Configure the Domain Name Service to establish the mapping between an IP name and an IPv4 or IPv6 address. DNS supports IPv4 and IPv6 addresses with no difference in

functionality or configuration using CLI.

You can configure connection for up to three different DNS servers—primary, secondary and tertiary. First the primary server is queried, and then the secondary, and finally the tertiary.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the DNS client:  

```
ip domain-name WORD<0-255>
```
3. (Optional) Add addresses for primary, secondary, or tertiary DNS servers:  

```
ip name-server <primary|secondary|tertiary> WORD<0-46>
```
4. (Optional) Delete addresses for primary, secondary, or tertiary DNS servers:  

```
no ip name-server <primary|primary-dynamic|secondary|secondary-dynamic|tertiary|tertiary-dynamic> WORD<0-46>
```
5. View the DNS client system status:  

```
show ip dns
```

#### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Add addresses for a tertiary DNS server:

```
Switch:1(config)# ip name-server tertiary 254.104.201.141
```

Delete address for a secondary dynamic DNS server:

```
Switch:1(config)#no ip name-server secondary-dynamic 192.0.2.12
```

### Variable Definitions

The following table defines parameters for the **ip domain-name** command.

| Variable            | Value                                                                                    |
|---------------------|------------------------------------------------------------------------------------------|
| <i>WORD</i> <0–255> | Configures the default domain name.<br><i>WORD</i> <0–255> is a string 0–255 characters. |

The following table defines parameters for the **ip name-server** command.

| Variable                                      | Value                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>primary secondary tertiary WORD</i> <0–46> | Configures the primary, secondary, or tertiary DNS server address. Enter the IP address in a.b.c.d format for IPv4 or hexadecimal format (string length 0–46) for IPv6. You can specify the IP address for only one server at a time; you cannot specify all three servers in one command. Use the no operator before this parameter, no <b>ip name-server</b> <primary secondary tertiary> |

## Querying the DNS host

### About This Task

Query the DNS host for information about host addresses.

You can enter either a hostname, an IPv4 or IPv6 address. If you enter the hostname, this command shows the IP address that corresponds to the hostname and if you enter an IP address, this command shows the hostname for the IP address. DNS supports IPv4 and IPv6 addresses with no difference in functionality or configuration using CLI.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. View the host information:  
`show hosts WORD`<0–256>

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

View the host information:

```
Switch:1(config)# show hosts 192.0.2.1
```

### Variable Definitions

The following table defines parameters for the **show hosts** command.

| Variable                       | Value                                                                                                                                                                                                                                                                                                             |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;0-256&gt;</code> | Specifies one of the following: <ul style="list-style-type: none"> <li>the name of the host DNS server as a string of 0-256 characters.</li> <li>the IP address of the host DNS server in a.b.c.d format.</li> <li>The IPv6 address of the host DNS server in hexadecimal format (string length 0-46).</li> </ul> |

## DNS configuration using EDM

This section describes how to configure the Domain Name Service (DNS) using Enterprise Device Manager (EDM).

DNS supports IPv4 and IPv6 addresses with no difference in functionality or configuration except for the following. Under the **DNS Servers** tab, in the **DnsServerListAddressType** box, you must select **ipv4** or **ipv6**.

### Configure the DNS Client

#### About This Task

You can configure connections for up to three different DNS servers—primary, secondary and tertiary. First the primary server is queried, and then the secondary, and finally the tertiary.

DNS supports IPv4 and IPv6 addresses. Under the **DNS Servers** tab, in the **DnsServerListAddressType** box, you must select **ipv4** or **ipv6**.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics**.
2. Click **DNS**.
3. Click the **DNS Servers** tab.
4. Click **Insert**.
5. In the **DnsServerListType** box, select the DNS server type.
6. In the **DnsServerListAddressType** box, select the IP version.
7. In the **DnsServerListAddress** box, enter the DNS server IP address.
8. Click **Insert**.

**DNS Servers** Field Descriptions

Use the data in the following table to use the **DNS Servers** tab.

| Name                             | Description                                                                                                                                                                        |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DnsServerListType</b>         | Configures the DNS server as primary, secondary, or tertiary.<br>OR<br>Removes a DNS server as primary, primaryDynamic, secondary, secondaryDynamic, tertiary, or tertiaryDynamic. |
| <b>DnsServerListAddressType</b>  | Configures the DNS server address type as IPv4 or IPv6.                                                                                                                            |
| <b>DnsServerListAddress</b>      | Specifies the DNS server address.                                                                                                                                                  |
| <b>DnsServerListStatus</b>       | Specifies the status of the DNS server.                                                                                                                                            |
| <b>DnsServerListRequestCount</b> | Specifies the number of requests sent to the DNS server.                                                                                                                           |
| <b>DnsServerListSuccessCount</b> | Specifies the number of successful requests sent to the DNS server.                                                                                                                |

## Query the DNS Host

**About This Task**

Query the DNS host for information about host addresses.

You can enter either a hostname or an IPv4 or IPv6 address. If you enter the hostname, this command shows the IP address that corresponds to the hostname and if you enter an IP address, this command shows the hostname for the IP address. DNS supports IPv4 addresses with no difference in functionality or configuration in this procedure.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit > Diagnostics**.
2. Click **DNS**.
3. Click the **DNS Host** tab.
4. In the **HostData** text box, enter the DNS host name, IPv4 or the IPv6 address.
5. Click **Query**.

**DNS Host** Field Descriptions

Use the data in the following table to use the **DNS Host** tab.

| Name                   | Description                                                                    |
|------------------------|--------------------------------------------------------------------------------|
| <b>HostData</b>        | Enter hostname or host IPv4 or IPv6 address to be identified.                  |
| <b>HostName</b>        | Identifies the host name. This variable is a read-only field.                  |
| <b>HostAddressType</b> | Identifies the address type of the host.                                       |
| <b>HostAddress</b>     | Identifies the host IP address. This variable is a read-only field.            |
| <b>HostSource</b>      | Identifies the DNS server IP or host file. This variable is a read-only field. |

|                                                                                                                                                                                                     | VSP 4900 Series | VOSS 8.1                                                                   |
|                                                                                                                                                                                                     | VSP 7200 Series | VOSS 6.0.1                                                                 |
|                                                                                                                                                                                                     | VSP 7400 Series | VOSS 8.0                                                                   |
|                                                                                                                                                                                                     | VSP 8200 Series | VOSS 6.0.1                                                                 |
|                                                                                                                                                                                                     | VSP 8400 Series | VOSS 6.0.1                                                                 |
|                                                                                                                                                                                                     | VSP 8600 Series | Not supported                                                              |
|                                                                                                                                                                                                     | XA1400 Series   | Not Supported                                                              |

**Table 80: Distributed Virtual Routing product support (continued)**

| Feature                                              | Product         | Release introduced |
|------------------------------------------------------|-----------------|--------------------|
| Distributed Virtual Routing (DvR) dvr-one-ip         | 5420 Series     | VOSS 8.4           |
|                                                      | 5520 Series     | VOSS 8.3           |
|                                                      | VSP 4450 Series | Not Supported      |
|                                                      | VSP 4900 Series | VOSS 8.3           |
|                                                      | VSP 7200 Series | VOSS 8.3           |
|                                                      | VSP 7400 Series | VOSS 8.3           |
|                                                      | VSP 8200 Series | VOSS 8.3           |
|                                                      | VSP 8400 Series | VOSS 8.3           |
|                                                      | VSP 8600 Series | VSP 8600 8.0       |
|                                                      | XA1400 Series   | Not Supported      |
| Distributed Virtual Routing (DvR) In-band Management | 5420 Series     | VOSS 8.4           |
|                                                      | 5520 Series     | VOSS 8.2.5         |
|                                                      | VSP 4450 Series | VOSS 6.1           |
|                                                      | VSP 4900 Series | VOSS 8.1           |
|                                                      | VSP 7200 Series | VOSS 6.0.1         |
|                                                      | VSP 7400 Series | VOSS 8.0           |
|                                                      | VSP 8200 Series | VOSS 6.0.1         |
|                                                      | VSP 8400 Series | VOSS 6.0.1         |
|                                                      | VSP 8600 Series | Not supported      |
|                                                      | XA1400 Series   | Not Supported      |

## Distributed Virtual Routing (DvR) Fundamentals

Distributed Virtual Routing (DvR) is a technology for router redundancy in a fabric deployment where IP subnets are stretched across multiple switches. DvR provides Default Gateway Redundancy and optimizes traffic flows to avoid traffic tromboning due to inefficient routing, thereby increasing the total routing throughput.

DvR can be deployed in Campus environments for stretching IP subnets between multiple aggregation layer switches and also simplifies data center deployments by introducing a Controller-Leaf architecture. In this architecture, Layer 3 configuration is required only on the Controller nodes, whereas the Leaf nodes require only Layer 2 configuration. All Layer 3 configuration is automatically distributed to the Leaf nodes by the Controller nodes.

For typical Campus DvR deployments, configure aggregation layer switches as DvR Controllers. Wiring closet access switches are then typically dual-homed to a pair of DvR Controllers.

IP subnets, which stretch between aggregation layer switches and multiple wiring closets, enable seamless IP roaming for wireless users while at the same time ensure optimal traffic forwarding. To

optimize automation, Fabric Attach is typically deployed between wiring closet and aggregation switches. In this construct, there would likely be no DvR Leaf configured.

In fabric deployments, DvR replaces VRRP (with VRRP-BackupMaster or RSMLT). The operator can chose for each I-SID/IP subnet what router redundancy method to use.

To migrate to a DvR-enabled I-SID/IP subnet, all member fabric switches of this I-SID must be either DvR Controllers or DvR Leafs. You can connect non fabric switches to DvR Leafs and DvR Controllers with manual configuration or Fabric Attach configuration. Until all fabric switches that are members of the I-SID/IP subnet are DvR-enabled, use VRRP or RSMLT as the router redundancy protocol.

## DvR Domain

To enable multi-site DvR deployments, a DvR domain concept has been introduced. Within a DvR domain, a set of up to eight DvR Controllers control the DvR domain Leaf switches. A domain can also include just DvR controllers without DvR Leafs. Typically, a DvR domain is restricted to one physical location. Traffic leaving this physical location always passes through DvR Controllers.

A DvR domain is a logical group of switches or nodes that are DvR enabled. These nodes are not physically connected but are connected over the SPB Fabric such that each node is aware of the BMAC addresses of all other nodes within the domain. A DvR domain does not contain nodes that are not DvR enabled. However, those nodes can co-exist with other DvR enabled nodes within the same SPB Fabric network.

You configure a common DvR domain ID for all nodes belonging to a DvR domain. This domain ID translates internally to a Domain Data Distribution (DDD) I-SID. All switch nodes that share the same DvR domain ID or DDD I-SID receive the Layer 3 information that is distributed from all other nodes belonging to that DvR domain.

A DvR domain can contain multiple Layer 3 VSNs and Layer 2 VSNs. Layer 2 and Layer 3 VSNs can span multiple DvR domains.

A DvR domain typically has the following members:

1. DvR Controller(s)
2. DvR Leaf nodes

For scaling information on the number of Controllers and Leaf nodes to configure in a DvR domain, see [VOSS Release Notes](#).

## DvR Controller

In a DvR domain, the Controller nodes are the central nodes on which Layer 3 is configured. They own all the Layer 3 configuration and push the configuration information to the Leaf nodes within the SPB network.

A DvR domain can have one or more controllers for redundancy and you must configure every Layer 2 VSN (VLAN) and Layer 3 VSN within the domain, on the Controller(s). A node that you configure as a DvR Controller is considered the controller for all the Layer 2 and Layer 3 VSNs configured on that node. A Controller is configured with its own subnet IP address for every DvR enabled Layer 2 VSN within the domain.

All Layer 2 VSNs on a DvR Controller need not be DvR enabled. A controller can be configured with individual Layer 2 VSNs that are DvR disabled.

The Layer 3 configuration data that is pushed to the Leaf nodes include the Layer 3 IP subnet information for all Layer 2 VSNs within the DvR domain. It also includes the IP routes learned or redistributed by the Controllers from networks outside the SPB network, into the DvR Domain. Controllers also send information on whether Multicast is enabled on a specific DvR enabled Layer 2 VSN, and the version of IGMP. DvR Controllers inject a default route into the DvR domain for external route reachability. Use route policies to inject specific routes into a DvR domain or inject host routes into OSPF or BGP.

A Controller can only belong to one DvR domain, based on the domain ID that you configure on the node.

DvR Controllers include all DvR Leaf functions, thus a Leaf node free deployment is a valid network deployment. Especially if you use DvR in Campus deployments to replace VRRP or RSMLT, a Controller-only deployment, as Fabric Attach server nodes, is a valid deployment option.

## DvR Leaf Node

DvR Leaf nodes are typically data center top of the rack (TOR) Fabric switches that aggregate physical and virtual servers or storage devices. DvR Leaf nodes operate in a reduced configuration mode, where Layer 3 is not configured locally, but pushed to them from the DvR Controller(s) within the domain. You need to configure only the IS-IS infrastructure and the Layer 2 VSNs on the Leaf nodes.

A DvR Leaf node also monitors local host attachments and communicates updates about the current state of those host attachments to the DvR domain. All DvR nodes exchange host attachment information using the DvR host distribution protocol, which leverages a DvR domain I-SID.

DvR leaf nodes are managed in-band through a local loopback address, which is exchanged using the IP Shortcut protocol.

### *Eligibility Criteria for a Leaf Node*

A Leaf node must support the following criteria:

- configuration of basic parameters of IP Multicast over Fabric Connect, such as the system ID, nickname, B-VLANs, SPBM instance, area, peer system ID and virtual BMAC
- configuration of a physical port as either an SPB NNI interface, a FLEX-UNI interface or an FA interface
- configuration of an MLT as either an SPB NNI interface, a FLEX-UNI interface or an FA interface
- configuration of an SMLT as a Flex-UNI Interface or an FA Interface
- configuration of Layer 2 VSN I-SID instances of type ELAN
- configuration of FLEX-UNI end-points as part of a Layer 2 VSN
- FA Server functionality on FA enabled interfaces
- SMLT and vIST
- configuration of a in-band management interface for in-band management of the node

## Configuration Limitations

The DvR Controller and the DvR Leaf node have the following configuration limitations:

- On a Controller, for any VLAN, you can either configure DvR or VRRP but not both. Similarly, you can either configure DvR or RSMLT but not both.
- On a leaf node, you cannot configure the following:
  - Layer 3 (for example, IP interfaces, IP routing and VRFs). You can only perform Layer 2 configuration.
  - platform VLANs. You cannot configure a platform VLAN directly on a DvR leaf node. However, you can configure a VLAN Management Instance on a DvR leaf node. After you configure the management VLAN, you can configure a platform VLAN.
- On a Controller, you cannot configure the following:
  - dynamic routing protocols like OSPF, RIP and BGP on a DVR enabled VLAN.
  - static routes such that the next-hop exists on any DVR enabled VLAN.

## Summary of Controller and Leaf Node Functions

A DvR Controller performs the following functions:

- pushes Layer 3 configuration data (IPv4 Unicast and Multicast) to the Leaf nodes for all the Layer 2 VSNs or subnets within the DvR domain.
- pushes the Layer 3 learned host routes (host routes learned on its own UNI ports) and route data learned through route redistribution or route policies, to the Leaf nodes.
- configures learned remote host routes from other Controllers and Leaf nodes, on its own device.

A DvR enabled Leaf node performs the following functions:

- configures the gateway MAC when the gateway IPv4 address is learned.
- pushes the Layer 3 learned remote host routes to other Controllers and Leaf nodes in the domain.
- configures learned remote host routes from other Controllers and Leaf nodes on its own device.
- configures ECMP routes (in the datapath only) for the Layer 2 VSN subnets, with each next hop as the Controller in the DvR domain.
- configures learned routes from the Controllers that are redistributed using DvR.
- handles host route response packet interception based on the Controller VLAN MAC or the gateway MAC.

## DvR backbone

The DvR backbone is automatically established among the DvR Controllers from all DvR domains. Every Controller node has an edge gateway to its DvR domain, to the DvR backbone and all other non-DvR domains within the network.

Controllers exchange host route information such that any host can be reached in a shortcut switched manner, irrespective of its location. For these host route information exchanges, controllers use an automatically assigned backbone I-SID. Local subnets to the Controllers are automatically injected into the DvR host route exchanges.

To redistribute DvR host routes into OSPF or BGP, you can configure route policies. These host routes are not injected into IS-IS.

### DvR Backbone Members

You can configure a non-DvR backbone edge bridge (BEB) to join the DvR backbone. This enables the node to receive redistributed DvR host routes from all DvR Controllers in the SPB network, just like a DvR Controller. However, unlike the Controller, you can neither configure a DvR interface on this node nor can the node inject its host routes into the DvR domain.

## DvR operation

In a DvR domain, DvR enabled Controller(s) handle the learning and distribution of Layer 3 configuration and route data to the DvR enabled Leaf nodes. The Leaf nodes in turn, use this data to automatically create distributed Layer 3 datapaths on themselves. In this way, Layer 3 configuration and learning remains only with the Controller(s) and there are distributed Layer 3 datapaths at the edges of the fabric network. This allows for destination lookups at the edge to happen quickly, and traffic is sent directly to their destinations without multiple lookups.

An important benefit of DvR is that only minimal configuration is required on the Leaf node. Based on the Layer 2 VSN that the Leaf node is a part of, all Layer 3 configuration information (IPv4 Unicast and Multicast configuration) is pushed from the Controllers in the domain. Thus the leaf nodes, although basically Layer 2 configured switches, become fully layer 3 capable devices.

**Figure 46: SPB Fabric network with central Layer 3 Controller and distributed Layer 3 datapath at the edges**

## ARP Learning

When DvR is enabled on a Controller, it initiates ARP requests for traffic to be routed to unknown destination hosts.

DvR enabled Controllers learn ARP requests from:

- DvR enabled Leaf nodes (here the Leaf node owns the ARPs)
- its own local UNI ports. Here, the controller owns the ARPs
- other DvR enabled Controllers

DvR enabled Leaf nodes learn ARP requests from:

- its own local UNI ports (here the Leaf node owns the ARPs)
- other DvR enabled Leaf nodes (that own the ARPs) and respond to ARP requests on their UNI ports
- DvR enabled Controllers (that own the local UNI ARPs)

Controllers only distribute ARP entries that are locally learned on its own UNI ports, to other DvR enabled nodes in the domain.

## dvr-leaf-mode boot flag

To configure a node to operate as a DvR Leaf node, you must first enable the `dvr-leaf-mode` boot flag.

- The `dvr-leaf-mode` boot flag is disabled by default. You must explicitly enable this flag before you configure a switch node to operate as a Leaf node.
- After you enable or disable the boot flag, you must save the configuration and reboot with the saved configuration, for the changes to take effect.

### Important

A node on which the `dvr-leaf-mode` boot flag is enabled cannot be configured as a DvR Controller.

## In-band management

Use in-band management to manage a DvR enabled Leaf node that does not have an out-of-band management port or a console port.

For in-band management of the node within the management subnet (for example, from a Controller node), you must configure a unique IPv4 address to be used as the in-band management IP address, on that node. This IPv4 address functions like a CLIP address.

## DvR deployment scenarios

The following sections describe typical deployments of the DvR infrastructure.

### *DvR deployment in a single data center*

The following topology shows DvR deployment in a single data center. This deployment consists of a single DvR domain comprising a Controller layer and a Leaf node layer. The Controller layer has two controllers (for redundancy), which are deployed closer to the boundary of the DvR domain and the rest of the SPB Fabric network. The DvR Leaf nodes or Top of Rack (TOR) switches are typically access or edge switches.

All switches that belong to the DvR domain are configured with the same DvR domain ID and communicate with each other over a predefined I-SID.

The Controller nodes control the Leaf nodes and also build the gateway between the DvR domain and the rest of the Fabric infrastructure. So traffic is either routed between the Leaf nodes, or through the Controllers, to the rest of the fabric infrastructure.

Two IP subnets (Layer 2 VSNs), yellow and green, span the Leaf nodes. Each subnet is configured with a virtual IP address that is shared among all Controller and Leaf nodes that belong to the subnet. The Controller and Leaf nodes are configured with routing interfaces to the subnets, as shown in the figure.

DvR works by enabling each Leaf node or Top of Rack (TOR) switch to bi-directionally route traffic for each IP subnet of which it is a member. This is done by distributing the Layer 3 configuration information (IP Unicast, IP Multicast and virtual IP configuration) needed to handle Layer 3 routing, from the Controllers to the Leaf nodes. Configuration information is pushed over the DvR Domain I-SID, as indicated by the blue arrows in the above figure.

Routing between the two IP subnets is achieved directly at the Leaf nodes when the Layer 3 distributed datapath is programmed at the Leaf Nodes, based on the Layer 3 configuration data that is pushed. Thus traffic within and between IP subnets is shortcut switched without having to traverse the central routing nodes, as shown in the figure below, if there are direct physical connections between them.

Thus, in a DvR deployment, all virtual IP and Layer 3 configuration is performed on the Controller nodes and pushed to the Leaf nodes, so that the Leaf nodes though basically Layer 2 configured switches, become fully layer 3 capable devices.

#### *DvR deployment in a dual data center*

The following example deployment shows two data centers each having its own DvR domain, connected through a backbone.

All nodes in data center Campus 1 belong to DvR domain shown in green, and the nodes in the data center Campus 3 belong to the DvR domain shown in orange. The two DvR domains are individually managed, so in this scenario, the controllers colored orange manage the orange Leaf nodes and the controllers colored green manage the green Leaf nodes. However, subnets can still be stretched across the DvR domains (and possibly between buildings), as shown in the figure.

Each DvR domain learns its own Layer 3 data and distributes this information to its own Leaf nodes. Layer 3 host information that is redistributed from other DvR Domains is learned by the Controllers only (through inter-DvR domain redistribution) and is programmed on the Leaf nodes in the same domain, but not in the other Domain. For example, Layer 3 information redistributed from domain 2 is learned by all controllers including the domain 1 controllers, but this information is not distributed to the Leaf nodes in domain 1. Hosts in one DvR domain can reach the hosts in the other DvR domain only through the Controllers.

**Figure 47: Shortest path routing between servers in different data centers**

All controllers in all domains are always part of the DvR backbone by default, as they are connected by the SPB Fabric. The DvR backbone connects many DvR domains.

Thus DvR can scale to multiple campuses, allowing a simplified way to deploy a large scale fully-routed infrastructure.

## DvR Route Redistribution

The following sections describe redistribution of IPv4 local and static routes from DvR Controllers into the DvR domain. It also describes redistribution of host routes that are learned on DvR enabled VLANs, to BGP and OSPF. You can configure route policies to control the selection of routes to be distributed. You can also configure IS-IS accept policies on DvR Controllers and non-DvR BEBs, to determine which DvR host routes to accept into the routing-table from the DvR backbone.

### *Redistribution of IPv4 Local and Static Routes*

The DvR feature supports redistribution of IPv4 local and static routes into the DvR domain.

#### Note

For every VRF instance and the Global Router, the Controller automatically injects a default route to the Leaf node, with a next hop as the advertising Controller. However, if you require only local or static routes to be advertised to the Leaf nodes, you can manually disable the injection of default routes on the Controller.

On a DvR Controller, you can configure (enable or disable) the redistribution of direct or static routes. Direct routes are redistributed with the route type as internal. Static routes are redistributed with the route type as external. You can apply route policies on the Controller to selectively permit the redistribution of these routes and also configure a metric value for the route that is redistributed. The

default metric for imported local routes is 1. For static routes, the configured route metric or cost is honored.

You can configure redistribution of static and direct routes from the Global Router, or within a VRF instance. For redistributed routes, the Controller configures the Layer 3 VSN as that of the VRF redistributing the route, and the next hop BEB as the system ID of the Controller injecting the route into the DvR domain.

The following example demonstrates how a DvR Leaf node benefits from the redistribution of local and static routes.

By default, if the injection of default routes is enabled on a DvR Controller, the DvR Leaf node can only route traffic to other nodes within the DvR enabled subnet. For the Leaf node to reach networks outside of the DvR enabled subnet, the Controllers must redistribute local and static routes from non-DvR subnets into the DvR domain. In the following figure, the DvR Leaf L1 can route traffic only to nodes in the DvR enabled subnet 10.10.10.0/24. To be able to reach hosts in VLAN 20 (20.20.20.0/24) or VLAN 30 (30.30.30.0/24), redistribution of local routes into DvR is required at each of the Controllers C1 and C2. For the Leaf node to reach hosts in remote networks 40.40.40.0/24 or 50.50.50.0/24, redistribution of static routes to the DvR domain is required.

You can apply route policies to control which local or static routes are to be redistributed into the DvR domain.

**Figure 48: Redistribution of IPv4 local and static routes**

#### *Redistribution of Routes to OSPF or BGP*

For non-SPB routers to benefit from the host accessibility information learned within a DvR domain, DvR supports the redistribution of host routes into OSPF or BGP. Redistribution of these host routes is only by the DvR Controllers and only for the intra-domain host routes within the DvR enabled subnets.

A DvR Controller can redistribute host routes for all hosts from a DvR domain into OSPF or BGP. You can also apply route policies on the Controller to select the routes to be redistributed. The Controller supports redistribution of routes from the Global Router or within a VRF instance. You can also configure the metric of the route before redistribution.

The following example demonstrates the benefit of redistribution of routes to BGP.

Consider a 10.1.0.0/16 network with a stretched Layer 2 VSN spanning two data centers. On the campus side of the network, BGP peering is configured between a non-Extreme router and one or more routers in the data center. BGP advertises the network route 10.1.0.0/16 to the campus BGP routers. Depending on which edge router the traffic is delivered to, it is possible that traffic from a host on the campus traverses the WAN a second time to reach the server that is physically connected to one segment of the data center, as shown in the following figure.

**Figure 49: Inefficient traffic flow**

Redistribution of the host routes from the DvR Controller to BGP solves this problem.

The following figure shows two DvR domains (shown in green and orange) configured at each data center. Each campus edge router establishes a BGP peering session with one or more Controllers in each data center (DvR domain). This enables BGP to advertise more specific routes to the campus BGP router so that the optimal routing path is always taken. So, there is no need for traffic to traverse the WAN multiple times. Also, in the case of server movement within or between data centers, the updated DvR host routes are propagated to BGP, thus ensuring that traffic flowing into the data center continues along the most optimal path.

For example, in the following figure, only the Controller attached to the Leaf node where the 10.1.0.111 server exists, advertises its accessibility over the 10.1.0.111/32 route. Similarly, the DvR Controller associated with the Leaf node connected to the 10.1.0.222 server advertises the 10.1.0.222/32 host route.

**Figure 50: Traffic flow optimized with route redistribution**

Controllers in each data center learn all host routes through the DvR backbone, but since those routes belong to different DvR domains, they are not all eligible for redistribution to OSPF or BGP.

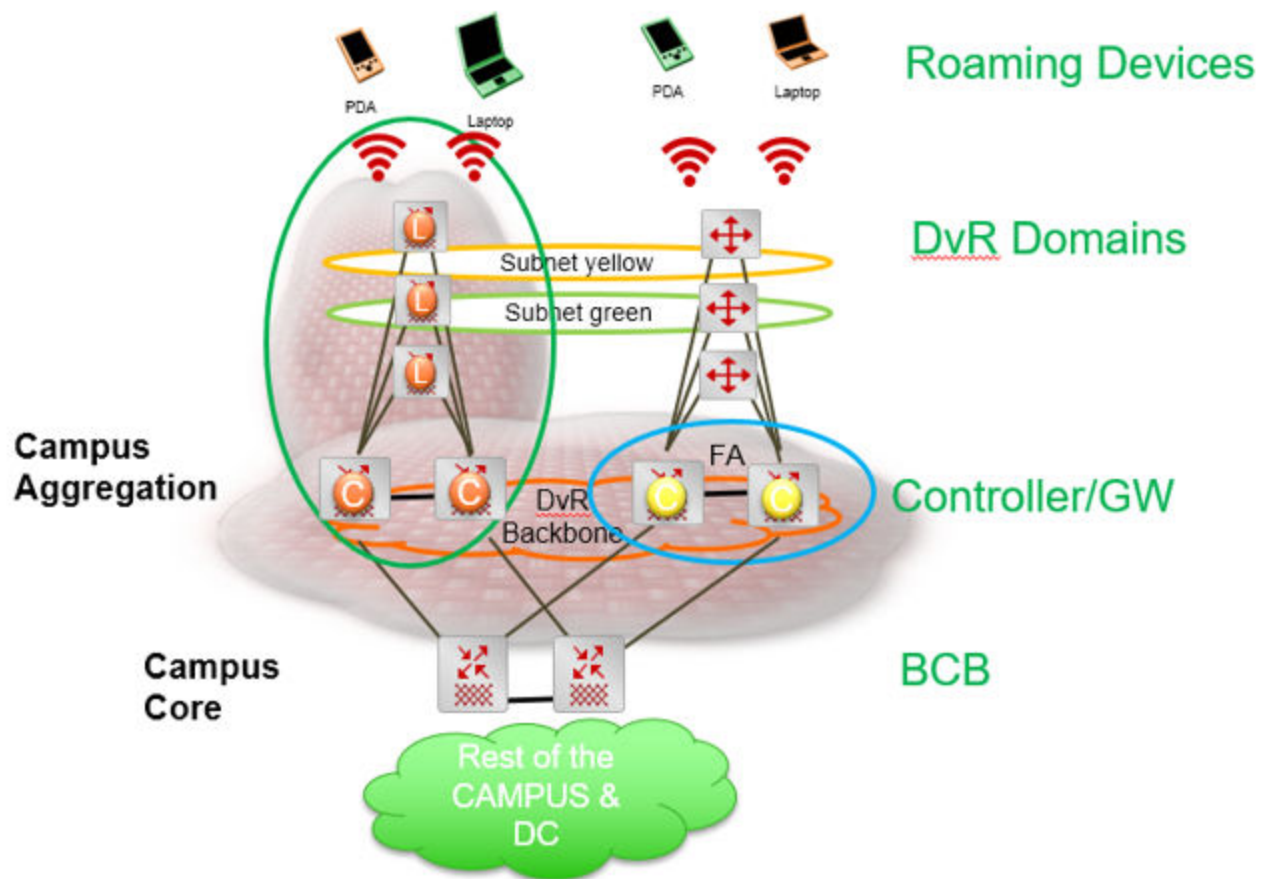

#### *Route Redistribution and IS-IS Accept Policies*

DvR route redistribution leverages IS-IS accept policies to control (accept or reject) DvR routes learned from the DvR backbone. You can configure accept policies on both Controllers and non-DvR BEBs in the SPB network.

For more information about accept policies, see [IS-IS Accept Policies](#) on page 1354.

#### *DvR Deployment for Wireless Roaming in Campus Deployments*

In fabric deployments where IP subnets/I-SIDs stretch between multiple buildings, you can use DvR instead of VRRP or RSMLT to avoid traffic tromboning issues. This deployment is supported with non-fabric switches that have Fabric Attach enabled, or switches that do not support Fabric Attach. You can use VSP 4450 Series as DvR Leafs in this context as well. IP subnets can stretch across one or multiple DvR domains as shown in the following figure.

**Figure 51: Wireless roaming in Campus**

## DvR Limitations

Review the following limitations and behavioral characteristics associated with DvR.

- The DvR feature does not affect out-of-band management on a switch chassis, if the chassis supports it.
- The DvR feature does not support a non-DvR BEB in a DvR enabled Layer 2 VSN.
- The number of host route records that can be stored in the datapath of a Leaf node is limited to the scaling capacity of the switch node. Different switch platforms have different scaling capacities.

For information on the scaling capacities of different platforms, see [VOSS Release Notes](#).

- You must first disable DvR on a Controller or Leaf node, before you attempt to change the domain ID of the node.
- You cannot configure IGMP snooping on DvR enabled nodes.
- DvR is only supported for IPv4.
- DvR is only supported in warm standby High Availability mode on the VSP 8600 Series.

### Configuration Limitations on a DvR Controller

- If you are using two different IP addresses for the DvR VLAN and the DvR GW IP, you must first configure a gateway IPv4 address and then configure an IP interface for the VLAN before you enable DvR on a Layer 2 VSN (VLAN). Both the VLAN IP address and the gateway IPv4 address must be in the same subnet.

For more information, see [Enable DvR on a Layer 2 VSN \(VLAN\)](#) on page 3778 and [Configure a Single IP Address for All DvR Controllers on a VLAN Subnet](#) on page 3779.

- You cannot configure VRRP on a DvR VLAN.

#### Note

A DvR VLAN is a VLAN configured on a DvR Controller with a VLAN IP address, a VLAN/I-SID, the DvR gateway IP address, and DvR enabled. This Layer 3 configuration for the DvR VLAN (the DvR gateway IP address and this DvR subnet) is pushed to the DvR Leaf nodes. The DvR gateway IP address must be the same address across all DvR Controllers for that DvR VLAN.

- You cannot configure RSMLT on a DvR VLAN.
- You cannot configure SPB-PIM Gateway (SPB-PIM GW) on a DvR VLAN.
- DvR-enabled VLAN/I-SIDs are for host connectivity only; you cannot connect a router to a DvR-enabled VLAN/I-SID and use dynamic or static routing. Use a non-DvR VLAN/I-SID instead to connect an external router.

