocol encountered when decoding received SNMP messages.                                                                                                                                                                                                       |
| <b>InTooBig</b>            | The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is tooBig.                                                                                                                                                                                      |
| <b>InNoSuchNames</b>       | The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is noSuchName.                                                                                                                                                                                  |
| <b>InBadValues</b>         | The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is badValue.                                                                                                                                                                                    |
| <b>InReadOnly</b>          | The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is readOnly. It is a protocol error to generate an SNMP PDU containing the value "readOnly" in the error-status field. This object is provided to detect incorrect implementations of the SNMP. |
| <b>InGenErrs</b>           | The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is genErr.                                                                                                                                                                                      |

## Viewing Chassis IP Statistics

View chassis IP statistics to monitor network performance.

### Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **IP** tab.

### *IP* Field Descriptions

The following table describes parameters on the **IP** tab.

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InReceives</b>      | The number of input datagrams received from interfaces, including those received in error.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>InHdrErrors</b>     | The number of input datagrams discarded due to errors in the IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, errors discovered in processing their IP options.                                                                                                                                                                                                                                            |
| <b>InAddrErrors</b>    | The number of input datagrams discarded because the IP address in the IP header destination field was not a valid address to be received at this entity. This count includes invalid addresses (for example, 0.0.0.0) and addresses of unsupported Classes (for example, Class E). For entities that are not IP Gateways and therefore do not forward datagrams, this counter includes datagrams discarded because the destination address was not a local address. |
| <b>ForwDatagrams</b>   | The number of input datagrams for which this entity was not their final IP destination, as a result of which an attempt was made to find a route to forward them to that final destination. In entities that do not act as IP Gateways, this counter includes only those packets that were Source-Routed by way of this entity and had successful Source-Route option processing.                                                                                   |
| <b>InUnknownProtos</b> | The number of locally addressed datagrams received successfully but discarded because of an unknown or unsupported protocol.                                                                                                                                                                                                                                                                                                                                        |
| <b>InDiscards</b>      | The number of input IP datagrams for which no problems were encountered to prevent their continued processing but that were discarded (for example, for lack of buffer space). This counter does not include any datagrams discarded while awaiting reassembly.                                                                                                                                                                                                     |
| <b>InDelivers</b>      | The number of input datagrams successfully delivered to IP user-protocols (including ICMP).                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OutRequests</b>     | The number of IP datagrams that local IP user-protocols (including ICMP) supplied to IP in requests for transmission. This counter does not include any datagrams counted in ipForwDatagrams.                                                                                                                                                                                                                                                                       |
| <b>OutDiscards</b>     | The number of output IP datagrams for which no problem was encountered to prevent their transmission to their destination, but that were discarded (for example, for lack of buffer space). This counter includes datagrams counted in ipForwDatagrams if any such packets met this (discretionary) discard criterion.                                                                                                                                              |

| Name               | Description                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OutNoRoutes</b> | The number of IP datagrams discarded because no route was found to transmit them to their destination. This counter includes any packets counted in ipForwDatagrams that meet this no-route criterion. This counter includes any datagrams a host cannot route because all default gateways are down.                             |
| <b>FragOKs</b>     | The number of IP datagrams that were successfully fragmented at this entity.                                                                                                                                                                                                                                                      |
| <b>FragFails</b>   | The number of IP datagrams that were discarded because they needed to be fragmented at this entity but can not be, for example, because the Don't Fragment flags were set.                                                                                                                                                        |
| <b>FragCreates</b> | The number of IP datagram fragments that were generated as a result of fragmentation at this entity.                                                                                                                                                                                                                              |
| <b>ReasmReqds</b>  | The number of IP fragments received that needed to be reassembled at this entity.                                                                                                                                                                                                                                                 |
| <b>ReasmOKs</b>    | The number of IP datagrams successfully reassembled.                                                                                                                                                                                                                                                                              |
| <b>ReasmFails</b>  | The number of failures detected by the IP reassembly algorithm (for whatever reason: timed out, errors, and so on). This number is not necessarily a count of discarded IP fragments because some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received. |

## Viewing Chassis ICMP In Statistics

View chassis ICMP In statistics to monitor network performance.

### Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **ICMP In** tab.

### *ICMP In* Field Descriptions

The following table describes parameters on the **ICMP In** tab.

| Name                 | Description                                                |
|----------------------|------------------------------------------------------------|
| <b>SrcQuenchs</b>    | The number of ICMP Source Quench messages received.        |
| <b>Redirects</b>     | The number of ICMP Redirect messages received.             |
| <b>Echos</b>         | The number of ICMP Echo (request) messages received.       |
| <b>EchoReps</b>      | The number of ICMP Echo Reply messages received.           |
| <b>Timestamps</b>    | The number of ICMP Timestamp (request) messages received.  |
| <b>TimestampReps</b> | The number of ICMP Timestamp Reply messages received.      |
| <b>AddrMasks</b>     | The number of ICMP Address Mask Request messages received. |
| <b>AddrMaskReps</b>  | The number of ICMP Address Mask Reply messages received.   |

| Name                | Description                                                   |
|---------------------|---------------------------------------------------------------|
| <b>ParmProbs</b>    | The number of ICMP Parameter Problem messages received.       |
| <b>DestUnreachs</b> | The number of ICMP Destination Unreachable messages received. |
| <b>TimeExcds</b>    | The number of ICMP Time Exceeded messages received.           |

## Viewing Chassis ICMP Out Statistics

View chassis ICMP Out statistics to monitor network performance.

### Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **ICMP Out** tab.

### *ICMP Out* Field Descriptions

The following table describes parameters on the **ICMP Out** tab.

| Name                 | Description                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>SrcQuenchs</b>    | The number of ICMP Source Quench messages sent.                                                                             |
| <b>Redirects</b>     | The number of ICMP Redirect messages received. For a host, this object is always zero, because hosts do not send redirects. |
| <b>Echos</b>         | The number of ICMP Echo (request) messages sent.                                                                            |
| <b>EchoReps</b>      | The number of ICMP Echo Reply messages sent.                                                                                |
| <b>Timestamps</b>    | The number of ICMP Timestamp (request) messages sent.                                                                       |
| <b>TimestampReps</b> | The number of ICMP Timestamp Reply messages sent.                                                                           |
| <b>AddrMasks</b>     | The number of ICMP Address Mask Request messages sent.                                                                      |
| <b>AddrMaskReps</b>  | The number of ICMP Address Mask Reply messages sent.                                                                        |
| <b>ParmProbs</b>     | The number of ICMP Parameter Problem messages sent.                                                                         |
| <b>DestUnreachs</b>  | The number of ICMP Destination Unreachable messages sent.                                                                   |
| <b>TimeExcds</b>     | The number of ICMP Time Exceeded messages sent.                                                                             |

## Viewing Chassis TCP Statistics

View TCP statistics to monitor network performance.

### Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **TCP** tab.

**TCP** Field Descriptions

The following table describes parameters on the **TCP** tab.

| Name                | Description                                                                                                                                                                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ActiveOpens</b>  | The number of times TCP connections made a direct transition to the SYN-SENT state from the CLOSED state.                                                                                                                                             |
| <b>PassiveOpens</b> | The number of times TCP connections made a direct transition to the SYN-RCVD state from the LISTEN state.                                                                                                                                             |
| <b>AttemptFails</b> | The number of times TCP connections made a direct transition to the CLOSED state from either the SYN-SENT state or the SYN-RCVD state, plus the number of times TCP connections made a direct transition to the LISTEN state from the SYN-RCVD state. |
| <b>EstabResets</b>  | The number of times TCP connections made a direct transition to the CLOSED state from either the ESTABLISHED state or the CLOSE-WAIT state.                                                                                                           |
| <b>CurrEstab</b>    | The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT.                                                                                                                                                        |
| <b>InSegs</b>       | The number of segments received, including those received in error. This count includes segments received on currently established connections.                                                                                                       |
| <b>OutSegs</b>      | The number of segments sent, including those on current connections, but excluding those containing only retransmitted octets.                                                                                                                        |
| <b>RetransSegs</b>  | The number of segments retransmitted that is, the number of TCP segments transmitted containing one or more previously transmitted octets.                                                                                                            |
| <b>InErrs</b>       | The number of segments received in error (for example, bad TCP checksums).                                                                                                                                                                            |
| <b>OutRsts</b>      | The number of TCP segments sent containing the RST flag.                                                                                                                                                                                              |
| <b>HCInSegs</b>     | The number of segments received, including those received in error. This count includes segments received on currently established connections. This object is the 64-bit equivalent of InSegs.                                                       |
| <b>HCOutSegs</b>    | The number of segments sent, including those on current connections, but excluding those containing only retransmitted octets. This object is the 64-bit equivalent of OutSegs.                                                                       |

## Viewing Chassis UDP Statistics

Display User Datagram Protocol (UDP) statistics to see information about the UDP datagrams.

**Procedure**

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **UDP** tab.
5. Select the information you want to graph.

6. Select the type of graph you want:
  - line
  - area
  - bar
  - pie
7. To clear counters, click **Clear Counters**. Discontinuities in the value of these counters can occur when the management system reinitializes, and at other times as indicated by discontinuities in the value of sysUpTime.

### *UDP Field Descriptions*

Use the data in the following table to use the **UDP** tab.

| Name                  | Description                                                                                                                                                                                                                                                                                                                  |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NoPorts</b>        | The number of received UDP datagrams with no application at the destination port.<br>Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by discontinuities in the value of sysUpTime.                                                      |
| <b>InErrors</b>       | The number of received UDP datagrams that were not delivered for reasons other than the lack of an application at the destination port.<br>Discontinuities in the value of this counter can occur at reinitialization of the management system and at other times as indicated by discontinuities in the value of sysUpTime. |
| <b>InDatagrams</b>    | The number of UDP datagrams delivered to UDP users, for devices that can receive more than 1 000 000 UDP datagrams for each second.<br>Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by discontinuities in the value of sysUpTime.    |
| <b>OutDatagrams</b>   | The number of UDP datagrams sent from this entity.<br>Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by discontinuities in the value of sysUpTime.                                                                                     |
| <b>HCInDatagrams</b>  | The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT.                                                                                                                                                                                                                               |
| <b>HCOutDatagrams</b> | The number of UDP datagrams sent from this entity, for devices that can transmit more than 1 million UDP datagrams for each second.<br>Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by discontinuities in the value of sysUpTime.    |

## Viewing Port Interface Statistics

View port interface statistics to manage network performance.

### **Procedure**

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.

- Click the **Interface** tab.