### Configuration Limitations on a DvR Leaf

- Enabling the **DvR-leaf-mode** boot flag before you configure a node as a DvR Leaf, automatically removes all existing non-DvR configuration on the node such as platform VLANs and their IP address configuration, CLIP configuration, routing protocol configuration and VRF configuration. The gateway IPv4 address, if configured, is also removed.
- You cannot configure SPB-PIM GW on a Leaf node. The configuration is supported only on a DvR Controller.
- You cannot configure Microsoft NLB on a Leaf node.
- You cannot configure Fabric Extend on a Leaf node.
- You cannot configure the VXLAN Gateway on a Leaf node.
- You cannot configure a T-UNI on a Leaf node.
- You cannot configure IPv4 multicast on a Leaf node. The configuration is supported only on a DvR Controller.
- You can configure only one instance of vIST on a Leaf node pair. Also, you cannot configure vIST on Leaf nodes from different domains.
- You cannot configure platform VLANs on a Leaf node. Only configuration of SPBM B-VLANs is supported.
- You cannot configure IP Shortcuts and IP Multicast over Fabric Connect on Leaf nodes. This configuration is pushed from the DvR Controllers in the domain.

- You must manually configure an I-SID on a Layer 2 VSN, on the Leaf node. This configuration is not pushed from a DvR Controller.
- DvR-enabled VLAN/I-SIDs are for host connectivity only; you cannot connect a router to a DvR-enabled VLAN/I-SID and use dynamic or static routing. Use a non-DvR VLAN/I-SID instead to connect an external router.

## Migrate from VRRP to DvR

### About This Task

If you have a VRRP network with a mix of existing routers that do not support DvR and VOSS devices that do support DvR, you can migrate your VRRP network to DvR using this high-level process. This migration process assumes the following design:

- Existing routers are the VRRP masters.
- Existing routers are the default gateways for all subnets.
- Fabric Connect network with DvR-capable nodes where DvR is configured globally, but not on I-SIDs, on the VOSS devices; and VOSS devices operate in Layer 2 mode for the VRRP VLANs that need to be migrated.

#### Important

When you configure DvR on Controllers with existing VRRP VLANs, ensure there is no VRRP VLAN with VRID 37 or VRID 38. VRID 37 conflicts with the DvR gateway MAC used by all DvR nodes. The DvR gateway MAC is a constant value 00:00:5e:00:01:25; VRRP VRID 37 translates to the same MAC. Similarly, VRRP VRID 38 translates to 00:00:5e:00:01:26, and is used within DvR. If you have a VRRP VLAN with either of these VRIDs, change the VRID to a different value.

### Procedure

1. Enable VRRP interfaces on the DvR Controllers but keep VRRP mastership on the existing routers.
2. Change VRRP mastership on the VLAN or IP Subnet in question on the DvR Controller by applying a higher priority than the current master.

#### Note

You can easily fall back to the original VRRP master to change VRRP priorities back.

3. Disable VRRP on the existing routers.

- Subnet by subnet (VLAN/I-SID), delete VRRP interfaces on all DvR Controllers first (this includes removing VRRP and removing the VLAN IP address), and then configure DvR interfaces (this includes adding the DVR-GW-IP, enabling DvR, and then adding the VLAN IP address) on the VLAN/I-SID instead. This might lead to a short traffic interruption.

### Note

For each VLAN/I-SID, ensure that VRRP is disabled on all nodes before you configure DvR interfaces on the Controllers for the VLAN/I-SID.

Keep in mind that you can only enable DvR on VLAN or I-SIDs where all participating BEBs are DvR-capable.

Anytime when falling back, you can delete the DvR interface on the I-SID (this includes disabling DvR, removing the DVR-GW-IP and removing the VLAN IP address) and configure the VRRP interface again (this includes adding the VLAN IP address and adding VRRP again), however, ensure you delete the DvR interfaces on all Controllers first before you enable VRRP again.

### Example

Start with VRRP VLAN:

```
vlan create 250 name vlan_test250 type port-mstprstp 0
vlan i-sid 250 111250
interface vlan 250
ip address 192.0.2.3 255.255.255.0
interface vlan 250
ip vrrp version 2
ip vrrp address 10 192.0.2.1
ip vrrp 10 priority 180
ip vrrp 10 backup-master enable
ip vrrp 10 enable
exit
```

Change to DvR VLAN:

```
interface vlan 250
no ip vrrp address 10 192.0.2.1
no ip address 192.0.2.3
exit
interface vlan 250
dvr gw-ipv4 192.0.2.1
dvr enable
ip address 192.0.2.3 255.255.255.0
exit
```

Change back to VRRP VLAN:

```
interface vlan 250
no dvr enable
no dvr gw-ipv4
no ip address 192.0.2.3
exit
interface vlan 250
ip address 192.0.2.3 255.255.255.0
ip vrrp version 2
ip vrrp address 10 192.0.2.1
ip vrrp 10 priority 180
ip vrrp 10 backup-master enable
```

```
ip vrrp 10 enable
exit
```

## DvR configuration using the CLI

The following sections describe configuration of Distributed Virtual Routing (DvR) using the Command Line Interface (CLI).

### Configuring a DvR Controller

#### About This Task

Configuring a node as a DvR Controller enables DvR globally on that node.

Perform this procedure to create a DvR domain with the domain ID that you specify, and configure the role of the node as the Controller of that domain. A Controller can belong to only one DvR domain.

#### Note

For a node to perform the role of both a Controller and a Leaf within a DvR domain, you must configure it as a Controller.

#### Before You Begin

- Ensure that you configure IP Shortcuts on the node. This is necessary for proper functioning of the node as a DvR Controller.
- Ensure that the `dvr-leaf-mode` boot flag is disabled on the node.

To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

#### Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure a DvR Controller.

```
dvr controller <1-255>
```
3. (Optional) Disable DvR on a DvR Controller.

```
no dvr controller
```

#### Caution

Disabling DvR on a DvR Controller destroys the domain ID and all dynamic content learned within the DvR domain.

However the switch retains the VLAN specific configuration and you can view the information using the command **show running-config**.

4. View a summary of the Controller configuration. Enter:

```
show dvr
```

## Example

Configure a node as a DvR Controller:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#dvr controller 5
Switch:1(config)#show dvr
```

```
=====
                        DVR Summary Info
=====

```

### Variable definitions

Use the data in the following table to use the **dvr controller** command.

| Variable | Value                                                                  |
|----------|------------------------------------------------------------------------|
| <1-255>  | Specifies the domain ID of the DvR domain that the controller belongs. |

## Disabling injection of default routes on a Controller

### About This Task

By default, a DvR Controller injects default routes into the DvR domain and all the Leaf nodes in that domain learn these routes with the next hop as the Controller that advertised them.

You can however disable default route injection for the GRT or a specific VRF on a Controller, to override this behavior.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
 

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```

2. Disable default route injection for the GRT or a specific VRF, on the Controller.

On the GRT:

```
dvr controller inject-default-route-disable
```

The `default` or the `no` operator enables injection of default routes for the GRT into the domain.

On a VRF instance:

```
dvr inject-default-route-disable
```

The `default` or the `no` operator enables injection of default routes for a specific VRF into the domain.

3. Verify the configuration.

On the GRT:

```
show dvr
```

On a VRF instance:

```
show dvr l3vsn
```

## Example

Disable injection of default routes for the GRT on a Controller.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#dvr controller inject-default-route-disable
Switch:1(config)#show dvr
```

```

## Configuring DvR route redistribution

### About This Task

Configure redistribution of direct or static routes into the DvR domain, on the Global Router or for a specific VRF instance.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
 

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```
2. Configure route redistribution of direct routes:
  - a. Configure route redistribution of direct routes on a VRF. The route type is internal.
 

```
dvr redistribute direct [metric <0-65535>] |[route-map WORD<1-64>]
```
  - b. Enable route redistribution.
 

```
dvr redistribute direct enable
```
  - c. Apply the configuration:
 

```
dvr apply redistribute direct
```
  - d. (Optional) Disable route redistribution of direct routes.
 

```
no dvr redistribute direct
```
3. Configure route redistribution of static routes:
  - a. Configure route redistribution of static routes on a VRF. The route type is external.
 

```
dvr redistribute static [metric <0-65535>] |[route-map WORD<1-64>]
```
  - b. Enable route redistribution.
 

```
dvr redistribute static enable
```
  - c. Apply the configuration.
 

```
dvr apply redistribute static
```
  - d. (Optional) Disable route redistribution of static routes.
 

```
no dvr redistribute static
```
4. Verify the route redistribution configuration. You can also verify it on a specific VRF instance.
 

```
show dvr redistribute [vrf WORD<1-16>]
```

### Example

Configure route redistribution of direct and static routes on the Global Router. Ensure that you apply the configuration.

```

Switch:1>enable
Switch:1#configure terminal

```

Enter configuration commands, one per line. End with CNTL/Z.

```
Switch:1(config)#dvr redistribute static
Switch:1(config)#dvr redistribute static metric 200
Switch:1(config)#dvr redistribute static enable
Switch:1(config)#dvr apply redistribute static
```

```
Switch:1(config)#dvr redistribute direct
Switch:1(config)#dvr redistribute direct metric 100
Switch:1(config)#dvr redistribute direct enable
Switch:1(config)#dvr apply redistribute direct
```

Verify configuration on the Global Router:

```
Switch:1(config)#show dvr redistribute
=====
                        DVR Redistribute List - GlobalRouter
=====
SOURCE MET MTYPE      ENABLE RPOLICY
-----
STAT   200 External   TRUE  -
LOC    100 Internal   TRUE  -
```

Configure redistribution of direct and static routes on the specific VRF instance `vrf1`. Ensure that you apply the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Switch:1(config)#router vrf vrf1
Switch:1(router-vrf)#dvr redistribute static
Switch:1(router-vrf)#dvr redistribute static metric 20000
Switch:1(router-vrf)#dvr redistribute static enable
Switch:1(router-vrf)#exit
Switch:1(config)#dvr apply redistribute static
```

```
Switch:1(router-vrf)#dvr redistribute direct
Switch:1(router-vrf)#dvr redistribute direct metric 10000
Switch:1(router-vrf)#dvr redistribute direct enable
Switch:1(router-vrf)#exit
Switch:1(config)#dvr apply redistribute static
```

Verify configuration on `vrf1`:

```
Switch:1(router-vrf)#show dvr redistribute vrf vrf1
=====
                        DVR Redistribute List - VRF vrf1
=====
SOURCE MET MTYPE      ENABLE RPOLICY
-----
STAT   20000 External   TRUE  -
LOC    10000 Internal   TRUE  -
```

### Variable definitions

Use the data in the following table to use the **dvr redistribute direct** or the **dvr redistribute static** commands.

| Variable                    | Value                                                                                             |
|-----------------------------|---------------------------------------------------------------------------------------------------|
| <i>enable</i>               | Enables DvR route redistribution on the VRF instance. Route redistribution is enabled by default. |
| <i>metric</i> <0-65535>     | Specifies the DvR route redistribution metric.                                                    |
| <i>route-map</i> WORD<1-64> | Specifies the route policy for DvR route redistribution.                                          |

Use the data in the following table to use the **show dvr redistribute** command.

| Variable              | Value                   |
|-----------------------|-------------------------|
| <i>vrf</i> WORD<1-16> | Specifies the VRF name. |

## Clearing DvR host entries

### About This Task

Clear DvR host entries (IPv4 remote host routes) on a Controller. The host entries are learned on the switch, either locally on its UNI port or dynamically from other nodes in the DvR domain.

#### Note

You can clear DvR host entries only on a DvR Controller.

An error message displays if you attempt clearing of host entries on a DvR Leaf node.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Clear the DvR host entries.

```
clear dvr host-entries [ipv4 {A.B.C.D}] | [l2isid <0-16777215>] |
[l3isid <0-16777215>]
```

### Example

In this example, you clear host entries for IP address 50.0.1.0 to clear host entries for IP addresses 50.0.1.2 and 50.0.1.3.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#clear dvr host-entries 50.0.1.0
```

### Variable definitions

Use the data in the following table to use the **clear dvr host-entries** command.

| Variable      | Value                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------|
| <i>ipv4</i>   | Specifies the IP address (IPv4) of the DvR host entries to clear.                                |
| <i>l2isid</i> | Specifies the Layer 2 VSN I-SID of the DvR host entries to clear<br>The range is 1 to 16777215.  |
| <i>l3isid</i> | Specifies the Layer 3 VSN I-SID of the DvR host entries to clear.<br>The range is 0 to 16777215. |

## Configuring a DvR Leaf

### About This Task

Perform this procedure to create a DvR domain with the domain ID that you specify, and configure the role of the node as a Leaf node. Configuring a node as a DvR Leaf automatically enables DvR globally on the node.

A Leaf node can belong to only one DvR domain.

#### Note

For a node to perform the role of both a Controller and a Leaf within the domain, you must configure it as a Controller.

#### Note

You must enable the VRF-scaling boot configuration flag on a DvR Leaf node, if more than 24 VRFs are required in the DvR domain.

For additional scaling information, see [VOSS Release Notes](#).

### Before You Begin

- You must enable the `dvr-leaf-mode` boot flag before you configure a node as a DvR Leaf node.

To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

#### Caution

Ensure that you save the current configuration on the switch, before you enable the flag. Enabling the flag removes all existing non-DvR configuration on the switch, such as platform VLANs and their IP address configuration, CLIP configuration, routing protocol configuration and VRF configuration. The gateway IPv4 address, if configured, is also removed.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure a node as a DvR Leaf.  

```
dvr leaf <1-255>
```
3. (Optional) Disable DvR on a DvR Leaf.  

```
no dvr Leaf
```

**Caution**

Disabling DvR on a Leaf node removes its membership with the DvR domain and all the dynamic content learned from the Controllers of that domain.

4. View a summary of the Leaf configuration.

```
show dvr
```

**Example**

Configure a node as a DvR Leaf:

```
Switch2:1>enable
Switch2:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch2:1(config)#boot config flags dvr-leaf-mode
Switch2:1(config)#save config
Switch2:1(config)#reset

Switch2:1(config)#dvr Leaf 5
Switch2:1(config)#show dvr

*Variable definitions*

Use the data in the following table to use the **dvr leaf** command.

| Variable | Value                                                                     |
|----------|---------------------------------------------------------------------------|
| <1-255>  | Specifies the domain ID of the DvR domain to which the Leaf node belongs. |

## Configuring vIST on a DvR Leaf node pair

### Before You Begin

Ensure that the nodes are configured as DvR Leaf nodes, before you configure vIST.

### About This Task

When you configure vIST on a DvR Leaf node pair, the switch generates an I-SID from the configured cluster ID. This I-SID is unique across the SPB network as long as the cluster ID is unique across the SPB network, for the vIST pair. You can configure only one instance of vIST on the Leaf node pair.

To configure vIST, both nodes must be Leaf nodes. You cannot configure vIST, for example, on a Controller-Leaf node pair.

Also both the nodes must belong to the same DvR domain. vIST configuration over Leaf nodes in different domains is not supported.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure vIST on the Leaf nodes:

```
dvr leaf virtual-ist {<A.B.C.D/X|<A.B.C.D> <A.B.C.D>} peer-ip
{A.B.C.D} cluster-id <1-1000>
```

3. (Optional) Disable vIST on the DvR Leaf node pair.

```
no dvr leaf virtual-ist
```

#### Caution

Disabling DvR on a Leaf node in a vIST pair removes all vIST configuration on that node, but not on the pair. The node on which DvR is disabled also loses its membership with the DvR domain and all the dynamic content learned from the Controllers in that domain.

If DvR is re-enabled on the node, you must manually configure vIST on that node again.

4. View a summary of vIST configuration on the Leaf nodes.

```
show dvr
```

### Example

Configure vIST on DvR Leaf nodes, with IP addresses 51.51.51.1 and 51.51.51.2 respectively:

```
Switch2:1>enable
Switch2:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch2:1(config)#dvr leaf virtual-ist 51.51.51.1 peer-ip 51.51.51.2 cluster-id 255
Switch2:1#show dvr

Virtual Ist ISID : 16677226

```

### Variable definitions

Use the data in the following table to use the **dvr leaf virtual-ist** command.

| Variable                            | Value                                                                          |
|-------------------------------------|--------------------------------------------------------------------------------|
| {<A.B.C.D/X <A.B.C.D><br><A.B.C.D>} | Specifies the local IP (IPv4) address and subnet mask of the node.             |
| {<A.B.C.D>}                         | Specifies the IP address (IPv4) of the vIST peer.                              |
| <1-1000>                            | Specifies the cluster ID of vIST.<br>It is set to 0 if vIST is not configured. |

## Configure a Management VLAN on a DvR Leaf Node

### About This Task

You cannot configure a platform VLAN directly on a DvR leaf node. However, you can configure a VLAN Management Instance on a DvR leaf node. After you configure the management VLAN, you can configure a platform VLAN.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
configure terminal
```
2. Create a management VLAN and associate it with an existing port-based VLAN:
 

```
mgmt vlan <2-4059>
```

#### Note

If you attempt to configure a VLAN ID that is already in use by DVR for created DVR interfaces, the following error message displays:

```
Error: This vlan id is already used by DVR. Please configure
another vlan id for the mgmt vlan
```

3. Create a platform VLAN:
 

```
vlan create <2-4059> [name WORD<0-64>] type port-mstprstp <0-63>
[color <0-32>]
```
4. Enter VLAN Management Instance mode:
 

```
mgmt vlan
```

5. Enable the management VLAN:

```
enable
```

### Variable Definitions

The following table defines parameters for the **mgmt vlan** command.

| Variable | Value                                                                            |
|----------|----------------------------------------------------------------------------------|
| <2-4059> | Specifies the existing port-based VLAN ID to associate with the management VLAN. |

The following table defines parameters for the **vlan create** command.

| Variable                                                                | Value                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <2-4059>                                                                | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <i>name</i> WORD<0-64>                                                  | Specifies the VLAN name. The name attribute is optional.                                                                                                                                                                                                                                                                                                                           |
| <i>type</i> port-<br><i>mstp</i> prstp <0-63><br>[ <i>color</i> <0-32>] | Creates a VLAN by port: <ul style="list-style-type: none"> <li>• &lt;0-63&gt; is the STP instance ID from 0 to 63.</li> <li>• <i>color</i> &lt;0-32&gt; is the color of the VLAN in the range of 0 to 32.</li> </ul> <p><b>Note:</b><br/>MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.</p>                                                               |

## Delete a Management VLAN on a DvR Leaf Node

You must perform deletion steps in the correct order.

If you attempt to delete the Management Instance VLAN before you delete the platform VLAN, the following error message displays:

```
Error: On a DVR leaf, the vlan must be deleted before the mgmt vlan instance
```

If you attempt to delete the platform VLAN before disabling the Management Instance VLAN, the following error message displays:

```
Error: Cannot delete vlan if mgmt vlan interface is enabled
```

### About This Task

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter VLAN Management Instance mode:  

```
mgmt vlan
```
3. Disable the management VLAN:  

```
no enable
```
4. Delete the platform VLAN:  

```
no vlan <2-4059>
```
5. Delete the management VLAN:  

```
no mgmt vlan
```

*Variable Definitions*

The following table defines parameters for the **no vlan** command.

| Variable | Value                                                |
|----------|------------------------------------------------------|
| <2-4059> | Specifies the ID of the platform VLAN to be deleted. |

## Moving a vIST Leaf node pair from one domain to another

### About This Task

Use this procedure to move a vIST Leaf node pair from one DvR domain to another.

For vIST to work properly, both Leaf nodes must be in the same domain.

### Procedure

1. Disable IS-IS on each vIST peer Leaf node, to remove the node from the SPB network.  

```
no router isis enable
```
2. Disable DvR on each Leaf node.  

```
no dvr leaf
```

#### Caution

Disabling DvR on a Leaf node in a vIST pair automatically removes all vIST configuration on that node, but not on the pair. The node on which DvR is disabled also loses its membership with the DvR domain and all the dynamic content learned from the Controllers in that domain.

When you re-enable DvR on the node, you must manually configure vIST on that node again.

3. Configure each node as a DvR Leaf node, with the new domain ID.  
 Ensure that you configure both nodes as Leaf nodes and with the same domain ID.  

```
dvr leaf <1-255>
```
4. Configure vIST on the DvR Leaf nodes.  

```
dvr leaf virtual-ist {<A.B.C.D/X|<A.B.C.D> <A.B.C.D>} peer-ip  
{A.B.C.D} cluster-id <1-1000>
```

5. Enable IS-IS on each vIST peer Leaf node, to add back the node to the SPB network.

```
router isis enable
```

### Example

Consider two vIST peer Leaf nodes Switch1 (IP address 51.51.51.1) and Switch2 (51.51.51.2) that belong to a DvR domain (with domain ID 4), that you need to move to another domain (with domain ID 5).

View a summary of existing Leaf configuration on each node.

```
Switch1:1(config)#show dvr

## Moving a vIST Controller pair from one domain to another

### About This Task

Use this procedure to move a vIST Controller node pair from one DvR domain to another.

For vIST to work properly, both Controller nodes must be in the same domain.

### Procedure

1. Disable IS-IS on each vIST peer Controller node, to remove the node from the SPB network.

```
no router isis enable
```

2. Disable DvR on each Controller node:

```
no dvr controller
```

#### Caution

Disabling DvR on a DvR Controller destroys the domain ID and all dynamic content learned within the DvR domain. However, the switch retains the VLAN specific configuration which you can view using the command **show running-config**.

3. Configure each node as a DvR Controller node, with the new domain ID. Ensure that you configure both nodes as Controller nodes and with the same domain ID.

```
dvr controller <1-255>
```

4. Enable IS-IS on each vIST peer Controller node, to add back the node to the SPB network.

```
router isis enable
```

### Example

Consider two vIST peer Controller nodes `Switch1` (IP address 51.51.51.3) and `Switch2` (51.51.51.4) that belong to a DvR domain (with domain ID 4), that you need to move to another domain (with domain ID 5).

View a summary of Controller configuration on each node:

```
Switch1:1(config)#show dvr
```

```

## Configure a non-DvR BEB to Join the DvR Backbone

### About This Task

Configure a non-DvR backbone edge bridge (BEB) to join the DvR backbone so that it can receive redistributed DvR host routes from all DvR Controllers in the SPB network.

#### Note

On a non-DVR BEB, the redistributed host routes from the DvR backbone are not automatically installed in the IP routing table. To utilize the backbone host routes to optimize traffic forwarding (forwarding in the data plane), you must explicitly configure an IS-IS accept policy with a backbone route policy using the command **accept backbone-route-map <route-map-name>**, and specifying a suitable route-map to select the list or range of DvR backbone host routes to be installed in the routing table.

For more information on configuring an IS-IS accept policy with a backbone route policy, see [Configuring IS-IS Accept Policies](#) on page 1371.

### Procedure

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
2. Configure a non-DvR BEB to join the DvR backbone.
 

```
[no] [[default] backbone enable
```
3. Verify the configuration using the following commands.
  - `show dvr backbone-members`
  - `show dvr backbone-members non-dvr-beb`
  - `show dvr backbone-entries`
  - `show isis`

### Example

```
Switch3:1>enable
Switch3:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch3:1(config)#router isis
Switch3:1(config-isis)#show dvr
```

```

## DvR show commands

The following section explains the show commands for DvR.

### Viewing DvR summary

Use this procedure to view a summary of the DvR configuration on a DvR Controller or a DvR Leaf.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View a summary of DvR configuration:  
show dvr

#### Example

View the information on a DvR Controller:

```
Switch:1#show dvr

=====
                        DVR Summary Info
=====
Domain ID      : 5
Domain ISID    : 16678219
Backbone ISID  : 16678216
```

```

Role : Controller
My SYS ID : 00:bb:00:00:81:21
Operational State : Up
GW MAC : 00:00:5e:00:01:25
InjectDefaultRouteDisable (GRT) : Enabled

```

View the information on a DvR Leaf:

```

Switch2:1#show dvr

=====
                        DVR Summary Info
=====
Domain ID : 5
Domain ISID : 16678219
Role : Leaf
My SYS ID : 00:bb:00:00:71:23
Operational State : Up
GW MAC : 00:00:5e:00:01:25
Inband Mgmt Clip IP : 72.54.44.1
Virtual Ist local address : 51.51.51.1
Virtual Ist local subnet mask : 255.255.255.0
Virtual Ist peer address : 51.51.51.2
Virtual Ist cluster-id : 255
Virtual Ist ISID : 16677226

```

*Viewing members of a DvR domain*

### About This Task

View the members of all DvR domains, namely the Controllers and Leaf nodes.

You can view this information on either a Controller or a Leaf node. Both the Controller and the Leaf node displays those members of the DvR domain to which it belongs.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. show dvr members [controller|leaf]

### Example

View all members of a DvR domain:

```

Switch:1#show dvr members

=====
                        DVR Members (Domain ID: 255)
=====
System Name           Nick-Name           Nodal MAC           Role
-----
Leaf-4:110            0.41.10            00:bb:00:00:41:10   Leaf
Leaf-1:Q:123         0.71.23            00:bb:00:00:71:23   Leaf
Leaf-2:K:124         0.71.24            00:bb:00:00:71:24   Leaf
Leaf-3:K:125         0.71.25            00:bb:00:00:71:25   Leaf
Ctrl-1:Q:121         0.81.21            00:bb:00:00:81:21   Controller

```

```
Ctrl-2:Q:122                0.81.22                00:bb:00:00:81:22        Controller
6 out of 6 Total Num of DVR Members displayed
-----
```

View member DvR Controllers:

```
Switch:1#show dvr members controller
-----
DVR Members (Domain ID: 255)
-----
System Name                Nick-Name                Nodal MAC                Role
-----
Ctrl-1:Q:121                0.81.21                00:bb:00:00:81:21        Controller
Ctrl-2:Q:122                0.81.22                00:bb:00:00:81:22        Controller
2 out of 6 Total Num of DVR Members displayed
-----
```

View member DvR Leaf nodes:

```
Switch:1#show dvr members leaf
-----
DVR Members (Domain ID: 255)
-----
System Name                Nick-Name                Nodal MAC                Role
-----
Leaf-4:110                0.41.10                00:bb:00:00:41:10        Leaf
Leaf-1:Q:123                0.71.23                00:bb:00:00:71:23        Leaf
Leaf-2:K:124                0.71.24                00:bb:00:00:71:24        Leaf
Leaf-3:K:125                0.71.25                00:bb:00:00:71:25        Leaf
4 out of 6 Total Num of DVR Members displayed
-----
```

### Viewing DvR interfaces

View the DvR interfaces on either a Controller or a Leaf node.

On Controllers, DvR interfaces are created when you configure IP on a DvR enabled Layer 2 VSN (VLAN, I-SID). Only Controllers display the administrative state of the interfaces because this is where you enable or disable the interfaces. The Leaf nodes display DvR interface information that is pushed from the Controllers, for example, subnet routes or gateway IP addresses for the Layer 2 VSNs.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. Enter Privileged EXEC mode:  
enable

- View the DvR interface information.

On a Controller:

```
show dvr interfaces [l3isid <0-16777215>] [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

On a Leaf node:

```
show dvr interfaces [l3isid <0-16777215>]
```

Viewing the DvR interface information for a specific VRF or VRF ID is not supported on a DvR Leaf node.

### Example

View DvR interfaces on a Controller node:

You can view DvR interface information on all interfaces or for a specific Layer 3 I-SID, VRF, or VRF ID.

```
Switch:1#show dvr interfaces

=====
DVR Interfaces
=====

```

## Variable definitions

Use the data in the following table to use the **show dvr interfaces** command.

| Variable      | Value                                                                         |
|---------------|-------------------------------------------------------------------------------|
| <i>l3isid</i> | Specifies the Layer 3 I-SID of the DvR interface. The range is 0 to 16777215. |
| <i>vrf</i>    | Specifies the VRF name.                                                       |
| <i>vrfids</i> | Specifies the VRF ID. The range is 0 to 512.                                  |

### Viewing DvR host entries

#### About This Task

View DvR host entries (IPv4 remote host routes) on either a Controller or a Leaf node. The node displays the host entries learned either locally on its Switched UNI port or dynamically from other nodes within the DvR domain.

#### Before You Begin

Ensure that you enable DvR globally on the node.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the DvR host entries.

On a Controller:

```
show dvr host-entries [domain-id <1-255>] [[ipv4 {A.B.C.D}]] [[l2isid <1-16777215>]] [[l3isid <0-16777215>]] [[nh-as-mac]] [[type <1-2>]] [[vrf WORD<1-16>]] [[vrfids WORD<0-512>]]
```

On a Leaf node:

```
show dvr host-entries [domain-id <1-255>] [[ipv4 {A.B.C.D}]] [[l2isid <1-16777215>]] [[l3isid <0-16777215>]] [[nh-as-mac]] [[type <1-2>]]
```

Viewing the DvR host entries for a specific VRF or VRF ID is not supported on a DvR Leaf node.

#### Example

View DvR host entries on either a Controller or a Leaf node.

Viewing the DvR host entries for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr host-entries domain-id 255 l3isid 55500

-----
DVR Host-Entries
-----
IP-ADDRESS      HOST          L3VSN      L2VSN      DOMAIN
MAC-ADDRESS     ISID         ISID       ISID       ID
TYPE            NEXT HOP
```

```

50.0.1.2      b0:ad:aa:42:ed:04  55500  50500  0      2/23  255      DYNAMIC  Cont-1:121
50.0.1.3      b0:ad:aa:4c:3d:01  55500  50500  0      cpp    255      LOCAL    Cont-2:122

2 out of 2 Total Num of DVR Host Entries displayed
-----

```

View DvR host entries for a specific IP address.

In this example, you enter IP address 50.0.1.0 to display host entries for IP addresses 50.0.1.2 and 50.0.1.3.

```

Switch:1#show dvr host-entries ipv4 50.0.1.0

-----
DVR Host-Entries
-----

1 out of 2 Total Num of DVR Host Entries displayed
-----

```

## Variable definitions

Use the data in the following table to use the **show dvr host-entries** command.

| Variable         | Value                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>domain-id</i> | Specifies the domain ID of the DvR host entry. The range is 1 to 255.                                                       |
| <i>ipv4</i>      | Specifies the IP address (IPv4) of the DvR host entry.                                                                      |
| <i>l2isid</i>    | Specifies the Layer 2 VSN I-SID of the DvR host entry. The range is 1 to 16777215.                                          |
| <i>l3isid</i>    | Specifies the Layer 3 VSN I-SID of the DvR host entry. The range is 0 to 16777215.                                          |
| <i>nh-as-mac</i> | Specifies the MAC address of the next hop node instead of the system name.                                                  |
| <i>type</i>      | Specifies the host type of the DvR host entry. A value of 1 indicates local hosts and a value of 2 indicates dynamic hosts. |
| <i>vrf</i>       | Specifies the VRF name of the DvR host entry.                                                                               |
| <i>vrfids</i>    | Specifies the VRF ID of the DvR host entry. The range is 0 to 512.                                                          |

## Viewing DvR routes

### About This Task

View the DvR routes (IPv4 network routes) on a DvR Controller or a Leaf node.

Controllers display all the IP subnet routes configured for that DvR domain. The Leaf nodes display the IP subnet routes that are learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. Leaf nodes also display routes that are redistributed by Controllers (direct routes, static routes and the default route), into the DvR domain.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the DvR routes.

On a Controller:

```
show dvr routes [ipv4 {A.B.C.D}]|[l3isid <0-16777215>]|[nh-as-mac] |
[vrf WORD<1-16>]|[vrfids WORD<0-512>]
```

On a Leaf node:

```
show dvr routes [ipv4 {A.B.C.D}]|[l3isid <0-16777215>]|[nh-as-mac]
```

Viewing the DvR routes for a specific VRF or VRF ID is not supported on a DvR Leaf node.

## Example

View DvR routes on either a Controller or a Leaf node.

Viewing the DvR routes for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr routes
-----
DVR Routes
-----
-----
DEST          MASK          NEXT          L3VSN        L2VSN

## Variable definitions

Use the data in the following table to use the **show dvr routes** command.

| Variable                         | Value                                                                        |
|----------------------------------|------------------------------------------------------------------------------|
| <i>ipv4 {A.B.C.D}</i>            | Specifies the IP address (IPv4) of the DvR route.                            |
| <i>l3isid &lt;0-16777215&gt;</i> | Specifies the Layer 3 I-SID of the DvR route.<br>The range is 0 to 16777215. |
| <i>nh-as-mac</i>                 | Specifies the MAC address of the next hop node instead of the system name.   |
| <i>vrf</i>                       | Specifies the VRF name of the DvR route.                                     |
| <i>vrfids</i>                    | Specifies the VRF ID of the DvR route.<br>The range is 0 to 512.             |

## Viewing DvR database information

### About This Task

View all DvR routes on a Controller or a Leaf node.

The Controller node displays all the IP subnet routes configured for that DvR domain. A Leaf node displays all IP subnet routes learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. It also displays the Host Routes (ARPs) learned from other DvR enabled nodes.

### Before You Begin

Ensure that DvR is enabled globally on the node.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the DvR database.

On a Controller:

```
show dvr database [home] [[ipv4 {A.B.C.D}]] [[l3isid<0-16777215>]] [[nh-as-
mac]] [[remote]] [[vrf WORD<1-16>]] [[vrfids WORD<0-512>]]
```

On a Leaf node:

```
show dvr database [home] [[ipv4 {A.B.C.D}]] [[l3isid<0-16777215>]] [[nh-as-
mac]] [[remote]]
```

Viewing the DvR database for a specific VRF or VRF ID is not supported on a DvR Leaf node.

### Example

View the DvR database on either a Controller or a Leaf node.

Viewing the DvR database for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr database

**Variable definitions**

Use the data in the following table to use the **show dvr database** command.

| Variable                         | Value                                                                              |
|----------------------------------|------------------------------------------------------------------------------------|
| <i>home</i>                      | Specifies the DvR database information for home instance.                          |
| <i>ipv4 {A.B.C.D}</i>            | Specifies the IP address (IPv4) of the DvR database entry.                         |
| <i>l3isid &lt;0-16777215&gt;</i> | Specifies the Layer 3 I-SID of the DvR database entry. The range is 0 to 16777215. |
| <i>nh-as-mac</i>                 | Specifies the MAC address of the next hop node instead of the system name.         |

| Variable      | Value                                                                  |
|---------------|------------------------------------------------------------------------|
| <i>remote</i> | Specifies the DvR database information for remote instance.            |
| <i>vrf</i>    | Specifies the VRF name of the DvR database entry.                      |
| <i>vrfids</i> | Specifies the VRF ID of the DvR database entry. The range is 0 to 512. |

Viewing DvR Backbone Entries

**About This Task**

View the DvR backbone entries (redistributed host routes) learned from all Controllers in all DvR domains.

**Note**

DvR backbone entries can be viewed only on a Controller. Viewing backbone entries is not applicable on a Leaf node.

**Before You Begin**

Ensure that you enable DvR globally on the node.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. View DvR backbone entries:  
show dvr backbone-entries [adv-controller WORD<1-255>] | [domain-id <1-255>] | [home] | [host-mac-address 0x00:0x00:0x00:0x00:0x00:0x00] | [ipv4 {A.B.C.D}] | [l2isid <1-16777215>] | [l3isid <0-16777215>] | [next-hop WORD<1-255>] | [nh-as-mac] | [remote]

**Example**

View all DvR backbone entries:

```
Switch:1#show dvr backbone-entries

## Variable definitions

Use the data in the following table to use the **show dvr backbone entries** command.

| Variable                                                        | Value                                                                              |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------|
| <i>adv-controller</i> <i>WORD</i> <1-255>                       | Specifies the system name of the advertising Controller.                           |
| <i>domain-id</i> <1-255>                                        | Specifies the domain ID of the DvR backbone entry. The range is 1 to 255.          |
| <i>home</i>                                                     | Display the DvR backbone entries for the home instance.                            |
| <i>host-mac-address</i><br><i>0x00:0x00:0x00:0x00:0x00:0x00</i> | Specifies the host MAC address of the DvR backbone entry.                          |
| <i>ipv4</i> { <i>A.B.C.D</i> }                                  | Specifies the IP address (IPv4) of the DvR backbone entry.                         |
| <i>l2isid</i> <1-16777215>                                      | Specifies the Layer 2 I-SID of the DvR backbone entry. The range is 1 to 16777215. |
| <i>l3isid</i> <0-16777215>                                      | Specifies the Layer 3 I-SID of the DvR backbone entry. The range is 0 to 16777215. |
| <i>next-hop</i> <i>WORD</i> <1-255>                             | Specifies the system name of the next hop node.                                    |
| <i>nh-as-mac</i>                                                | Specifies the MAC address of the next hop node instead of the system name.         |
| <i>remote</i>                                                   | Display the DvR backbone entries for the remote instance.                          |

*Viewing DvR backbone members***About This Task**

DvR backbone members are either DvR Controllers or non-DvR BEBs that receive redistributed host routes from all other DvR Controllers in the SPB network.

**Before You Begin**

Ensure that DvR is enabled globally on the node.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. View DvR backbone member information:  
show dvr backbone-members [controller | home | non-dvr-beb | remote]

**Example**

View all DvR backbone members:

```
Switch:1#show dvr backbone-members

=====
DVR BB Members
=====
System Name      Nick-Name      Nodal MAC      Role      Domain Id  Area      Area-Name
-----
DVR-D2-C1-40    0.82.40       00:00:82:84:40:00  NON-DVR-BEB  2          HOME      area-0.00.20
Ctrl1-2:8200:122 0.81.22       00:bb:00:00:81:22  Controller  2          HOME      area-0.00.20

Home: 2 out of 2 Total Num of DVR Backbone Members displayed
=====
```

View backbone members that are DvR controllers:

```
Switch:1#show dvr backbone-members controller

=====
DVR BB Members (Domain ID: 255)
=====
System Name      Nick-Name      Nodal MAC      Role      Domain Id  Area      Area-Name
-----
Ctrl1-2:8200:122 0.81.22       00:bb:00:00:81:22  Controller  2          HOME      area-0.00.20

Home: 1 out of 2 Total Num of DVR Backbone Members displayed
=====
```

View backbone members that are non-DvR BEBs:

```
Switch:1#show dvr backbone-members non-dvr-beb

=====
DVR BB Members
=====
System Name      Nick-Name      Nodal MAC      Role      Domain Id  Area      Area-Name
-----
DVR-D2-C1-40    0.82.40       00:00:82:84:40:00  NON-DVR-BEB  2          HOME      area-0.00.20
```

```
Home: 1 out of 2 Total Num of DVR Backbone Members displayed
-----
```

## Variable definitions

Use the data in the following table to use the **show dvr backbone-members** command.

| Variable           | Value                                                               |
|--------------------|---------------------------------------------------------------------|
| <i>controller</i>  | Specifies backbone members that are DvR Controllers.                |
| <i>home</i>        | Specifies DvR backbone members information for the home instance.   |
| <i>non-dvr-beb</i> | Specifies backbone members that are non-DvR BEBs.                   |
| <i>remote</i>      | Specifies DvR backbone members information for the remote instance. |

## Viewing Layer 3 VSN information

### About This Task

View VRFs corresponding to Layer 3 (routed) VSN I-SIDs on either a Controller or a Leaf node.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the Layer 3 VSN information:

```
show dvr l3vsn [l3isid <0-16777215>] | [vrf WORD<1-16>] | [vrfids
WORD<0-512>]
```

### Example

View Layer 3 VSN information on a DvR Controller:

```
Switch:1#show dvr l3vsn

=====
                        DVR L3VSN
=====
VRF ID          L3VSN ISID      VRF NAME      INJECT-DEFAULT-ROUTE-DISABLE
-----
1                55500           vrf600        Disabled
2                55501           vrf601        Disabled
3                55502           vrf602        Disabled
4                55503           vrf603        Disabled

4 out of 4 Total Num of DVR L3VSN displayed
-----
```

View Layer 3 VSN information on a DvR Leaf node:

```
Switch2:1#show dvr l3vsn
```

```

=====
                        DVR L3VSN
=====
VRF ID          L3VSN ISID      VRF NAME
-----
1                55500           vrf600
2                55501           vrf601
3                55502           vrf602

3 out of 3 Total Num of DVR L3VSN displayed
=====

```

### Variable definitions

Use the data in the following table to use the **show dvr l3vsn** command.

| Variable                               | Value                                                                     |
|----------------------------------------|---------------------------------------------------------------------------|
| <code>l3isid &lt;0-16777215&gt;</code> | Specifies the Layer 3 VSN I-SID. The range is 0 to 16777215.              |
| <code>vrf WORD&lt;1-16&gt;</code>      | Specifies the VRF name of the VRF corresponding to the Layer 3 VSN I-SID. |
| <code>vrfids WORD&lt;0-512&gt;</code>  | Specifies the VRF ID of the VRF.                                          |

### Viewing DvR domain redistribution information

#### About This Task

View DvR domain redistribution information on a Controller or a Leaf node.

#### Note

You can view DvR domain redistribution information only on a DvR Controller. An error message displays if you attempt to view this information on a DvR Leaf node.

#### Before You Begin

Ensure that you enable DvR globally on the node.

#### Procedure

- Enter Privileged EXEC mode:
 

```
enable
```
- View DvR domain redistribution information:
 

```
show dvr redistribute [vrf WORD<1-16>] | [vrfids WORD<0-512>]
```

#### Example

View DvR domain redistribution information on a Controller:

```

Switch:1#show dvr redistribute
=====
                        DVR Redistribute List - GlobalRouter
=====
SOURCE MET MTYPE          ENABLE RPOLICY
-----

```

```
STAT 1 External TRUE -
```

View DvR domain redistribution information for a particular VRF.

```
Switch:1#show dvr redistribute vrf vrf1
=====
DVR Redistribute List - VRF vrf1
=====
SOURCE MET MTYPE      ENABLE RPOLICY
-----
STAT  20000 External  TRUE  -
LOC   10000 Internal  TRUE  -
```

### Variable definitions

Use the data in the following table to use the **show dvr redistribute** command.

| Variable                        | Definitions                      |
|---------------------------------|----------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies the VRF name.          |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies the VRF ID of the VRF. |

### Configure a DvR Solution

The following section describes a simple configuration example to configure Distributed Virtual Routing (DvR) over a Fabric Connect (SPB) network.

### About This Task

In this example, you configure two DvR Controllers (with IP addresses 10.133.226.101 and 10.133.226.102) and two DvR Leaf nodes (with IP addresses 10.133.226.103 and

10.133.226.104), in a single DvR domain with domain ID 9. Hosts connect to the DvR nodes as shown in the figure.

### Before You Begin

On the switches to be configured as DvR Controllers:

- Ensure that you configure Fabric Connect.
- Ensure that you configure IP Shortcuts on the node. This is necessary for proper functioning of the node as a DvR Controller.
- Verify that the `dvr-leaf-mode` boot flag is disabled on the node. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

On the switches to be configured as DvR Leaf nodes:

- Ensure that you configure Fabric Connect.

### Procedure

#### DvR Controller configuration — Controller 1 and Controller 2:

1. Verify configuration of Fabric Connect on each of the switches to be configured as the DvR Controllers.

The following examples show verification on one of the switches. Perform this verification on both switches.

- a. Verify the SPB configuration:

```
Switch1:1>en
Switch1:1#show spbm
                    spbm : enable
                    ethertype : 0x8100
                    nick-name server : enable
                    nick-name allocation : static
                    nick-name server range : B.00.00-B.FF.FF

Switch1:1#show isis spbm

=====
                        ISIS SPBM Info
=====
SPBM      B-VID      PRIMARY      NICK      LSDB      IP      IPV6      MULTICAST      SPB-PIM-GW
INSTANCE  VLAN        NAME        TRAP
-----
1         4051-4052  4051        0.10.01  disable  enable  disable  enable        disable

=====
                        ISIS SPBM SMLT Info
=====
SPBM      SMLT-SPLIT-BEB      SMLT-VIRTUAL-BMAC      SMLT-PEER-SYSTEM-ID
INSTANCE
-----
1         primary            00:00:00:00:00:00

-----
Total Num of SPBM instances: 1
-----
```

- b. Verify the global IS-IS configuration:

```
Switch1:1#show isis

=====
                        ISIS General Info
=====

```

2. Configure the DvR Controllers.

- a. Configure Controller 1 (IP address 10.133.226.101) with DvR domain ID 9.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#dvr controller 9
Switch:1(config)#show dvr

=====
                        DVR Summary Info
=====

### Layer 2 VSN (VLAN) configuration on the DvR Controllers:

3. Configure Layer 2 VSN on the DvR Controllers, Controller 1 and Controller 2.
- Configure platform VLANs on Controller 1 (VLAN ID=200 and VLAN ID=202). Associate the VLANs with the I-SIDs 20200 and 20202 respectively. Configure gateway IPv4 addresses 20.0.1.1 and 20.2.1.1 respectively, and enable DvR on those interfaces.

```

Switch1:1(config)#vlan create 200 type port-mstprstp 0
Switch1:1(config)#vlan i-sid 200 20200
Switch1:1(config)#interface vlan 200
Switch1:1(config)#dvr gw-ipv4 20.0.1.1
Switch1:1(config)#dvr enable
Switch1:1(config)#ip address 20.0.1.2 255.255.0.0

Switch1:1(config)#vlan create 202 type port-mstprstp 0
Switch1:1(config)#vlan i-sid 202 20202
Switch1:1(config)#interface vlan 202
Switch1:1(config)#dvr gw-ipv4 20.2.1.1
Switch1:1(config)#dvr enable
Switch1:1(config)#ip address 20.2.1.2 255.255.0.0
Switch1:1(config)#exit
Switch1:1#

```

- Configure the platform VLANs on Controller 2. Ensure that you configure the same gateway IPv4 addresses on the corresponding VLANs, as on Controller 1.

```

Switch2:1(config)#vlan create 200 type port-mstprstp 0
Switch2:1(config)#vlan i-sid 200 20200
Switch2:1(config)#interface vlan 200
Switch2:1(config)#dvr gw-ipv4 20.0.1.1
Switch2:1(config)#dvr enable
Switch2:1(config)#ip address 20.0.1.3 255.255.0.0

Switch2:1(config)#vlan create 202 type port-mstprstp 0
Switch2:1(config)#vlan i-sid 202 20202
Switch2:1(config)#interface vlan 202
Switch2:1(config)#dvr gw-ipv4 20.2.1.1
Switch2:1(config)#dvr enable
Switch2:1(config)#ip address 20.2.1.3 255.255.0.0
Switch2:1(config)#exit
Switch2:1#

```

- c. Verify Layer 2 VSN (VLAN) configuration on the Controllers. The following example shows the verification on Controller 1. Perform this verification on both Controllers.  
View the DvR interfaces.

On Controllers, DvR interfaces are created when you configure IP on a DvR enabled Layer 2 VSN (VLAN, I-SID). You can also view the administrative state of these interfaces on the Controller.

```
Switch1:1#show dvr interfaces

=====
DVR Interfaces
=====
Interface      Mask      L3ISID  VRFID  L2ISID  VLAN  GW IPv4      Admin State      SPBMC State      IGMPC Version

### Layer 3 configuration on the DvR Controllers

#### 4. Configure Layer 3 (VRF) on the DvR Controllers, Controller 1 and Controller 2.

- a. Configure Layer 3 on Controller 1. As part of this configuration, you configure a VRF `vrf501` and associate it with a DvR VLAN.

```

Switch1:1(config)#ip vrf vrf501 vrfid 501
Switch1:1(config)#vlan create 501 type port-mstprstp 0
Switch1:1(config)#vlan i-sid 501 50501
Switch1:1(config)#interface Vlan 501
Switch1:1(config)#vrf vrf501
Switch1:1(config)#dvr gw-ipv4 50.1.1.1
Switch1:1(config)#dvr enable
Switch1:1(config)#ip address 50.1.1.2 255.255.0.0

Switch1:1(config)#router vrf vrf501
Switch1:1(router-vrf)#i-sid 55501
Switch1:1(router-vrf)#ipvpn enable
Switch1:1(router-vrf)#exit
Switch1:1(config)#

```

- b. Configure Layer 3 on Controller 2.

```

Switch2:1(config)#ip vrf vrf501 vrfid 501
Switch2:1(config)#vlan create 501 type port-mstprstp 0
Switch2:1(config)#vlan i-sid 501 50501
Switch2:1(config)#interface Vlan 501
Switch2:1(config)#vrf vrf501
Switch2:1(config)#dvr gw-ipv4 50.1.1.1
Switch2:1(config)#dvr enable
Switch2:1(config)#ip address 50.1.1.3 255.255.0.0

Switch2:1(config)#router vrf vrf501
Switch2:1(router-vrf)#i-sid 55501
Switch2:1(router-vrf)#ipvpn enable
Switch2:1(router-vrf)#exit
Switch2:1(config)#

```

- c. Verify Layer 3 configuration. The following example shows verification on Controller 1. Perform this verification on both Controllers.

View the DvR host entries.

```

Switch2:1(config)#show dvr host-entries l3isid 55501

### DvR Leaf configuration — Leaf 1 and Leaf 2

- Configure the boot flag `dvr-leaf-mode` on the switches to be configured as DvR Leaf nodes.

#### Caution

Ensure that you save the current configuration on the switch, before you enable the flag. Enabling the flag removes all existing non-DvR configuration on the switch, such as platform VLANs and their IP address configuration, CLIP configuration, routing protocol configuration and VRF configuration. The gateway IPv4 address, if configured, is also removed.

On switch with IP address 10.133.226.104, configure the boot flag and reboot the switch.

```

Switch3:1>en
Switch3:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch3:1(config)#boot config flags dvr-leaf-mode
Switch3:1(config)#save config
Switch3:1(config)#reset

```

On switch with IP address 10.133.226.105, configure the boot flag and reboot the switch.

```

Switch4:1>en
Switch4:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch4:1(config)#boot config flags dvr-leaf-mode
Switch4:1(config)#save config
Switch4:1(config)#reset

```

- After the switches come back up, configure the nodes as DvR Leaf nodes.

Configure switch with IP address 10.133.226.104 as DvR Leaf 1; verify the configuration.

```

Switch3:1(config)#dvr Leaf 9
Switch3:1(config)#show dvr

```

```

## DvR Configuration Using the EDM

The following sections describe configuration of Distributed Virtual Routing (DvR) using the Enterprise Device Manager (EDM).

### Configure a DvR Controller or a DvR Leaf Globally

#### About This Task

Configure a node to perform the role of either a Controller or a Leaf, within the DvR domain.

#### Before You Begin

#### Important

##### For DvR Leaf Configuration only:

You must enable the `dvr-leaf-mode` boot flag before you configure a node as a DvR Leaf node. Navigate to **Configuration > Edit > Chassis**. On the **Boot Config** tab, select **EnableDvrLeafMode**.

Ensure that you save the current configuration on the switch, before you enable the flag. Enabling the flag removes all non-DvR configuration on the switch.

#### Procedure

- In the navigation pane, expand the **Configuration > Edit** folders.

2. Click **DVR**.
3. Click the **Globals** tab.
4. Enter the domain ID in the **DomainId** field.

**Note**

A Controller or a Leaf node can belong to only one DvR domain.

5. Select the role of the node in the **Role** field.
6. (Optional) On a Controller node, disable injection of default routes into the DvR domain. Select **InjectDefaultRouteDisable**.

**Note**

This field applies only to Controllers. Attempting to select this field on a Leaf node displays an error message.

7. Update the fields as necessary, and then click **Apply** to save your configuration.

**Globals** Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Field                                                                                                | Descriptions                                                                                                                                                         |
|------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DomainId</b>                                                                                      | Uniquely identifies the domain that the node belongs to.<br>The range for a Controller or a Leaf is 1 to 255. Set to 0 if is not configured.                         |
| <b>Role</b>                                                                                          | Specifies the role of the node in the domain, that is, either a Controller or a Leaf.                                                                                |
| <b>Enable</b>                                                                                        | Specifies whether DvR is enabled on the node. Configuring a Controller or Leaf sets this parameter to true.                                                          |
| <b>DomainIsid</b>                                                                                    | Uniquely identifies the domain I-SID that the node belongs to.<br>The range is 16678217 to 16678727. 0 indicates that is not configured.                             |
| <b>BackboneIsid</b>                                                                                  | Uniquely identifies the backbone I-SID that the node belongs to.<br>The valid backbone I-SID is 16678216. It is set to 0 if is not configured.                       |
| <b>GatewayMac</b>                                                                                    | Specifies the Gateway MAC address used by all Domains.                                                                                                               |
| <b>InbandMgmtIp</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series. | Specifies the In-band Management IP address configured under IS-IS.<br>You can use this IP address to manage the node, irrespective of whether DvR is enabled on it. |

| Field                            | Descriptions                                                                                                                                                                                                                                                                                                          |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InjectDefaultRouteDisable</b> | Specifies whether injection of default routes is disabled on the Controller in the domain. By default, Controllers inject default routes into the domain so that all Leaf nodes in the domain learn these routes with the next hop as the Controller that advertised it. Selecting this field disables this behavior. |
| <b>VirtualIstLocalAddr</b>       | Specifies the local IP address of vIST, if vIST is configured on a Leaf.<br>vIST cannot be configured on a Controller.                                                                                                                                                                                                |
| <b>VirtualIstLocalMask</b>       | Specifies the local subnet mask of vIST, if vIST is configured on a Leaf.<br>vIST cannot be configured on a Controller.                                                                                                                                                                                               |
| <b>VirtualIstPeerAddr</b>        | Specifies the peer IP address of vIST, if vIST is configured on a Leaf.<br>vIST cannot be configured on a Controller.                                                                                                                                                                                                 |
| <b>VirtualIstClusterId</b>       | Specifies the cluster ID of vIST, if vIST is configured on a Leaf.<br>vIST cannot be configured on a Controller.<br>Set to 0 if vIST is not configured.                                                                                                                                                               |
| <b>VirtualIstIsid</b>            | Specifies the I-SID if vIST is configured.                                                                                                                                                                                                                                                                            |
| <b>OperState</b>                 | Specifies the operational state of the node.                                                                                                                                                                                                                                                                          |

## View DvR Routes

### About This Task

View the DvR routes (host routes and the IPv4 network routes) that are learned on a DvR Controller or a Leaf node.

Controllers display all the IP subnet routes configured for that DvR domain. Leaf nodes display the IP subnet routes learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. Leaf nodes also display any redistributed routes into the DvR Domain that are learned from the Controllers (direct routes, static routes and the default route).

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Routes** tab.
4. To filter the rows based on the specific criteria, click **Filter**.

### *Routes field descriptions*

Use the data in the following table to use the **Routes** tab.

| Name                  | Description                                                     |
|-----------------------|-----------------------------------------------------------------|
| <b>DestIpAddrType</b> | Specifies the IPv4 destination address type of the DvR route.   |
| <b>DestIpAddr</b>     | Specifies the IPv4 destination address of the DvR route.        |
| <b>DestMask</b>       | Specifies the destination mask of the DvR route.                |
| <b>L3lsid</b>         | Specifies the Layer 3 I-SID of the DvR route.                   |
| <b>EcmpIndex</b>      | Specifies the ECMP index for the ECMP routes of the DvR route.  |
| <b>NextHopMac</b>     | Specifies the MAC address of the next hop BEB in the DvR route. |
| <b>L2lsid</b>         | Specifies the Layer 2 I-SID of the DvR route.                   |
| <b>VrfId</b>          | Specifies the VRF ID.                                           |
| <b>Cost</b>           | Specifies the SPB cost of the DvR route.                        |
| <b>NextHopName</b>    | Specifies the host name of the next hop BEB, in the DvR route.  |
| <b>Type</b>           | Specifies the route type of the DvR route.                      |

## View Members of a DvR Domain

### About This Task

View the members of all DvR domains namely the Controllers and Leaf nodes.

You can view this information on either a Controller or a Leaf node. Both the Controller and the Leaf node displays the members of the DvR domain to which it belongs.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **DVR**.
3. Select the **Members** tab.
4. (Optional) To filter the rows based on specific criteria, click **Filter**.

### *Members* field descriptions

Use the data in the following table to use the **Members** tab.

| Name              | Description                                                          |
|-------------------|----------------------------------------------------------------------|
| <b>MacAddress</b> | Specifies the system ID or the nodal MAC address of this DvR member. |
| <b>SysName</b>    | Specifies the system name of this DvR member.                        |

| Name            | Description                                                            |
|-----------------|------------------------------------------------------------------------|
| <b>NickName</b> | Specifies the nick name of this DvR member.                            |
| <b>Role</b>     | Specifies the DvR role (Controller or Leaf) of this DvR member.        |
| <b>DomainId</b> | Specifies the domain ID of the DvR domain that this member belongs to. |

## View DvR Backbone Members

### About This Task

DvR backbone members are either DvR Controllers or non-DvR BEBs that receive redistributed host routes from all other DvR Controllers in the SPB network.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Backbone Members** tab.
4. (Optional) To filter the rows based on specific criteria, click **Filter**.

### **Backbone Members** field descriptions

Use the data in the following table to use the **Backbone Members** tab.

| Name              | Description                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>MacAddress</b> | Specifies the system ID or the nodal MAC address of this DvR backbone member.                                            |
| <b>SysName</b>    | Specifies the system name of this DvR backbone member.                                                                   |
| <b>NickName</b>   | Specifies the nick name of this DvR backbone member.                                                                     |
| <b>Role</b>       | Specifies the role of this DvR backbone member. It is either a DvR Controller or a non-DvR BEB.                          |
| <b>DomainId</b>   | Specifies the domain ID of the DvR domain that this backbone member belongs to.<br>The domain ID is 0 for a non-DvR BEB. |

## View Remote DvR Backbone Members

### Note

This procedure only applies to the VSP 7400 Series.

### Before You Begin

Ensure that you enable DvR globally on the node.

### About This Task

Perform this procedure to view the remote DvR backbone members. DvR backbone members are either DvR Controllers or non-DvR BEBs that receive redistributed host routes from all other DvR Controllers in the SPB network.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **DVR Remote**.
3. Select the **Backbone Members** tab.
4. (Optional) To filter the rows based on specific criteria, click **Filter**.

### **Backbone Members** Field Descriptions

Use the data in the following table to use the **Backbone Members** tab.

| Name              | Description                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>MacAddress</b> | Specifies the system ID or the nodal MAC address of this DvR backbone member.                                         |
| <b>SysName</b>    | Specifies the system name of this DvR backbone member.                                                                |
| <b>NickName</b>   | Specifies the nick name of this DvR backbone member.                                                                  |
| <b>Role</b>       | Specifies the role of this DvR backbone member. It is either a DvR Controller or a non-DvR BEB.                       |
| <b>DomainId</b>   | Specifies the domain ID of the DvR domain that this backbone member belongs to. The domain ID is 0 for a non-DvR BEB. |

## View DvR Interfaces

### About This Task

View the DvR interfaces on either a Controller or a Leaf node.

On Controllers, DvR interfaces are created when you configure IP on a DvR enabled Layer 2 VSN (VLAN, I-SID). Only Controllers display the administrative state of the interfaces because this is where you enable or disable the interfaces. On a Leaf node, the DvR interface information that the Controllers push, for example, subnet routes and the gateway IP addresses for the Layer 2 VSNs, are displayed.

### Before You Begin

Ensure that you enable DvR globally on the node.

## Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Interfaces** tab.  
Click **Filter** to filter rows based on specific filter criteria.

### *Interfaces* field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name                  | Description                                                                    |
|-----------------------|--------------------------------------------------------------------------------|
| <b>VlanIpAddrType</b> | Specifies the VLAN IP address type of the DvR interface.                       |
| <b>VlanIpAddr</b>     | Specifies the VLAN IP address (IPv4) of the DvR interface.                     |
| <b>L3Isid</b>         | Specifies the Layer 3 I-SID of the DvR interface. The range is 1 to 16777215.  |
| <b>L2Isid</b>         | Specifies the Layer 2 I-SID of the DvR interface. The range is 1 to 16777215.  |
| <b>VlanIpMask</b>     | Specifies the VLAN IP address mask of the DvR interface.                       |
| <b>Vrfid</b>          | Specifies the VRF ID of the DvR interface. The VRF ID is 0 for the GRT.        |
| <b>VlanId</b>         | Specifies the VLAN ID of the DvR interface.                                    |
| <b>GwIpAddrType</b>   | Specifies the address type of the DvR gateway IP address (IPv4).               |
| <b>GwIpAddr</b>       | Specifies the DvR gateway IP address (IPv4).                                   |
| <b>AdminState</b>     | Specifies the administrative state of the DvR interface.                       |
| <b>SpbmcState</b>     | Specifies the state of IP Multicast over Fabric Connect, on the DvR interface. |
| <b>IgmpVersion</b>    | Specifies the version of IGMP that runs on the DvR interface.                  |

## View DvR Host Entries

### About This Task

View DvR host entries (IPv4 remote ARPs) on either a Controller or a Leaf node. The node displays the host entries learned either locally on its UNI port or dynamically from other nodes in the DvR domain.

### Before You Begin

Ensure that you enable DvR globally on the node.

## Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Host Entries** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

### *Host Entries* field descriptions

Use the data in the following table to use the **Host Entries** tab.

| Name               | Description                                                         |
|--------------------|---------------------------------------------------------------------|
| <b>IpAddrType</b>  | Specifies the address type of the DvR host entry (IPv4 remote ARP). |
| <b>IpAddr</b>      | Specifies the IPv4 address of the DvR host entry.                   |
| <b>Mask</b>        | Specifies the subnet mask of the DvR host entry.                    |
| <b>L3lsid</b>      | Specifies the Layer 3 I-SID of the DvR host entry.                  |
| <b>MacAddr</b>     | Specifies the MAC address of the DvR host entry.                    |
| <b>L2lsid</b>      | Specifies the Layer 2 I-SID of the DvR host entry.                  |
| <b>Vrfid</b>       | Specifies the VRF ID associated with the DvR host entry.            |
| <b>Port</b>        | Specifies the port of the DvR host entry.                           |
| <b>DomainId</b>    | Specifies the DvR domain ID of the DvR host entry.                  |
| <b>Type</b>        | Specifies the host type of the DvR host entry.                      |
| <b>NextHopName</b> | Specifies the next hop system name of the DvR host entry.           |
| <b>NextHopMac</b>  | Specifies the next hop system MAC address of the DvR host entry.    |
| <b>ClearEntry</b>  | Clears the entry if the configured value is true.                   |

## View Remote DvR Host Entries

### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to view the remote DvR host entries (IPv4 remote ARPs) on either a Controller or a Leaf node. The node displays the host entries learned either locally on its UNI port or dynamically from other nodes in the DvR domain.

### Before You Begin

Ensure that you enable DvR globally on the node.

## Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **DVR Remote**.
3. Select the **Host Entries** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

### *Host Entries* Field Descriptions

Use the data in the following table to use the **Host Entries** tab.

| Name               | Description                                                         |
|--------------------|---------------------------------------------------------------------|
| <b>IpAddrType</b>  | Specifies the address type of the DvR host entry (IPv4 remote ARP). |
| <b>IpAddr</b>      | Specifies the IPv4 address of the DvR host entry.                   |
| <b>Mask</b>        | Specifies the subnet mask of the DvR host entry.                    |
| <b>L3lsid</b>      | Specifies the Layer 3 I-SID of the DvR host entry.                  |
| <b>MacAddr</b>     | Specifies the MAC address of the DvR host entry.                    |
| <b>L2lsid</b>      | Specifies the Layer 2 I-SID of the DvR host entry.                  |
| <b>Vrfid</b>       | Specifies the VRF ID associated with the DvR host entry.            |
| <b>Port</b>        | Specifies the port of the DvR host entry.                           |
| <b>DomainId</b>    | Specifies the DvR domain ID of the DvR host entry.                  |
| <b>Type</b>        | Specifies the host type of the DvR host entry.                      |
| <b>NextHopName</b> | Specifies the next hop system name of the DvR host entry.           |
| <b>NextHopMac</b>  | Specifies the next hop system MAC address of the DvR host entry.    |
| <b>ClearEntry</b>  | Clears the entry if the configured value is true.                   |

## Clear DvR Host Entries

### About This Task

Clear DvR host entries (IPv4 remote host routes) on a Controller. The host entries are learned on the switch either locally on its UNI port or dynamically from other nodes in the DvR domain.

#### Note

You can clear DvR host entries only on a DvR Controller.

An error message displays if you attempt clearing of host entries on a DvR Leaf node.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Clear Host Entries** tab.
4. Update the fields as necessary, and then click **Apply** to save your configuration.

### *Clear Host Entries* field descriptions

Use the data in the following table to use the **Clear Host Entries** tab.

| Name               | Description                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ClearAll</b>    | Select to clear all DvR host entries.                                                                                                                     |
| <b>ClearIpv4</b>   | Specifies the IPv4 address of the DvR host entries to clear.<br>The IPv4 address must not be the VLAN IP address on any Controller within the DvR domain. |
| <b>ClearL2Isid</b> | Specifies the Layer 2 VSN I-SID of the DvR host entries to clear.<br>The range is 0 to 16777215.                                                          |
| <b>ClearL3Isid</b> | Specifies the Layer 3 VSN I-SID of the DvR host entries to clear.<br>The range is 0 to 16777215.                                                          |

## View Layer 3 VSN Information

### About This Task

View VRFs corresponding to Layer 3 (routed) VSN I-SIDs on either a Controller or a Leaf node.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **L3-VSN** tab.

Click **Filter** to filter rows based on specific filter criteria.

### *L3-VSN* field descriptions

Use the data in the following table to use the **L3-VSN** tab.

| Name         | Description                                                             |
|--------------|-------------------------------------------------------------------------|
| <b>Vrfid</b> | Specifies the VRF ID of the VRF corresponding to the Layer 3 VSN I-SID. |
| <b>Isid</b>  | Specifies the Layer 3 VSN I-SID.                                        |

| Name                             | Description                                                               |
|----------------------------------|---------------------------------------------------------------------------|
| <b>VrfName</b>                   | Specifies the VRF name of the VRF corresponding to the Layer 3 VSN I-SID. |
| <b>InjectDefaultRouteDisable</b> | Specifies whether injection of default routes is disabled.                |

## View the DvR Database

### About This Task

View all DvR routes on a Controller or a Leaf node.

The Controller node displays all the IP subnet routes configured for that DvR domain. A Leaf node displays all IP subnet routes learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. It also displays the Host Routes (ARPs) learned from other DvR enabled nodes.

### Before You Begin

Ensure that you enable DvR on the node.

### Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Database** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

### *Database field descriptions*

Use the data in the following table to use the **Database** tab.

| Name                  | Description                                                                           |
|-----------------------|---------------------------------------------------------------------------------------|
| <b>DestIpAddrType</b> | Specifies the address type of the IPv4 destination address of the DvR database entry. |
| <b>DestIpAddr</b>     | Specifies the IPv4 destination address of the DvR database entry.                     |
| <b>DestMask</b>       | Specifies the destination mask of the DvR database entry.                             |
| <b>L3Isid</b>         | Specifies the Layer 3 I-SID of the DvR database entry.                                |
| <b>EcmpIndex</b>      | Specifies the ECMP index for the DvR database entry.                                  |
| <b>NextHop</b>        | Specifies the MAC address of the next hop BEB, in the DvR database entry.             |
| <b>L2Isid</b>         | Specifies the Layer 2 I-SID of the DvR database entry.                                |
| <b>VrfId</b>          | Specifies the VRF ID for the DvR database entry.                                      |

| Name                     | Description                                                                   |
|--------------------------|-------------------------------------------------------------------------------|
| <b>OutgoingInterface</b> | Specifies the outgoing interface (port or MLT) of the DvR database entry.     |
| <b>SpbCost</b>           | Specifies the SPB cost of the DvR database entry.                             |
| <b>PrefixCost</b>        | Specifies the prefix cost of the DvR database entry.                          |
| <b>NextHopName</b>       | Specifies the host name of the next hop BEB, in the DvR database table entry. |
| <b>Age</b>               | Specifies the uptime since creation of the DvR database table entry.          |

## View the Remote DvR Database

### Note

This procedure only applies to the VSP 7400 Series.