### **Interface** Field Descriptions

The following table describes parameters on the **Interface** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InOctets</b>         | Specifies the number of octets received on the interface, including framing characters.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OutOctets</b>        | Specifies the number of octets transmitted from the interface, including framing characters.                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>InUcastPkts</b>      | Specifies the number of packets delivered by this sublayer to a higher sublayer that were not addressed to a multicast or broadcast address at this sublayer.                                                                                                                                                                                                                                                                                                                      |
| <b>OutUcastPkts</b>     | Specifies the number of packets that higher-level protocols requested be transmitted that were not addressed to a multicast address at this sublayer. The total number includes those packets discarded or not sent.                                                                                                                                                                                                                                                               |
| <b>InMulticastPkts</b>  | Specifies the number of packets delivered by this sublayer to a higher sublayer that were addressed to a multicast address at this sublayer. For a MAC layer protocol, this number includes both group and functional addresses.                                                                                                                                                                                                                                                   |
| <b>OutMulticastPkts</b> | Specifies the number of packets that higher-level protocols requested be transmitted, and that are addressed to a multicast address at this sublayer, including those that were discarded or not sent. For a MAC layer protocol, this number includes both group and functional addresses.                                                                                                                                                                                         |
| <b>InBroadcastPkts</b>  | Specifies the number of packets delivered by this sublayer to a higher sublayer that are addressed to a broadcast address at this sublayer.                                                                                                                                                                                                                                                                                                                                        |
| <b>OutBroadcastPkts</b> | Specifies the number of packets that higher-level protocols requested be transmitted, and that were addressed to a broadcast address at this sublayer, including those that were discarded or not sent.                                                                                                                                                                                                                                                                            |
| <b>InDiscards</b>       | Specifies the number of inbound packets that are discarded because of frames with errors or invalid frames or, in some cases, to fill up buffer space.                                                                                                                                                                                                                                                                                                                             |
| <b>InErrors</b>         | For packet-oriented interfaces, specifies the number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. For character-oriented or fixed-length interfaces, the number of inbound transmission units that contained errors preventing them from being deliverable to a higher-layer protocol.                                                                                                                              |
| <b>InUnknownProtos</b>  | For packet-oriented interfaces, specifies the number of packets received through the interface that are discarded because of an unknown or unsupported protocol. For character-oriented or fixed-length interfaces that support protocol multiplexing, the number of transmission units received through the interface that were discarded because of an unknown or unsupported protocol. For any interface that does not support protocol multiplexing, this counter is always 0. |

| Name                      | Description                                                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HCInPfcPkts</b>        | Specifies the total number of Priority Flow Control (PFC) packets received by this interface. This number does not increment for port-level flow control. |
| <b>HCOuPfcPkts</b>        | Specifies the total number of PFC packets transmitted by this interface. This number does not increment for port-level flow control.                      |
| <b>InFlowCtrlPkts</b>     | Specifies the number of port-level flow control packets received by this interface.                                                                       |
| <b>OutFlowCtrlPkts</b>    | Specifies the number of port-level flow control packets transmitted by this interface.                                                                    |
| <b>InPfcPkts</b>          | Specifies the total number of port-level flow control packets received by this interface.                                                                 |
| <b>OutPfcPkts</b>         | Specifies the total number of port-level flow control packets transmitted by this interface.                                                              |
| <b>NumStateTransition</b> | Specifies the number of times the port went in and out of service; the number of state transitions from up to down.                                       |

## Viewing Port Ethernet Errors Statistics

View port Ethernet errors statistics to manage network performance.

### Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **Ethernet Errors** tab.

**Ethernet Errors** Field Descriptions

The following table describes parameters on the **Ethernet Errors** tab.

| Name                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AlignmentErrors</b>           | Specifies account of frames received on a particular interface that are not an integral number of octets in length and do not pass the FCS check. The count represented by an instance of this object increments when the alignmentError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions obtain are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.                                                                                        |
| <b>FCSErrors</b>                 | Specifies a count of frames received on a particular interface that are an integral number of octets in length but do not pass the FCS check. The count represented by an instance of this object increments when the frameCheckError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions obtained are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.                                                                                         |
| <b>InternalMacTransmitErrors</b> | Specifies a count of frames for which transmission on a particular interface fails due to an internal MAC sublayer transmit error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the LateCollisions object, the ExcessiveCollisions object, or the CarrierSenseErrors object. The precise meaning of the count represented by an instance of this object is implementation-specific. In particular, an instance of this object can represent a count of transmission errors on a particular interface that are not otherwise counted. |
| <b>InternalMacReceiveErrors</b>  | Specifies a count of frames for which reception on a particular interface fails due to an internal MAC sublayer receive error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the FrameTooLongs object, the AlignmentErrors object, or the FCSErrors object. The precise meaning of the count represented by an instance of this object is implementation-specific. In particular, an instance of this object can represent a count of receive errors on a particular interface that are not otherwise counted.                        |
| <b>CarrierSenseErrors</b>        | Specifies the number of times that the carrier sense condition is lost or not asserted when the switch attempts to transmit a frame on a particular interface. The count represented by an instance of this object increments at most once for each transmission attempt, even if the carrier sense condition fluctuates during a transmission attempt.                                                                                                                                                                                                                                                    |

| Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FrameTooLongs</b>           | Specifies a count of frames received on a particular interface that exceed the maximum permitted frame size. The count represented by an instance of this object increments when the frameTooLong status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions obtained are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC. |
| <b>SQETestErrors</b>           | Specifies a count of times that the SQE TEST ERROR message is generated by the PLS sublayer for a particular interface. The SQE TEST ERROR message is defined in section 7.2.2.2.4 of ANSI/IEEE 802.3-1985 and its generation described in section 7.2.4.6 of the same document.                                                                                                                                                                                               |
| <b>DeferredTransmissions</b>   | Specifies a count of frames for which the first transmission attempt on a particular interface is delayed because the medium is busy. The count represented by an instance of this object does not include frames involved in collisions.                                                                                                                                                                                                                                      |
| <b>SingleCollisionFrames</b>   | Specifies a count of successfully transmitted frames on a particular interface for which transmission is inhibited by exactly one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the UcastPkts, MulticastPkts, or BroadcastPkts objects and is not counted by the corresponding instance of the MultipleCollisionFrames object.                                                                      |
| <b>MultipleCollisionFrames</b> | Specifies a count of successfully transmitted frames on a particular interface for which transmission is inhibited by more than one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the UcastPkts, MulticastPkts, or BroadcastPkts objects and is not counted by the corresponding instance of the SingleCollisionFrames object.                                                                      |
| <b>LateCollisions</b>          | Specifies the number of times that a collision is detected on a particular interface later than 512 bit-times into the transmission of a packet; 512 corresponds to 51.2 microseconds on a 10 Mb/s system. A (late) collision included in a count represented by an instance of this object is also considered as a (generic) collision for purposes of other collision-related statistics.                                                                                    |
| <b>ExcessiveCollisions</b>     | Specifies a count of frames for which transmission on a particular interface fails due to excessive collisions.                                                                                                                                                                                                                                                                                                                                                                |
| <b>FrameTooShorts</b>          | Specifies the number of frames, encountered on this interface, that are too short.                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>LinkFailures</b>            | Specifies the number of link failures encountered on this interface.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>PacketErrors</b>            | Specifies the number of packet errors encountered on this interface.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>CarrierErrors</b>           | Specifies the number of carrier errors encountered on this interface.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>LinkInactiveErrors</b>      | Specifies the number of link inactive errors encountered on this interface.                                                                                                                                                                                                                                                                                                                                                                                                    |

## Viewing Port Bridging Statistics

View port bridging errors statistics to manage network performance.

### Note

This tab is not available on all hardware platforms.

### Procedure

1. In the Device Physical View, select a port.
2. In the navigation tree, expand the following folders: **Configuration** > **Graph**.
3. Click **Port**.
4. Click the **Bridging** tab.

### **Bridging** Field Descriptions

The following table describes parameters on the **Bridging** tab.

| Name                     | Description                                            |
|--------------------------|--------------------------------------------------------|
| <b>InUnicastFrames</b>   | The number of incoming unicast frames bridged.         |
| <b>InMulticastFrames</b> | The number of incoming multicast frames bridged.       |
| <b>InBroadcastFrames</b> | The number of incoming broadcast frames bridged.       |
| <b>InDiscards</b>        | The number of frames discarded by the bridging entity. |
| <b>OutFrames</b>         | The number of outgoing frames bridged.                 |

## Viewing Port Routing Statistics

View port routing statistics to manage network performance.

### Note

This tab is not available on all hardware platforms.

### Procedure

1. In the Device Physical View, select a port.
2. In the navigation tree, expand the following folders: **Configuration** > **Graph**.
3. Click **Port**.
4. Click the **Routing** tab.

### **Routing** Field Descriptions

Use the data in the following table to use the **Routing** tab.

| Name                     | Description                                           |
|--------------------------|-------------------------------------------------------|
| <b>InUnicastFrames</b>   | The number of incoming unicast frames routed.         |
| <b>InMulticastFrames</b> | The number of incoming multicast frames routed.       |
| <b>InDiscards</b>        | The number of frames discarded by the routing entity. |

| Name                      | Description                                     |
|---------------------------|-------------------------------------------------|
| <b>OutUnicastFrames</b>   | The number of outgoing unicast frames routed.   |
| <b>OutMulticastFrames</b> | The number of outgoing multicast frames routed. |

## DHCP option 82

The DHCP option 82 is the DHCP Relay Agent Information option. The DHCP relay agent inserts option 82 when it forwards the client-originated DHCP packets to a DHCP server. The Relay Agent Information option is organized as a single DHCP option that contains one or more sub-options that convey information known by the relay agent. The DHCP server echoes the option back to the relay agent in server-to-client replies, and the relay agent removes the option before forwarding the reply to the client.

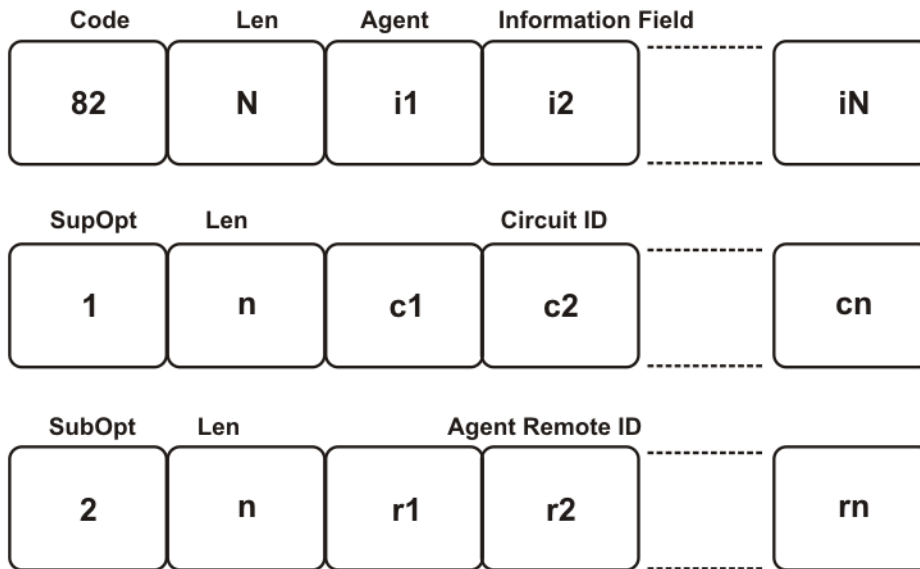

The DHCP option 82 is added at the DHCP relay level as shown in the following image.