### Before You Begin

Ensure that you enable DvR on the node.

### About This Task

Perform this procedure to view all remote DvR routes on a Controller or a Leaf node.

The Controller node displays all the IP subnet routes configured for that DvR domain. A Leaf node displays all IP subnet routes learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. It also displays the Host Routes (ARPs) learned from other DvR enabled nodes.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **DVR Remote**.
3. Select the **Database** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

### *Database Field Descriptions*

Use the data in the following table to use the **Database** tab.

| Name                  | Description                                                                           |
|-----------------------|---------------------------------------------------------------------------------------|
| <b>DestIpAddrType</b> | Specifies the address type of the IPv4 destination address of the DvR database entry. |
| <b>DestIpAddr</b>     | Specifies the IPv4 destination address of the DvR database entry.                     |
| <b>DestMask</b>       | Specifies the destination mask of the DvR database entry.                             |

| Name                     | Description                                                                   |
|--------------------------|-------------------------------------------------------------------------------|
| <b>L3lsid</b>            | Specifies the Layer 3 I-SID of the DvR database entry.                        |
| <b>EcmpIndex</b>         | Specifies the ECMP index for the DvR database entry.                          |
| <b>NextHop</b>           | Specifies the MAC address of the next hop BEB, in the DvR database entry.     |
| <b>L2lsid</b>            | Specifies the Layer 2 I-SID of the DvR database entry.                        |
| <b>Vrfid</b>             | Specifies the VRF ID for the DvR database entry.                              |
| <b>OutgoingInterface</b> | Specifies the outgoing interface (port or MLT) of the DvR database entry.     |
| <b>SpbCost</b>           | Specifies the SPB cost of the DvR database entry.                             |
| <b>PrefixCost</b>        | Specifies the prefix cost of the DvR database entry.                          |
| <b>NextHopName</b>       | Specifies the host name of the next hop BEB, in the DvR database table entry. |
| <b>Age</b>               | Specifies the uptime since creation of the DvR database table entry.          |

## View DvR Backbone Entries on a Controller

### About This Task

View the DvR backbone entries (redistributed host routes) learned from all Controllers in all DvR domains.

#### Note

You can view DvR backbone entries only on a Controller. Viewing backbone entries does not apply to a Leaf node.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. In the navigation pane, expand **Configuration** > **Edit** folders.
2. Select **DVR**.
3. Select the **Backbone Entries** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

### **Backbone Entries** field descriptions

Use the data in the following table to use the **Backbone Entries** tab.

| Name                     | Description                                                               |
|--------------------------|---------------------------------------------------------------------------|
| <b>IpAddrType</b>        | Specifies the address type of the DvR backbone host (IPv4 remote ARP).    |
| <b>IpAddr</b>            | Specifies the IPv4 address of the DvR backbone host.                      |
| <b>L3lsid</b>            | Specifies the Layer 3 I-SID of the DvR backbone host.                     |
| <b>DomainId</b>          | Specifies the domain ID of the DvR backbone host.                         |
| <b>EcmpIndex</b>         | Specifies the ECMP index of the DvR backbone host.                        |
| <b>HostMacAddr</b>       | Specifies the MAC address of DvR backbone host.                           |
| <b>L2lsid</b>            | Specifies the Layer 2 I-SID of the DvR backbone host.                     |
| <b>AdvControllerName</b> | Specifies the host name of the advertising Controller.                    |
| <b>AdvController</b>     | Specifies the host MAC address of the advertising Controller.             |
| <b>NextHopName</b>       | Specifies the host name of the next hop Backbone host in the DvR route.   |
| <b>NextHopMac</b>        | Specifies the MAC address of the next hop Backbone host in the DvR route. |

## View Remote DvR Backbone Entries on a Controller

### Note

This procedure only applies to the VSP 7400 Series.

### Before You Begin

Ensure that you enable DvR globally on the node.

### About This Task

Perform this procedure to view the remote DvR backbone entries (redistributed host routes) learned from all Controllers in all DvR domains.

### Note

You can view DvR backbone entries only on a Controller. Viewing backbone entries does not apply to a Leaf node.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **DVR Remote**.
3. Select the **Backbone Entries** tab.

4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

### **Backbone Entries** Field Descriptions

Use the data in the following table to use the **Backbone Entries** tab.

| Name                     | Description                                                               |
|--------------------------|---------------------------------------------------------------------------|
| <b>IpAddrType</b>        | Specifies the address type of the DvRbackbone host (IPv4 remote ARP).     |
| <b>IpAddr</b>            | Specifies the IPv4 address of the DvR backbone host.                      |
| <b>L3Isid</b>            | Specifies the Layer 3 I-SID of the DvR backbone host.                     |
| <b>DomainId</b>          | Specifies the domain ID of the DvR backbone host.                         |
| <b>EcmpIndex</b>         | Specifies the ECMP index of the DvR backbone host.                        |
| <b>HostMacAddr</b>       | Specifies the MAC address of DvR backbone host.                           |
| <b>L2Isid</b>            | Specifies the Layer 2 I-SID of the DvR backbone host.                     |
| <b>AdvControllerName</b> | Specifies the host name of the advertising Controller.                    |
| <b>AdvController</b>     | Specifies the host MAC address of the advertising Controller.             |
| <b>NextHopName</b>       | Specifies the host name of the next hop Backbone host in the DvR route.   |
| <b>NextHopMac</b>        | Specifies the MAC address of the next hop Backbone host in the DvR route. |

## View DvR Multi-area SPB Backbone Entries on a Controller

### Note

This procedure only applies to the VSP 7400 Series.

### Before You Begin

Enable Distributed Virtual Routing (DvR) globally on the node.

### About This Task

Perform this procedure to view the DvR Multi-area SPB backbone entries that the system learns from all Controllers in all DvR domains.

### Note

You can view the backbone entries only on a DvR Controller. Viewing backbone entries does not apply to a DvR Leaf node.

**Procedure**

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Select **DVR**.
3. Select the **MultiArea Backbone Entries** tab.
4. (Optional) Select the **Filter** button to filter the rows on basis of specific criteria.

**MultiArea Backbone Entries** Field Descriptions

Use the data in the following table to use the **MultiArea Backbone Entries** tab.

| Name                     | Description                                                               |
|--------------------------|---------------------------------------------------------------------------|
| <b>IpAddrType</b>        | Specifies the address type of the DvR backbone host (IPv4 remote ARP).    |
| <b>IpAddr</b>            | Specifies the IPv4 address of the DvR backbone host.                      |
| <b>L3lsid</b>            | Specifies the Layer 3 I-SID of the DvR backbone host.                     |
| <b>DomainId</b>          | Specifies the domain ID of the DvR backbone host.                         |
| <b>EcmpIndex</b>         | Specifies the ECMP index of the DvR backbone host.                        |
| <b>HostMacAddr</b>       | Specifies the MAC address of DvR backbone host.                           |
| <b>L2lsid</b>            | Specifies the Layer 2 I-SID of the DvR backbone host.                     |
| <b>AdvControllerName</b> | Specifies the host name of the advertising Controller.                    |
| <b>AdvController</b>     | Specifies the host MAC address of the advertising Controller.             |
| <b>NextHopName</b>       | Specifies the host name of the next hop Backbone host in the DvR route.   |
| <b>NextHopMac</b>        | Specifies the MAC address of the next hop Backbone host in the DvR route. |
| <b>Area</b>              | Specifies the type of area as home or remote.                             |

## View Remote DvR Multi-area SPB Backbone Entries on a Controller

**Note**

This procedure only applies to the VSP 7400 Series.

**Before You Begin**

Enable Distributed Virtual Routing (DvR) globally on the node.

## About This Task

Perform this procedure to view the remote DvR Multi-area SPB backbone entries that the system learns from all Controllers in all DvR domains.

### Note

You can view the backbone entries only on a DvR Controller. Viewing backbone entries does not apply to a DvR Leaf node.

## Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **DVR Remote**.
3. Select the **MultiArea Backbone Entries** tab.
4. (Optional) Select the **Filter** button to filter the rows on basis of specific criteria.

### **MultiArea Backbone Entries** Field Descriptions

Use the data in the following table to use the **MultiArea Backbone Entries** tab.

| Name                     | Description                                                               |
|--------------------------|---------------------------------------------------------------------------|
| <b>IpAddrType</b>        | Specifies the address type of the DvR backbone host (IPv4 remote ARP).    |
| <b>IpAddr</b>            | Specifies the IPv4 address of the DvR backbone host.                      |
| <b>L3Isid</b>            | Specifies the Layer 3 I-SID of the DvR backbone host.                     |
| <b>DomainId</b>          | Specifies the domain ID of the DvR backbone host.                         |
| <b>EcmpIndex</b>         | Specifies the ECMP index of the DvR backbone host.                        |
| <b>HostMacAddr</b>       | Specifies the MAC address of DvR backbone host.                           |
| <b>L2Isid</b>            | Specifies the Layer 2 I-SID of the DvR backbone host.                     |
| <b>AdvControllerName</b> | Specifies the host name of the advertising Controller.                    |
| <b>AdvController</b>     | Specifies the host MAC address of the advertising Controller.             |
| <b>NextHopName</b>       | Specifies the host name of the next hop Backbone host in the DvR route.   |
| <b>NextHopMac</b>        | Specifies the MAC address of the next hop Backbone host in the DvR route. |
| <b>Area</b>              | Specifies the type of area as home or remote.                             |

|                                       | XA1400 Series   | Not Supported      |

## EAPoL

Extensible Authentication Protocol over LAN (EAPoL or EAP) is a port-based network access control protocol. EAP provides security by preventing users from accessing network resources before they are authenticated. The EAP authentication feature prevents users from accessing a network to assume a valid identity and access confidential material or launch denial-of-service attacks.

You can use EAP to set up network access control on internal LANs and to exchange authentication information between an end station or server that connects to a switch and an authentication server (such as a RADIUS server). This security feature extends the benefits of remote authentication to internal LAN clients. For example, if a new client PC fails the authentication process, EAP prevents the new client PC from accessing the network.

## EAP terminology

This section lists some components and terms used with EAP-based security.

- Supplicant—a device, such as a PC, that applies for access to the network.
- Authenticator—software on a switch that authorizes or rejects a Supplicant attached to the other end of a LAN segment.
  - Port Access Entity (PAE)—software that controls each port on the device. The PAE, which resides on the switch, supports the Authenticator functionality.
  - Controlled Port—any port on the device with EAP enabled.
- Authentication Server—a RADIUS server that provides AAA services to the authenticator.

## EAP Configuration Considerations

This section lists EAP configuration considerations.

- You must configure at least one EAP RADIUS server and shared secret fields.
- You cannot configure EAP on ports that are currently configured for the following:
  - Shared segments
  - MultiLink Trunking
- Change the authentication status to auto for each port that you want to control. The *auto* setting automatically authenticates the port according to the results of the RADIUS server. The default authentication setting for each port is *authorized*.
- When multiple clients are authenticated on the same port, the priority of the latest incoming client is applied on the port, and this priority is retained until all the clients log out on that port.

### Configuration Process

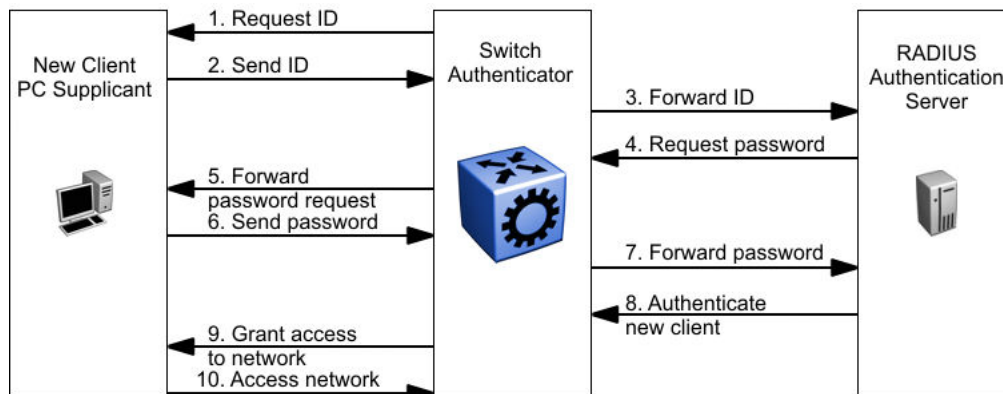

The Authenticator facilitates the authentication exchanges that occur between the Supplicant and the Authentication Server. The Authenticator PORT ACCESS ENTITY (PAE) encapsulates the EAP message into a RADIUS packet, and then sends the packet to the Authentication Server.

The Authenticator manages the access to controlled port. At system initialization, or when a Supplicant initially connects to one of the controlled ports on the device, the system blocks data traffic of the Supplicant until gets authenticated. After the Authentication Server notifies the Authenticator PAE about the success or failure of the authentication, the Authenticator decides whether to permit/deny the traffic of client on controlled port.

non-EAPoL (NEAP) frames transmit according to the following rules:

- If authentication succeeds, the client blocked from accessing is allowed to the controlled port, which means the system allows all the incoming and outgoing traffic from that client through the port.
- If authentication fails, client is blocked from accessing, which means both incoming and outgoing traffic is not allowed to client.

The following figure illustrates how the switch, configured with EAP, reacts to a new network connection.

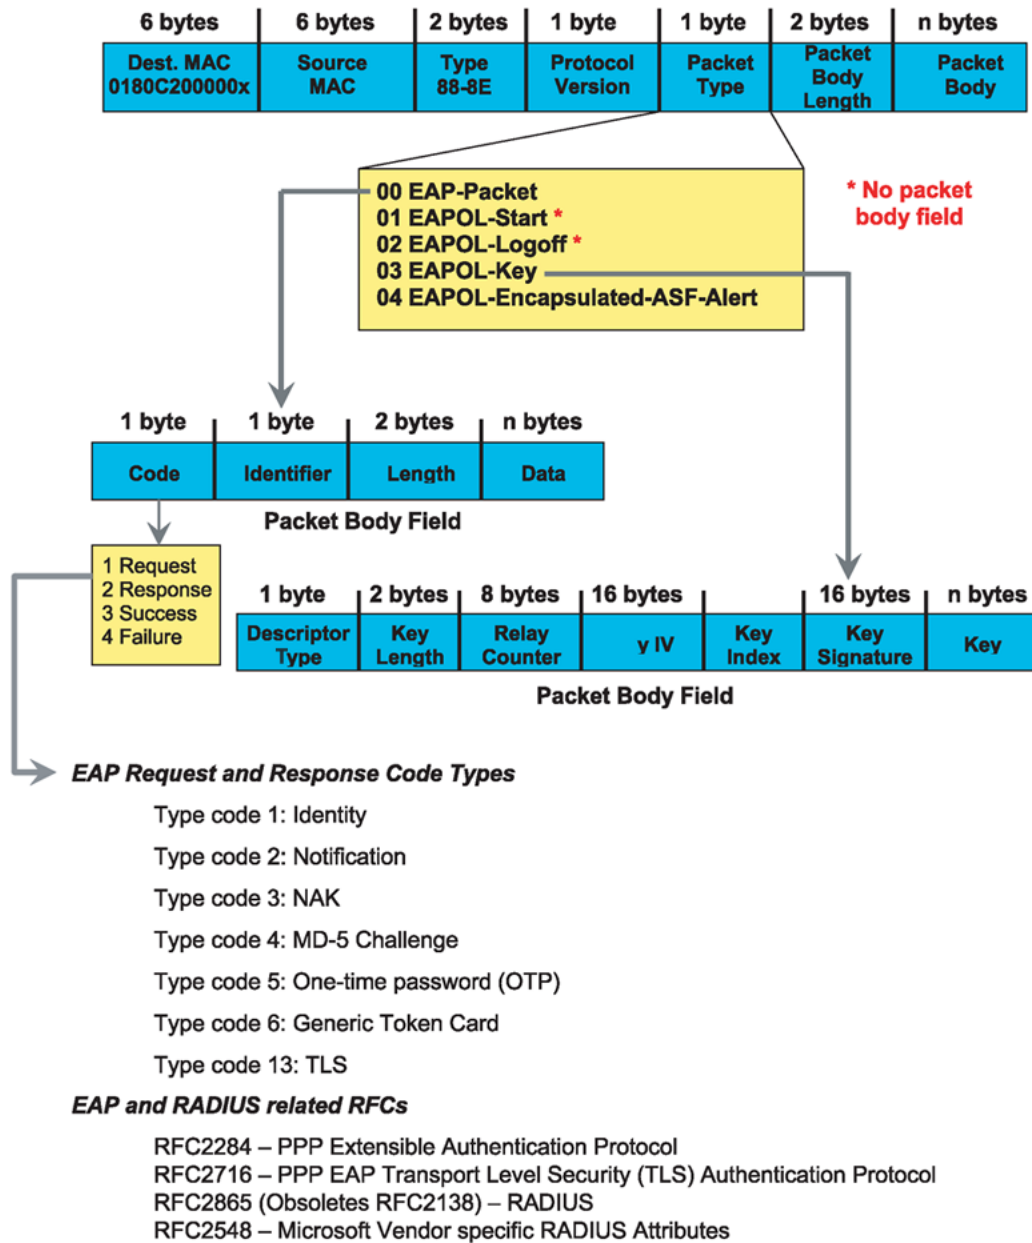

**Figure 52: EAP configuration example**

In the preceding figure, the switch uses the following steps to authenticate a new client:

1. The switch detects a new connection on one of its EAP-enabled ports and requests a user ID from the new client PC.
2. The new client sends its user ID to the switch.
3. The switch uses RADIUS to forward the user ID to the RADIUS server.
4. The RADIUS server responds with a request for the password of the user.
5. The switch forwards the request from the RADIUS server to the new client.
6. The new client sends an encrypted password to the switch, within the EAP packet.
7. The switch forwards the EAP packet to the RADIUS server.
8. The RADIUS server authenticates the password.
9. The switch grants the new client access to the network.
10. The new client accesses the network.

If the RADIUS server cannot authenticate the new client, it denies the new client access to the network.

The following figure shows the Ethernet frames and the corresponding codes for EAP as specified by 802.1x.

**Figure 53: 802.1x Ethernet frame**

The following figure shows the flow diagram for EAP on a switch.

**Figure 54: EAP flow diagram**

### EAP System Requirements

The following are the minimum system requirements for EAP:

- RADIUS server

- Client software that supports EAP

You must specify the RADIUS server that supports EAP as the primary RADIUS server for the switch. You must configure your switch for VLANs and EAP security.

If you configure EAP on a port, the following limitations apply:

- You cannot enable EAP on ports that belong to an MLT group.
- You cannot add EAP-enabled ports to an MLT group.
- You can configure a total of 32 MAC clients, EAP and NEAP hosts, on an EAP-enabled port. Two MAC clients per port is a typical configuration.
- You cannot configure EAP on MLT/LACP interfaces.
- You cannot add EAP-enabled ports to an MLT/LACP group.
- You cannot enable VLACP on EAP enabled ports.
- Manual VLAN changes on a EAP enabled port is restricted.
- You cannot change the VLAN port tagging on EAP enabled ports.
- You cannot configure the default VLAN ID. Use the Guest VLAN configuration to access unauthenticated devices.
- You cannot enable MACsec on EAP enabled ports.
- You cannot enable EAP on NNI interfaces.
- You cannot egress mirror an EAP PDU.
- Do not use EAP with a brouter port.
- Ping to and from services between nodes over the NNI will work even when it contains only EAP enabled ports with no authenticated clients on it.
- MHSa and Fail Open VLAN are mutually exclusive.
- Fail-Open I-SID is not supported in MHSa mode.
- You cannot change the EAP operation mode on EAP enabled ports.
- You cannot configure private VLANs as Fail Open VLAN or Guest VLAN.
- You cannot configure SPBM B-VLAN as Fail Open VLAN or Guest VLAN.
- You cannot delete a VLAN if the VLAN is configured as Fail Open VLAN or Guest VLAN.

## EAP Dynamic VLAN Assignment

If you configure a RADIUS server to send a VLAN ID in the Access-Accept response, the EAP feature dynamically changes the VLAN configuration of the port by adding the port to the specified VLAN.

EAP dynamic VLAN assignment affects the following VLAN configuration values:

- Port membership
- Port priority
- Default VLAN ID

When you disable EAP on a port that was previously authorized, VLAN configuration values for that port are restored directly from the nonvolatile random access memory (NVRAM) of the device.

You can set up your Authentication Server (RADIUS server) for EAP dynamic VLAN assignments. You can use the Authentication Server to configure user-specific settings for VLAN memberships and port priority.

When you log on to a system that is configured for EAP authentication, the Authentication Server recognizes your user ID and notifies the device to assign preconfigured (user-specific) VLAN membership and port priorities to the device. The configuration settings are based on configuration parameters that were customized for your user ID and previously stored on the Authentication Server.

**Note**

Static entries like IGMP, ARP, FDB configured on a port of a VLAN interface, will not be retained if the port is assigned a same VLAN by the RADIUS server and the client authenticated on the port gets disconnected or unauthenticated.

## Multiple Host Multiple VLAN

With the MHMV feature, you can assign multiple authenticated devices to different VLANs on the same EAP-enabled port using device MAC addresses. Using RADIUS VLAN attributes, different clients can access different VLANs. This separates traffic for different MAC clients.

In MHMV mode, the port-priority assigned by the RADIUS server is configured by MAC address for each authenticated client. After configuration, the QoS level on the port does not change.

Use MHMV to assign multiple authenticated devices to different VLANs on the same port. Clients can access different VLANs access using the MAC address of the devices. Different clients with different level of access (unauthorized to authorized) in different VLANs and with different QoS priorities, can exist on the same port.

With MHMV, EAP Multihost VLAN supports tagged and untagged ports. A port can be a member of multiple tagged and untagged VLANs.

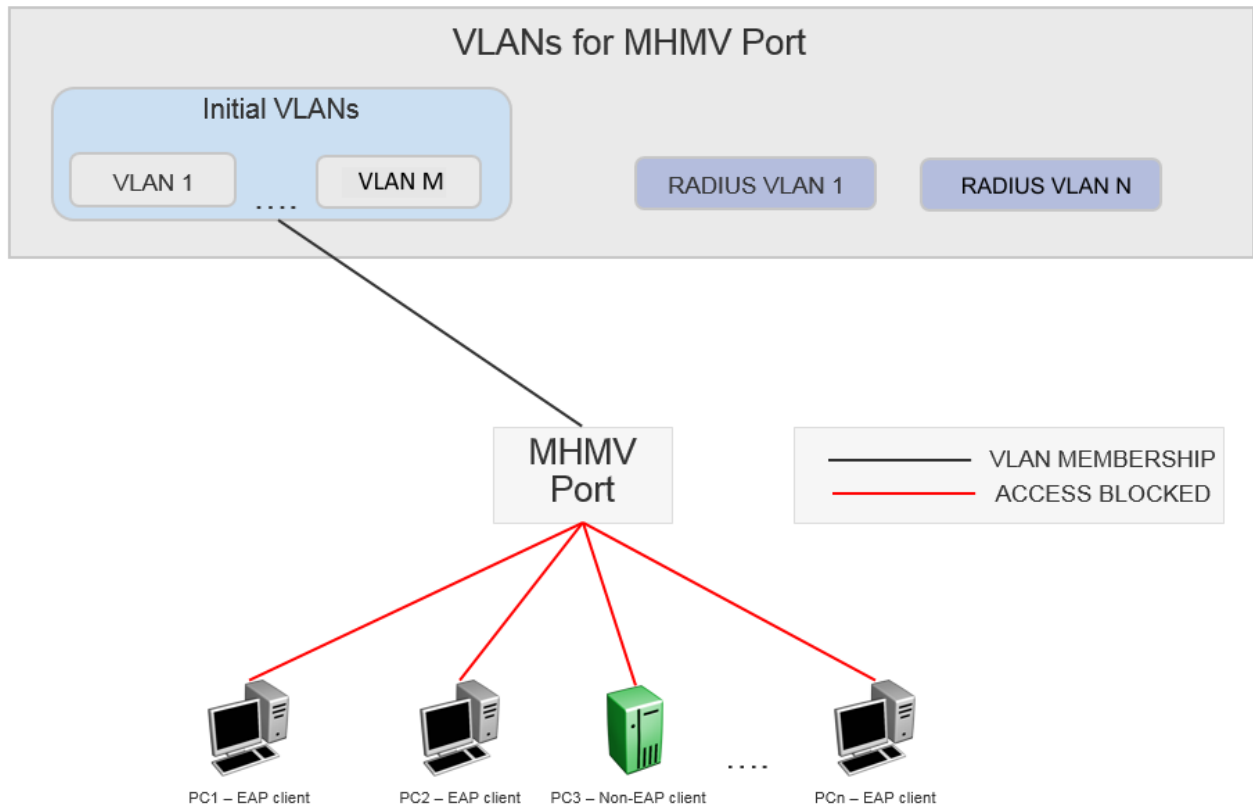

In MHMV mode, MAC based VLANs support traffic separation between different authenticated MAC clients. MAC based VLAN traffic separation applies only to untagged VLAN traffic. If the data traffic is tagged and if VLAN is configured on the port, then the traffic is forwarded to the VLAN associated with the tag.

### *Multiple Host Multiple VLAN Usage*

The following example illustrates the usage scenario for a MHMV port with n unauthenticated clients:

- Clients (n) connect to a switch port. The maximum number of clients (EAP + NEAP) allowed on a port is 8192.
- EAP is enabled and the default operation mode is MHMV.
- Modify client counters to authenticate n clients.
- Initial VLANs are the VLANs which are manually set up before EAP is enabled.
- Port default VLAN ID is equal to one of the initial VLAN ID.
- All clients are unauthenticated, hence the clients cannot access the network.

The following figure represents the functionality when clients are not authenticated.

### Note

The clients cannot access the network as they are not authenticated.

When client PC1 authenticates, there are two scenarios:

1. Client PC1 does not receive RADIUS VLAN attribute:
  - There are no changes to the port membership and port default VLAN ID.
  - PC1 is the only client that is allowed access to the initial VLANs.
  - A VLAN MAC rule is added that associates the MAC with the default VLAN ID.
  - If the VLAN is configured on the port, then the tagged traffic from PC1 is forwarded to the VLAN associated with the tag.
  - Untagged traffic from PC1 is forwarded to the port default VLAN.
2. Client PC1 receives RADIUS VLAN attribute:
  - The port is left in all initial VLANs and added to the VLAN corresponding to the RADIUS VLAN attribute.
  - Port default VLAN remains unchanged.
  - A VLAN MAC based rule is configured for client PC1.
  - Using the VLAN MAC based capabilities, the untagged traffic from PC1 goes to the RADIUS assigned VLAN 1 as shown in the figure below.

- Client PC1 can access all initial VLANs using tagged frames.
- The remaining clients stay unauthenticated and cannot access any VLANs.

The following figure represents the functionality when client PC1 authenticates.

**Note**

PC1 is authenticated with RADIUS VLAN 1. The other clients cannot access the network as they are unauthenticated.

When a client disconnects the following happens:

- The MAC VLAN rule is removed from the switch.
- If the RADIUS VLAN attribute was used with the client was authenticated and no other clients are authenticated on that RADIUS VLAN, then the port is removed from the VLAN.
- The RADIUS accounting attribute Acct-Terminate-Cause indicates how a session was terminated.
- The RADIUS accounting attribute Event-Timestamp indicates the time that an event occurred on the Network Access Server (NAS).

### EAP Functionality on Flex UNI Ports

After you enable EAP on a port, all client MACs (MHMV mode) must be authenticated by the RADIUS server in order to have network access. In Multiple Host Multiple VLAN (MHMV) mode, the RADIUS server allocates a MAC to I-SID binding to each client that connects to the switch and uses it to transmit

traffic. The binding is not between the MAC and the VLAN. Untagged S-UNIs generated from the RADIUS server for a MAC or MACs are considered as MAC-based S-UNIs.

The RADIUS server also provides the VLAN:ISID binding for the MAC, which results in the addition of an untagged Switched UNI (S-UNI) for that particular I-SID. Only the MAC or MACs that receive the I-SID from the RADIUS server can transmit traffic to Extensible Authentication Protocol (EAP)-enabled Flex UNI ports.

The switch uses MAC-based S-UNIs with EAP-enabled Flex UNI ports in MHMV mode only.

The MAC-based S-UNI model does not apply to MHSA mode. In Multiple Host Single Authentication (MHSA) mode used in the untagged S-UNI model that exists on VOSS switches. S-UNIs generated from the information obtained from the RADIUS server are considered as classic or default untagged S-UNIs.

**Note**

EAP is not supported on MLT/SMLTs. Only the EAP I-SIDs are synchronized between one vIST peer and another vIST peer. S-UNIs are not synchronized with the vIST peer.

EAP with Flex UNI is supported on Distributed Virtual Routing (DvR) Leafs. An untagged S-UNI (where the system learns MACs based on the I-SID to MAC binding) must have a platform VLAN associated with it. If a default untagged S-UNI is used, the corresponding S-UNI must be received from the DvR Controllers.

## EAP and Fabric Attach

With Extensible Authentication Protocol (EAP) and Fabric Attach (FA), FA-capable switches can forward traffic from EAP/NEAP clients over the SPB cloud. The traffic for authenticated clients is mapped to I-SIDs received from RADIUS server.

You must configure the desired bindings for EAP/NEAP clients on the RADIUS server. When confirming the authentication request, the RADIUS server also sends the corresponding binding for the EAP/NEAP client.

The FA Proxy sends to the FA Server the binding received from the RADIUS server. If the FA Server rejects all the bindings, the client is disconnected. EAP clients are moved from AUTHENTICATED state to HELD state.

On an FA Server, when an EAP/NEAP device is authenticated and an FA binding is received from the RADIUS server, a Switched UNI (S-UNI) is created.

After an EAP/NEAP client is disconnected, the switch cleans-up the binding associated with the client, if no other EAP/NEAP client on that port uses it.

EAP and FA can be enabled in any order; however, EAP must have Flex UNI enabled in order to function on an FA-enabled port.

FA clients that generate S-UNI bindings must be used with EAP MHSA mode, while FA clients that do not generate S-UNI bindings should be used with EAP MHMV mode.

## MAC Move Detection on EAP Ports

The MAC moves mechanism detects when a MAC address migrates from one port to another port, such as:

- EAPoL-enabled port to EAPoL-enabled port
- EAPoL-enabled port to non-EAPoL (NEAP)-enabled port
- non EAPoL-enabled port to EAPoL-enabled port

When a MAC address migrates from one port to another port, the new EAPoL-enabled port triggers a new RADIUS authentication. New bindings are applied on the new EAPoL-enabled port. The old port detects the MAC is moved and automatically deletes the old binding or bindings.

The Mac moves mechanism works between vIST peers when a MAC address on one peer migrates to the other peer but only if the I-SID in which the MAC address is learned exists on the new and the old peer.

## Auto-sense Ports

EAP and NEAP is integrated with Auto-sense infrastructure. If a RADIUS server is configured on the switch, Auto-sense-enabled ports activate EAP and NEAP authentication automatically.

For more information about Auto-sense functionality, see [Auto-sense](#) on page 16.

## RADIUS-Assigned VLAN or VLAN:ISID Bindings

RADIUS-assigned VLAN and VLAN:ISID bindings provide greater flexibility and a more centralized assignment. The RADIUS server can dynamically assign VLANs or VLAN:ISID bindings to a port.

Use VLAN attributes for RADIUS assignments in VLAN mode. This mode applies when the EAP-enabled port does not have Flex-UNI enabled.

Use VLAN:ISID attributes for RADIUS assignments in I-SID mode. This mode applies when the EAP-enabled port does have Flex-UNI enabled.

For more information, see [RADIUS Attributes](#) on page 2759.

## RADIUS Port and VLAN Based Attributes

RADIUS port and VLAN based attributes automate switch configuration using port and VLAN based attributes received from the RADIUS Server.

Extreme-Dynamic-Config Vendor Specific Attribute (VSA) dynamically configures the following features:

- VLAN Based Features
  - IGMP Snooping
  - DHCP Snooping
  - Dynamic ARP Inspection (DAI)

- Port Based Features
  - IP Source Guard (IPSG)
  - Simple Loop Prevention Protocol (SLPP) Guard
  - Bridge Protocol Data Unit (BPDU) Guard
  - Traffic Control (Wake on LAN - WoL)
  - Custom Auto-Negotiation Advertisements

### *SBP Support*

In an SPB environment, settings for VLAN based features are enabled on the platform VLANs associated with the I-SID received from the RADIUS server. If the I-SID received from the RADIUS server does not have a platform VLAN associated with it, settings are not applied. When a platform VLAN is then associated with the I-SID, EAP reauthentication is generated to apply the settings by bouncing a port, bouncing EAP on a port, or by using CoA Reauthenticate.

When a platform VLAN is removed from the I-SID, all applied dynamic settings for the VLAN are also removed.

### *MHSA Support*

When port is configured in Multiple Host Single Authentication (MHSA) mode and VLAN based attributes are received from the RADIUS server, features enable on all VLANs containing the authentication port. If Flex-UNI is enabled on a port, features enable on all platform VLANs containing the authentication port.

### *MHMV Support*

When port is configured in Multiple Host Multiple VLAN (MHMV) mode and VLAN based attributes are received from the RADIUS server, features enable on the default VLAN and on all VLANs containing the authentication port. If Flex-UNI is enabled on a port, features enable on any untagged I-SIDs and on all platform VLANs associated with the I-SID received from the RADIUS server.