**Figure 43: DHCP Client-Relay-Server Architecture**

The Relay Agent Information option (code 82) is a container for specific agent-supplied suboptions; Agent Circuit ID (code 1) and Agent Remote ID (code 2). The suboptions can represent different information relevant for the relay. The fields are encoded in the following manner, where N or n is the total number of octets in the Agent Information Field (all bytes of the suboptions):

**Figure 44: Format of the Relay Agent Information**

Because at least one of the sub-options must be defined, the minimum Relay Agent Information length is two (2), and the length *n* of the suboption can be zero (0). The sub-options do not have to display in any particular order. No pad suboption is defined and the Information field is not terminated with 255 suboption.

## DHCP Suboptions

The suboptions are Agent Circuit ID and Agent Remote ID.

The DHCP relay agents can add the Agent Circuit ID to terminate switched or permanent circuits. The Agent Circuit ID encodes an agent-local identifier of the circuit from which a DHCP client-to-server packet was received. Agents can use the Circuit ID to relay DHCP responses back to the proper circuit. In the switch, the Agent Circuit ID field contains the *ifIndex* of the interface on which the packet is received.

DHCP relay agents can add the Agent Remote ID to terminate switched or permanent circuits, and can identify the remote host end of the circuit. The switch uses the Agent Remote ID field to encode the MAC address of the interface on which the packet is received. The Agent Remote ID must be globally unique.

## Agent Operations

A DHCP relay agent adds a Relay Agent Information field as the last option in the DHCP options field of any recognized BOOTP or DHCP packet forwarded from a client to a server. However, if the End Option

255 is present, then the DHCP relay agent adds a Relay Agent information field before the End Option 255 field.

Relay agents can receive a DHCP packet from an untrusted circuit with the gateway IP address (GIADDR) set to zero to indicate that the relay agent is the first-hop router from the gateway. If a Relay Agent Information option is present in the packet, the relay agent discards the packet and increments an error counter. A trusted circuit can contain a trusted downstream network element, for example, a bridge, between the relay agent and the client. The bridge can add a relay agent option but does not set the GIADDR field. In this case, the relay agent forwards the DHCP packet per normal DHCP relay agent operations, and sets the GIADDR field to the relay address. The relay agent does not add a second relay agent option.

You can distinguish between a trusted circuit and an untrusted circuit based on the type of circuit termination equipment you use. To make a circuit trusted, set the trusted flag under DHCP for each interface.

After packets append the Relay Agent Information option, the packets that exceed the MTU or the vendor size buffer of 64 bits, are forwarded without adding the Agent Information option, and an error counter is incremented.

The relay agent or the trusted downstream network element removes the Relay Agent Information option echoed by a server that is added when forwarding a server-to-client response back to the client.

The following list outlines the operations that the relay agent does not perform:

- The relay agent does not add an Option Overload option to the packet or use the file or sname fields to add the Relay Agent Information option. The agent does not parse or remove Relay Agent Information options, the system can display it in the sname or file fields of a server-to-client packet forwarded through the agent.
- The relay agent does not monitor or modify client-originated DHCP packets addressed to a server unicast address; this includes the DHCP-REQUEST sent when entering the RENEWING state.
- The relay agent does not modify DHCP packets that use the IPSEC Authentication Header or IPSEC Encapsulating Security Payload.

A DHCP relay agent can receive a client DHCP packet forwarded from a BOOTP/DHCP relay agent closer to the client. This packet has a GIADDR as non-zero, and may or may not already have a DHCP Relay Agent option in it.

Relay agents configured to add a Relay Agent option which receive a client DHCP packet with a nonzero GIADDR, discards the packet if the GIADDR spoofs a GIADDR address implemented by the local agent itself. Otherwise, the relay agent forwards any received DHCP packet with a valid non-zero GIADDR without adding any relay agent options. The GIADDR value does not change.

## DHCP Relay for IPv6

---

The Dynamic Host Configuration Protocol (DHCP) for IPv6 (RFC 3315) enables DHCP servers to pass configuration parameters such as IPv6 network addresses to IPv6 nodes. DHCP supports automatic allocation of reusable network addresses and of additional configuration parameters. This protocol is a stateful counterpart to stateless address autoconfiguration, and you can use it separately or concurrently with the latter to obtain configuration parameters. For more information about stateless address autoconfiguration, see [Host autoconfiguration](#) on page 1964.

To request the assignment of one or more IPv6 addresses, a client first locates a DHCP server, and then requests the assignment of addresses and other configuration information from the server:

1. The client sends a solicit message to the All\_DHCP\_Relay\_Agents\_and\_Servers (FF02::1:2) multicast address to find available DHCP servers.
2. Any server that can meet the requirements responds with an advertise message.
3. The client then chooses one of the servers and sends a request message to the server asking for confirmed assignment of addresses and other configuration information.
4. The server responds with a reply message that contains the confirmed addresses and configuration.

If a DHCP client does not need a DHCP server to assign it an IPv6 address, the client can obtain configuration information such as a list of available DNS servers or NTP servers through a single message and reply exchanged with a DHCP server.

IPv6 DHCP clients use link-local addresses to send and receive DHCP messages. To permit a DHCP client to send a message to a DHCP server that is not attached to the same link, you must configure a DHCP relay agent on the client link to relay messages between the client and server. The operation of the relay agent is transparent to the client.

A relay agent relays messages from clients and messages from other relay agents. The switch supports DHCP Relay for IPv6. Configure at least one relay agent when the client and server are in different networks.

You must configure the relay agent to use a list of destination addresses for available DHCP servers. The software does not support IPv6 multicast for site-local and global addresses.

The DHCP relay can be a Virtual Router Redundancy Protocol (VRRP) Address. The relay forwards the DHCP messages only if VRRP is in the Master state, otherwise the relay discards the messages.

**Note**

DHCP cannot work on the backup VRRP if the master fails. To achieve optimum results and to leverage redundancy, you must configure DHCP on the backup VRRP.

Clients listen for DHCP messages on UDP port 546. Servers and relay agents listen for DHCP messages on UDP port 547.

## Remote ID

IPv6 DHCP Relay supports the remote ID parameter (RFC4649). After you enable remote ID on the switch, the relay agent adds information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The server can use the supplied information in the process of assigning the addresses, delegated prefixes, and configuration parameters that the client is to receive.

The remote ID option contains two fields:

- vendor ID
- MAC address of the client

The switch uses a vendor ID of 1584.

## Limitations

The following list identifies configuration limitations:

- You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.
- The maximum number of servers to which a relay can send a message from one client, is 10.
- You can configure the number of forwarding paths per system. For information on the maximum limit, see [VOSS Release Notes](#).

## DHCP Relay Network Topology and Workflow

The following example depicts the interaction between a DHCP client and a server:

**Figure 45: DHCP Client-Relay-Server Architecture**

The following list outlines the operations that the DHCP relay agent performs to forward the message to the server :

- When a client sends a request for the IP address or configuration parameters, the server responds with the details as requested by the client.

**Note**

There should be at least one relay agent when client and server are located in different networks.

- A DHCP Relay IPv6 is established only between agents within the context of each VRF and when no cross VRF interaction is present.

**Note**

**All\_DHCP\_Servers** multicast address option is not implemented for IPv6, as there is no IPv6 MCAST support for site-local and global address.

---

## UDP broadcast forwarding

---

Some network applications, such as the NetBIOS name service, rely on a User Datagram Protocol (UDP) broadcast to request a service or locate a server for an application. If a host is on a network, subnet segment, or VLAN that does not include a server for the service, UDP broadcasts are by default not forwarded to the server located on a different network segment or VLAN. You can resolve this problem by forwarding the broadcasts to the server through physical or virtual router interfaces.

UDP broadcast forwarding is a general mechanism for selectively forwarding limited UDP broadcasts received on an IP interface out to other router IP interfaces as a rebroadcast or to a configured IP address. If the address is that of a server, the packet is sent as a unicast packet to this address. If the address is that of an interface on the router, the frame is rebroadcast.

After a UDP broadcast is received on a router interface, it must meet the following criteria to be eligible for forwarding:

- It must be a MAC-level broadcast.
- It must be an IP limited broadcast.
- It must be for the specified UDP protocol.
- It must have a time-to-live (TTL) value of at least 2.

For each ingress interface and protocol, the policy specifies how the UDP broadcast is retransmitted: to a unicast host address or to a broadcast address.

---

## DHCP and UDP configuration using the CLI

---

Use Dynamic Host Configuration Protocol (DHCP), an extension of the Bootstrap Protocol (BootP), to provide host configuration information to the workstations dynamically. Use the DHCP relay commands to configure DHCP relay behavior on a port or on a VLAN.

This section describes CLI commands for DHCP and User Datagram Protocol (UDP) configuration.

### Configure DHCP Parameters Globally

#### Before You Begin

- Configure an IP address on the interface to be used as the DHCP relay interface.

#### About This Task

Configure DHCP relay parameters for the port or the VLAN.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Create the forwarding path from the client to the server:  

```
ip dhcp-relay fwd-path <A.B.C.D> <A.B.C.D>
```

3. Enable the forwarding path from the client to the server:

```
ip dhcp-relay fwd-path <A.B.C.D> <A.B.C.D> enable
```

**Note**

If the agent IP address (the first <A.B.C.D> variable) is a VLAN or port IP address, you must enable DHCP Relay on that VLAN or port by running **ip dhcp-relay** within the VLAN context. However, if the first <A.B.C.D> variable is a VRRP address, you do not need to enable DHCP Relay on the VLAN or port in which the VRRP address resides.

4. Modify DHCP mode to forward BootP messages only, DHCP messages only, or both:

```
ip dhcp-relay fwd-path <A.B.C.D> <A.B.C.D> mode <bootp|bootp_dhcp|dhcp>
```