### *Operational Considerations*

Consider the following when you use port and VLAN based attributes:

- Configuring Custom Auto-Negotiation Advertisements on a port triggers a port bounce, which generates new client authentication.
- DHCP Snooping Option 82 is not supported.
- IGMP is not supported on DVR Leaf.
- Change-of-Authorization (CoA) functionality is not supported; Disconnect and Reauthenticate options are supported.
- Only settings that can be configured manually can be configured dynamically using EAP.
- IP Source Guard restrictions apply even if the feature is configured on the RADIUS server.
  - Maximum 10 entries per port
  - Maximum 1000 entries per server
  - DHCP Snooping and DAI must be enabled on all VLAN members of the RADIUS configured port.
- If multiple client authentication is permitted in MHMV mode, RADIUS settings can be applied incrementally as subsequent clients authenticate.

If a client authenticates with DHCP Snooping, DAI, and IP Source Guard attributes on the VLAN and a second client attempts to authenticate with the same attributes, consider the following:

- If the second client uses the same VLAN as the first client, only IP Source Guard applies on the RADIUS configuration port.
- If the second client uses a different VLAN, DHCP Snooping and DAI apply on the VLAN and the IP Source Guard applies on the RADIUS configuration port.
- If you configure a Guest VLAN on a port and the RADIUS server returns IP Source Guard as a result of EAP or NEAP authentication, then you should manually remove static VLANs from that port. Alternatively, you can enable DHCP Snooping and DAI on static VLANs.
- If you configure a port with multiple platform VLANs and the RADIUS server returns IP Source Guard as a result of EAP/NEAP authentication, then you must manually configure DHCP Snooping and DAI on static platform VLANs.
- Dynamic cleanup is supported. When the last client to authenticate using a dynamic setting is removed, the following dynamic settings are also removed:
  - Dynamic ARP Inspection (DAI)
  - DHCP Snooping
  - IGMP Snooping
  - IP Source Guard

However, the following settings can only be removed by disabling EAP:

- SLPP Guard
- BPDU Guard
- Traffic Control (Wake on LAN)
- Custom Auto-Negotiation Advertisements

For more information, see [Extreme-Dynamic-Config](#) on page 2761.

## RADIUS Configuration Prerequisites for EAP

Connect the RADIUS server to a force-authorized port. This ensures that the port is always available and not tied to whether or not the device is EAP-enabled.

## RADIUS Accounting for EAP

The switch provides the ability to account EAP and NEAP sessions using the RADIUS accounting protocol. A user session is defined as the time frame between when a user is authenticated until the user is unauthenticated.

The following table summarizes the accounting events and information logged.

**Table 82: Summary of accounting events and information logged**

| Event                        | RADIUS attributes    | Description                                                                                                                                                              |
|------------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| User is authenticated by EAP | Acct-Status-Type     | Start                                                                                                                                                                    |
|                              | Nas-IP-Address       | IP address to represent the switch                                                                                                                                       |
|                              | Nas-Port             | Port number on which the user is EAP or NEAP authorized                                                                                                                  |
|                              | Acct-Session-ID      | Unique string representing the session                                                                                                                                   |
|                              | User-Name            | EAP user name or NEAP MAC                                                                                                                                                |
| User logs off                | Acct-Status-Type     | Stop                                                                                                                                                                     |
|                              | Nas-IP-Address       | IP address to represent the switch                                                                                                                                       |
|                              | Nas-Port             | Port number on which the user is EAP or NEAP unauthorized                                                                                                                |
|                              | Acct-Session-ID      | Unique string representing the session                                                                                                                                   |
|                              | User-Name            | EAP user name                                                                                                                                                            |
|                              | Acct-Input-Octets    | Number of octets input to the port during the session                                                                                                                    |
|                              | Acct-Output-Octets   | Number of octets output to the port during the session                                                                                                                   |
|                              | Acct-Terminate-Cause | Reason for terminating user session. For more information about the mapping of 802.1x session termination cause to RADIUS accounting attribute, see the following table. |
| Acct-Session-Time            | Session interval     |                                                                                                                                                                          |

The following table describes the mapping of the causes of 802.1x session terminations to the corresponding RADIUS accounting attributes.

**Table 83: 802.1x session termination mapping**

| IEEE 802.1Xdot1xAuthSessionTerminateCause Value | RADIUSAcct-Terminate-Cause Value |
|-------------------------------------------------|----------------------------------|
| supplicantLogoff(1)                             | User Request (1)                 |
| portFailure(2)                                  | Lost Carrier (2)                 |

## RADIUS Dynamic User-Based Policies

RADIUS Dynamic User-Based Policies is a security feature to control access services on user devices that connect to the network. Before enabling any services on the user device, the RADIUS server authenticates each device that connects to the switch port and assigns that port to a VLAN or a VLAN to I-SID binding. RADIUS Dynamic User-Based Policies implement a dynamic method to apply filter Access Control List (ACL) rules to Extensible Authentication Protocol (EAP) and Non-EAP (NEAP) authenticated user traffic. The RADIUS server authenticates the user device for switch access and sends rules for that user device to the switch.

The system clears the rules when the following events occur:

- You disable EAPoL globally on the switch.
- EAP and NEAP sessions are cleared.
- You shutdown the port.

### Note

- You must enable RADIUS and EAP over LAN (EAPoL) on the switch. For more information, see [Enabling RADIUS authentication](#) on page 2713 and [Globally enabling EAP on the device](#) on page 787.
- You must configure an EAP-enabled RADIUS server. For more information, see [Configure an EAP-enabled RADIUS Server](#) on page 790.

RADIUS Dynamic User-Based Policies support one time configuration of policy attributes on the RADIUS server and dynamically creates the policies on multiple switches within the network. This process of automatically creating policies enhances the speed of network access for authenticated users and also facilitates faster network synchronization in the event of network-wide policy changes.

Extreme Vendor ID 1916 supports the following RADIUS Vendor Specific Attribute (VSA) for RADIUS Dynamic User-Based Policies:

- Extreme-Dynamic-ACL (ID 251)

For more information, see [RADIUS Attributes](#) on page 2759.

The RADIUS server contains the RADIUS VSAs in a configuration file for each EAP or NEAP client that the switch authenticates. Following is an example of a RADIUS VSA configured on the RADIUS server:

```
00000000000a Cleartext-Password :="000000000000a"
Service-Type = Framed-User,
Framed-Protocol = PPP,
Auth-Type := Accept,
Fabric-Attach-ISID = 10:100,
Extreme-Dynamic-ACL = "CLIENT RadiusGuest",
```

```
Extreme-Dynamic-ACL += "acl inPort",
Extreme-Dynamic-ACL += "ace 1 sec name ACE-A1 ethernet ether-type eq 0x800 & action deny count & ip ip-
protocol-type eq 17 & protocol dst-port eq 4000",
Extreme-Dynamic-ACL += "ace 2 sec name ACE-A2 ethernet ether-type eq ip & ip dst-ip eq 10.10.10.1 &
action deny",
Extreme-Dynamic-ACL += "acl set default-action deny",
```

When the switch receives a new VSA with ACL and Access Control Entries (ACE) rules from the RADIUS server, the switch dynamically creates the ACL infrastructure based on the following:

- Dynamic ACLs - the switch allocates one dynamic ACL for each EAP enabled port. You cannot manually configure the dynamic ACL. The dynamic behavior of the ACL depends on the EAP port state (MHMV or MHSA). RADIUS Dynamic User-Based Policies support the inPort and outPort ACL types. You can display the filter ACL configuration on the switch using the **show filter acl** command, to identify the source of ACL configuration (static or dynamic).
- Dynamic ACEs - after the switch configures an ACL as dynamic, the system automatically considers the ACEs in that ACL as dynamic. You cannot manually configure the ACEs in a dynamic ACL. When the switch receives an ACE rule from the RADIUS server, the system allocates an ACE ID to it. Each ACE rule carries a relative order that helps the switch to set priority for the ACE rules that the switch receives. For handling of Radius ACL rules, the switch parses the rules first. Based on the actions, the system classifies the rules as security ACEs or QoS ACEs. If the switch is unable to recognize the qualifiers or actions in a rule, then the switch ignores that rule.
- Multiple Host Multiple VLAN (MHMV) operating mode - the system authenticates each MAC that the switch receives on the EAP-enabled port and assigns the MAC to a specific VLAN or VLAN to I-SID binding. The system uses the VLAN to I-SID binding when Flex UNI is enabled on a port. The system processes the ACE rules that the switch receives from the RADIUS server on a per MAC basis, the system translates the default-action into an ACE rule with actions, deny or permit. When the switch processes the RADIUS VSAs, the system adds the MAC as a qualifier for each ACE rule.
- Multiple Host Single Authentication (MHSA) operating mode - the system processes the ACE rules that it receives from the RADIUS server on a per port basis.

## NEAP host

The following section provides information about NEAP hosts on EAP-enabled ports and RADIUS authentication.

### *NEAP Hosts on EAP Enabled Ports*

For an EAP-enabled port configured for NEAP host support, devices with MAC addresses getting authenticated are allowed access to the port.

The switch allows the following types of NEAP users:

- NEAP hosts whose MAC addresses are authenticated by RADIUS.

Support for NEAP hosts on EAP-enabled ports is primarily intended to accommodate printers and other passive devices sharing a hub with EAP clients.

Support for NEAP hosts on EAP-enabled ports includes the following features:

- Authenticated NEAP clients are hosts that satisfy one of the following criteria:
  - Host MAC address is authenticated by RADIUS.
- NEAP hosts are allowed even if no authenticated EAP hosts exist on the port.

- When a new host is seen on the port, NEAP authentication is performed as follows:
  - The switch generates a <username, password> pair, which it forwards to the network RADIUS server for authentication.

### NEAP MAC RADIUS Authentication

For RADIUS authentication of a NEAP host MAC address, the switch generates a <username, password> pair as follows:

- The username is the NEAP MAC address in string format.
- The password is a string that combines the switch IP address, MAC address, port number and user-configurable key string. If padding option is enabled, the system will specify a dot(.) for every missing parameter. IP address is represented by three decimal characters per octet.

#### Important

Follow these Global Configuration examples to select a password format that combines one or more of these three elements:

- Padding enabled , password = 010010011253..05. (when the switch IP address and port are used).
- Padding enabled, password = 010010011253... (when only the switch IP address is used).
- No padding (default option). Password = 000011220001 (when only the user's MAC address is used).

The following example illustrates the <username, password> pair format with no padding enabled and using the IP address, MAC address, and key-string as the password.

```
switch IP address = 192.0.2.5
non-EAP host MAC address = 00 C0 C1 C2 C3 C4
port = 25
Key-String = abcdef
```

- username = 00C0C1C2C3C4
- password = 010010011253.00C0C1C2C3C4.25.abcdef

Use the command **show eapol system** to verify the formatting.

```
Switch:1>show eapol system
```

```
=====
                               Eapol System
=====
                               eap : enabled
                               Eapol Version : 3
                               non-eap-pwd-fmt : mac-addr
                               non-eap-pwd-fmt key : *****
                               non-eap-pwd-fmt padding : disabled
                               auto-isid-offset status : disabled
                               auto-isid-offset value : 15980000
```

## NEAP client

The following section provides information for NEAP client.

### *NEAP Client Re-Authentication*

The NEAP client re-authentication feature supports the re-authentication of NEAP clients at defined intervals.

When you enable NEAP client re-authentication, an authenticated NEAP client is only removed from the authenticated client list if you remove the client account from the RADIUS server, or if you clear the NEAP authenticated client from the switch.

If an authenticated NEAP client does not generate traffic on the network, the system removes the MAC address for that client from the MAC address table when MAC ages out. Although the system does not display the client MAC address in the MAC Address table and it can display the client as an authenticated client.

If you enable NEAP client re-authentication and the RADIUS server that the switch connects to becomes unavailable, the system clears all authenticated NEAP and removes those clients from the switch NEAP client list.

You cannot authenticate one NEAP client on more than one switch port simultaneously. If you connect NEAP clients to a switch port through a hub, those clients are authenticated on that switch port. If you disconnect a NEAP client from the hub and connect it directly to another switch port, the client is authenticated on the new port and its authentication is removed from the port to which the hub is connected.

### *MAC Move for Authenticated Non-EAP Clients*

When you move a Non-EAP client that is authenticated on a specific port, to another port on which EAPoL or Non-EAP is enabled, MAC move of the client to the new port does not automatically happen. This is as designed.

As a workaround, do one of the following:

- Clear the non-EAP session on the port that the client is first authenticated on, before you move the client to another port.
- Create a VLAN on the switch with the same VLAN ID as that dynamically assigned by the RADIUS server during client authentication. Use the command **vlan create <2-4059> type port-mstprstp <0-63>**. Ensure that the new port is a member of this VLAN.

### *NEAP MAC Learning and Authentication*

The system learns the MACs based on the I-SID to MAC binding. When a packet ingresses on a port, which is associated with Switched UNI (S-UNI) I-SID, the system performs MAC look up based on the I-SID. The RADIUS server provides the VLAN:I-SID assignment.

#### **Important**

If the default untagged S-UNI is used, you must have a platform VLAN associated with it. This is required to properly transmit traffic and to generate MAC learning events for traffic sent to MAC-based S-UNIs.

When an untagged S-UNI is present on the port, the untagged MAC is initially learned on that S-UNI. When an untagged S-UNI does not exist on the port, the untagged MAC is learned on a special (internal) VLAN. The RADIUS server provides the VLAN:I-SID assignment.

MAC learning for tagged traffic occurs only if there is a tagged S-UNI with the corresponding C-VID on that port. The RADIUS server reconfirms the S-UNI that performed MAC learning.

## EAP and NEAP Limitations

The EAP and NEAP MAC clients on port limits the maximum number of all EAP and NEAP clients per port. EAP and NEAP MAC clients on port enhancements independently limits the EAP and NEAP clients per port.

The following enhancements are added:

- EAP-MAC-MAX : Limits the total number of EAP clients
- NON-EAP-MAC-MAX: Limits the total number of NEAP clients

### Note

Do not connect more than 100 EAP and 100 NEAP devices on the switch.

### *EAP and NEAP mac-max Settings*

The total number of EAP clients can be set between 0 and 32, while the total number of NEAP clients can be set between 0 and 8192.

### Note

EAP-MAC-MAX is overwritten by MAC-MAX. Even if EAP-MAC-MAX is set to a higher limit, then MAC-MAX must not exceed and you must not authenticate more than MAC-MAX clients.

### Note

NON-EAP-MAC-MAX is overwritten by MAC-MAX. Even if NON-EAP-MAC-MAX is set to a higher limit, then MAC-MAX must not exceed and you must not authenticate more than MAC-MAX clients.

## Example Scenarios

1. Scenario 1:
  - EAP-MAC-MAX 32
  - NON-EAP-MAC-MAX 32
  - MAC-MAX 10

In this scenario, there are ten EAP and NEAP authenticated clients, in the order of authentication.

2. Scenario 2:
  - EAP-MAC-MAX 1
  - NON-EAP-MAC-MAX 1
  - MAC-MAX 1

In this scenario, only one EAP or one NEAP client is authenticated, in the order of authentication.

3. Scenario 3:
  - EAP-MAC-MAX 5
  - NON-EAP-MAC-MAX 10
  - MAC-MAX 32

In this scenario, up to five EAP clients and ten NEAP clients are allowed.

4. Scenario 4:

- EAP-MAC-MAX 5
- NON-EAP-MAC-MAX 8
- MAC-MAX 7

In this scenario, up to five EAP clients and seven NEAP clients are allowed. The total number of EAP or NEAP clients is limited to seven.

## Multiple Host Single Authentication

Multiple Host Single Authentication (MHSA) allows MACs to access the network without EAP and NEAP authentication. Unauthenticated devices can access the network only after an EAP or NEAP client is successfully authenticated on a port. The VLAN to which the devices are allowed is the client authenticated VLAN. Unless Guest VLAN is configured, there is no authenticated client on the port, and no MAC is allowed to access the network.

MHSA is primarily intended to accommodate printers and other passive devices sharing a hub with EAP and NEAP clients.

MHSA support is on a port-by-port basis for EAP enabled ports.

MHSA supports the following functionality:

- The port remains unauthorized when no authenticated hosts exist on the port. Before the first successful authentication occurs, both EAP and NEAP clients are allowed to negotiate access on that port but only one host is allowed to perform authentication.
- In MHSA mode, QoS level is configured when processing the Port-Priority attribute, because there can only be one authenticated client. The devices behind the authenticated client use the port priority established by the main client.
- In MHSA mode, the Guest VLAN applies only when no authenticated client is present on the port.
- After the first EAP or NEAP client successfully authenticates on a port, other clients cannot negotiate authentication on that port.
- After the first successful authentication, MACs that are already learned on that port is flushed.
- NEAP clients are not removed at age event in MHSA mode.
- There is no limit to the number of MACs that are allowed after first successful authentication.

### *EAP and NEAP MAC Clients on a Port with MHSA*

EAP and NEAP client counters, such as MAC-MAX, EAP-MAC-MAX, and NON-EAP-MAC-MAX do not apply when the port operates in MHSA mode. In MHSA mode, there can be only one authenticated client (EAP or NEAP). Subsequent MACs seen on the port are allowed automatically without authentication.

## Guest VLAN

Guest VLAN support provides limited network access until the client is authenticated. Guest VLAN is configured irrespective of the number of authenticated clients present on the port. Guest VLAN is

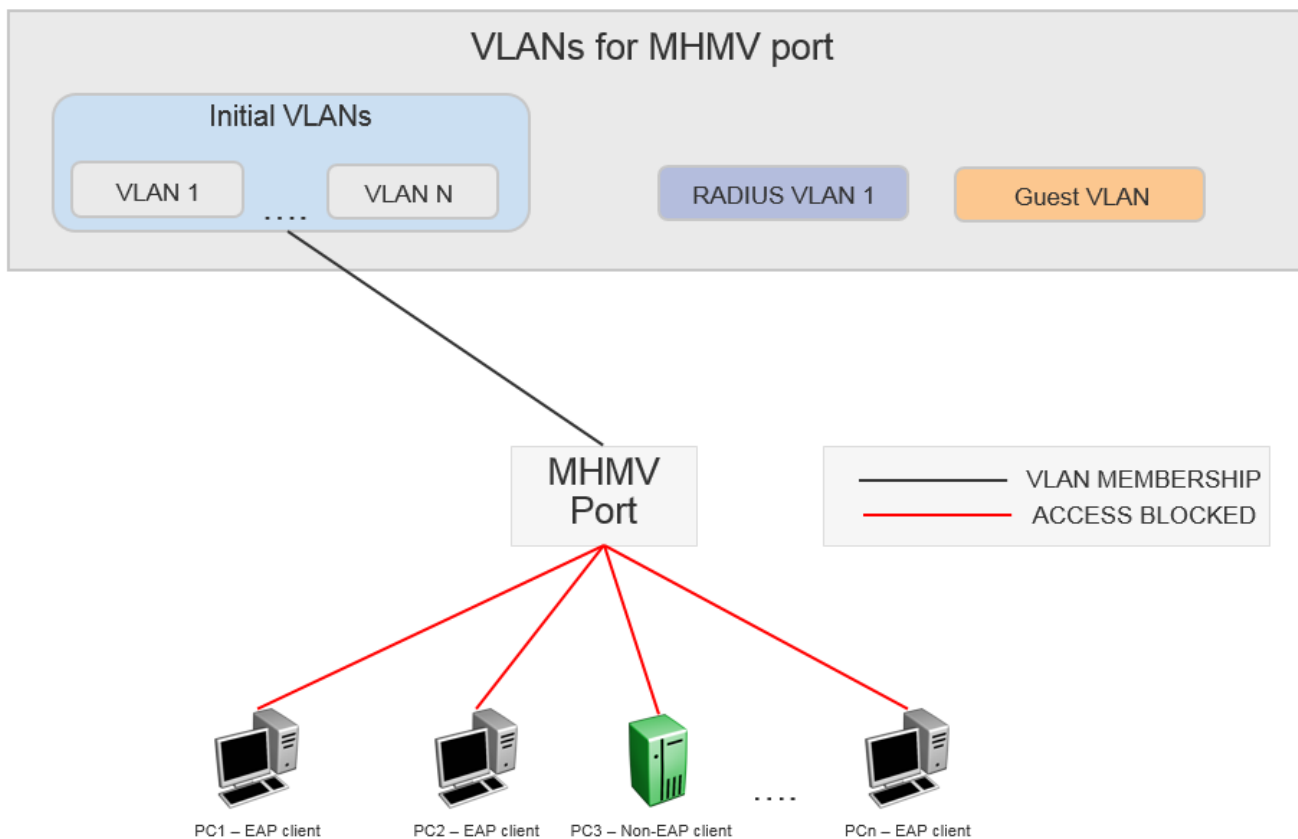

available for each port. Only port based VLANs are used as Guest VLANs. When the Guest VLAN is active, port is added to the VLAN ID, and port default VLAN ID changes to Guest VLAN ID.

*Guest VLAN on a MHMV Port Usage Scenario*

The following example illustrates the configuration of Guest VLAN support with an EAP MHMV port:

- Clients connect to a switch port through a hub.
- The initial VLANs are the VLANs on which the ports resides after a switch reboot.
- EAP is enabled.
- The port is a member of initial VLANs. The clients cannot access the VLANs since the VLANs are not authenticated. The port default VLAN ID corresponds to one of the initial VLAN IDs.
- Guest VLAN support is not activated.

The following figure represents the functionality when clients are not authenticated.

**Note**

The clients cannot access the network as they are not authenticated and Guest VLAN is not configured.

- Guest VLAN support is activated.
- The MHMV port is in the initial VLAN stage but gets added to the Guest VLAN ID. The default VLAN ID is updates to correspond to the Guest VLAN ID.

- All Clients behind the port can access the Guest VLAN.

The following figure represents the functionality when Guest VLAN is activated.

#### Note

All clients have Guest VLAN access.

- A client behind the MHSV port gets authenticated. For this usage scenario let us consider PC1 as the authenticated client.
- The port default VLAN ID is equal to the Guest VLAN ID and remains unchanged.
- The port is copied into the RADIUS assigned VLAN (if any).
- The untagged traffic that originates from PC1 (identified by MAC address) can access only the RADIUS assigned VLAN or the initial port default VLAN ID, if the RADIUS VLAN attribute is missing.
- The remaining clients that send untagged traffic are unauthenticated devices. The unauthenticated devices can access only the Guest VLAN because the port VLAN ID is equal to the Guest VLAN ID.
- The initial VLANs are accessed by the following devices:
  - Authenticated devices that are missing RADIUS VLAN attributes.
  - Authenticated devices that send corresponding tagged packets.
- When another client gets authenticated, the authenticated client undergoes the same process as PC1.

The following figure represents the functionality when a client gets authenticated:

#### Note

PC1 is authenticated with RADIUS VLAN 1. The remain clients have guest VLAN access.

When a client disconnects the following happens:

- The MAC VLAN rule is removed from the switch.
- If the RADIUS VLAN attribute was used with the client was authenticated and no other clients are authenticated on that RADIUS VLAN, then the port is removed from the VLAN. If other clients are authenticated on that RADIUS VLAN, then the VLAN MAC rule is deleted.
- If RADIUS VLAN attribute is not used when the client is authenticated, then only the VLAN MAC rule is deleted.

#### Guest VLAN on a MHS A Port Usage Scenario

The following is a usage example when Guest VLAN is configured with an EAP MHS A port:

- There are no authenticated EAP or NEAP clients on a port.
- The port is removed from the initial VLANs and moved to Guest VLAN ID.
- The default port VLAN ID changes to Guest VLAN ID.
- All MACs seen on the port have Guest VLAN access.
- Port is removed from the Guest VLAN ID.
- If no RADIUS assigned VLAN is present, then the VLAN membership and the default port VLAN ID is restored to default settings.

- If the RADIUS assigned VLAN is present, then the VLAN membership and the default port VLAN ID is changed according to its value.
- Guest VLAN loses its purpose because all MACs are allowed automatically without authentication

In MHSa mode, the Guest VLAN applies only when no authenticated client is present on the port.

## Guest I-SID

Guest I-SID support provides limited network access until the client is authenticated. The switch uses the Guest I-SID to forward traffic until the client authenticates and receives other VLAN:ISID bindings from the RADIUS server.

Guest I-SID is a per-port option. You must configure an I-SID either as a C-VLAN or as an ELAN with an associated platform VLAN before you can configure it as the Guest I-SID. After you configure the Guest I-SID and you enable EAP, an untagged S-UNI is created based on the supplied I-SID. When you change the Guest I-SID while EAP is enabled, the untagged S-UNI is replaced on the port.

In MHSa mode, only one untagged S-UNI can exist on a port at one time. Consider the following:

- If there is a manually configured untagged S-UNI on the port, the untagged S-UNI, which uses the Guest I-SID replaces it.
- If the RADIUS server provides an untagged S-UNI after the client is authenticated, it replaces the untagged S-UNI, which was created based on the Guest I-SID.
- If the Guest I-SID is removed, the previous manually configured untagged S-UNI is automatically restored.
- If the RADIUS-assigned untagged S-UNI is no longer present, EAP recreates the untagged S-UNI created based on the Guest I-SID.

In MHMV mode, the untagged S-UNIs provided by the RADIUS server are treated as MAC-based untagged S-UNIs, which are different from the untagged S-UNI on the port. Consider the following factors:

- If there is a manually configured untagged S-UNI on the port, the untagged S-UNI, which uses the Guest I-SID, replaces it.
- If the Fail-Open I-SID and the Guest I-SID are both configured, the Guest I-SID is applied, as long as a RADIUS server is reachable.
- If the RADIUS server becomes unreachable, the untagged S-UNI based on the Fail-Open I-SID is removed and the untagged S-UNI is created based on the Guest I-SID.

## EAP and NEAP separation

EAP and NEAP separation provide the ability to have only NEAP clients allowed on one port. This is done by allowing `eap-mac-max` to be set to 0. This enhancement gives you the ability to disable EAP clients authentication without disabling NEAP clients. There are no additional configuration commands. For more information, see [Configuring maximum EAP clients](#) on page 804 and [Configuring maximum NEAP clients](#) on page 805.

## EAP and NEAP VLAN names

VLAN names configures VLAN membership of EAP and NEAP clients. You do not have to configure this feature as this mode is always enabled by default.

## Fail Open VLAN

Fail Open VLAN provides network connectivity when the switch cannot connect to a RADIUS server. If the switch cannot connect to the primary and secondary RADIUS servers, then after a specified number of attempts to restore connectivity, the switch declares the RADIUS servers unreachable. Fail Open VLAN provides the below functionality:

- When the EAP RADIUS servers are not reachable, Fail Open VLAN provides restricted access to devices, which is separate from the Guest VLAN.
- The EAP and NEAP clients are not affected when the RADIUS servers are not reachable.

Fail Open VLAN is a per-port option. Enable Fail Open VLAN by setting a valid Fail Open VLAN ID. Configure the selected VLAN ID on the switch. Only port based VLANs must be used as Fail Open VLANs.

When you configure Fail Open VLAN on a port and the RADIUS servers are not reachable, then the Fail Open VLAN provides the following functionality:

- The port is removed from Guest VLAN if configured, but all other VLAN membership is kept and in addition the port is added to the Fail Open VLAN.
- Default VLAN ID is changed to Fail Open VLAN ID.
- Traffic from the authenticated EAP and NEAP clients are forwarded as before.
- If re-authentication is enabled in Fail Open VLAN mode, then EAP and NEAP clients stop performing re-authentication.
- All new MACs seen on the port are considered as potential EAP and NEAP clients and is granted Fail Open VLAN access.

When at least one RADIUS server recovers, all EAP enabled ports are removed from the Fail Open VLAN. All unauthenticated MACs are flushed in order to give the MACs an opportunity to authenticate.

### *Fail Open VLAN with Guest VLAN scenarios*

When an EAP port is configured with both Fail Open VLAN and Guest VLAN, consider the following scenarios:

1. EAP port operating in MHMV mode:
  - If the EAP RADIUS servers are reachable, then all the authenticated clients have Guest VLAN ID access.
  - If the EAP RADIUS servers are not reachable, then Guest VLAN must be removed from the port completely. Fail Open VLAN is the new default VLAN. All unauthenticated MACs have Fail Open VLAN access.
2. EAP port operating in MHSA mode:
  - Fail Open VLAN has no impact on the Guest VLAN functionality in MHSA mode.

## Fail Open I-SID

Fail Open I-SID provides network connectivity with restricted access to devices when the switch cannot connect to a RADIUS server. If the switch cannot connect to the primary and secondary RADIUS servers after a specified number of attempts to restore connectivity, the switch declares the RADIUS servers unreachable.

### Note

EAP and NEAP clients are not affected when the RADIUS servers are unreachable.

Fail Open I-SID is a per-port option. You must configure an I-SID either as a C-VLAN or as an ELAN with an associated platform VLAN before you can configure it as the Fail-Open I-SID. After you configure the Fail Open I-SID and you enable EAP, an untagged S-UNI is created based on the supplied I-SID. When you change the Fail Open I-SID while EAP is enabled, the untagged S-UNI is replaced on the port.

### Note

Fail-Open I-SID is not supported in MHSA mode.

In MHMV mode, the untagged S-UNIs provided by the RADIUS server are treated as MAC-based untagged S-UNIs, which are different from the untagged S-UNIs on the port. Consider the following factors:

- If there is a manually configured untagged S-UNI on the port, the untagged S-UNI, which uses the Fail Open I-SID, replaces it.
- Caution is advised when both Fail-Open I-SID and Guest I-SID are configured. In this scenario, if a RADIUS server becomes reachable, the untagged S-UNI created based on the Fail-Open I-SID is removed and another untagged S-UNI based on the Guest I-SID is created.

## EAP Auto-ISID-Offset

EAP auto-isid-offset functionality is used for MACs that do not receive an I-SID attribute from the RADIUS server. The configured I-SID offset value is used to calculate an I-SID value for a Switched UNI (S-UNI) when the switch receives only the VLAN attribute from the RADIUS server (not the FA VLAN:I-SID binding). In that case, the I-SID value is calculated as follows: I-SID = VLAN ID + configured I-SID offset value.

## Wake On LAN

Wake On LAN (WoL) networking standard enables remotely powering-up a shutdown computer from a sleeping state. In this process, the computer is shutdown with power reserved for the network card. A packet known as Magic Packet is broadcast on the local LAN or subnet. The network card on, receiving the Magic Packet, verifies the information. If the information is valid, the network card powers-up the shutdown computer.

The WoL Magic Packet is a broadcast frame sent over a variety of connectionless protocols, such as UDP. The most commonly used connectionless protocol is UDP. The Magic Packet contains data that is a defined constant represented in hexadecimal as FF:FF:FF:FF:FF:FF, followed by 16 repetitions of the target computer MAC address and possibly by a four or six byte password.

If you implement enhanced network security using 802.1X, the transmission of Magic Packets to sleeping or unauthorized network devices is blocked. You can use an interface specific 802.1X feature known as traffic-control to address this requirement of supporting both WoL and 802.1X Authentication simultaneously. The default mode is *in-out*. This mode blocks both ingress and egress unauthenticated traffic on an 802.1X port. Configuring the traffic control mode to *in* enables the transmission of Magic Packets to sleeping or unauthenticated devices. This mode allows any network control traffic, such as a WoL Magic Packet, to be sent to a workstation irrespective of the authentication or sleep status.

**Important**

If a PC client is assigned to a VLAN based on a previous RADIUS Assigned VLAN, when the client goes into sleep or hibernation mode it reverts to either the default port-based VLAN or Guest VLAN configured for that port. Therefore, the WoL Magic Packet must be sent to the default VLAN or Guest VLAN.

## EAPoL Configuration Using CLI

---

EAPoL (EAP) uses RADIUS protocol for EAP-authorized logons. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Before configuring your device, you must configure at least one EAP RADIUS server and shared secret fields.

You cannot configure EAP on ports that are currently configured for:

- Shared segments
- MultiLink Trunking (MLT)

Change the status of each port that you want to be controlled to auto. The auto setting automatically authenticates the port according to the results of the RADIUS server. The default authentication setting for each port is authorized.

### Globally enabling EAP on the device

Enable EAP globally on the switch before you enable it on a port or interface.

**Procedure**

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Globally configure EAP:  
`eapol enable`

**Example**

Enable EAP globally:

```
Switch:1> enable
Switch:1#config t
Switch:1(config)#eapol enable
```

## Configure EAP on an Interface

Configure EAP on an interface.

### Before You Begin

- EAP must be globally enabled.

### About This Task

When you configure a port with the EAP status of auto (Authorization depends on result of EAP authentication), only one supplicant is allowed on this port. Multiple EAP supplicants are not allowed on the same physical switch port.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable EAP on an interface:

```
eapol status {authorized|auto}
```

3. Disable EAP on on interface:

```
no eapol status
```

### Examples

Enable EAP on an interface:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface GigabitEthernet 1/2  
Switch:1(config-if)# eapol status auto
```

Disable EAP on an interface:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface GigabitEthernet 1/2  
Switch:1(config-if)# no eapol status
```

### Variable Definitions

The following table defines parameters for the **eapol status** command.

| Variable          | Value                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <i>authorized</i> | Specifies that the port is always authorized. The default value is authorized.                                                            |
| <i>auto</i>       | Specifies that port authorization depends on the results of the EAP authentication by the RADIUS server. The default value is authorized. |

## Configuring EAP on a port

Configure EAP on a specific port when you do not want to apply EAP to all of the switch ports.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum EAP requests sent to the supplicant before timing out the session:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} max-
request <1-10>
```

3. Configure the time interval between authentication failure and the start of a new authentication:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
quiet-interval <1-65535>
```

4. Enable reauthentication:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} re-
authentication enable
```

5. Configure the time interval between successive authentications:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} re-
authentication-period <1-65535>
```

#### Note

The EAP re-authentication period value is between 1-65535. Early releases support up to 2147483647. To maintain backward compatibility the CLI value is between 1-2147483647. Trying to configure above 65535 results in an error.

6. Configure the EAP authentication status:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
status {authorized|auto}
```

## Example

Configure the maximum EAP requests sent to the supplicant before timing out the session:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)#eapol max-request 10
Switch:1(config-if)#eapol port 1/2 quiet-interval 500
```

## Variable Definitions

The following table defines parameters for the **eapol port** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Specifies the port or list of ports used by EAP. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>max-request &lt;1-10&gt;</i>                              | Specifies the maximum EAP requests sent to the supplicant before timing out the session. The default is 2.                                                                                                                                                                                                                                                                                                     |
| <i>quiet-interval &lt;1-65535&gt;</i>                        | Specifies the time interval in seconds between the authentication failure and start of a new authentication. The default is 60.                                                                                                                                                                                                                                                                                |
| <i>re-authentication enable</i>                              | Enables reauthentication of an existing supplicant at a specified time interval.                                                                                                                                                                                                                                                                                                                               |
| <i>re-authentication-period &lt;1-65535&gt;</i>              | Specifies the time interval in seconds between successive reauthentications. The default is 3600 (1 hour).<br><br><b>Note:</b><br>The EAP re-authentication period value is between 1–65535. Early releases support up to 2147483647. To maintain backward compatibility the CLI value is between 1–2147483647. Trying to configure above 65535 results in an error.                                           |
| <i>status {authorized auto}</i>                              | Specifies the desired EAP authentication status for this port.                                                                                                                                                                                                                                                                                                                                                 |

## Configure an EAP-enabled RADIUS Server

The switch uses RADIUS servers for authentication and accounting services. Use the no form to delete a RADIUS server.

### Before You Begin

- You must enable EAP globally.

### About This Task

The RADIUS server uses the secret key to validate users.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add an EAP-enabled RADIUS server:

```
radius server host WORD <0-46> used-by eapol acct-enable
```

```
radius server host WORD <0-46> used-by eapol acct-port <1-65536>
```

```
radius server host WORD <0-46> used-by eapol enable
```

```
radius server host WORD <0-46> used-by eapol key WORD<0-20>
```

```
radius server host WORD <0-46> used-by eapol port <1-65536>
```

```
radius server host WORD <0-46> used-by eapol priority <1-10>
```

```
radius server host WORD <0-46> used-by eapol retry <0-6>
```

```
radius server host WORD <0-46> used-by eapol secure-enable
```

```
radius server host WORD <0-46> used-by eapol secure-log-level
```

```
radius server host WORD <0-46> used-by eapol secure-mode
```

```
radius server host WORD <0-46> used-by eapol secure-profile
```

```
radius server host WORD <0-46> used-by eapol source-ip WORD <0-46>
```

```
radius server host WORD <0-46> used-by eapol timeout <1-180>
```

By default, the switch uses RADIUS UDP port 1812 for authentication, and port 1813 for accounting. You can change the port numbers or other RADIUS server options.

## Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Add an EAP RADIUS server:

```
Switch:1(config)# radius server host fe80:0:0:0:21b:4fff:fe5e:73fd key  
radiustest used-by eapol
```

### Variable Definitions

The following table defines parameters to configure an EAP-enabled RADIUS server with the **radius server host** command.

| Variable               | Value                                                                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>host</i> WORD<0-46> | Specifies the IP address of the selected server. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration. |
| <i>WORD</i> <0-20>     | Specifies the secret key, which is a string of up to 20 characters.                                                                             |

The following table defines parameters to use optional arguments of the **radius server host** command.

| Variable                                                      | Value                                                                                                                                                                                               |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>port</i> <1-65535>                                         | Specifies the port ID number.                                                                                                                                                                       |
| <i>priority</i> <1-10>                                        | Specifies the priority number. The lowest number is the highest priority.                                                                                                                           |
| <i>retry</i> <0-6>                                            | Specifies the retry count of the account.                                                                                                                                                           |
| <i>timeout</i> <1-180>                                        | Specifies the timeout of the server. The default is 30.                                                                                                                                             |
| <i>enable</i>                                                 | Enables the functions used by the RADIUS server host.                                                                                                                                               |
| <i>acct-port</i> <1-65536>                                    | Specifies the port account.                                                                                                                                                                         |
| <i>acct-enable</i>                                            | Enables the account.                                                                                                                                                                                |
| <i>secure-enable</i>                                          | Enable secure mode on the server.                                                                                                                                                                   |
| <i>secure-log-level</i>                                       | Specifies the RADIUS secure server log severity level. Possible values are: <ul style="list-style-type: none"> <li>critical</li> <li>debug</li> <li>error</li> <li>info</li> <li>warning</li> </ul> |
| <i>secure-mode</i>                                            | Specifies the protocol for establishing the secure connection with the server.                                                                                                                      |
| <i>secure-profile</i>                                         | Specifies the secure profile name.                                                                                                                                                                  |
| <i>source-ip</i> WORD<0-46>                                   | Specifies the IP source. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.                                                                             |
| <b>Note:</b><br>Exception: only supported on VSP 8600 Series. |                                                                                                                                                                                                     |

## Configure the Switch for EAP and RADIUS

Perform the following procedure to configure the switch for EAP and RADIUS.

## About This Task

You must configure the switch, through which user-based-policy (UBP) users connect to communicate with the RADIUS server to exchange EAP authentication information, as well as user role information. You must specify the IP address of the RADIUS server, as well as the shared secret (a password that authenticates the device with the RADIUS server as an EAP access point). You must enable EAP globally on each device, and you must configure EAP authentication on each device port, through which EAP/UBP users connect.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

For more information about EPM and UBP, see the user documentation for your Enterprise Policy Manager (EPM) application.

## Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Create a RADIUS server that is used by EAP:  
`radius server host WORD <0-46> key WORD<0-20> used-by eapol`
3. Log on to the Interface Configuration mode:  
`interface vlan <1-4059>`
4. Enable the device to communicate through EAP:  
`eapol enable`
5. Exit from VLAN interface mode:  
`exit`
6. Enter Interface Configuration mode:  
`interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}`
7. Enable device ports for EAP authentication:  
`eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} status  
auto`
8. Enable periodic supplicant re-authenticating:  
`eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} re-  
authentication enable`
9. Save your changes:  
`save config`

## Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Create a RADIUS server that is used by EAP:
```

```

Switch:1(config)# radius server host fe90:0:0:0:21b:4eee:fe5e:75fd key
radiustest used-by eap1

Switch:1(config)# interface vlan 2

Enable the device to communicate through EAP:

Switch:1(config-if)# eap1 enable

Save your changes:

Switch:1(config-if)# save config

```

### Variable Definitions

The following table defines parameters for the **radius server host WORD<0-46> usedby eap1** command.

| Variable                     | Value                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>host WORD&lt;0-46&gt;</i> | Specifies the IP address of the selected server. This address tells the device where to find the RADIUS server, from which it obtains EAP authentication and user role information. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.                                                                                    |
| <i>key WORD&lt;0-20&gt;</i>  | Specifies the shared secret key that you use for RADIUS authentication. The shared secret is held in common by the RADIUS server and all EAP-enabled devices in your network. It authenticates each device with the RADIUS server as an EAP access point. When you configure your RADIUS server, you must configure the same shared secret value as you specify here. |

## Change the Authentication Status of a Port

The switch authorizes ports by default, which means that the ports are always authorized and are not authenticated by the RADIUS server.

You can also make the ports controlled so that they are dependent on being authorized by the Radius Server when you globally enable EAP (auto).

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the authorization status of a port:

```
eapol status {authorized|auto}
```

### Example

Configure the authorization status of a port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 3/1
Switch:1(config-if)#eapol status auto
```

### Variable Definitions

The following table defines parameters for the **eapol status** command.

| Variable          | Value                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <i>authorized</i> | Specifies that the port is always authorized. The default value is authorized.                                                            |
| <i>auto</i>       | Specifies that port authorization depends on the results of the EAP authentication by the RADIUS server. The default value is authorized. |

## Deleting an EAP-enabled RADIUS server

Delete an EAP-enabled RADIUS server if you want to remove the server.

### About This Task

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Delete an EAP-enabled RADIUS server:
 

```
no radius server host WORD<0-46> used-by eapol
```

### Example

```
Switch:1> enable

Switch:1# configure terminal

Switch:1(config)# no radius server host fe79:0:0:0:21d:4fdf:fe5e:73fd
used-by eapol
```

### Variable Definitions

The following table defines parameters for the **radius server host WORD<0-46>** used by **eapol** command.

| Variable                     | Value                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>host WORD&lt;0-46&gt;</i> | Specifies the IP address of the selected server. This address tells the device where to find the RADIUS server, from which it obtains EAP authentication and user role information. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.                                                                                    |
| <i>key WORD&lt;0-20&gt;</i>  | Specifies the shared secret key that you use for RADIUS authentication. The shared secret is held in common by the RADIUS server and all EAP-enabled devices in your network. It authenticates each device with the RADIUS server as an EAP access point. When you configure your RADIUS server, you must configure the same shared secret value as you specify here. |

## Configuring Fail Open VLAN

### About This Task

Use this procedure to configure Fail Open VLAN.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Fail Open VLAN:

```
eapol fail-open-vlan <1-4059>
```

### Example

Configure the Fail Open VLAN.

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface gigabitEthernet 1/1  
Switch:1(config)#eapol fail-open-vlan 10
```

### Variable Definitions

The following table defines parameters for the **eapol fail-open-vlan** command.

| Variable | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## Display the Current EAP-Based Security Status

Use the following procedure to display the status of the EAP-based security.

### Procedure

1. Enter Privileged EXEC mode:  
enable

2. Display the current EAP-based security status:

```
show eapol auth-stats interface [gigabitEthernet {slot/port[/sub-port]}
[-slot/port[/sub-port]] [,...]]
```

```
show eapol multihost non-eap-mac status [vlan <1-4059>] [{slot/port[/sub-
port]} [-slot/port[/sub-port]] [,...]]
```

#### Note

This command only applies to VSP 8600 Series.

```
show eapol port {interface [gigabitEthernet {slot/port[/sub-port]} [-
slot/port[/sub-port]] [,...]] | {slot/port[/sub-port]} [-slot/port[/
sub-port]] [,...]]
```

```
show eapol session-stats interface [gigabitEthernet {slot/port[/sub-
port]} [-slot/port[/sub-port]] [,...]]
```

```
show eapol status interface [vlan <1-4059>] [gigabitEthernet {slot/
port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```

#### Note

This command only applies to VSP 8600 Series.

```
show eapol sessions {eap | neap} [vlan <1-4059>] [{slot/port[/sub-
port]} [-slot/port[/sub-port]] [,...]] [verbose]
```

#### Note

This command does not apply to VSP 8600 Series or XA1400 Series.

```
show eapol summary port [{slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...]]
```

```
show eapol system
```

### Examples

#### Note

Product Notice: auto-isid-offset functionality is not available on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

```
Switch:1>show eapol system

If no port is entered, all ports are displayed.</p>                                                                                                                                                                                                              |
| <pre>session-stats interface [gigabitEthernet {slot/ port[/sub-port] [-slot/ port[/sub-port]] [,...]]</pre>                                                                                                                     | <p>Displays the authentication session statistics interface.</p>                                                                                                                                                                                                                                    |
| <pre>sessions {eap   neap} [vlan &lt;1-4059&gt;][{slot/ port[/sub-port] [-slot/ port[/sub-port]] [,...]] [verbose]</pre> <p><b>Note:</b><br/> Exception: This parameter does not apply to VSP 8600 Series or XA1400 Series.</p> | <p>Displays EAP and non-EAP authentication sessions on the port.</p>                                                                                                                                                                                                                                |

| Variable                                                                                                                                                                                                 | Value                                       |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| <code>status interface [vlan &lt;1-4059&gt;] [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]</code><br><b>Note:</b><br>Exception: This parameter applies to VSP 8600 Series only. | Displays the port EAP operation statistics. |
| <code>summary port[{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]</code>                                                                                                                          | Displays EAP and NEAP clients.              |
| <code>system</code>                                                                                                                                                                                      | Displays EAP settings.                      |

## Displaying the port VLAN information

Use the following procedure to display the port VLAN information.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Display the port VLAN information:  
`show interfaces [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]] [vlan <1-4059>]`

### Example

```
Switch:#enable
Switch:1#show interfaces gigabitethernet vlan
=====
                        Port Vlans
=====
PORT          DISCARD DISCARD  DEFAULT VLAN      PORT  UNTAG  DYNAMIC  UNTAG
NUM   TAGGING TAGFRAM UNTAGFRAM VLANID  IDS   TYPE   DEFVLAN VLANS   VLANS
-----
1/1   disable false  false   1       1     normal  disable P       1
1/2   enable  false  false   1       1,3,10 normal  disable P       1,10
1/3   enable  false  false   1       1,10,20 normal  disable P
```

*Variable Definitions*

The following table defines parameters for the **show interfaces** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <code>&lt;1-4059&gt;</code>                                        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

### Configuring the format of the RADIUS password attribute when authenticating NEAP MAC addresses using RADIUS

Use the following procedure to configure the format of the RADIUS password when authenticating NEAP MAC addresses using RADIUS.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the RADIUS password format:  

```
eapol multihost non-eap-pwd-fmt {[ip-addr] [key WORD<1-32>] [mac-addr] [padding] [port-number]}
```

*Variable Definitions*

The following table defines parameters for the **eapol multihost non-eap-pwd-fmt** command.

| Variable                          | Value                                       |
|-----------------------------------|---------------------------------------------|
| <code>ip-addr</code>              | Management ip-address of the switch.        |
| <code>key WORD&lt;1-32&gt;</code> | Key value used for non-eap password format. |
| <code>mac-addr</code>             | Mac-Address of the client.                  |

| Variable           | Value                                                              |
|--------------------|--------------------------------------------------------------------|
| <i>padding</i>     | Includes a dot in the RADIUS password for every missing parameter. |
| <i>port-number</i> | Index of the port on which MAC is received.                        |

**Note**

To derive the port number for an interface, use the command **show interfaces gigabit** **[{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]]** .

If you configure interface 1/6 on the product, to derive the port-number for this interface, use the command **show interfaces gigabitEthernet 1/6**. From this command, you can ascertain that port number used in the NEAP password is 197.

```
Switch:1(config)# show interfaces gigabitEthernet 1/6
```

```
=====
```

| Port Interface |       |             |              |              |      |                     |                         |    |  |
|----------------|-------|-------------|--------------|--------------|------|---------------------|-------------------------|----|--|
| PORT<br>NUM    | INDEX | DESCRIPTION | LINK<br>TRAP | PORT<br>LOCK | MTU  | PHYSICAL<br>ADDRESS | STATUS<br>ADMIN OPERATE |    |  |
| 1/6            | 197   | 1000BaseTX  | true         | false        | 1950 | f8:15:47:e1:dd:05   | up                      | up |  |

```
=====
```

## Enabling RADIUS authentication of NEAP hosts on EAP enabled ports

For RADIUS authentication of NEAP hosts on EAP-enabled ports, you must enable EAP globally on the switch and then enable NEAP hosts on the local interface.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[, ...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable RADIUS authentication of NEAP hosts on the local interface:

```
eapol multihost radius-non-eap-enable
```

## Configuring the maximum MAC clients

Use this procedure to configure the maximum EAP and NEAP MAC clients supported on a port.

**Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Set the maximum limit of allowed EAP and NEAP MAC clients supported on the port:

```
eapol multihost mac-max <1-8192>
```

**Example**

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface GigabitEthernet 1/16
Switch:1(config-if)# eapol multihost mac-max <1-8192>
```

*Variable Definitions*

The following table defines parameters for the **eapol multihost mac-max** command.

| Variable                | Value                                                                                                                    |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>mac-max</i> <1-8192> | Specifies the maximum number of EAP and NEAP MAC addresses allowed on the port. The maximum limit is 8192 MAC addresses. |

## Configuring maximum EAP clients

**About This Task**

Use this procedure to configure the maximum EAP clients allowed on the port at one time.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum EAP clients:

```
eapol multihost eap-mac-max <0-32>
```

#### Note

*eap-mac-max* is also used to provide EAP and NEAP separation functionality. By default the EAP clients are enabled per port and *eap-mac-max* limit is 2. If *eap-mac-max* is set to 0 then EAP client authentication is disabled.

### Example

Configure the maximum EAP clients allowed on the port at one time.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol multihost eap-mac-max 10
```

### Variable Definitions

The following table defines parameters for the **eapol multihost eap-mac-max** command.

| Variable | Value                                                                                |
|----------|--------------------------------------------------------------------------------------|
| <0-32>   | Specifies the maximum EAP clients allowed on the port at one time. The default is 2. |

## Configuring maximum NEAP clients

### About This Task

Use this procedure to configure the maximum NEAP clients allowed on the port at one time.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum NEAP clients:

```
eapol multihost non-eap-mac-max <0-8192>
```

#### Note

*non-eap-mac-max* is also used to provide EAP and NEAP separation functionality. By default the NEAP clients are enabled per port and *non-eap-mac-max* limit is 2. If *non-eap-mac-max* is set to 0 then NEAP client authentication is disabled.

### Example

Configure the maximum NEAP clients allowed on the port at one time.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol multihost non-eap-mac-max 10
```

#### Variable Definitions

The following table defines parameters for the **eapol multihost non-eap-mac-max** command.

| Variable | Value                                                                                 |
|----------|---------------------------------------------------------------------------------------|
| <0-8192> | Specifies the maximum NEAP clients allowed on the port at one time. The default is 2. |

## Configuring the Guest VLAN ID

### About This Task

Use this procedure to configure the Guest VLAN ID.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Guest VLAN ID:

```
eapol guest-vlan <1-4059>
```

## Example

Configure the Guest VLAN ID.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol guest-vlan 10
```

## Variable Definitions

The following table defines parameters for the **eapol guest-vlan** command.

| Variable | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## Clearing NEAP session

Use this procedure to clear the NEAP session that is learnt on the switch.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Clear the NEAP session:

```
clear eapol non-eap [<0x00:0x00:0x00:0x00:0x00:0x00>] [{slot/port[/sub-port]
[-slot/port[/sub-port]][,...]}
<0x00:0x00:0x00:0x00:0x00:0x00>]
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# clear 1/16 00:1b:63:84:45:e6
```

### Variable Definitions

The following table defines parameters for the **clear eapol non-eap** command.

| Variable                                                           | Value                                                    |
|--------------------------------------------------------------------|----------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Specifies the port list on which the NEAP MAC is learnt. |
| <code>0x00:0x00:0x00:0x00:0x00:0x00</code>                         | Specifies the MAC-Address on the NEAP session.           |

## Configuring EAP operational mode

### About This Task

Use this procedure to configure the EAP operational mode.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. configure the EAP operational mode:

```
eapol multihost eapol-oper-mode {mhmV | mhsa}
```

#### Note

The default EAP operational mode is MHMV.

### Example

Configure the EAP operational mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol eapol-oper-mode mhsa
```

### Variable Definitions

The following table defines parameters for the **eapol multihost eap-oper-mode** command.

| Variable   | Value                                                                      |
|------------|----------------------------------------------------------------------------|
| <i>mhm</i> | Specifies the EAP operational mode as Multiple Host Multiple VLAN.         |
| <i>mhs</i> | Specifies the EAP operational mode as Multiple Host Single Authentication. |

## Enabling dynamic changes to EAP sessions on a port

### About This Task

Configure a port to allow dynamic changes to EAP sessions. The default is enable.

### Before You Begin

You must enable EAP globally and at the port level.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable RADIUS dynamic authorization server processing requests.

```
eapol radius-dynamic-server enable
```

### Example

```
Switch:1>enable  
Switch:1#config terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
Switch:1(config)#interface gigabitEthernet 1/4  
Switch:1(config-if)#eapol radius-dynamic-server enable
```

## Configure EAP auto-isid-offset

#### Note

This procedure does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

**Before You Begin**

- Enable EAP globally or on the port.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure an I-SID offset value:  

```
eapol auto-isid-offset <0-15995903>
```
3. Enable EAP globally:  

```
eapol enable
```
4. Confirm that your configuration is correct:  

```
show eapol system
```

*Examples*

Configure an I-SID offset value and enable I-SID offset globally on the switch:

```
Switch:1> enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#eapol auto-isid-offset 1000
Switch:1(config)#eapol enable
```

View the current device configuration:

**Note**

Not all fields are supported on all hardware platforms.

```
Switch:1>show eapol system
=====
                        Eapol System
=====
                        eap : disabled
                        Eapol Version : 3
                        non-eap-pwd-fmt : mac-addr
                        non-eap-pwd-fmt key : *****
                        non-eap-pwd-fmt padding : disabled
                        auto-isid-offset status : disabled
                        auto-isid-offset value : 1000
=====
```

### Variable Definitions

The following table defines parameters for the **eapol auto-isid-offset** command.

| Variable                                                                                                                           | Value                                                              |
|------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| <code>&lt;0-15995903&gt;</code><br><b>Note:</b><br>Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Specifies the auto I-SID offset value.<br>The default is 15995903. |
| <code>enable</code><br><b>Note:</b><br>Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.             | Enables auto I-SID offset.<br>The default is disabled.             |

## Configure the Guest I-SID

### Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

### Before You Begin

Configure a platform VLAN and associate the Guest I-SID. 0 indicates that Guest I-SID is not enabled for this port.

### About This Task

Use this procedure to configure the Guest I-SID.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Guest I-SID:

```
eapol guest-isid <1-16000000>
```

## Example

Configure the Guest I-SID.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/10
Switch:1(config-if)#eapol guest-isid 1000
```

### Variable Definitions

The following table defines parameters for the **eapol guest-isid** command.

| Variable     | Value                                                                                          |
|--------------|------------------------------------------------------------------------------------------------|
| <0-16000000> | Specifies the Guest I-SID value.<br>0 indicates that Guest I-SID is not enabled for this port. |

## Configure Fail Open I-SID

### Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

### Before You Begin

Configure a platform VLAN and associate the Fail Open I-SID.

### About This Task

Use this procedure to configure Fail Open I-SID. If the switch declares the RADIUS servers unreachable, then all new devices gain access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Fail Open I-SID:

```
eapol fail-open-isid <0-16000000>
```

## Example

Configure the Fail Open I-SID.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#interface gigabitEthernet 1/10
Switch:1(config-if)#eapol fail-open-isid 1000
```

### Variable Definitions

The following table defines parameters for the **eapol fail-open-isid** command.

| Variable     | Value                                                                                                  |
|--------------|--------------------------------------------------------------------------------------------------------|
| <0-16000000> | Specifies the Fail Open I-SID value.<br>0 indicates that Fail Open I-SID is not enabled for this port. |

## Configure Wake-On-LAN

Use the following procedure to configure Wake-On-LAN functionality.

### Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Wake-On-LAN:

```
eapol traffic-control <in | in-out>
```

### Variable Definitions

The following table defines parameters for the **eapol traffic-control** command.

| Variable      | Value                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>in</i>     | Specifies incoming traffic is blocked when there is no authenticated device.                                              |
| <i>in-out</i> | Specifies incoming and outgoing traffic is blocked when there is no authenticated device.<br>The default value is in-out. |

## Show the EAPoL Status of the Device

Display the current device configuration.

### Note

Use the **clear-stats** command to clear EAP or NEAP statistics.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the current device configuration by using the following command:

```
show eapol system
```

### Example

### Note

Product Notice: auto-isid-offset functionality is not available on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

```
Switch:1>show eapol system
=====
                        Eapol System
=====
          eap : disabled
    Eapol Version : 3
    non-eap-pwd-fmt : mac-addr
    non-eap-pwd-fmt key : *****
    non-eap-pwd-fmt padding : disabled
    auto-isid-offset status : disabled
    auto-isid-offset value : 1000
=====
```

## Show EAPoL Authenticator Statistics

Display the authenticator statistics to manage network performance.

### Note

Use the **clear-stats** command to clear EAP or NEAP statistics.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the authenticator statistics:

```
show eapol auth-stats interface [gigabitEthernet [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]]
```

**Example**

```
Switch:1#show eapol auth-stats interface
=====
                        Eap Authenticator Statistics
=====
PORT  EAP    AUTH-EAP   START LOGOFF  INVALID  LENGTH  LAST-RX   LAST-RX

--More-- (q = quit)
```

*Variable Definitions*

Use the data in the following table to use the **show eapol auth-stats interface** command.

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

**View EAPoL Session Statistics**

View EAPoL session statistics to manage network performance.

**Note** Use the **clear-stats** command to clear EAP/NEAP statistics.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the session statistics:

```
show eapol session-stats interface [gigabitEthernet [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]]
```

### Example

```
Switch:1#show eapol session-stats interface
=====
                        Eap Authenticator Session Statistics
=====
PORT  MAC                SESSION  AUTHENTIC  SESSION  TERMINATE  USER
NUM   MAC                ID       METHOD      TIME     CAUSE      NAME
-----
1/1   18:a9:05:b1:04:ce   cb000000 remote-server 0 day(s), 05:58:16 not-terminated sachin
1/4   00:00:00:00:00:01   cb000002 remote-server 0 day(s), 05:48:01 not-terminated 000000000001
=====
```

### Variable Definitions

Use the data in the following table to use the **show eapol session-stats interface** command.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## View Non-EAPoL MAC Information

### Note

This procedure only applies to VSP 8600 Series.

Use this procedure to view non-EAPoL client MAC information on a port.

### Note

Use the **clear-stats** command to clear EAP and NEAP statistics.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the non-EAPoL MAC information:

```
show eapol multihost non-eap-mac status [vlan <1-4059>] [verbose]
[ {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...] }
```

### Example

### Note

Not all fields are supported on all hardware platforms.

```
Switch:1(config)#show eapol multihost non-eap-mac status
=====
                        Eap Oper Status
=====

-----
Total Number of NEAP Sessions: 1
    
```

### Variable Definitions

Use the data in the following table to use the **show eapol multihost non-eap-mac status** command.

| Variable                                                                                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]</code>                                       | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <code>&lt;1-4059&gt;</code>                                                                            | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>verbose</code>                                                                                   | Displays non-EAPoL client MAC information.                                                                                                                                                                                                                                                                                                                                                                                 |
| <p><b>Note:</b><br/>Exception: Not supported on VSP 4450 Series, XA1400 Series, or VSP 8600 Series</p> |                                                                                                                                                                                                                                                                                                                                                                                                                            |

## View Port EAPoL Operation Statistics

Use this procedure to view port EAPoL operation statistics.

**Note**  
Use the **clear-stats** command to clear EAP/NEAP statistics.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the port EAPoL operation statistics information:

```

show eapol status interface [gigabitEthernet [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [vlan <1-4059>] [verbose]
    
```