**Example**

Create the forwarding path from the client to the server. Enable the forwarding path from the client the server. Modify DHCP mode to forward both BootP and DHCP messages.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.120 192.0.2.50
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.128 192.0.2.50 enable
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.128 192.0.2.50 mode bootp_dhcp
```

*Variable Definitions*

The following table defines parameters for the **ip dhcp-relay fwd-path** command.

| Variable                                                | Value                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>fwd-path &lt;A.B.C.D&gt; &lt;A.B.C.D&gt;</i>         | Configures the forwarding path from the client to the server. The first <A.B.C.D> variable is the agent IP address configured on an interface (a locally configured IP address). The second <A.B.C.D> variable is the IP address of the DHCP server in the network. If this IP address corresponds to the locally configured IP network, the DHCP packet is broadcast out from the interface. |
| <i>fwd-path &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; disable</i> | Disables DHCP relaying on the path from the IP address to the server. This feature is disabled by default. The first <A.B.C.D> variable is the agent IP address configured on an interface (a locally configured IP address). The second <A.B.C.D> variable is the IP address of the DHCP server in the network.                                                                              |

| Variable                                                                                          | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fwd-path &lt;A.B.C.D&gt;<br/>&lt;A.B.C.D&gt; enable</code>                                  | <p>Enables DHCP relaying on the path from the IP address to the server.<br/>The first &lt;A.B.C.D&gt; variable is the agent IP address configured on an interface (a locally configured IP address).</p> <p><b>Note:</b><br/>If the agent IP address (the first &lt;A.B.C.D&gt; variable) is a VLAN or port IP address, you must enable DHCP Relay on that VLAN or port by running <b>ip dhcp-relay</b> within the VLAN context. However, if the first &lt;A.B.C.D&gt; variable is a VRRP address, you do not need to enable DHCP Relay on the VLAN or port in which the VRRP address resides.</p> <p>The second &lt;A.B.C.D&gt; variable is the IP address of the DHCP server in the network. If this IP address corresponds to the locally configured IP network, the DHCP packet is broadcast out from the interface.</p> |
| <code>fwd-path &lt;A.B.C.D&gt;<br/>&lt;A.B.C.D&gt; mode &lt;bootp <br/>bootp_dhcp dhcp&gt;</code> | <p>Modifies DHCP mode to forward BootP messages only, DHCP messages only, or both. The default is both.<br/>The <i>mode</i> is {bootp   bootp_dhcp   dhcp}.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Showing DHCP relay information

Display relay information to show relay information about DHCP routes and counters.

For scaling information on DHCP Relay forwarding (IPv4 or IPv6), see [VOSS Release Notes](#).

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Display information about DHCP relay forward paths:  
`show ip dhcp-relay fwd-path [vrf WORD<1-16>] [vrfids WORD<0-512>]`
3. Display information about DHCP relay counters:  
`show ip dhcp-relay counters [vrf WORD<1-16>] [vrfids WORD<0-512>]`
4. Display the options for each listed interface:  
`show ip dhcp-relay interface [gigabitethernet {slot/port[/sub-port]} [-slot/port[/sub-port]][,...]] [vlan <1-4059>] [vrf WORD <1-16>] [vrfids WORD <0-512>]`

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1#show ip dhcp-relay interface
```

```
=====
Port Dhcp

Variable definitions

Use the data in the following table to use the **show ip dhcp-relay** command.

| Variable                              | Value                                                             |
|---------------------------------------|-------------------------------------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | The name of the VRF.                                              |
| <code>vrfids WORD&lt;0-512&gt;</code> | The ID of the VRF. The value is an integer in the range of 0-512. |

Use the data in the following table to use the **show ip dhcp-relay interface** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                          |
| <code>[vlan &lt;1-4059&gt;]</code>                                 | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>[vrf WORD&lt;1-16&gt;]</code>                                | Specifies the name of the VRF.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>[vrfids WORD&lt;0-512&gt;]</code>                            | Specifies the ID of the VRF. The value is an integer from 0- 512.                                                                                                                                                                                                                                                                                                                                                                      |

### Configuring DHCP option 82

Configure the DHCP option 82 to enable the circuit ID to encode an agent-local identifier of the circuit from which a DHCP client-to-server packet is received. Configure the DHCP option 82 to enable the remote ID to encode the MAC address of the interface on which the packet is received. By default, the DHCP option 82 is disabled.

**Before You Begin**

- You must enable ip and dhcp-relay on the VLAN.

## About This Task

To configure the DHCP option 82 on a VLAN, you must enter the VLAN Interface Configuration mode.

To configure the DHCP option 82 on a brouter port, you must enter the GigabitEthernet Interface Configuration mode.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable the circuit ID:

```
ip dhcp-relay circuitID
```

3. Enable the remote ID:

```
ip dhcp-relay remoteID
```

4. Configure the circuit as trusted:

```
ip dhcp-relay trusted
```

5. Show statistics for option 82, which is the relay agent information option:

```
show ip dhcp-relay counters option82 [vrf WORD<1-16>] [vrfids WORD <0-  
512>]
```

## Example

```
Switch:1> enable  
Switch:1# configure terminal  
Switch:1(config)# interface gigabitethernet 1/10
```

Enable the circuit ID:

```
Switch:1(config-if)# ip dhcp-relay circuitID
```

Enable the remote ID:

```
Switch:1(config-if)# ip dhcp-relay remoteID
```

Configure the circuit as trusted:

```
Switch:1(config-if)# ip dhcp-relay trusted
```

Show statistics for option 82, which is the relay agent information option:

```
Switch:1(config-if)# show ip dhcp-relay counters option82
```

## Variable Definitions

Use the data in the following table to configure the DHCP option 82.

| Variable         | Value                        |
|------------------|------------------------------|
| <i>circuitID</i> | Enables the Circuit ID.      |
| <i>remoteID</i>  | Enables the Remote ID.       |
| <i>trusted</i>   | Sets the circuit as trusted. |

Use the data in the following table to use the **show ip dhcp-relay counters option82 [vrf WORD<1-16>] [vrfids WORD <0-512>]** command.

| Variable                         | Value                                                                                 |
|----------------------------------|---------------------------------------------------------------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>      | Displays DHCP counters for a particular VRF. WORD<1-16> specifies the VRF name.       |
| <i>vrfids WORD &lt;0-512&gt;</i> | Displays a DHCP forward path for a particular VRF. WORD <0-512> specifies the VRF ID. |

## Configuring DHCP relay on a port or VLAN

You can view and configure the DHCP parameters on specific ports or on a VLAN.

### Before You Begin

- You must configure IP on the interface.

### Procedure

- Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Enable DHCP parameters on a specified port or VLAN:

```
ip dhcp-relay
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/10
```

Enable DHCP parameters on a specified port or VLAN:

```
Switch:1(config-if)# ip dhcp-relay
```

Variable definitions

Use the data in the following table to use the **ip dhcp-relay** command.

Use the **no** operator to disable DHCP parameters on specified ports: **no ip dhcp-relay**.

Note

The **no ip dhcp-relay** command disables DHCP Relay, it does not delete the DHCP entry.

To configure this option to the default value, use the **default** operator with this command.

| Variable                                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>broadcast</i>                                                                        | Enables the device to send the server reply as a broadcast to the end station. After you disable this variable, the device sends the server reply as a unicast to the end station. Use the <b>no</b> operator to disable broadcast: <b>no ip dhcp-relay broadcast</b> .<br>To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                       |
| <i>circuitId</i>                                                                        | Enables Option 82 circuit ID on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>clear-counters</i>                                                                   | Clears DHCP Relay counters for the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>fwd-path &lt;A.B.C.D&gt; [vrid &lt;1-255&gt;]</i>                                    | Creates a forward path server with a virtual router ID (or VRRP ID), a mode, and a state.<br><i>A.B.C.D</i> is the IP address.<br><i>vrid &lt;1-255&gt;</i> is the ID of the virtual router and is an integer from 1 to 255.<br>Use the <b>no</b> operator to delete a forward path server with a specific value and virtual router ID: <b>no ip dhcp-relay fwd-path &lt;A.B.C.D&gt; [vrid &lt;1-255&gt;]</b><br>To configure this option to the default value, use the <b>default</b> operator with this command. |
| <i>fwd-path &lt;A.B.C.D&gt; disable [vrid &lt;1-255&gt;]</i>                            | Disables a forward path server with a specific value and virtual router ID.<br><i>A.B.C.D</i> is the IP address.<br><i>vrid &lt;1-255&gt;</i> is the ID of the virtual router (or VRRP ID) and is an integer from 1 to 255.                                                                                                                                                                                                                                                                                        |
| <i>fwd-path &lt;A.B.C.D&gt; enable [vrid &lt;1-255&gt;]</i>                             | Enables a forward path server with a specific value and virtual router ID (or VRRP ID).<br><i>A.B.C.D</i> is the IP address in the form a.b.c.d.<br><i>vrid &lt;1-255&gt;</i> is the ID of the virtual router and is an integer from 1 to 255.                                                                                                                                                                                                                                                                     |
| <i>fwd-path &lt;A.B.C.D&gt; mode &lt;bootp bootp_dhcp dhcp&gt; [vrid &lt;1-255&gt;]</i> | Configures the forward path mode for a VLAN. This command string is available only in VLAN Interface Configuration mode.<br><i>A.B.C.D</i> is the IP address in the form a.b.c.d.<br><i>mode</i> is a choice of bootp, dhcp, or bootp_dhcp.<br><i>vrid &lt;1-255&gt;</i> is the ID of the virtual router (or VRRP ID) and is an integer from 1 to 255.<br>To configure this option to the default value, use the <b>default</b> operator with this command.                                                        |

| Variable                            | Value                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>max-hop</i> <1-16>               | Configures the maximum number of hops before a BootP/DHCP packet is discarded (1 to 16). The default is 4. To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                      |
| <i>min-sec</i> <0-65535>            | Configures the minimum seconds count for DHCP. If the secs field in the BootP/DHCP packet header is greater than this value, the device relays or forwards the packet; otherwise, the packet is dropped (0 to 65535). The default is 0 seconds. To configure this option to the default value, use the <b>default</b> operator with this command. |
| <i>mode</i> <bootp bootp_dhcp dhcp> | Configures DHCP mode to forward BootP messages only, DHCP messages only, or both. The default is both. To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                          |
| <i>remoteId</i>                     | Enables Option82 remote ID on the interface.                                                                                                                                                                                                                                                                                                      |
| <i>trusted</i>                      | Configures the DHCP circuit as trusted.                                                                                                                                                                                                                                                                                                           |

## Displaying DHCP-relay Statistics for Specific Ports

Display individual DHCP-relay statistics for specific ports to manage network performance.

### Note

Slot and port information can differ depending on hardware platform.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View DHCP-relay statistics for a specific port or VRF.

```
show interfaces GigabitEthernet statistics dhcp-relay [vrf WORD<1-16>]
[vrfids WORD<0-255>] [{slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]]
```

### Example

View DHCP-relay statistics:

```
Switch:1>enable
Switch:1#show interfaces gigabitethernet statistics dhcp-relay
```

```
=====
                        Port Stats Dhcp
=====
PORT_NUM VRF NAME          NUMREQUEST NUMREPLY
-----
1/12     GlobalRouter             0           2
1/13     GlobalRouter             3           2
2/3      GlobalRouter             0           2
=====
```

Variable Definitions

Use the data in the following table to use the **show interfaces GigabitEthernet statistics dhcp-relay** command.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>                                   | Specifies a VRF instance by VRF name.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>vrfids WORD&lt;0-255&gt;</code>                               | Specifies the ID of the VRF.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (1/1). Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Displaying DHCP-relay Statistics for all Interfaces

### About This Task

Display DHCP-relay statistics for all interfaces to manage network performance.

**Note**

Slot and port information can differ depending on hardware platform.

### Procedure

1. Show the number of requests and replies for each interface:  
`show ip dhcp-relay counters [vrf WORD<1-16>] [vrfids WORD<0-512>]`
2. Show counters for Option 82:  
`show ip dhcp-relay counters option82 [vrf WORD<1-16>] [vrfids WORD<0-512>]`

### Example

```
Switch:1>show ip dhcp-relay counters option82
=====
DHCP Counters Option82 - GlobalRouter
=====
      FOUND DROP  CIRCUIT ADD  REMOVE REMOTE      ADD  REMOVE
INTERFACE OPT82 PKT   ID    CIRC  CIRC  ID          REMOTE REMOTE
-----
Port 1/12  0    0   395    0    0    00:24:7f:9d:0a:00  0    0
Vlan40    0    0  2088    0    0    00:24:7f:9d:0a:01  0    0
```

*Variable Definitions*

Use the data in the following table to use the **show ip dhcp-relay counters** command.

| Variable                              | Value                                     |
|---------------------------------------|-------------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF instance by the VRF name. |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies the ID of the VRF.              |

## Configuring UDP broadcast forwarding

### About This Task

By default, routers do not forward broadcasts. UDP broadcast forwarding is a generalized mechanism for the router to selectively forward UDP broadcasts. You must set up UDP broadcast forwarding on the system. Configure UDP broadcast forwarding to forward the UDP broadcasts of network applications to the required server through physical or virtual router interfaces.

### Procedure

1. Enter protocols into a table.
2. Create policies (protocol/server pairs).
3. Assemble the policies into lists or profiles.
4. Apply the list to the appropriate interfaces.

## Configuring UDP protocols

### About This Task

Configure UDP protocols to determine which UDP broadcasts are forwarded.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
 

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```
2. Configure a UDP protocol:
 

```
ip forward-protocol udp <1-65535> WORD<1-15>
```
3. Confirm your configuration:
 

```
show ip forward-protocol udp interface [vrf WORD<1-16>][vrfids
WORD<0-512>] portfwd [vrf WORD<1-16>][vrfids WORD<0-512>]
portfwddlist <1-1000>[vrf WORD<1-16>][vrfids WORD<0-512>] vrf
WORD<1-16> vrfids WORD<0-512>
```

### Example

Configure a UDP protocol and confirm your configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip forward-protocol udp 53 DNS
Switch:1(config)#show ip forward-protocol udp
```

```
=====
                        Udp Protocol Tbl - GlobalRouter
=====
UDP_PORT  PROTOCOL_NAME
-----
37        Time Service
49        TACACS Service
53        DNS
69        TFTP
137       NetBIOS NameSrv
138       NetBIOS DataSrv
```

### Variable definitions

Use the data in the following table to use the **ip forward-protocol udp** command.

| Variable             | Value                                                                                                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-65535> WORD<1-15> | Creates a new UDP protocol. <1-65535> WORD<1-15> is the UDP protocol name as a string. Use the <b>no</b> operator to delete a UDP protocol no ip forward-protocol udp <1-65535>. |
| portfwd              | Displays portfwd information.                                                                                                                                                    |
| portfwdlist          | Displays port forward list information.                                                                                                                                          |
| vrf WORD<1-16>       | Specifies the name of the VRF.                                                                                                                                                   |
| vrfids WORD<0-512>   | Specifies the ID of the VRF.                                                                                                                                                     |

## Configuring a UDP port forward entry

Configure a UDP port forward entry to add or remove a port forward entry.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:  

```
enable
```

```
configure terminal
```

Optional: router vrf WORD<1-16>
2. Configure a UDP port forward entry:  

```
ip forward-protocol udp portfwd <1-65535> {A.B.C.D}
```
3. Confirm your configuration:  

```
show ip forward-protocol udp portfwd [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

## Example

Configure a UDP port forward entry:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip forward-protocol udp portfwd 150 192.0.2.10
```

### Variable definitions

Use the data in the following table to use the **ip forward-protocol udp portfwd** command.

| Variable                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-65535&gt; {A.B.C.D}</code> | Adds a UDP protocol port to the specified port forwarding list. <code>1-65535</code> is a UDP protocol port in the range of 1-65535. <code>A.B.C.D</code> is an IP address in a.b.c.d format. Use the <b>no</b> operator to remove a protocol port forwarding entry and IP address from the list: <code>no ip forward-protocol udp portfwd &lt;1-65535&gt; &lt;A.B.C.D&gt;</code> . To configure this option to the default value, use the <b>default</b> operator with this command. |
| <code>vrf WORD&lt;1-16&gt;</code>      | Specifies the name of the VRF.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>vrfids WORD&lt;0-512&gt;</code>  | Specifies the ID of the VRF.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Configuring the UDP port forwarding list

Configure the UDP port forwarding list to assign protocols and servers to the port forward list.

### About This Task

You can perform this procedure in Global Configuration mode, VLAN Interface Configuration mode, or VRF Router Configuration mode.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the UDP port forwarding list:
 

```
ip forward-protocol udp portfwdlist <1-1000>
```

#### Important

The following two steps are not available in the Global Configuration or VRF Router Configuration mode. The following two commands are available in VLAN Interface Configuration mode only.

3. Enter VLAN Interface Configuration mode:
 

```
interface vlan <1-4059>
```
4. Configure the broadcast mask:
 

```
ip forward-protocol udp broadcastmask {A.B.C.D}
```

5. Configure the maximum time to live:

```
ip forward-protocol udp maxttl <1-16>
```

6. Confirm your configuration:

```
show ip forward-protocol udp portfwddlist <1-1000> [vrf WORD<1-16>]
[vrfids WORD<0-512>]
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
```

Configure the UDP port forwarding list:

```
Switch:1(config)# ip forward-protocol udp portfwddlist 1
```

Log on to the VLAN interface configuration mode:

```
Switch:1(config)# interface vlan 3
```

Configure the broadcast mask:

```
Switch:1(config-if)# ip forward-protocol udp broadcastmask 192.0.2.255
```

Configure the maximum time to live:

```
Switch:1(config-if)# ip forward-protocol udp maxttl 10
```

Confirm the configuration:

```
Switch:1(config-if)# show ip forward-protocol udp portfwddlist
```

### Variable definitions

Use the data in the following table to use the **ip forward-protocol udp portfwddlist** command.

| Variable            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-1000>            | Creates a UDP port forwarding list in the range of 1-1000.                                                                                                                                                                                                                                                                                                                                                                               |
| <1-65535> {A.B.C.D} | Adds a UDP protocol port to the specified port forwarding list.<br>1-65535 is a UDP protocol port in the range of 1-65535.<br>A.B.C.D is an IP address in a.b.c.d format.<br>Use the <b>no</b> operator to remove or delete a port forwarding list ID,<br>no ip forward-protocol udp portfwddlist <1-1000> <1-65535> <A.B.C.D>.<br>To configure this option to use the default value, use the <b>default</b> operator with this command. |
| name WORD<0-15>     | Changes the name of the port forwarding list.                                                                                                                                                                                                                                                                                                                                                                                            |

Use the data in the following table to use the **ip forward-protocol udp** command.

| Variable                                                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>broadcastmask {A.B.C.D}</code>                                           | Configures the interface broadcast mask (the interface broadcast mask can be different from the interface mask). <i>A.B.C.D</i> is an IP address in a.b.c.d format. Use the <b>no</b> operator to delete the broadcast mask:<br><pre>no ip forward-protocol udp broadcastmask {A.B.C.D}</pre> To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                                                                              |
| <code>maxttl &lt;1-16&gt;</code>                                               | Configures the maximum time-to-live value (TTL) for the UDP broadcast forwarded by the interface. The range is 1-16.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>portfwddlist &lt;1-1000&gt;</code>                                       | Assigns the list to the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>vlan &lt;1-4059&gt;</code><br><code>[portfwddlist &lt;1-1000&gt;]</code> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. If you use the portfwddlist variable with the VLAN variable, it assigns the list to the specified VLAN, regardless of which VLAN context you currently configure. |

## Showing UDP forward information

Show UDP forward information to view information about the UDP forwarding characteristics of the device. UDP forwarding only supports 128 entries.

### About This Task

There are four show options:

- Show the interface information
- Show the port forward information
- Show the port forward list information
- Show the protocol information

### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Display information about the UDP interface for all IP addresses or a specified IP address:  

```
show ip forward-protocol udp interface [<A.B.C.D>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
3. Display the UDP port forwarding table:  

```
show ip forward-protocol udp portfwd [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

4. Display the UDP port forwarding list table for the specified list or all lists on the device:  

```
show ip forward-protocol udp portfwldlist [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
5. Display the UDP protocol table with the UDP port numbers for each supported or designated protocol:  

```
show ip forward-protocol udp [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

**Example**

Display the UDP protocol table with the UDP port numbers for each supported or designated protocol:

```
Switch:1>enable
Switch:1#show ip forward-protocol udp

=====
                        Udp Protocol Tbl - GlobalRouter
=====
UDP_PORT  PROTOCOL_NAME
-----
37        Time Service
49        TACACS Service
53        DNS
69        TFTP
137       NetBIOS NameSrv
138       NetBIOS DataSrv
```

*Variable Definitions*

Use the data in the following table to use the **show ip forward-protocol udp interface** command.

| Variable           | Value                                                                   |
|--------------------|-------------------------------------------------------------------------|
| <A.B.C.D>          | Specifies the IP address for the interface in a.b.c.d format.           |
| vrf WORD<1-16>     | Specifies the name of the VRF.                                          |
| vrfids WORD<0-512> | Specifies the ID of the VRF and is an integer in the range of 0 to 512. |

## IPv6 DHCP Relay Configuration using CLI

### Configure a DHCP Relay Forwarding Path

Configure a forwarding path to specify the relay agent address and the DHCP server address to which to forward packets.

To use DHCP Relay for IPv6, you must configure at least one forwarding path and enable the relay on one interface.

**Before You Begin**

For a VRF other than GlobalRouter, the interface must be first associated to that VRF.

## About This Task

The relay agent can use the IPv6 address of the interface or the VRRP global address linked to that interface. The relay forwards the DHCP messages only if VRRP is in the master state, otherwise the relay discards the messages.

You can configure only one relay agent on an interface. If you need to change the relay agent, you must delete all the forwarding paths with the old relay agent, and then configure the new relay agent.

For scaling information on DHCP Relay forwarding paths, see [VOSS Release Notes](#).

## Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure a forwarding path:

```
ipv6 dhcp-relay fwd-path WORD<0-255> WORD<0-255> [enable]
```

If you configure the forwarding path globally, the relay agent address can be any configured IP address of the relay interface or the VRRP global address linked to the relay interface.

3. To configure a forwarding path on an interface, enter Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

OR

```
interface vlan <1-4059>
```

4. Configure a forwarding path:

```
ipv6 dhcp-relay fwd-path WORD<0-255> [enable] [vrid WORD<1-255>]
```

If you configure the forwarding path on an interface, the relay agent address is either the smallest IP configured on the interface or the first VRRP global address configured, if the relay is the VRRP master. You do not specify the relay agent address as part of the command.

### Note

IPv6 DHCP Relay is established only between agents within the context of each VRF.

## Examples

Configure a forwarding path globally:

```
Switch:1(config)#ipv6 dhcp-relay fwd-path 1111::1111 1234::1234 enable
```

Configure a forwarding path on an interface:

```
Switch:1(config)#interface GigabitEthernet 1/1
Switch:1(config-if)#ipv6 dhcp-relay fwd-path 1234::1234 enable
```

Configure the VRRP master as the relay:

```
Switch:1(config-if)#ipv6 dhcp-relay fwd-path 1234::1234 vrid 12 enable
```

### Variable Definitions

Use the data in the following table to use the **ipv6 dhcp-relay fwd-path** command.

| Variable                                                          | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                                          | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>enable</i>                                                     | Enables the forwarding path. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                      |
| { <i>slot/port</i> [/sub-port] [-slot/port] [/sub-port]] [, ...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <i>vrid</i> WORD<1-255>                                           | Specifies the VRRP ID to use the VRRP master as the relay agent interface.                                                                                                                                                                                                                                                                                                                                                 |
| WORD<0-255>                                                       | Specifies the IPv6 address of the DHCP server for the interface configuration.                                                                                                                                                                                                                                                                                                                                             |
| WORD<0-255><br>WORD<0-255>                                        | Specifies the IPv6 address of the relay agent interface and the IPv6 address of the DHCP server for the global configuration.                                                                                                                                                                                                                                                                                              |

## Configuring DHCP Relay for an interface

Configure the DHCP relay behavior on the interface.