## Example

### Note

Not all fields are supported on all hardware platforms.

```
Switch:1(config)#show eapol status interface
```

```
=====
                        Eap Oper Status
=====
PORT  MAC                STATE          VLAN  PRI  Flex-UNI  I-SID  VLAN:I-SID

### Variable Definitions

Use the data in the following table to use the **show eapol status** command.

| Variable                                                                                       | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>                            | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>&lt;1-4059&gt;</code>                                                                    | Specifies the VLAN ID for which to show the statistics.                                                                                                                                                                                                                                                                                                       |
| <code>verbose</code>                                                                           | Displays detailed statistics information.                                                                                                                                                                                                                                                                                                                     |
| <b>Note:</b><br>Exception: Not supported on VSP 4450 Series, XA1400 Series, or VSP 8600 Series |                                                                                                                                                                                                                                                                                                                                                               |

## EAP Configuration Using Enterprise Device Manager

EAPoL (EAP) uses RADIUS protocol for EAP-authorized logons. RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration in all but the following case. When adding

a RADIUS server in Enterprise Device Manager (EDM) or modifying a RADIUS configuration in EDM, you must specify if the address type is an IPv4 or an IPv6 address.

### Before You Begin

- Before configuring your device, you must configure at least one EAP RADIUS server and shared secret fields.
- You cannot configure EAP on ports that are currently configured for:
  - Shared segments
  - MultiLink Trunking (MLT)
- Change the status of each port that you want to be controlled to auto. For more information on changing the status, see [Configure EAP on a Port](#) on page 820. The auto setting automatically authenticates the port according to the results of the RADIUS server. The default authentication setting for each port is force-authorized.

## Globally Configure EAP on the Server

### About This Task

Globally enable or disable EAP on the switch. By default, EAP is disabled.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **802.1X - EAPOL**.
3. Select the **Global** tab.
4. From the AccessControl options, select **enable**.
5. (Optional) Select the appropriate **NonEapRadiusPwdAttrFmt** check boxes to configure the format of the RADIUS password when authenticating non-EAP MAC addresses using RADIUS.
6. (Optional) Enter the key string in the **NonNonEapRadiusPwdAttkeystring** field.
7. (Optional) Check the **ClearNonEap** check box to clear the NEAP session that is learned on the switch.
8. (Optional) Type an I-SID offset number in the **AutolsidOffset** field.  
This step does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.
9. (Optional) Select the **AutolsidOffsetEnable** check box to enable Auto I-SID offset on the switch.  
This step does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.
10. Select **Apply**.

### *Global* field descriptions

Use the data in the following table to use the **Global** tab.

| Name                 | Description                                                        |
|----------------------|--------------------------------------------------------------------|
| <b>EapolVersion</b>  | Displays the EAP version on the switch.                            |
| <b>AccessControl</b> | Enables system authentication control. EAP is disabled by default. |

| Name                                                                                                                        | Description                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NonEapRadiusPwdAttrFmt</b>                                                                                               | Specifies the password attribute format for non EAP RADIUS authentication. <ul style="list-style-type: none"> <li>ipAdd: Specifies IP address.</li> <li>macAddr: Specifies MAC address.</li> <li>portNumber: Specifies port number</li> <li>padding: Specifies padding.</li> </ul> |
| <b>NonEapRadiusPwdAttrKeyString</b>                                                                                         | Specifies the attribute key string for non EAP RADIUS password. The range is 0– 32 characters.                                                                                                                                                                                     |
| <b>ClearNonEap</b>                                                                                                          | Clears the NEAP session that is learned on the switch.                                                                                                                                                                                                                             |
| <b>AutolsidOffset</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.       | Specifies the Auto I-SID Offset value. The range is 0-15995903.                                                                                                                                                                                                                    |
| <b>AutolsidOffsetEnable</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Enables or disables the Auto I-SID Offset feature.                                                                                                                                                                                                                                 |

## Configure EAP on a Port

### About This Task

Configure EAP or change the authentication status on one or more ports.

Ports are force-authorized by default. Force-authorized ports are always authorized and are not authenticated by the RADIUS server. You can change this setting so that the ports are always unauthorized.

### Procedure

1. In the Device Physical View tab, select the port you need to configure.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **EAPOL** tab.
5. (Optional) Select the **AllowNonEapHost** check box to enable hosts that do not participate in 802.1X authentication to get network access.
6. Select the **Status** option as **auto** or **forceAuthorized**.
7. In the **MultiHostMaxClients** field, type the maximum limit of allowed EAP and NEAP clients supported on this port.
8. In the **GuestVlanId** field, type the VLAN ID to be used as a Guest VLAN ID.  
This step does not apply to VSP 8600 Series or XA1400 Series.
9. In the **FailOpenVlanId** field, type the Fail Open VLAN ID.  
This step does not apply to VSP 8600 Series or XA1400 Series.

10. In the **NonEapMaxClients** field, type the maximum number NEAP authentication MAC addresses allowed on this port.
11. In the **EapMaxClients** field, type the maximum number of EAP authentication MAC addresses allowed on this port.
12. Select the **MultiHostSingleAuthEnabled** check box to automatically authenticate NEAP MAC addresses on this port.
13. In the **PortGuestIsid** field, type the I-SID to be used as a Guest I-SID.  
This step does not apply to VSP 8600 Series or XA1400 Series.
14. In the **FailOpenIsid** field, type the Fail Open I-SID.  
This step does not apply to VSP 8600 Series or XA1400 Series.
15. Select the **AdminTrafficControl** option as **inOut** or **in**.
16. (Optional) Select the **LldpAuthEnabled** check box to enable LLDP authentication for network access.  
This step does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.
17. Select the **ReAuthEnabled** field.
18. In the **QuietPeriod** field, type the time interval.
19. In the **ReauthPeriod** field, type the time between reauthentication.
20. In the **RetryMax** field, type the number of times.
21. Select **Apply**.

### **EAPoL** Field Descriptions

Use the data in the following table to use the **EAPoL** tab.

| Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PortCapabilities</b>        | Displays the capabilities of the Port Access Entity (PAE) associated with the port. This parameter indicates whether Authenticator functionality, supplicant functionality, both, or neither, is supported by the PAE of the port. The following capabilities are supported by the PAE of the port: <ul style="list-style-type: none"> <li>• <b>authImplemented</b>: A Port Access Controller Protocol (PACP) Extensible Authentication Protocol (EAP) authenticator functions are implemented.</li> <li>• <b>virtualPortsImplemented</b>: Virtual Port functions are implemented.</li> </ul> |
| <b>PortVirtualPortsEnable</b>  | Displays the status of the Virtual Ports function for the real port as True or False.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>PortCurrentVirtualPorts</b> | Displays the current number of virtual ports running in the port                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>PortAuthenticatorEnable</b> | Displays the status of the Authenticator function in the Port Access Entity (PAE) as True or False.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>PortSupplicantEnable</b>    | Displays the Supplicant function in the Port Access Entity (PAE) as True or False.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>AllowNonEapHost</b>         | Enables network access to hosts that do not participate in 802.1X authentication. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Authenticator configuration</b>                                                                                            | Displays the current Authenticator Port Access Entity (PAE) state.<br>The states are: <ul style="list-style-type: none"> <li>• authenticate</li> <li>• authenticated</li> <li>• Failed</li> </ul>                                                                                                                                                                  |
| <b>ReAuthEnabled</b>                                                                                                          | Reauthenticates an existing supplicant at the time interval specified in ReAuthPeriod. The default is disabled.                                                                                                                                                                                                                                                    |
| <b>QuietPeriod</b>                                                                                                            | Configures the time interval (in seconds) between authentication failure and the start of a new authentication.                                                                                                                                                                                                                                                    |
| <b>ReAuthPeriod</b>                                                                                                           | Reauthenticates an existing supplicant at the time interval specified in ReAuthPeriod.<br>Configures the time interval (in seconds) between successive reauthentications. The default is 3600 (1 hour).                                                                                                                                                            |
| <b>RetryMax</b>                                                                                                               | Specifies the maximum Extensible Authentication Protocol (EAP) requests sent to the supplicant before timing out the session. The default is 2.                                                                                                                                                                                                                    |
| <b>RetryCount</b>                                                                                                             | Specifies the maximum number of retries attempted.                                                                                                                                                                                                                                                                                                                 |

## Configure EAP on an Extreme Integrated Application Hosting Port

### About This Task

Perform this procedure to configure EAP or change the authentication status on Extreme Integrated Application Hosting (IAH) ports. IAH ports are force-authorized by default and are not authenticated by the RADIUS server. You can change this setting so that the IAH ports stay unauthorized.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **EAPOL** tab.
4. (Optional) Select **AllowNonEapHost**.
5. In the **Status** field, select the required option.
6. In the **MultiHostMaxClients** field, enter a value.
7. In the **GuestVlanId** field, enter a VLAN ID.
8. In the **FailOpenVlanId** field, enter a VLAN ID.
9. In the **NonEapMaxClients** field, enter a value.
10. In the **EapMaxClients** field, enter a value.
11. Select **MultiHostSingleAuthEnabled**.
12. In the **PortGuestIsid** field, type the I-SID to be used as a Guest I-SID.  
This step does not apply to VSP 8600 Series or XA1400 Series.
13. In the **FailOpensid** field, type the Fail Open I-SID.  
This step does not apply to VSP 8600 Series or XA1400 Series.
14. Select the **AdminTrafficControl** option as **inOut** or **in**.  
This step does not apply to VSP 8600 Series or XA1400 Series.
15. Select the **LldpAuthEnabled** check box to enable LLDP authentication for network access.  
This step does not apply to VSP 8600 Series or XA1400 Series.
16. Select **ReAuthEnabled**.
17. In the **QuietPeriod** field, enter a time interval.
18. In the **ReAuthPeriod** field, enter a time interval.
19. In the **RetryMax** field, type a value.
20. Select **Apply**.

**EAPOL** Field Descriptions

Use data in the following table to use the **EAPOL** tab.

| Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PortCapabilities</b>        | Shows the capabilities of the Port Access Entity (PAE) associated with the Extreme Integrated Application Hosting (IAH) port. This parameter indicates whether Authenticator functionality, supplicant functionality, both, or neither, is supported by the PAE of the IAH port. The following capabilities are supported by the PAE of the IAH port: <ul style="list-style-type: none"> <li>• <b>authImplemented:</b> A Port Access Controller Protocol (PACP) Extensible Authentication Protocol (EAP) authenticator functions are implemented.</li> <li>• <b>virtualPortsImplemented:</b> Virtual Port functions are implemented.</li> </ul> |
| <b>PortVirtualPortsEnable</b>  | Shows the status of the Virtual Ports function for the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>PortCurrentVirtualPorts</b> | Shows the current number of virtual ports running on the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>PortAuthenticatorEnable</b> | Shows the status of the Authenticator function in the PAE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>PortSupplicantEnable</b>    | Shows the Supplicant function in the PAE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>AllowNonEapHost</b>         | Enables network access to hosts that do not participate in 802.1X authentication. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Status</b>                  | Specifies the authentication status for the IAH port. <ul style="list-style-type: none"> <li>• <b>auto</b> - enables EAP authentication process by sending the EAP request messages to the RADIUS server.</li> <li>• <b>forceAuthorized</b> - disables EAP authentication and puts the IAH port into force-full authorized mode.</li> </ul> The default is forceAuthorized.                                                                                                                                                                                                                                                                     |
| <b>MultiHostMaxClients</b>     | Specifies the maximum number of supplicants authenticated on the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>GuestVlanId</b>             | Specifies the VLAN ID to be used as a Guest. Access to unauthenticated hosts connected to the IAH port is provided through this VLAN. 0 indicates that Guest VLAN is not enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>FailOpenVlanId</b>          | Specifies the Fail Open VLAN ID for the specific IAH port. If RADIUS server is not reachable on the switch, then all new devices are allowed access to the configured Fail Open VLAN ID. 0 indicates that Fail Open VLAN ID is not enabled.                                                                                                                                                                                                                                                                                                                                                                                                     |

| Name                                                                                                                   | Description                                                                                                                                                                                                                                                                  |
|------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NonEapMaxClients</b>                                                                                                | Specifies the maximum number of NEAP authentication MAC addresses allowed on the specific IAH port. 0 indicates that NEAP authentication is disabled.                                                                                                                        |
| <b>EAPMaxClients</b>                                                                                                   | Specifies the maximum number of EAP authentication MAC addresses allowed on the specific IAH port. 0 indicates that EAP authentication is disabled.                                                                                                                          |
| <b>MultiHostSingleAuthEnabled</b>                                                                                      | Enables the functionality for network access to the unauthenticated devices only after an EAP or NEAP client is successfully authenticated on the IAH port. The VLAN ID to which the devices are allowed access is the authenticated client's VLAN. The default is disabled. |
| <b>PortGuestIsid</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                     | Specifies the I-SID to be used as a Guest I-SID. Access to unauthenticated hosts connected to the IAH port is provided through this I-SID. 0 indicates that Guest I-SID is not enabled for this port.                                                                        |
| <b>FailOpenIsid</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                      | Specifies the Fail Open I-SID for the IAH port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.                           |
| <b>FlexUniStatus</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.   | Displays the current Flex-UNI status for this IAH port.                                                                                                                                                                                                                      |
| <b>AdminTrafficControl</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.               | Configures the Administrative Traffic Control. The default is inOut.<br><ul style="list-style-type: none"> <li>• inOut: enables the Admin Traffic Control for input and output traffic.</li> <li>• in: enables the Admin Traffic Control for input traffic only.</li> </ul>  |
| <b>OperTrafficControl</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                | Displays the current Operational Traffic Control status.                                                                                                                                                                                                                     |
| <b>LldpAuthEnabled</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Enables LLDP authentication for this IAH port. The default is disabled.                                                                                                                                                                                                      |

| <b>ReAuthEnabled</b>                                                                                                          | Enables reauthentication of an existing supplicant based on the specified reauthentication time interval. The default is disabled.                                                                                                                                                                                                                                 |
| <b>QuietPeriod</b>                                                                                                            | Specifies the time interval (in seconds) between authentication failure and start of authentication.                                                                                                                                                                                                                                                               |
| <b>ReauthPeriod</b>                                                                                                           | Specifies the time interval (in seconds) between successive reauthentications. The default is 3600 (1 hour).                                                                                                                                                                                                                                                       |
| <b>RetryMax</b>                                                                                                               | Specifies the maximum Extensible Authentication Protocol (EAP) requests sent to the supplicant before timing out the session. The default is 2.                                                                                                                                                                                                                    |
| <b>RetryCount</b>                                                                                                             | Specifies the maximum number of retries attempted.                                                                                                                                                                                                                                                                                                                 |

## Show the Port Access Entity Port Table

### About This Task

Use the Port Access Entity (PAE) Port Table to display system-level information for each port the PAE supports. An entry display in this table for each port of this system.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **802.1X - EAPOL**.
3. Select the **EAP Security** tab.

### *EAP Security Field Descriptions*

Use the data in the following table to use the **EAP Security** tab.

| Name                              | Description                                                                                                                                                                                                                                                       |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PortNumber</b>                 | Indicates the port number associated with this port.                                                                                                                                                                                                              |
| <b>PortCapabilities</b>           | Indicates the capabilities of this PAE port. <ul style="list-style-type: none"> <li>authImplemented—PACP EAP authenticator functions are implemented in this PAE.</li> <li>virtualPortsImplemented—Virtual Port functions are implemented in this PAE.</li> </ul> |
| <b>PortVirtualPortsEnable</b>     | Displays the status of the Virtual Ports function for the real port as True or False.                                                                                                                                                                             |
| <b>PortCurrentVirtualPorts</b>    | Displays the current number of virtual ports running in the port                                                                                                                                                                                                  |
| <b>PortAuthenticatorEnable</b>    | Displays the status of the Authenticator function in the Port Access Entity (PAE) as True or False.                                                                                                                                                               |
| <b>PortSupplicantEnable</b>       | Displays the Supplicant function in the Port Access Entity (PAE) as True or False.                                                                                                                                                                                |
| <b>AllowNonEapHost</b>            | Displays the status if the system is enabled to allow hosts that do not participate in 802.1X authentication to get network access.                                                                                                                               |
| <b>Status</b>                     | Displays the authentication status for this port. The default is forceAuthorized.                                                                                                                                                                                 |
| <b>MultiHostMaxClients</b>        | Indicates the value representing the maximum number of supplicants allowed to get authenticated on the port.                                                                                                                                                      |
| <b>GuestVlanId</b>                | Specifies the VLAN to be used as a Guest VLAN. Access to unauthenticated hosts connected to this port is provided through this VLAN. 0 indicates that Guest VLAN is not enabled for this port.                                                                    |
| <b>FailOpenVlanId</b>             | Specifies the Fail Open VLAN ID for the port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open VLAN. 0 indicates that Fail Open VLAN is not enabled for this port.                    |
| <b>NonEapMaxClients</b>           | Indicates the maximum number of non-EAPoL authentication MAC addresses allowed on this port. Zero indicates that non-EAPoL authentication is disabled for this port.                                                                                              |
| <b>EapMaxClients</b>              | Indicates the maximum number of EAPoL authentication MAC addresses allowed on this port. Zero indicates that EAPoL authentication is disabled for this port.                                                                                                      |
| <b>MultiHostSingleAuthEnabled</b> | Indicates that the unauthenticated devices can access the network only after an EAP or NEAP client is successfully authenticated on the port. The VLAN to which the devices are allowed access is the authenticated client's VLAN. The default is false.          |
| <b>ProcessRadiusCOAPackets</b>    | Specifies whether to process any RADIUS requests-server packets that are received on this port.                                                                                                                                                                   |

| Name                                                                                                                      | Description                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PortGuestIsid</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                        | Specifies the I-SID to be used as a Guest I-SID. Access to unauthenticated hosts connected to this port is provided through this I-SID. 0 indicates that Guest I-SID is not enabled for this port.                                                                                                                                                                 |
| <b>FailOpensid</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                          | Specifies the Fail Open I-SID for the port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.                                                                                                                     |
| <b>FlexUniStatus</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.      | Displays the Flex-UNI status for the port.                                                                                                                                                                                                                                                                                                                         |
| <b>AdminTrafficControl</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                  | Specifies the Administrative Traffic Control for the port. The default is inOut.                                                                                                                                                                                                                                                                                   |
| <b>OperTrafficControl</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                   | Displays the Operating Traffic Control for the port.                                                                                                                                                                                                                                                                                                               |
| <b>LldpAuthEnabled</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                      | Specifies if LLDP Authentication is enabled. The default is 0 (disabled).                                                                                                                                                                                                                                                                                          |
| <b>PortOrigin</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                           | Displays the Port Origin configuration status for the port.                                                                                                                                                                                                                                                                                                        |
| <b>DynamicMHSAEnabled</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Displays the Dynamic MHSA status for the port.                                                                                                                                                                                                                                                                                                                     |
| <b>TrafficControlOrigin</b>                                                                                               | Specifies the origin of Traffic Control configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>• config - Traffic Control is enabled by the user.</li> <li>• radius - Traffic Control is enabled by Extensible Authentication Protocol (EAP) through Remote Authentication Dial-In User Service (RADIUS) response.</li> </ul> |

## Show EAP Authentication

### About This Task

Use the Authenticator Configuration table to display configuration objects for the Authenticator PAE associated with each port.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Click **802.1X - EAPOL**.
3. Click the **Authentication** tab.

### **Authentication** Field Descriptions

Use the data in the following table to use the **Authentication** tab.

| Name                 | Description                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PortNumber</b>    | Indicates the number associated with this port.                                                                                                 |
| <b>Authenticate</b>  | Indicates the status of the Port Access Entity (PAE) authenticator requesting authentication.                                                   |
| <b>Authenticated</b> | Indicates the current authentication status of the Port Access Entity (PAE) authenticator.                                                      |
| <b>Failed</b>        | Indicates the authentication status for failed or terminated state .                                                                            |
| <b>ReAuthEnabled</b> | Indicates the re-authentication status of an existing supplicant at the time interval specified in ReAuthPeriod. The default is false.          |
| <b>QuietPeriod</b>   | Indicates the time interval (in seconds) between authentication failure and the start of a new authentication.<br>The default is 60.            |
| <b>ReAuthPeriod</b>  | Indicates the time interval in seconds between successive re-authentications. The default is 3600 (1 hour ).                                    |
| <b>RetryMax</b>      | Indicates the maximum Extensible Authentication Protocol (EAP) requests sent to the supplicant before timing out the session. The default is 2. |
| <b>RetryCount</b>    | Indicates the count of the number of authentication attempts.                                                                                   |

## View Multihost Status Information

Use the following procedure to display multiple host status for a port.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **802.1X - EAPOL**.
3. Select the **MultiHost Status** tab.

**MultiHost Status** Field Descriptions

The following table describes values on the **MultiHost Status** tab.

| Name                                                                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Priority</b>                                                                                                      | Specifies the priority associated with this client MAC. This priority could be the Radius assigned priority or the port QOS level.                                                                                                                                                                                                                                                   |
| <b>SwUniBindings</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Indicates the Extensible Authentication Protocol (EAP) VLAN:ISID bindings that the switch represents as an hexadecimal value.                                                                                                                                                                                                                                                        |
| <b>IsidSource</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.    | Indicates the origin of I-SID value: <ul style="list-style-type: none"> <li>radius - received from the RADIUS server.</li> <li>autoconfig - calculated using the <b>auto-isid-offset</b> command, that the user configures on the switch.</li> <li>config - configured statically.</li> <li>notAvaliable - does not use EAP with FlexUNI, hence there is no I-SID to use.</li> </ul> |
| <b>AcId</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.          | Indicates the dynamic Access Control List (ACL) on the specific port.                                                                                                                                                                                                                                                                                                                |
| <b>AceldList</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.     | Indicates the list of dynamic Access Control Entries (ACE) on the specific port.                                                                                                                                                                                                                                                                                                     |
| <b>DynamicSettings</b>                                                                                               | Displays the Dynamic settings received from the Remote Authentication Dial-In User Service (RADIUS) server.                                                                                                                                                                                                                                                                          |

## View EAP Session Statistics

Use the following procedure to display multiple host session information for a port.

**Procedure**

1. In the navigation pane, expand **Configuration --> Security --> Data Path**.
2. Click **802.1X - EAPOL**.
3. Click the **MultiHost Session** tab.

*MultiHost Session Field Descriptions*

The following table describes values on the **MultiHost Session** tab.

| Name                      | Description                                                                 |
|---------------------------|-----------------------------------------------------------------------------|
| <b>StatsPortNumber</b>    | Indicates the port number associated with this port.                        |
| <b>StatsClientMACAddr</b> | Indicates the MAC address of the client.                                    |
| <b>Id</b>                 | Indicates the unique identifier for the session.                            |
| <b>AuthenticMethod</b>    | Indicates the authentication method used to establish the session.          |
| <b>Time</b>               | Indicates the elapsed time of the session.                                  |
| <b>TerminateCause</b>     | Indicates the cause of the session termination.                             |
| <b>UserName</b>           | Indicates the user name that represents the identity of the supplicant PAE. |

## Viewing EAPoL Authenticator Statistics

Use EAPoL Authenticator statistics to display the Authenticator Port Access Entity (PAE) statistics for each selected port.

### Procedure

- On the Device Physical View, select the port you want to graph.  
The system displays a yellow outline around the selected ports  
  
If you want to select multiple ports, press Ctrl and hold down the key while you click the ports you want to configure. The system displays a yellow outline around the selected ports.
- In the navigation pane, expand the **Configuration > Graph** folders.
- Click **Port**.
- Click **EAPOL Stats**.
- If you selected multiple ports, from the Graph port EAPoL Stats tab Show list, select: Absolute Value, Cumulative, Average/sec, Minimum/sec, Maximum/sec, or LastVal/sec.

*EAPOL Stats Field Descriptions*

The following table describes values on the **EAPOL Stats** tab.

| Name                          | Description                                                                                                          |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>InvalidFramesRx</b>        | Displays the number of EAPoL frames received by this Authenticator in which the frame type is not recognized.        |
| <b>EapLengthErrorFramesRx</b> | Displays the number of EAPoL frames received by this Authenticator in which the Packet Body Length field is invalid. |
| <b>StartFramesRx</b>          | Displays the number of EAPoL start frames received by this Authenticator.                                            |

| Name                      | Description                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------|
| <b>EapFramesRx</b>        | Displays the number of EAPoL-EAP frames received by this Authenticator.                 |
| <b>LogoffFramesRx</b>     | Displays the number of EAPoL Logoff frames received by this Authenticator.              |
| <b>LastRxFrameVersion</b> | Displays the last received version of the EAPoL frame by this Authenticator.            |
| <b>LastRxFrameSource</b>  | Displays the source MAC address of the last received EAPoL frame by this Authenticator. |
| <b>AuthEapFramesTx</b>    | Displays the number of EAPoL-EAP frames transmitted by the Authenticator.               |

## View NEAP MAC Information

Use this procedure to view NEAP client MAC information on a port.

### Procedure

1. In the navigation pane, expand **Configuration** --> **Security** --> **Data Path**.
2. Select **802.1X - EAPOL**.
3. Select **NEAP Radius** tab.

### NEAP Radius Field Descriptions

The following table describes values on the **NEAP Radius** tab.

| Name                                                                                         | Description                                                                                                                                                                                                                   |
|----------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MacPort</b>                                                                               | Indicates the port number associated with this port.                                                                                                                                                                          |
| <b>MacAddr</b>                                                                               | Indicates the MAC address of the client.                                                                                                                                                                                      |
| <b>MacStatus</b>                                                                             | Indicates the authentication status of the NEAP host that is authenticated using the RADIUS server.                                                                                                                           |
| <b>VlanId</b>                                                                                | Indicates the VLAN assigned to the client.                                                                                                                                                                                    |
| <b>MacClear</b>                                                                              | Clears the non EAP MAC entry associated with a specific index.                                                                                                                                                                |
| <b>MacPriority</b>                                                                           | Indicates the priority associated with this Non-EAP client MAC. This priority could be the Radius assigned priority or the port QOS level.                                                                                    |
| <b>SwUniBindings</b>                                                                         | Indicates the VLAN and I-SID bindings. VLAN is represented with 2 bytes and I-SID is represented with 4 bytes. The output is a continuous hexadecimal representation of the VLAN that is followed by the corresponding I-SID. |
| <b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. |                                                                                                                                                                                                                               |

| Name                                                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                       | XA1400 Series   | VOSS 8.2                                                                                                                                                                                                                                                                                     |

For the most current information on switches supported by ExtremeCloud™ IQ, see [ExtremeCloud™ IQ Learning What's New](#).

ExtremeCloud IQ provides cloud-managed networking, and delivers unified, full-stack management of wireless access points, switches, and routers. It enables onboarding, configuration, monitoring, troubleshooting, reporting, and more. Using innovative machine learning and artificial intelligence technologies, ExtremeCloud IQ analyzes and interprets millions of network and user data points, from

the network edge to the data center, to power actionable business and IT insights, and to deliver new levels of network automation and intelligence.

VOSS supports a zero touch connection to ExtremeCloud IQ. Zero touch deployment is used to deploy and configure a switch using ExtremeCloud IQ.

VOSS integrates with ExtremeCloud IQ using ExtremeCloud IQ Agent. When you enable IQAgent, you can configure and monitor VOSS devices using ExtremeCloud IQ.

ExtremeCloud IQ supports the following features for VOSS:

- Firmware upgrade
- IQAgent upgrade
- Supplemental CLI

You can configure the following features using the ExtremeCloud IQ interface:

- Hostname configuration
- SNMP location
- Device-level MTU
- Flow control
- Port state, usage type, and settings
- VLAN configuration
- DNS, NTP, SNMP, and Syslog servers

For more information about ExtremeCloud IQ, see <https://www.extremenetworks.com/support/documentation/extremecloud-iq/>.

---

## ExtremeCloud IQ Agent Configuration Considerations

---

The following configuration considerations apply to ExtremeCloud IQ Agent:

- SSH and SSH password authentication is required.

**boot config flag ssh** is enabled when ExtremeCloud IQ Agent is enabled. **boot config flag ssh** cannot be disabled while ExtremeCloud IQ Agent is enabled.

- SNMP is required.

**boot config flag block-snmp** is disabled when ExtremeCloud IQ Agent is enabled. **boot config flag block-snmp** cannot be enabled while ExtremeCloud IQ Agent is enabled.

- High Secure mode disables ExtremeCloud IQ Agent automatically. ExtremeCloud IQ Agent must be enabled manually when this mode is enabled.
- ExtremeCloud IQ Agent is not supported in Enhanced Secure mode.
- An IP address that corresponds to the ExtremeCloud IQ pool and can display it in the NTP list. The IP does not try to synchronize if NTP is globally disabled on the switch. If NTP is enabled, you can see synchronization failure messages if the IP for the pool is blocked or is unreachable. As a best

practice, if you have issues connecting to the cloud, check the clock on the switch and if it is incorrect, resolve this by either configuring an NTP server or manually configuring the correct time.

#### Note

You must configure a Segmented Management Instance to use ExtremeCloud IQ Agent. For more information, see [Segmented Management](#) on page 60.

For information about onboarding switches, see <https://www.extremenetworks.com/support/documentation/extremecloud-iq/>.

## Zero Touch Deployment

---

Zero Touch Deployment enables a VOSS switch to be deployed automatically with ExtremeCloud IQ but you still must onboard the switch on the ExtremeCloud IQ side. When the switch powers on, the DHCP Client obtains the IP address and gateway from the DHCP Server, and discovers the Domain Name Server, connecting the switch automatically to Extreme Management Center or ExtremeCloud IQ - Site Engine or to ExtremeCloud IQ cloud management applications.

With Zero Touch Deployment, ExtremeCloud IQ Agent is enabled by default.

To use zero touch functionality, your switch must be in a Zero Touch Deployment-ready configuration mode, which means the switch cannot have existing primary or secondary configuration files loaded. Factory shipped switches are Zero Touch Deployment ready because they deploy without configuration files. However, existing switches require manual preparation before Zero Touch Deployment can function.

For more information about preparing your switch for Zero Touch Deployment, see [Zero Touch Deployment](#) on page 50.

## DHCP Option 43 Support

With the support of DHCP option 43, DHCP can dynamically configure the IP address of a private/non-public ExtremeCloud IQ server for zero touch deployments when the default ExtremeCloud IQ server (hac.extremecloudiq.com) is not desired.

To use this functionality, DHCP Client must be enabled. For information about DHCP Client for a Segmented Management Instance, see [DHCP Client for Segmented Management Instance](#) on page 75.

## Considerations

The following considerations apply with DHCP option 43:

- A dynamic IP address overwrites the default value (hac.extremecloudiq.com) or 0.0.0.0.
- A static server IP address overwrites a dynamic server IP address.
- A dynamic server IP address does not overwrite an existing static server IP address.

If a static server IP address is already configured and a new value is received from the DHCP server, the following warning displays on the console: `WARNING Dynamic Cloud IQ Server Address x.x.x.x provided by DHCP option 43 could not be set. Static`

configured server address y.y.y.y cannot be overwritten by a dynamic address.

- The default value (nac.extremecloudiq.com) replaces the dynamic server IP address if the DHCP Client is disabled on the switch.
- The dynamic server IP address is not saved in the running configuration.

## ExtremeCloud IQ Agent Configuration using CLI

---

After your VOSS device is onboarded (that is, the serial number for the device is associated with your ExtremeCloud IQ account), you are only required to enable ExtremeCloud IQ Agent. Other feature configuration, such as configuring proxy parameters and configuring access to ExtremeCloud IQ is optional.

### Note

You must configure a Segmented Management Instance to use ExtremeCloud IQ Agent. For more information, see [Segmented Management Instance Configuration using the CLI](#) on page 77.

For information about onboarding switches, see <https://www.extremenetworks.com/support/documentation/extremecloud-iq/>.

## Configure ExtremeCloud IQ Agent

You must first onboard the VOSS device. When zero touch connection establishes, IQ Agent is enabled, by default. Before IQ Agent is operational, you must first disable IQ Agent, configure the ExtremeCloud IQ IPv4 address or DNS name, and then reenable IQ Agent.

### Before You Begin

You must first onboard the VOSS device.

### Procedure

1. Enter Application Configuration mode:  

```
enable
```

```
configure terminal
```

```
application
```
2. Disable IQ Agent:  

```
no iqagent enable
```
3. Configure the ExtremeCloud IQ IPv4 address or DNS name:  

```
iqagent server address WORD<1-255>
```
4. Enable IQ Agent:  

```
iqagent enable
```

**Example**

Configure IQ Agent:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#no iqagent enable
Switch:1(config-app)#iqagent server address hac.extremecloudiq.com
Switch:1(config-app)#iqagent enable
```

Display default IQ Agent configuration:

```
Switch:1>show application iqagent

=====
IQAgent Info
=====
Agent Admin State      : true

Proxy TCP Port         : 0
Proxy Username         :
```

## Configure Access to ExtremeCloud IQ

Use this task to configure IQ Agent parameters to access ExtremeCloud IQ.

**Before You Begin**

You must onboard the VOSS device and configure any optional IQ Agent parameters on the supported VOSS device before you enable IQ Agent.

You can configure the IQ Agent parameters on the supported VOSS devices first, and then onboard the devices (that is, add the serial numbers for the devices in the ExtremeCloud IQ GUI) or vice versa.

For information about onboarding switches, see <https://www.extremenetworks.com/support>.

**Procedure**

1. Enter Application Configuration mode:
 

```
enable

configure terminal

application
```
2. Configure the ExtremeCloud IQ IPv4 address or DNS name:
 

```
iqagent server address WORD<1-255>
```

**Example**

Configure access to ExtremeCloud IQ using an IPv4 address:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#application
Switch:1(config-app)#iqagent server address 192.0.2.1
```

Configure access to ExtremeCloud IQ using a DNS name:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent server address extremecloudiq.com
```

### Variable Definitions

The following table defines parameters for the **iqagent server** command.

| Variable                    | Value                                                   |
|-----------------------------|---------------------------------------------------------|
| <i>address</i> <WORD 1-255> | Specifies the ExtremeCloud IQ IPv4 address or DNS name. |

## Configure Proxy Parameters

If you use a proxy https server in your network, you must configure proxy parameters so that the IQ Agent on the device can communicate with ExtremeCloud IQ through the proxy.

Use this task to configure the proxy parameters for ExtremeCloud IQ on the IQ Agent.

### Note

You must onboard the VOSS device and configure any optional IQ Agent parameters on the supported VOSS device before you enable IQAgent.

You can configure the IQ Agent parameters on the supported VOSS devices first, and then onboard the devices (that is, add the serial numbers for the devices in the ExtremeCloud IQ GUI) or vice versa.

For information about onboarding switches, see <https://www.extremenetworks.com/support>.

### Procedure

1. Enter Application Configuration mode:
 

```
enable

configure terminal

application
```
2. Configure the proxy IPv4 address or DNS name:
 

```
iqagent proxy address <WORD 1-255> tcp-port <1-49151>
```
3. Configure the proxy username and password for the ExtremeCloud IQ account:
 

```
iqagent proxy username <WORD 1-64> password <WORD 1-128>
```

### Example

Configure proxy parameters using an IPv4 address:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
```

```
Switch:1(config-app)#iqagent proxy address 192.0.2.254 tcp-port 21
Switch:1(config-app)#iqagent proxy username admin password ****
```

Configure proxy parameters using a DNS name:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent proxy address hac.extremecouldiq.com tcp-port 21
Switch:1(config-app)#iqagent proxy username admin password ****
```

### Variable Definitions

The following table defines parameters for the **iqagent proxy** command.

| Variable                     | Value                                         |
|------------------------------|-----------------------------------------------|
| <i>address</i> <WORD 1-255>  | Specifies the proxy IPv4 address or DNS name. |
| <i>tcp-port</i> <1-49151>    | Specifies the TCP port.                       |
| <i>username</i> <WORD 1-64>  | Specifies the proxy server username.          |
| <i>password</i> <WORD 1-128> | Specifies the proxy server password.          |

## Display ExtremeCloud IQ Agent Information

### About This Task

Use this task to display ExtremeCloud IQ Agent configuration information and status.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IQ Agent configuration information and status:

```
show application iqagent
```

### Example

Display IQ Agent configuration information and status when IQ Agent is enabled using the default ExtremeCloud IQ server:

```
Switch:1>show application iqagent

=====
                               IQAgent Info
=====
Agent Admin State      : true
Agent Version          : 0.2.7
Agent Oper State       : connected
Server Address         : hac.extremecouldiq.com
Server Address Origin  : None
Proxy Address          : extremeiq.com
Proxy TCP Port         : 21
Proxy Username         : admin
```

Display IQ Agent disabled state:

```
Switch:1>show application iqagent

=====
                        IQAgent Info
=====
Agent Admin State      : false
Agent Version          : 0.2.7
Agent Oper State       : disconnected
Server Address         : 0.0.0.0
Server Address Origin  : None
Proxy Address          : 0.0.0.0
Proxy TCP Port         : 0
Proxy Username         :
```

Display IQ Agent configuration information and status when DHCP provides a dynamic server IP address:

```
Switch:1>show application iqagent

=====
                        IQAgent Info
=====
Agent Admin State      : true
Agent Version          : 0.2.7
Agent Oper State       : disconnected
Server Address         : 192.0.2.1
Server Address Origin  : DHCP
Proxy Address          : 0.0.0.0
Proxy TCP Port         : 0
Proxy Username         :
```

Display IQ Agent configuration information and status when DHCP Client is disabled on the switch:

```
Switch:1>show application iqagent

=====
                        IQAgent Info
=====
Agent Admin State      : false
Agent Version          : 0.2.7
Agent Oper State       : disconnected
Server Address         : hac.extremecloudiq.com
Server Address Origin  : None
Proxy Address          : 0.0.0.0
Proxy TCP Port         : 0
Proxy Username         :
```

## Display ExtremeCloud IQ Agent Status

### About This Task

Use this task to display IQ Agent status information.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IQ Agent status information:
 

```
show application iqagent status
```

**Example**

```
Switch:1>show application iqagent status
=====
IQAgent Status
=====
Connection Status           : Connected
Last Onboard Time          : 18:54:23 11 27 2019 UTC

Last Poll Status           : SUCCESS
Last Poll Success Time     : 14:39:16 11 28 2019 UTC
Last Health Status        : SUCCESS
Last Health Success Time   : 14:38:35 11 28 2019 UTC
Last Monitor Status        : SUCCESS
Last Monitor Success Time  : 14:38:35 11 28 2019 UTC
```

**Reinstall ExtremeCloud IQ Agent Firmware**

Perform this procedure to return the ExtremeCloud IQ Agent firmware version on the switch to the version bundled with the VOSS image currently installed on the switch, for example, if you downgrade the VOSS image version and do not reconnect to ExtremeCloud IQ automatically.

**Procedure**

1. Enter Application Configuration mode:
 

```
enable

configure terminal

application
```
2. Disable ExtremeCloud IQ Agent:
 

```
no iqagent enable
```
3. Reinstall the ExtremeCloud IQ Agent firmware:
 

```
software iqagent reinstall
```
4. Enable ExtremeCloud IQ Agent:
 

```
iqagent enable
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#application
Switch:1(config-app)#no iqagent enable
Switch:1(config-app)#software iqagent reinstall

Reinstalling IQAgent from VOSS image
Switch:1(config-app)#iqagent enable
```

## ExtremeCloud IQ Agent Configuration using EDM

Perform the procedures in this section to configure ExtremeCloud IQ Agent on the switch using the Enterprise Device Manager (EDM).

### Configure ExtremeCloud IQ Agent

#### Before You Begin

You must first onboard the VOSS device and configure any optional IQ Agent parameters before you enable IQ Agent.

#### Procedure

1. In the navigation pane, expand **Configuration > Serviceability**.
2. Select **IQAgent**.
3. Select the **Globals** tab.
4. Configure optional parameters as required.
5. Select **Apply**.
6. Select **Enable**.
7. Select **Apply**.