### About This Task

You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[, ...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable DHCP on the interface:  
`ipv6 dhcp-relay`
3. Configure the maximum hop count:  
`ipv6 dhcp-relay max-hop <1-32>`
4. Enable the remote ID:  
`ipv6 dhcp-relay remote-id`

**Example**

Configure the maximum hop count:

```
Switch:1(config-if)#ipv6 dhcp-relay max-hop 30
```

Disable the remote ID:

```
Switch:1(config-if)#no ipv6 dhcp-relay remote-id
```

*Variable Definitions*

Use the data in the following table to use the **ipv6 dhcp-relay** command.

| Variable                          | Value                                                                                                                                                  |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>max-hop &lt;1-32&gt;</code> | Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.                                |
| <code>remote-id</code>            | Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled |

Use the data in the following table to use the **interface** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-4059&gt;</code>                                        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                          |

**View DHCP Relay Information**

View DHCP Relay information to display the current configuration for the forwarding path and the interface configuration.

**About This Task**

Not all parameters are available in non-default VRFs.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View DHCP Relay global information:  
show ipv6 dhcp-relay {counters [vrf WORD<1-16> | vrfids WORD<0-512>] | fwd-path [vrf WORD<1-16> | vrfids WORD<0-512>]}
3. View IPv6 DHCP Relay interface configuration:  
show ipv6 dhcp-relay interface {gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | vlan <1-4059>}

#### Note

The **no ipv6 dhcp-relay** command disables DHCP on the interface but does not delete the entry.

### Example

```
Switch:1(config-if)#show ipv6 dhcp-relay fwd-path

=====
                        DHCPv6 Fwd-path - GlobalRouter
=====
INTERFACE                SERVER                ENABLE
-----
1111:0:0:0:0:0:1111      1234:0:0:0:0:0:1234      enable
```

#### Variable Definitions

Use the information in the following table to help you use the **show ipv6 dhcp-relay** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| vlan<1-4059>                                          | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| vrf WORD<1-16>                                        | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                                                    |
| vrfids WORD<0-512>                                    | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                      |

## Viewing IPv6 DHCP Relay Statistics

Display individual IPv6 DHCP Relay statistics for specific interfaces to manage network performance.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. View statistics:

```
show ipv6 dhcp-relay counters
```

**Note**

Use the `sys action reset counters` command to clear DHCP Relay statistics.

**Example**

```
Switch:1#show ipv6 dhcp-relay counters

=====
                                DHCPv6 Counters
=====
INTERFACE                        REQUESTS  REPLIES
-----
1111:0:0:0:0:0:1111              1         1
```

## DHCP and UDP configuration using Enterprise Device Manager

Dynamic Host Configuration Protocol (DHCP), an extension of the Bootstrap Protocol (BootP), dynamically provides host configuration information to workstations. To lower administrative overhead, network managers prefer to configure a small number of DHCP servers in a central location. Using few DHCP servers requires the routers connecting to the subnets or bridge (or VLAN) domains to support the BootP/DHCP relay function so that hosts can retrieve the configuration information from servers several router hops away.

User datagram protocol (UDP) is a connectionless protocol that adds reliability and multiplexing to IP. It describes how messages reach application programs within a destination computer. Some network applications, such as the NetBIOS name service, rely on a UDP broadcast to request a service or to locate a service. By default, broadcasts are not forwarded by a router. UDP broadcast forwarding is a generalized mechanism for the router to selectively forward UDP broadcasts.

**Important**

BootP/DHCP relays are supported only on IP routed port-based VLANs and protocol-based VLANs.

**Before You Begin**

You must enable DHCP relay on the path for port or VLAN configuration to take effect.

### Configuring DHCP on a brouter port or a VRF instance

**Before You Begin**

- You must first enable BootP/DHCP relay on a port (or VLAN).
- You must enable DHCP and forwarding path.
- You must enable IP Routing on the interface.

### About This Task

Use the DHCP tab to configure the DHCP behavior on a router port or a VRF instance. The DHCP tab is available only if the port is routed (that is, assigned an IP address).

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **DHCP Relay** tab.
5. Click **Enable** to select the DHCP option. The default is disable.
6. Configure the other parameters as needed.
7. Click **Apply**.

### DHCP field descriptions

Use data from the following table in the DHCP Relay tab.

| Name                   | Description                                                                                                                                                                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>          | Lets you use BootP/DHCP on the port. The default is disable.                                                                                                                                                                                                                                 |
| <b>MaxHop</b>          | Sets the maximum number of hops before a BootP/DHCP packet is discarded (1 to 16). The default is 4.                                                                                                                                                                                         |
| <b>MinSec</b>          | The secs field in the BootP/DHCP packet header represents the elapsed time since the client first sent the message. If the secs field in the packet header is greater than this value, the system relays or forwards the packet; otherwise, the packet is dropped. The default is 0 seconds. |
| <b>Mode</b>            | Sets the interface to process only BootP, only DHCP, or both types of packets. The default is both.                                                                                                                                                                                          |
| <b>AlwaysBroadcast</b> | When enabled, the server reply is sent as a broadcast back to the end station. The default is disable.                                                                                                                                                                                       |
| <b>CircuitId</b>       | Indicates whether DHCP Relay inserted the option 82 circuit ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.                                                                                                                 |
| <b>RemoteId</b>        | Indicates whether DHCP Relay inserted the option 82 remote ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.                                                                                                                  |
| <b>Trusted</b>         | Indicates if DHCP packets come through a trusted DHCP circuit. Only packets with GIADDR configured to 0 and containing option 82 are forwarded if the circuit is trusted. The default value is false.                                                                                        |

## Configuring BootP/DHCP on a VLAN or VRF instance

### Before You Begin

- You must enable IP Routing on the interface.

## About This Task

Use the DHCP Relay tab to configure the DHCP behavior on a VLAN. The DHCP Relay tab is available only if the VLAN is routed and is assigned an IP address.

## Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs > Basic**.
3. Select a VLAN.
4. Click **IP**.
5. Click the **DHCP Relay** tab.
6. Select **Enable**.
7. Configure the parameters as required.
8. Click **Apply**.

### *DHCP Relay* field descriptions

Use the data in the following table to use the **DHCP Relay** tab.

| Variable               | Value                                                                                                                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>          | Lets you use BootP/DHCP on the port. The default is disable.                                                                                                                                                            |
| <b>MaxHop</b>          | Sets the maximum number of hops a BootP/DHCP packet can take from the DHCP client to the DHCP server. The maximum number of hops is 16. The default is 4.                                                               |
| <b>MinSec</b>          | Represents the minimum number of seconds to wait between receiving a DHCP packet and forwarding the DHCP packet to the DHCP server. A value of 0 indicates that forwarding is done immediately. The default value is 0. |
| <b>Mode</b>            | Indicates the type of DHCP packet required. The options are: <ul style="list-style-type: none"> <li>• bootp</li> <li>• dhcp</li> <li>• both</li> </ul> The default is both.                                             |
| <b>AlwaysBroadcast</b> | When enabled, the DHCP Reply packets are sent as a broadcast to the DHCP client. The default is disable.                                                                                                                |
| <b>CircuitId</b>       | Indicates whether DHCP Relay inserted the option 82 circuit ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.                                            |

| Variable        | Value                                                                                                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Remoteld</b> | Indicates whether DHCP Relay inserted the option 82 remote ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.                           |
| <b>Trusted</b>  | Indicates if DHCP packets come through a trusted DHCP circuit. Only packets with GIADDR configured to 0 and containing option 82 are forwarded if the circuit is trusted. The default value is false. |

## Configuring DHCP relay

### About This Task

After you configure the BootP/DHCP relay on an IP interface, you can configure forwarding paths to indicate where packets are forwarded. The forwarding paths are based on the type of packet and where the packet is received.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **DHCP Relay**.
3. Click the **Globals** tab.
4. Click **Insert**.
5. In the **AgentAddr** box, type the agent address.
6. In the **ServerAddr** list, type the server address.
7. Click **Enable** to enable BootP/DHCP relay. You can enable or disable each agent server forwarding policy. The default is enabled.
8. In the **Mode** box, select the type of messages to relay.  
Both the mode setting for the DHCP interface and the mode setting for the agent interface determine which packets are forwarded.
9. Click **Insert**.

### *Globals* field descriptions

Use the data in the following table to use the **Globals** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AgentAddr</b>  | The IP address of the input interface (agent) on which the BootP/DHCP request packets are received for forwarding. This address is the IP address of either a brouter port or a VLAN for which forwarding is enabled.                                                                                                                                                                                               |
| <b>ServerAddr</b> | This parameter is either the IP address of the BootP/DHCP server or the address of another local interface. <ul style="list-style-type: none"> <li>• If it is the address of the BootP/DHCP server, the request is unicast to the server address.</li> <li>• If the address is one of the IP addresses of an interface on the system, the BootP/DHCP requests are broadcast out of that local interface.</li> </ul> |

| Name          | Description                                                                                                                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b> | Enables BootP/DHCP relay.                                                                                                                                                                                                    |
| <b>Mode</b>   | Specifies the type of messages relayed: <ul style="list-style-type: none"> <li>• Only BootP</li> <li>• Only DHCP</li> <li>• Both types of messages</li> </ul> <p>The default is to forward both BootP and DHCP messages.</p> |

## Viewing DHCP relay configuration information

### About This Task

Use the DHCP Relay Interfaces tab to view configuration information about the DHCP relay. To change the configuration information, double-click the value in the field under the required interface, and enter a new value.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **DHCP Relay**.
3. Click the **Interfaces** tab.

### *Interfaces* field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Variable               | Value                                                                                                                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>         | A read-only interface number that represents a physical interface, or the VLAN logical interface.                                                                                                                       |
| <b>MaxHop</b>          | Sets the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The maximum number of hops is 16. The default is 4.                                                                     |
| <b>MinSec</b>          | Represents the minimum number of seconds to wait between receiving a DHCP packet and forwarding the DHCP packet to the DHCP server. A value of 0 indicates that forwarding is done immediately. The default value is 0. |
| <b>Mode</b>            | Indicates the type of DHCP packet required. The options are: <ul style="list-style-type: none"> <li>• bootp</li> <li>• dhcp</li> <li>• both</li> </ul> <p>The default is both.</p>                                      |
| <b>AlwaysBroadcast</b> | Indicates if DHCP Reply packets can be sent as a broadcast to the DHCP client. The default is false.                                                                                                                    |

| Variable         | Value                                                                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CircuitId</b> | Indicates whether DHCP Relay inserted the option 82 circuit ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.                          |
| <b>Remoteld</b>  | Indicates whether DHCP Relay inserted the option 82 remote ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.                           |
| <b>Trusted</b>   | Indicates if DHCP packets come through a trusted DHCP circuit. Only packets with GIADDR configured to 0 and containing option 82 are forwarded if the circuit is trusted. The default value is false. |

## Viewing DHCP Statistics for an Interface

View DHCP statistics to manage network performance.

### Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **DHCP Relay**.
3. Click the **Interfaces Stats** tab.

### **Interfaces Stats** Field Descriptions

Use the data in the following table to use the **Interfaces Stats** tab.

| Name               | Description                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>     | Identifies the physical interface.                                                                                                                     |
| <b>AgentAddr</b>   | Shows the IP address configured as the relay on this interface. This address is either the IP of the physical interface or the IP of the VRRP address. |
| <b>NumRequests</b> | Shows the number of DHCP and BootP requests on this interface.                                                                                         |
| <b>NumReplies</b>  | Shows the number of DHCP and BootP replies on this interface.                                                                                          |

## Graphing DHCP Statistics for a Port

View DHCP statistics to manage network performance.

### Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **DHCP** tab.
5. Select one or more values.

- Click the type of graph to create.

### **DHCP** Field Descriptions

The following table describes parameters on the **DHCP** tab.

| Name               | Description                                                 |
|--------------------|-------------------------------------------------------------|
| <b>NumRequests</b> | The number of DHCP and/or BootP requests on this interface. |
| <b>NumReplies</b>  | The number of DHCP and/or BootP replies on this interface.  |

## Viewing DHCP Statistics for a Port

View DHCP statistics to manage network performance.

### Procedure

- In the Device Physical view, select a port.
- In the navigation pane, expand the **Configuration > Edit > Port** folders.
- Click **IP**.
- Click the **DHCP Relay** tab.
- Click **Graph**.
- Select one or more values.
- Click the type of graph.

### **DHCP Stats** Field Descriptions

Use the data in the following table to use the **DHCP Stats** tab.

| Name               | Description                                              |
|--------------------|----------------------------------------------------------|
| <b>NumRequests</b> | The number of DHCP and BootP requests on this interface. |
| <b>NumReplies</b>  | The number of DHCP and BootP replies on this interface.  |

## Displaying DHCP-relay Statistics for Option 82

Display DHCP-relay statistics for all interfaces to manage network performance.

### Procedure

- In the navigation pane, expand the **Configuration > IP** folders.
- Click **DHCP-Relay**.
- Click the **Option 82 Stats** tab.

**Option 82 Stats** *Field Descriptions*

Use the data in the following table to use the **Option 82 Stats** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>          | Shows the name of the interface on which you enabled option 82. Shows the port number if the interface is a brouter port or the VLAN number if the interface is a VLAN.                                                                                                                                                                          |
| <b>AgentAddr</b>        | Shows the IP address configured as the relay on this interface. This address is either the IP of the physical interface or the IP of the VRRP address.                                                                                                                                                                                           |
| <b>FoundOp82</b>        | Shows the number of packets that the interface received that already had option82 in them.                                                                                                                                                                                                                                                       |
| <b>Dropped</b>          | Shows the number of packets the interface dropped because of option 82-related issues. These reasons could be that the packet was received from an untrusted source or spoofing was detected. To determine the cause of the drop, you must enable trace on level 170.                                                                            |
| <b>CircuitId</b>        | Shows the value inserted in the packets as the circuit ID. The value is the index of the interface.                                                                                                                                                                                                                                              |
| <b>AddedCircuitId</b>   | Shows how many packets (requests from client to server) the circuit ID was inserted for that interface.<br>If you expect this value to increase but it does not, and the interface does not drop a packet, it is possible the packet does not have enough space to insert the option. You must enable trace on level 170 to determine the cause. |
| <b>RemovedCircuitId</b> | Shows how many packets (replies from server to client) the circuit id was removed for that interface.                                                                                                                                                                                                                                            |
| <b>RemoteId</b>         | Shows the value inserted in the packets as the remote ID. The value is the MAC address of the interface.                                                                                                                                                                                                                                         |
| <b>AddedRemoteId</b>    | Shows how many packets (requests from client to server) the remote ID was inserted for that interface.<br>If you expect this value to increase but it does not, and the interface does not drop a packet, it is possible the packet does not have enough space to insert the option. You must enable trace on level 170 to determine the cause.  |
| <b>RemovedRemoteId</b>  | Shows how many packets (replies from server to client) the remote ID was removed for that interface.                                                                                                                                                                                                                                             |

**Graphing DHCP Statistics for a VLAN**

View DHCP statistics to manage network performance.

**Procedure**

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **VLANs**.
3. On the **Basic** tab, select a VLAN.
4. Click **IP**.
5. Click the **DHCP Relay** tab.
6. Click **Graph**.
7. Select one or more values.
8. Click the type of graph.

**DHCP Stats Field Descriptions**

Use the data in the following table to use the **DHCP Stats** tab.

| Name               | Description                                              |
|--------------------|----------------------------------------------------------|
| <b>NumRequests</b> | The number of DHCP and BootP requests on this interface. |
| <b>NumReplies</b>  | The number of DHCP and BootP replies on this interface.  |

Managing UDP forwarding protocols

**About This Task**

The switch configures the following protocols, by default:

- Time Service
- Terminal Access Controller Access Control System (TACACS) Service
- Domain Name System (DNS)
- Trivial file transfer protocol (TFTP)
- Network Basic Input/Output System (NetBIOS) NameSrv
- NetBIOS DataSrv

You can use these protocols to create forwarding entries and lists but you cannot delete them; you can add or remove other protocols to the list of protocols.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **UDP Forwarding**.
3. Click **Insert**.
4. In the **PortNumber** field, type a UDP port number.  
 This number defines the UDP port used by the server process as its contact port. The range is from 1 to 65535 and cannot be one of the UDP port numbers or a number previously assigned.
5. In the **Name** field, type a name for the protocol.
6. Click **Insert**.  
 The protocol is added to the Protocol table. After you create a protocol, you cannot change its name or number.

**Protocols** field descriptions

Use the data in the following table to use the **Protocols** tab.

| Name              | Description                                                                     |
|-------------------|---------------------------------------------------------------------------------|
| <b>PortNumber</b> | Defines the UDP port (1 to 65535).                                              |
| <b>Name</b>       | Specifies an administratively assigned name for this list (0 to 15 characters). |

Managing UDP forwarding

**About This Task**

You manage UDP forwarding by defining the destination addresses for the UDP protocol.

**Procedure**

1. In the navigation tree, expand the following folders:**Configuration > IP.**
2. Click **UDP Forwarding.**
3. Click the **Forwardings** tab.
4. Click **Insert.**
5. In the Insert Forwardings dialog box, select a destination UDP port from the defined protocols in the **DestPort** box.
6. Enter a destination IP address in the **DestAddr** box.  
 The destination address can be any IP server address for the protocol application or the IP address of an interface on the router.
7. Click **Insert.** The information is added to the Forwarding tab.

**Forwardings** field descriptions

Use the data in the following table to use the **Forwardings** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DestPort</b>      | Specifies the port number defined for UDP, depending upon the protocol type.                                                                                                                                                                                                                                                                                                            |
| <b>DestAddr</b>      | Specifies the destination address can be any IP server address for the protocol application or the IP address of an interface on the router: <ul style="list-style-type: none"> <li>• If the address is that of a server, the packet is sent as a unicast packet to this address.</li> <li>• If the address is that of an interface on the router, the frame is rebroadcast.</li> </ul> |
| <b>Id</b>            | Specifies an integer that identifies this entry internally.                                                                                                                                                                                                                                                                                                                             |
| <b>NumFwdPackets</b> | Specifies the total number of UDP broadcast packets forwarded using this policy.                                                                                                                                                                                                                                                                                                        |

| Name                             | Description                                                                                                            |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>NumDropPacketsTtlExpired</b>  | Specifies the total number of UDP broadcast packets dropped because the time-to-live value (TTL) expired.              |
| <b>NumDropPacketsDestUnreach</b> | Specifies the total number of UDP broadcast packets dropped because the specified destination address was unreachable. |

## Creating the forwarding profile

### About This Task

A forwarding profile is a collection of port and destination pairs. When you configure UDP forwarding list entries, be sure to first configure the UDP forwarding list. Then, configure your UDP forwarding list entries and assign them to a UDP forwarding list. If you do not assign a UDP forwarding list entry to at least one UDP forwarding list, the UDP forwarding list is lost after a restart.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **UDP Forwarding**.
3. Click the **Forwarding Lists** tab.
4. Click **Insert**.
5. In the **Id** field, type the forwarding list ID.
6. In the **Name** field, type the name of the forwarding list if required.  
The system displays the forwarding list in the **FwdIdList** box.
7. Click **Insert**.

### *Forwarding Lists* field descriptions

Use the data in the following table to use the **Forwarding Lists** tab and **Insert Forwarding Lists** dialog box.

| Name             | Description                                                                                                                                                                                                                                       |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>        | Specifies a value that uniquely identifies this list of entries (1 to 1000).                                                                                                                                                                      |
| <b>Name</b>      | Specifies an administratively assigned name for this list (0 to 15 characters).                                                                                                                                                                   |
| <b>FwdIdList</b> | Specifies the zero or more port forwarding entries associated with this list. Each list identifier is stored as 2 bytes in this array, starting from 0 bytes (size=64). Clicking on the ellipsis (...) button in this field displays the ID list. |

## Managing the broadcast interface

### About This Task

Manage the broadcast interface by specifying and displaying which router interfaces can receive UDP broadcasts to forward.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **UDP Forwarding**.
3. Click the **Broadcast Interfaces** tab.
4. Click **Insert**.
5. In the **LocalIfAddr** field, click the ellipsis (...) to select a local interface IP address from the list, and then click **OK**.
6. In the **UdpPortFwdListId** field, click the ellipsis (...) to select a forwarding list ID from the list, and then click **OK**.
7. In the **MaxTtl** field, type the maximum number of hops an IP broadcast can take from the source device to the destination device (the default is 4; the range is 1 to 16).
8. In the **BroadCastMask** field, enter the subnet mask of the local interface that broadcasts the UDP broadcast packets.

When you configure the UDP forwarding broadcast mask, the broadcast mask must be less specific (shorter in length) or equally specific (equal in length) to the subnet mask of the IP interface on which it is configured. If the UDP forwarding broadcast mask is more specific than the subnet mask of the corresponding IP interface, UDP forwarding does not function properly.

9. Click **Insert**.

**Broadcast Interfaces** field descriptions

Use the data in the following table to use the **Broadcast Interfaces** tab.

| Name                            | Description                                                                                                                                                                                   |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LocalIfAddr</b>              | Specifies the IP address of the local router interface that receives forwarded UDP broadcast packets.                                                                                         |
| <b>UdpPortFwdListId</b>         | Specifies the number of the UDP lists or profiles that this interface is configured to forward (0 to100). A value of 0 indicates that the interface cannot forward any UDP broadcast packets. |
| <b>MaxTtl</b>                   | Specifies the maximum number of hops an IP broadcast packet can take from the source device to the destination device (the default is 4; the range is 1 to 16).                               |
| <b>NumRxPkts</b>                | Specifies the total number of UDP broadcast packets received by this local interface.                                                                                                         |
| <b>NumFwdPkts</b>               | Specifies the total number of UDP broadcast packets forwarded by this local interface.                                                                                                        |
| <b>NumDropPktsMaxTtlExpired</b> | Specifies the total number of UDP broadcast packets dropped because the time-to-live (TTL) value expired.                                                                                     |
| <b>NumDropPktsDestUnreach</b>   | Specifies the total number of UDP broadcast packets dropped because the destination was unreachable.                                                                                          |
| <b>NumDropPktsUnknownPort</b>   | Specifies the total number of UDP broadcast packets dropped because the destination port or protocol specified has no matching forwarding policy.                                             |
| <b>BroadCastMask</b>            | Specifies the subnet mask of the local interface that broadcasts the UDP broadcast packets.                                                                                                   |

## Viewing UDP endpoint information

View UDP Endpoints to confirm correct configuration.

### About This Task

You can use UDP endpoint information to display local and remote UDP activity.

Since UDP is a protocol used to establish connectionless network sessions, you need to monitor local and remote UDP activity and to know which applications are running over UDP.

You can determine which applications are active by checking the port number.

Processes are further identified with a UDP session to allow for the multiplexing of a port mapping for UDP.

### Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **TCP/UDP**.
3. Click the **UDP Endpoints** tab.

### **UDP Endpoints** field descriptions

Use the data in the following table to use the **UDP Endpoints** tab.

| Name                     | Description                                                             |
|--------------------------|-------------------------------------------------------------------------|
| <b>LocalAddressType</b>  | Displays the local address type (IPv6 or IPv4).                         |
| <b>LocalAddress</b>      | Displays the local IPv6 address.                                        |
| <b>LocalPort</b>         | Displays the local port number.                                         |
| <b>RemoteAddressType</b> | Displays the remote address type (IPv6 or IPv4).                        |
| <b>RemoteAddress</b>     | Displays the remote IPv6 address.                                       |
| <b>RemotePort</b>        | Displays the remote port number.                                        |
| <b>Instance</b>          | Distinguishes between multiple processes connected to the UDP endpoint. |
| <b>Process</b>           | Displays the ID for the UDP process.                                    |

## IPv6 DHCP Relay Configuration using EDM

### Configure a DHCP Relay Forwarding Path

Configure a forwarding path to specify the relay agent address and the DHCP server address to which to forward packets.

To use DHCP Relay for IPv6, you must configure at least one forwarding path and enable the relay on one interface.

### Before You Begin

Change the VRF instance as required to configure a DHCP Relay forwarding path on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### About This Task

The relay agent can use the IPv6 address of the interface or the VRRP global address linked to that interface. The relay forwards the DHCP messages only if VRRP is in the Master state, otherwise the relay discards the messages.

You can configure only one relay agent on an interface. If you need to change the relay agent, you must delete all the forwarding paths with the old relay agent, and then configure the new relay agent.

For scaling information on DHCP Relay forwarding paths, see [VOSS Release Notes](#).

### Procedure

1. In the navigation tree, expand **Configuration > IPv6**.
2. Select **DHCP Relay**.
3. Select the **Forward Path** tab.
4. Select **Insert**.
5. In the **AgentAddr** field, type the address of the input interface that forwards the packets.
6. In the **ServerAddr** field, type the address of the DHCP server.
7. Select **Enabled**.
8. Select **Insert**.

#### *Forward Path* field descriptions

Use the data in the following table to use the **Forward Path** tab.

| Name              | Description                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AgentAddr</b>  | Specifies the IP address of the input interface (relay agent) on which the DHCP request packets are received for forwarding. This address is the IPv6 or VRRP global address of either a brouter port or a VLAN for which forwarding is enabled. |
| <b>ServerAddr</b> | Specifies the IP address of the DHCP server. The request is unicast to the server address.                                                                                                                                                       |
| <b>Enabled</b>    | Enables DHCP Relay for the system. The default is disabled (clear).                                                                                                                                                                              |

## Configuring DHCP Relay for an interface

Configure the DHCP relay behavior on the interface.

### Before You Begin

Change the VRF instance as required to configure DHCP Relay for an interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### About This Task

You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

You can modify the DHCP Relay configuration for a brouter port through the **Edit > Port > IPv6** navigation path, and for a VLAN through the **VLAN > VLANs > Basic > IPv6** navigation path. This procedure uses the main IPv6 navigation path where you can configure both types of interfaces.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **DHCP Relay**.
3. Click the **Interface** tab.
4. Click **Insert**.
5. Beside the **IfIndex** field, click **Port** or **Vlan**.
6. Select a port or VLAN, and then click **OK**.
7. Click **Insert**.

### *Interface field descriptions*

Use the data in the following table to use the **Interface** tab.

| Name                   | Description                                                                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>         | Shows the unique value to identify an IPv6 interface. For the brouter port, the value is the ifindex of the port and, in the case of the VLAN, the value is the ifindex of the VLAN. |
| <b>MaxHop</b>          | Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.                                                              |
| <b>RemoteIdEnabled</b> | Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled (clear or false).             |

## Modifying DHCP Relay for a VLAN

Modify the existing DHCP relay behavior on the VLAN interface.

### About This Task

You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.

3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IPv6**.
6. Click the **DHCP Relay** tab.
7. Double-click a cell to change the value.
8. Click **Apply**.

**DHCP** field descriptions

Use the data in the following table to use the **DHCP Relay** tab.

| Name                   | Description                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>         | Shows the unique value to identify an IPv6 interface.                                                                                                                    |
| <b>MaxHop</b>          | Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.                                                  |
| <b>RemoteldEnabled</b> | Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled (clear or false). |
| <b>DhcpEnabled</b>     | Enables (true) or disables (false) DHCP Relay for an interface with an existing DHCP Relay configuration.                                                                |

## Modifying DHCP Relay for a port

Modify the existing DHCP relay behavior on the router port interface.

### About This Task

The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

### Procedure

1. In the Device Physical View, select the port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IPv6**.
4. Click **DHCP Relay**.
5. Double-click a cell to change the value.
6. Click **Apply**.

**DHCP Relay** field descriptions

Use the data in the following table to use the **DHCP Relay** tab.

| Name                | Description                                                                                                                                                                                                                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>      | Shows the unique value to identify an IPv6 interface. For the brouter port, the value is the ifindex of the port and, in the case of the VLAN, the value is the ifindex of the VLAN.                                                                                                                                             |
| <b>MaxHop</b>       | Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.                                                                                                                                                                                                          |
| <b>RelayEnabled</b> | Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled (clear or false).                                                                                                                                                         |
| <b>DhcpEnabled</b>  | Enables (true) or disables (false) DHCP Relay for an interface with an existing DHCP Relay configuration. The system displays this field on the <b>DHCP Relay</b> tab for a brouter port only if you modify an existing configuration. The system does not display this field if you create a new DHCP Relay port configuration. |

## Viewing DHCP Statistics for an IPv6 Interface

View IPv6 DHCP statistics to manage network performance.

### Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Select **DHCP Relay**.
3. Select the **Interfaces Stats** tab.

### *Interfaces Stats* Field Descriptions

Use the data in the following table to use the **Interfaces Stats** tab.

| Name               | Description                                                    |
|--------------------|----------------------------------------------------------------|
| <b>IfIndex</b>     | Identifies the physical interface.                             |
| <b>NumRequests</b> | Shows the number of DHCP and BootP requests on this interface. |
| <b>NumReplies</b>  | Shows the number of DHCP and BootP replies on this interface.  |

## Viewing IPv6 DHCP Relay Statistics for a Port

Display individual IPv6 DHCP Relay statistics for specific ports to manage network performance. You can also create a graph of selected statistical values.

### Procedure

1. On the Device Physical view, select a port.
2. In the navigation pane, expand the **Configuration > IPv6** folders.

3. Click the **DHCP Relay** tab.
4. Click the **Interface** tab.
5. Select the interface on which you want to view the IPv6 DHCP Relay statistics.
6. Click **Statistics**.
7. Select one or more values.
8. Click the type of graph.

### **Statistics** Field Descriptions

Use the data in the following table to use the **Statistics** tab.

| Name               | Description                                                    |
|--------------------|----------------------------------------------------------------|
| <b>NumRequests</b> | Shows the number of DHCP and BootP requests on this interface. |
| <b>NumReplies</b>  | Shows the number of DHCP and BootP replies on this interface.  |

|                                         | VSP 4450 Series | VOSS 4.1           |
|                                         | VSP 4900 Series | VOSS 8.1           |
|                                         | VSP 7200 Series | VOSS 4.2.1         |
|                                         | VSP 7400 Series | VOSS 8.0           |
|                                         | VSP 8200 Series | VOSS 4.1           |
|                                         | VSP 8400 Series | VOSS 4.2           |
|                                         | VSP 8600 Series | VSP 8600 6.2       |
|                                         | XA1400 Series   | Not Supported      |

The following sections provide information on the Domain Name Service (DNS) implementation for the switch.

---

## DNS fundamentals

---

This section provides conceptual material on the Domain Name Service (DNS) implementation for the switch. Review this content before you make changes to the configurable DNS options.

### DNS client

Every equipment interface connected to a Transmission Control Protocol over IP (TCP/IP) network is identified with a unique IPv4 or IPv6 address. You can assign a name to every machine that uses an IPv4 or IPv6 address. The TCP/IP does not require the usage of names, but these names make the task easier for network managers in the following ways:

- An IP client can contact a machine with its name, which is converted to an IP address, based on a mapping table. All applications that use this specific machine do not depend on the addressing scheme.
- It is easier to remember a name than a full IP address.

To establish the mapping between an IP name and an IPv4 or an IPv6 address you use the Domain Name Service (DNS). DNS is a hierarchical database that you can distribute on several servers for backup and load sharing. After you add a new hostname, update this database. The information is sent to all the different hosts. An IP client that resolves the mapping between the hostname and the IP address sends a request to one of the database servers to resolve the name.

After you establish the mapping of IP name and IP address, the application is modified to use a hostname instead of an IP address. The switch converts the hostname to an IP address.

If the entry to translate the hostname to IP address is not in the host file, the switch queries the configured DNS server for the mapping from hostname to IP address. You can configure connections for up to three different DNS servers—primary, secondary and tertiary. First the primary server is queried, and then the secondary, and finally the tertiary.

The DNS client tracks any server addresses or domain names provided from a DHCP server. If a DHCP server provides info to the DNS client, the DNS configuration is classified as dynamic. You can manually delete dynamic DNS entries, but cannot manually add dynamic DNS entries. You can view the Dynamic DNS entries with **show ip dns** or **show sys dns**. Dynamic DNS entries are not saved in the configuration file. The status monitoring of DNS occurs every 60 seconds.

DNS modifies Ping, Telnet, and copy applications. You can enter a hostname or an IP address to invoke Ping, Telnet, and copy applications.

A log/debug report is generated for all the DNS requests sent to DNS servers and all successful DNS responses received from the DNS servers.

### IPv6 Support

The Domain Name Service (DNS) used by the switch supports both IPv4 and IPv6 addresses with no difference in functionality or configuration.

---

## DNS configuration using CLI

---

This section describes how to configure the Domain Name Service (DNS) client using Command Line Interface (CLI).

DNS supports IPv4 and IPv6 addresses.

### Configuring the DNS client

#### About This Task