#### *Globals* Field Descriptions

Use the data in the following table to use the **Global** tab to configure the ExtremeCloud IQ Agent.

| Name                       | Description                                                                                                                                                                                                           |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>              | Specifies whether IQ Agent is enabled. The default is enabled.                                                                                                                                                        |
| <b>Version</b>             | Displays the ExtremeCloud IQ Agent firmware version running on the switch.                                                                                                                                            |
| <b>OperStatus</b>          | Displays the operational status of ExtremeCloud IQ Agent on the switch.                                                                                                                                               |
| <b>ServerAddressType</b>   | Specifies the address type of the ExtremeCloud IQ server address.                                                                                                                                                     |
| <b>Server/Address</b>      | Specifies the ExtremeCloud IQ IPv4 address or DNS name.<br>The default is hac.extremcloudiq.com.                                                                                                                      |
| <b>ServerAddressOrigin</b> | Specifies the origin for the ExtremeCloud IQ server address: <ul style="list-style-type: none"> <li>• none—not configured</li> <li>• configured—manual configuration</li> <li>• dhcp—obtained through DHCP</li> </ul> |
| <b>Address</b>             | Specifies the proxy IPv4 address or DNS name.                                                                                                                                                                         |
| <b>TcpPort</b>             | Specifies the TCP connection port.                                                                                                                                                                                    |
| <b>UserName</b>            | Specifies the proxy server password.                                                                                                                                                                                  |
| <b>Password</b>            | Specifies the proxy server username.                                                                                                                                                                                  |

| Name                     | Description                                                        |
|--------------------------|--------------------------------------------------------------------|
| <b>AssociationUrl</b>    | Displays the association URL of ExtremeCloud IQ.                   |
| <b>PollUrl</b>           | Displays the poll URL of ExtremeCloud IQ.                          |
| <b>MonitorFreq</b>       | Displays the monitoring frequency, in seconds, of ExtremeCloud IQ. |
| <b>PollFreq</b>          | Displays the polling frequency, in seconds, of ExtremeCloud IQ.    |
| <b>LastOnboardTime</b>   | Displays the last onboard time of ExtremeCloud IQ.                 |
| <b>LastPollStatus</b>    | Displays the last poll status of ExtremeCloud IQ.                  |
| <b>LastPollTime</b>      | Displays the last poll time for a successful attempt.              |
| <b>LastMonitorStatus</b> | Displays the last monitoring status of ExtremeCloud IQ.            |
| <b>LastMonitorTime</b>   | Displays the last monitor time for a successful attempt.           |
| <b>LastHealthStatus</b>  | Displays the last health status of ExtremeCloud IQ.                |
| <b>LastHealthTime</b>    | Displays the last health time for a successful attempt.            |

|                                                                                 | VSP 8600 Series | Not Supported      |
|                                                                                 | XA1400 Series   | Not Supported      |

## Extreme Integrated Application Hosting

Extreme Integrated Application Hosting (IAH) architecture provides a flexible and open solution that enables organizations to deploy high-performance and flexible visibility applications pervasively throughout their network for improved monitoring and troubleshooting. Enabled by VOSS, this preconfigured Quick Emulator (QEMU) Kernel-based Virtual Machine (KVM) environment leverages high performance x86 CPUs to host these applications, extending visibility customized to the business and operational needs of the organization across the entire network.

The QEMU KVM environment supports several pretested and well-known packet capture applications in a Linux virtual machine, including Wireshark and tcpdump. There are a wide variety of additional applications, tools, and utilities that organizations are able to run in this environment, such as data analytics applications, packet generators, monitoring tools, troubleshooting utilities, and many others. While the QEMU KVM environment is open and can host any application, it is designed and ideally suited for networking applications, tools, and utilities.

IAH architecture supports the creation and use of virtualization domains, such as virtual machines, and Docker containers. This design creates a common-use host, which coordinates and automates multiple guest-networking functions into chains. The hardware boots into the virtual Linux OS, providing the ability to run additional applications or services within a specific virtual machine or a Docker container, and simultaneously supporting the regular functionality of the switch.

Yet Another Next Generation (YANG) model is used to manage configuration and retrieve operational data. You access the YANG model through Representational State Transfer Configuration Protocol (RESTCONF) using a northbound interface, namely Extreme Management Center or ExtremeCloud IQ - Site Engine, that provides an additional way to configure and monitor the switch. For more information on RESTCONF, see [Representational State Transfer Configuration Protocol \(RESTCONF\) Fundamentals](#) on page 2768.

## Virtual Services Resources

The virtual services resources are isolated from each other, as well as from the Network Operating System (NOS) running the switch.

The resources available for all virtual services on VSP 7400 Series switches are as follows:

- Six Central Processing Unit (CPU) cores
- 12 GB Random Access Memory (RAM)
- 100 GB Solid State Drive (SSD) flash memory

The resources available for all virtual services on VSP 4900 Series switches are as follows:

### Note

You must install a modular SSD unit to use virtual services on VSP 4900 Series switches.

- Two CPU cores
- 4 GB RAM
- 120 GB SSD flash memory (separately available modular SSD unit), with 104 GB dedicated for IAH storage.

The switch OS uses the following resources on VSP 7400 Series and VSP 4900 Series:

- Two CPU cores
- 4 GB RAM
- 8 GB internal flash memory storage

## Extreme Integrated Application Hosting Ports

Extreme Integrated Application Hosting (IAH) ports are labeled as Insight ports, which are internal ports used to support Ethernet connectivity by the virtual services configured on the switch. IAH ports operate at 10 Gigabits per second (Gbps). The following features support IAH ports on the switch:

- VLANs
- Filters
- Port Statistics
- Basic Interface Configuration
- Mirroring
- Switched UNI
- Transparent Port UNI

### Note

Network-to-network (NNI) interface support is not available for IAH ports. IS-IS adjacencies cannot be established on IAH ports.

For information about how to configure IAH ports, see the following tasks:

- [Configure a Virtual Service](#) on page 856
- [Configure Virtual Ports](#) on page 871

### Connection Types

The VM and Docker virtual ports map to a physical Extreme Integrated Application Hosting port using the following connection types:

- Open vSwitch (OVS)
- Single Root I/O Virtualization (SR-IOV).
- Virtualization Technology for Directed I/O (VT-d)

**Note**

You must enable trunking on the Extreme Integrated Application Hosting port when you use SR-IOV and OVS connection types. For more information about enabling trunking, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2334.

You can configure Extreme Integrated Application Hosting ports 1/s1 and 1/s2 to accommodate different connect types. Extreme Integrated Application Hosting ports 1/s1 and 1/s2 can accommodate virtual ports of SR-IOV, OVS, or VT-d connect types. Two VT-d connection types are supported on either 1/s1 or 1/s2 Extreme Integrated Application Hosting ports. Using the **virtual-service** command, you can specify which Extreme Integrated Application Hosting port is associated with the configured connect type. You can also configure the Network Interface Card (NIC) type of the virtual port using the **virtual-service** command.

The following table lists the compatible Extreme Integrated Application Hosting port connect type configurations.

**Note**

You cannot configure two virtual services with conflicting connect types or two virtual services with VT-d connect type on the same Extreme Integrated Application Hosting port.

| Extreme Integrated Application Hosting port 1/s1 | Extreme Integrated Application Hosting port 1/s2 |
|--------------------------------------------------|--------------------------------------------------|
| SR-IOV                                           | OVS                                              |
| SR-IOV                                           | SR-IOV                                           |
| OVS                                              | SR-IOV                                           |
| OVS                                              | OVS                                              |
| VT-d                                             | VT-d                                             |

### Link Flapping

When the switch initializes, the Extreme Integrated Application Hosting ports connect to the underlying Linux hypervisor. When a virtual port of connection type OVS or SR-IOV is configured on the switch, the Linux hypervisor saves this connection, and the link state of the Extreme Integrated Application Hosting port does not change. However, when a virtual port of connection type VT-d is configured on the switch, control of the Extreme Integrated Application Hosting port is passed from the Linux hypervisor to the configured Virtual Machine (VM). The Extreme Integrated Application Hosting port flaps due to this transition, and the switch reports it in the system log. The Extreme Integrated Application Hosting port flaps twice during the transition:

1. when the Extreme Integrated Application Hosting port is removed from the Linux hypervisor.

2. when the Extreme Integrated Application Hosting port is added to the VM.

A similar link flap sequence takes place on the Extreme Integrated Application Hosting port when the associated VM is disabled on the switch, and the control of the Extreme Integrated Application Hosting port is passed from the VM back to the Linux hypervisor.

### Configuration Requirements

- To use an Extreme Integrated Application Hosting port as an analyzer port on a monitoring BEB for Fabric RSPAN (Mirror to I-SID), you must associate outer-tag 4091 to egress port 1/s1 or 1/s2 if the connect type is OVS or SR-IOV. Use the **monitor-by-isid <1-1000> map-to-vid <1-4093>** command to configure VLAN 4091 for Fabric RSPAN.
- To use an Extreme Integrated Application Hosting port with a connect type as OVS or SR-IOV for Port Mirroring, associate VLAN 4091 to the virtual machine (VM) vport to send the mirrored packets to the VM.
- To enable Flex UNI on an Extreme Integrated Application Hosting port with a connect type of VT-d, enable dot1q encapsulation on the VM interfaces. Flex UNI enables tagging on these ports by default; you must tag the VM ports with the VLANs that these ports use.

## Third Party Virtual Machine

The Extreme Integrated Application Hosting (IAH) feature supports the pre-installed Third Party Virtual Machine (TPVM). For switches that use a modular Solid State Drive (SSD) for IAH, the virtual machine is pre-installed on the modular SSD. For switches that do not use a modular Solid State Drive (SSD) for IAH, the virtual machine is pre-installed on the switch.

You can use the **show virtual-service config** command to view the information about the pre-installed virtual machine on the switch. For more information, see [Display Virtual Service Configuration](#) on page 862.

### Important

You must upgrade virtual services independently of a VOSS upgrade; separate images for virtual services are available. For more information, see [Upgrade a Virtual Service](#) on page 866.

For more information about how to configure virtual services, see [Virtual Services Configuration using CLI](#) on page 854 and [Virtual Services Configuration using EDM](#) on page 868.

Third Party Virtual Machine (TPVM) provides a set of troubleshooting tools on the switch. The following installed packages are available on TPVM:

- build-essential
- checkinstall
- iperf
- mtools
- netperf
- qemu-guest-agent
- tshark
- valgrind

- vim-gnome
- wireshark
- xterm

### Important

TPVM includes an administrator account with a default username and password. To ensure security, you must change the default password when you access TPVM for the first time, before enabling the IAH ports using the **no shutdown** command. The software automatically prompts you to change this password at first boot; no action can be taken with the VM until you change the password.

The following user applications are available on TPVM:

- Dynamic Host Configuration Protocol (DHCP) server
- Domain Name Server (DNS)
- Authentication, authorization, and accounting (AAA) server for Remote Access Dial-In User Service (RADIUS) and Terminal Access Controller Access Control Service Plus (TACACS+).
- Syslog server
- Simple Network Management Protocol (SNMP) trap receiver
- Suricata - a free and open-source robust network threat detection engine that provides real time intrusion detection (IDS), inline intrusion prevention (IPS), network security monitoring (NSM), and offline packet capture (pcap) processing.
- Wireshark – a protocol analyzer that provides packet capturing and analysis.
- Ostinato - provides packet crafting, network traffic generation, and analysis with a user-friendly Graphical User Interface (GUI).

### Note

If you start the console for TPVM without network connectivity to a DHCP server, the VM remains in a retry loop for approximately 5 minutes while it tries to obtain a DHCP address. The system displays the following message: `[FAILED] Failed to start Raise network interfaces`, and then the VM continues to boot. The VM does start but with the virtual port, eth0, in the administratively down state.

The following are the virtual services resources for TPVM:

- Two CPU cores
- 4 GB RAM

- One virtual port of VT-d connection type
- 1.8 GB up to 32 GB SSD

**Note**

To use this feature on the applicable models of VSP 4900 Series, you must install an SSD module in the switch.

**Important**

To enable SR-IOV and VT-d, the guest OS must have Ethernet drivers (ixgbe) that support these Intel technologies. These drivers are not available by default in many OS distribution versions. The TPVM version based on Ubuntu 16.04 is enhanced to include updated driver versions to support SR-IOV and VT-d. If you upgrade the TPVM guest OS kernel, you override these drivers and the VM does not support SR-IOV or VT-d vport connection types.

Do not perform a kernel upgrade from within the TPVM. If necessary, you can upgrade individual packages. You can upgrade to Ubuntu 18.04, which includes support for these new driver versions by default.

## Fabric IPsec Gateway Fundamentals

---

The Fabric IPsec Gateway feature introduces a Virtual Machine (VM) that supports aggregation of Fabric Extend Tunnels with fragmentation, reassembly, and Internet Protocol Security (IPsec) encryption functions.

The minimum configuration requirements for the Fabric IPsec Gateway VM are as follows:

- Two Central Processing Unit (CPU) cores
- 4 GB Random Access Memory (RAM)
- One Virtualization Technology for Directed I/O (VT-d) vport (eth0)
- Minimum 10 GB SSD

**Note**

To use this feature on the applicable models of VSP 4900 Series, you must install an SSD module in the switch.

To configure IPsec on a switch through the Fabric IPsec Gateway VM, see [Fabric IPsec Gateway Configuration using CLI](#) on page 874.

Fabric IPsec Gateway supports the following services through the VM:

- IPsec with fragmentation and reassembly - for the VXLAN traffic that needs IPsec, the network routes the packets through the Fabric IPsec Gateway VM that provides IPsec encryption and decryption for VXLAN packets. The system also supports fragmentation and reassembly for IPsec tunnels that you configure on the VM, and a minimum of 1300 bytes of Maximum Transmission Unit (MTU) value. You can configure fragmentation to occur before the packets are encrypted.
- Fragmentation and reassembly - the Fabric IPsec Gateway VM performs fragmentation and reassembly for VXLAN and IPsec tunnels, for which the network routes the packets through the VM. The system supports a minimum of 750 bytes of Maximum Transmission Unit (MTU) value.

## IPsec Coupled and Decoupled Mode

A device is in IPsec decoupled mode when IPsec and Fabric Extend (FE) termination takes place on two different IP addresses. A device is in IPsec coupled mode when IPsec and Fabric Extend (FE) termination takes place on the same IP address.

The XA1400 Series devices, which use VOSS for Fabric Extend over IPsec, support both IPsec decoupled and coupled modes. The VSP 4900 Series and VSP 7400 Series devices, which use Fabric IPsec Gateway for Fabric Extend over IPsec, support IPsec in decoupled mode only. You must configure the IPsec tunnel in decoupled mode to enable IPsec termination in the Fabric IPsec Gateway VM. For more information about how to configure IPsec tunnels on the VM, see [Configure IPsec Tunnels on Fabric IPsec Gateway VM](#) on page 880.

## Digital Certificates for Fabric IPsec Gateway

Fabric IPsec Gateway supports digital certificates for IPsec authentication of Fabric Extend tunnels. To support different certificates for different IPsec tunnels, you can configure multiple certificate authority (CA) trustpoints and identity subject certificates.

If you are not familiar with digital certificates, see [Digital Certificate/PKI](#) on page 2999 for additional background information like digital certificate terminology.

### *Online Certificate Provisioning*

The switch uses IPsec Simple Certificate Enrollment Protocol (SCEP) to obtain the CA certificate, and then validates the CA certificate against the certificate chain.

#### **Note**

Extreme validated the Fabric IPsec Gateway SCEP implementation with EJBCA CA Server only. Fabric IPsec Gateway SCEP cannot currently use Win CA like digital certificate support in VOSS.

Use trustpoints to manage and track CAs and certificates. The switch can enroll with a trustpoint to obtain an identity certificate. You must configure the CA URL, the CA common name, and select the HTTP request type to configure the CA server trustpoint.

Configure the certificate subject parameters to provide the device distinguished name (DN) and key name for the generated key pair (the private key). If you do not configure a private key, the switch generates one. The switch validates the returned certificate against the trustpoint's CA certificate.

You can remove subject certificates from the CA trustpoint or clean the CA trustpoint only if the subject-label is not configured on an IPsec tunnel.

### *Offline Certificate Provisioning*

Offline certificate management supports switches that cannot communicate with the CA to obtain the identity certificate online by certificate enrollment operation.

The switch generates the certificate signing request (CSR) using the subject DN and the private key that you configure in the CLI. If you do not configure a private key, the switch generates one.

Transfer the CSR to the offline CA to be signed. Retrieve the signed certificate to validate against the original CSR. You must manually transfer all certificates in the certificate chain to the switch. The signed certificate must include the subject-label to map it to a locally-generated CSR for validation.

You must manually download Certificate Revocation List (CRL) files. You can remove offline subject certificates only if the subject-label is not configured on an IPsec tunnel.

## Egress Shaping for Fabric Extend Tunnels on Fabric IPsec Gateway

You can configure the egress shaping rate to limit egress bandwidth for tunnels on the Fabric IPsec Gateway Virtual Machine (VM).

### Considerations

Consider the following when you configure the egress shaper rate:

- If the ingress data traffic receives excessive packets with the following DSCP or 802.1p values (high priority control packets) and egress shaping is configured, a IS-IS flap can be seen.

| DHCP value | 802.1p value |
|------------|--------------|
| 0x28       | 6            |
| 0x2E       | 6            |
| 0x2F       | 6            |
| 0x30       | 7            |
| 0x38       | 7            |

- The egress tunnel shaping rate is impacted if the incoming packet size is greater than the Fabric Extend tunnel MTU. This is due to the additional packet header required for fragmentation.

## Operational Considerations and Restrictions

Consider the following when deploying Extreme Integrated Application Hosting (IAH) on various switches:

**Table 86: Operational Considerations**

|                                | VSP 7400 Series                                     | VSP 4900 Series                                     |
|--------------------------------|-----------------------------------------------------|-----------------------------------------------------|
| Number of IAH ports            | VSP 7432CQ: 2<br>VSP 7400-48Y: 1                    | VSP4900-12MXU-12XE: 2<br>VSP4900-24XE: 2            |
| Multiple simultaneous VMs      | Supported                                           | Not supported                                       |
| Pre-installed VM               | Third Party Virtual Machine<br>Fabric IPsec Gateway | Third Party Virtual Machine<br>Fabric IPsec Gateway |
| Additional components required | None                                                | Modular Solid State Drive (SSD)                     |

## Virtual Services Configuration using CLI

Perform the procedures in this section to configure Extreme Integrated Application Hosting (IAH) virtual services on the switch using the command line interface (CLI).

## Access a Virtual Service Console

The virtual services running on a Virtual Machine (VM) require a console for configuration and monitoring purposes.

### About This Task

Perform this procedure to access the virtual service console port for the specific VM.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Enter the following command to access the virtual service console:  
`virtual-service WORD<1-128> console`

#### Note

Type CTRL+Y to exit the console.

### Example

```
Switch:1>enable
Switch:1#virtual-service tpvm console
```

### Variable Definitions

The following table defines parameters for the **virtual-service** command.

| Variable                       | Value                                                  |
|--------------------------------|--------------------------------------------------------|
| <code>WORD&lt;1-128&gt;</code> | Specifies the virtual service name.                    |
| <code>console</code>           | Accesses the console for the specific virtual service. |

## Install a Virtual Service

A virtual service provides the ability to support additional applications or services and simultaneously support the regular switching functionality. Each virtual service provides an Open Virtual Appliance (OVA) image, which is installed on Extreme Integrated Application Hosting (IAH) through Extreme Management Center or ExtremeCloud IQ - Site Engine.

### Before You Begin

Use FTP or SFTP to transfer the OVA image to the `/var/lib/insight/packages/` directory on the switch.

#### Note

The Fabric IPsec Gateway image includes no integrity check. Use SCP to copy the file to the switch and confirm the file size before installation.

### About This Task

Perform this procedure to install a package file to a specific location indicated by a virtual service name. This procedure also verifies if the package is in OVA format, and if a certificate is provided in the package.

### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Install the virtual service package:  

```
virtual-service WORD<1-128> install package WORD<1-512>
```

### Variable Definitions

The following table defines parameters for the **virtual-service** command.

| Variable                         | Value                                 |
|----------------------------------|---------------------------------------|
| <i>WORD&lt;1-128&gt;</i>         | Specifies the virtual service name.   |
| <i>install</i>                   | Installs the virtual service package. |
| <i>package WORD&lt;1-512&gt;</i> | Specifies the package name and path.  |

## Configure a Virtual Service

### About This Task

Perform this procedure to configure a virtual service on the switch.

#### Note

- Following procedure lists the general sequence to configure a virtual service.
- The names of Ethernet ports appearing in a specific Virtual Machine (VM) are not correlated to the configured virtual port names. Each VM renames the Ethernet ports as per its requirements, after they are discovered during the VM initialization.
- By default, the system displays all virtual ports of OVS connection type first in the alphabetical order of their configured names, followed by the virtual ports of SR-IOV and VT-d connection types.

### Before You Begin

- You must enable trunking on the Extreme Integrated Application Hosting (IAH) port when you use SR-IOV and OVS connection types. For more information about enabling trunking, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2334.
- Ensure the switch has the Ethernet drivers installed as per the SR-IOV standard, to support the VT-d and the SR-IOV connection type for the configured virtual ports.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a VLAN:

### Note

Virtual service configuration supports port-based VLANs only.

```
vlan create <2-4059> name WORD<0-64> type {port-mstprstp <0-63>}
[color <0-32>]
```

3. Add the IAH and faceplate port to the VLAN:

```
vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

4. Enter GigabitEthernet Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

5. Enable the IAH and faceplate ports:

```
no shutdown
```

6. Exit to Global Configuration mode:

```
exit
```

7. (Optional) Create a virtual service:

```
virtual-service WORD<1-128>
```

8. (Optional) Configure the number of CPU cores to be assigned to the virtual service created:

```
virtual-service WORD<1-128> num-cores <1-6>
```

9. (Optional) Configure the memory size to be assigned to the virtual service created:

```
virtual-service WORD<1-128> mem-size <1-50000>
```

10. (Optional) Configure the disk to be assigned to the virtual service created:

```
virtual-service WORD<1-128> disk WORD<1-32> size <1-30>
```

11. Configure the virtual port connection type:

### Note

Ensure the connection type you configure for the virtual port matches the connection type supported by the IAH port.

```
virtual-service WORD<1-128> vport WORD<1-32> connect-type {ovs | sriov
| vtd}
```

12. Configure the IAH port to associate with the connection type:

```
virtual-service WORD<1-128> vport WORD<1-32> port WORD<1-32>
```

### Important

You cannot configure two virtual services with conflicting connect types on the same IAH port. You cannot configure two virtual services with VT-d connect type on the same IAH port.

13. Configure the NIC type of the IAH port:

```
virtual-service WORD<1-128> vport WORD<1-32> port WORD<1-32> nic-type  
{virtio | e1000}
```

14. Add the virtual port to the VLAN created:

```
virtual-service WORD<1-128> vport WORD<1-32> vlan <1-4096>
```

15. Enable the virtual service:

```
virtual-service WORD<1-128> enable
```

## Example

Configuring the TPVM virtual service using IAH port 1/s1 with an SR-IOV connection type:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/s1
Switch:1(config-if)#encapsulation dot1q
Switch:1(config-if)#exit
Switch:1(config)#vlan create 10 name tpvm-lan-vlan type port-mstprstp 0
Switch:1(config)#vlan members add 10 1/s1,1/6/2
Switch:1(config)#interface GigabitEthernet 1/s1,1/6/2
Switch:1(config-if)#no shutdown
Switch:1(config-if)#exit
Switch:1(config)#virtual-service tpvm vport eth0 connect-type sriov
Switch:1(config)#virtual-service tpvm vport eth0 vlan 10
Switch:1(config)#virtual-service tpvm enable
```

Configuring the TPVM virtual service on IAH port 1/s2 with a VT-d connection type:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan create 10 type port-mstprstp 0
Switch:1(config)#vlan member add 10 1/1,1/s2
Switch:1(config)#interface GigabitEthernet 1/s2,1/1
Switch:1(config-if)#no shutdown
Switch:1(config-if)#exit
Switch:1(config-if)#virtual-service tpvm vport eth0 port 1/s2
Switch:1(config)#virtual-service tpvm enable
```

### Variable Definitions

The following table defines parameters for the **vlan create** command.

| Variable                    | Value                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <2-4059>                    | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| color<0-32>                 | Specifies the color of the VLAN.                                                                                                                                                                                                                                                                                                                                                   |
| nameWORD<0-64>              | Specifies a name for the VLAN to be created.                                                                                                                                                                                                                                                                                                                                       |
| type {port-mstp rstp<0-63>} | Creates a VLAN by port, with the STP instance ID ranging from 0 to 63.<br><br><b>Note:</b><br>MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.                                                                                                                                                                                                              |

The following table defines parameters for the **vlan members** command.

| Variable                                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                            | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| {slot/port[/sub-port][-slot/port[/sub-port]][,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| add                                                 | Adds ports to a specified VLAN ID.                                                                                                                                                                                                                                                                                                                                                                                         |

The following table defines parameters for the **virtual-service** command.

| Variable                                      | Value                                                                                                                                                                                                                                                             |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;1-128&gt;</code>                | Specifies a name for virtual service.                                                                                                                                                                                                                             |
| <code>connect-type {ovs   sriov   vtd}</code> | Specifies the connection type for the virtual port created. The default is VT-d. The switch supports the following maximums for virtual ports: <ul style="list-style-type: none"> <li>• OVS - 16</li> <li>• SR-IOV - 16</li> <li>• VT-d - 2</li> </ul>            |
| <code>disk WORD&lt;1-32&gt;</code>            | Specifies the disk assigned to the virtual service.                                                                                                                                                                                                               |
| <code>mem-size &lt;1-50000&gt;</code>         | Specifies the memory size in Megabytes assigned to the virtual service. The default value is 1024 Megabytes.                                                                                                                                                      |
| <code>nic-type [virtio   e1000]</code>        | Specifies the Virtual Port NIC type. The default is e1000.<br><br><b>Note:</b><br>Configure this value only when the <b>connect-type</b> parameter is <b>ovs</b> .                                                                                                |
| <code>num-cores &lt;1-6&gt;</code>            | Specifies the number of cores assigned to the virtual service. The default value is 1.                                                                                                                                                                            |
| <code>port WORD&lt;1-32&gt;</code>            | Specifies the name of the Extreme Integrated Application Hosting (IAH) port associated with the virtual port. Depending on the hardware, the switch can support the following IAH ports: <ul style="list-style-type: none"> <li>• 1/s1</li> <li>• 1/s2</li> </ul> |
| <code>size &lt;1-30&gt;</code>                | Specifies the size of the disk in Gigabytes.                                                                                                                                                                                                                      |
| <code>vlan &lt;1-4096&gt;</code>              | Specifies the VLAN ID used by the virtual port.                                                                                                                                                                                                                   |
| <code>vport WORD&lt;1-32&gt;</code>           | Specifies the name of the virtual port.                                                                                                                                                                                                                           |

## Shut Down a Virtual Service

### About This Task

Perform this procedure to disable the virtual service.

### Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Disable the virtual service:

```
no virtual-service WORD<1-128> enable
```

## Example

Disable the virtual service.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no virtual-service tpvm enable
```

## Delete Virtual Service Resources

### About This Task

Perform this procedure to delete the virtual service resource allocation.

#### Note

If a corresponding virtual machine is running, it is stopped, and then the virtual service configuration is deleted.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Delete the virtual service resource allocation:  
no virtual-service WORD<1-128> [disk WORD<1-32>] [vport WORD<1-32>]

### Example

Delete all virtual service resource allocation.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no virtual-service tpvm
```

## Uninstall a Virtual Service

### About This Task

Perform this procedure to uninstall a configured virtual service.

#### Note

If a virtual machine is running, it is stopped, and then the service directory is uninstalled.

### Before You Begin

You must disable the virtual service before you uninstall it.

### Procedure

1. Enter Privileged EXEC mode:  
enable

2. Uninstall a specific virtual service:

```
virtual-service WORD<1-128> uninstall
```

**Example**

```
Switch:1>enable
Switch:1#virtual-service tpvm uninstall
```

*Variable Definitions*

Use data in the following table to use the **virtual-service** command.

| Variable                 | Value                                          |
|--------------------------|------------------------------------------------|
| <i>WORD&lt;1-128&gt;</i> | Specifies the virtual service name.            |
| <i>uninstall</i>         | Uninstalls the specified virtual service name. |

## Display Virtual Service Configuration

**About This Task**

Perform this procedure to display the virtual service configuration on the switch.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the virtual-service configuration:

```
show virtual-service config [WORD<1-128>]
```

**Example**

Display the configuration of all virtual services:

```
Switch:1>show virtual-service config
=====
                        Installed Packages
=====
Package:                figw
Package App Name:       FabricIPSecGW_VM_4.0.0.0
Package Version:        4

=====
```

## Display Virtual Service Installation Status

### About This Task

Perform this procedure to display the installation status for the specific virtual service. This procedure indicates if the installation finished successfully or failed to complete.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display installation status for a specific virtual service:  

```
show virtual-service install WORD<1-128>
```

### Example

Display installation status for a specific virtual service:

```
Switch:1>show virtual-service install tpvm
  Stage:   Convert
  Status:  In Progress
```

## Display Virtual Services Resources

### About This Task

Perform the following procedure to display the number of remaining virtual services resources on the switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display statistics for all virtual services configured on the switch or a specific virtual service:  

```
show virtual-service statistics [WORD<1-128>]
```

### Example

```
Switch:1>show virtual-service statistics

## Run a VM command from VOSS CLI

### About This Task

Perform this task to run the **ls** command for the VM `configs` directory from the VOSS CLI.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Run a VM command from VOSS:
 

```
virtual-service WORD<1-128> exec-command WORD<1-256>
```

### Example

From VOSS, list the contents of the `home/rwa/configs` directory in the Fabric IPsec Gateway VM.

```

Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#virtual-service figw exec-command "ls /home/rwa/configs"
config.cfg
figw_cli.log
shadov.txt

```

### Variable Definitions

The following table defines parameters for the **virtual-service** command.

| Variable                       | Value                                                                                                             |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;1-128&gt;</code> | Specifies the virtual service name.                                                                               |
| <code>WORD&lt;1-256&gt;</code> | Specifies the VM command to run. To include spaces in the syntax, include the text string in quotation marks ("). |

## Copy VM Files

### About This Task

Perform this task to copy files between VOSS and a VM or between VMs.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Copy a file:
 

```
virtual-service copy-file WORD<1-256> WORD<1-256>
```

### Examples

Copy a file from VOSS to a VM:

```
Switch:1>enable
Switch:1#virtual-service copy-file /intflash/config_figw.cfg figw:/home/rwa/configs/
config.cfg
```

Copy a file from a VM to VOSS:

```
Switch:1>enable
Switch:1#virtual-service copy-file figw:/home/rwa/configs/config.cfg /intflash/
config_figw.cfg
```

Copy a file between VMs:

```
Switch:1>enable
Switch:1#virtual-service copy-file figw:/home/rwa/configs/config.cfg figw2:/home/rwa/
configs/config.cfg
```

### Variable Definitions

The following table defines parameters for the **virtual-service copy-file** command.

| Variable                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD&lt;1-256&gt;</i> | <p>Specifies the source and destination file to copy. To specify a VM location, use the format <code>&lt;VM_name&gt;:&lt;VM_file_path/filename&gt;</code>. To specify a VOSS location, use the format <code>&lt;/file_path/filename&gt;</code> where the valid path can be one of the following:</p> <ul style="list-style-type: none"> <li>• /intflash</li> <li>• /extflash</li> <li>• /usb</li> <li>• /var/lib/insight/packages</li> </ul> |

## Change a VM User Password from VOSS CLI

### About This Task

Perform this task to change the password for a VM user. The password must be greater than, or equal to, 8 characters.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Change the password:  

```
virtual-service WORD<1-128> change-user-pass WORD<1-20>
```
3. Enter the new password.
4. Enter the new password a second time.

### Example

Change the password for the rwa user account in the Fabric IPsec Gateway VM:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#virtual-service figw change-user-pass rwa
Enter password : *****
Re-enter password : *****
```

### Variable Definitions

The following table defines parameters for the **virtual-service WORD<1-128> change-user-pass** command.

| Variable                 | Value                               |
|--------------------------|-------------------------------------|
| <i>WORD&lt;1-20&gt;</i>  | Specifies the username.             |
| <i>WORD&lt;1-128&gt;</i> | Specifies the virtual service name. |

## Upgrade a Virtual Service

If Extreme Networks makes a new version of the virtual service available, uninstall the original virtual service and install the newer virtual service.

### Important

You can perform an upgrade of Linux inside the virtual service by standard Linux upgrade procedures. For example, TPVM is Ubuntu based, so you can use **sudo apt-get update** and **sudo apt-get upgrade**. If you complete such an upgrade, Extreme Networks is not responsible for the behavior of the VM; it has not been tested with that version on the OS.

## Before You Begin

- Ensure the new virtual service image version is compatible with the VOSS release that runs on the switch. For compatibility statements, see [VOSS Release Notes](#). If necessary, upgrade the VOSS image before you upgrade the virtual service image.
- If you installed applications in the Third Party Virtual Machine (TPVM), you must migrate important data for those applications before you perform this procedure.
- If you created new users in the TPVM, follow standard Linux procedures to back up user names and passwords.
- For Fabric IPsec Gateway, back up the configuration files (\*.cfg) and the `shadow.txt` file, which is an encrypted file that contains the authentication keys for the IPsec tunnels. You can use the **ls** command within the VM to see the file list. Use FTP within the VM to transfer the files for backup or see [Copy VM Files](#) on page 865.
- Use FTP or SFTP to transfer the new OVA image to the `/var/lib/insight/packages/` directory on the switch.

### Note

The Fabric IPsec Gateway image includes no integrity check. Use SCP to copy the file to the switch and confirm the file size before installation.

## About This Task

When you uninstall the original virtual service, the system removes the complete virtual service configuration from the configuration file.

## Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Disable the virtual service:  
`no virtual-service WORD<1-128> enable`
3. Return to Privileged EXEC mode:  
`end`
4. Uninstall the virtual service:  
`virtual-service WORD<1-128> uninstall`
5. Install the virtual service package using the new OVA image:  
`virtual-service WORD<1-128> install package WORD<1-512>`
6. Reconfigure the virtual service; for more information, see [Configure a Virtual Service](#) on page 856.
7. Remove the original OVA image from the `/var/lib/insight/packages/` directory on the switch:  
`remove WORD<1-255>`

## Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no virtual-service tpvm enable
```

```

Switch:1(config)#end
Switch:1#virtual-service tpvm uninstall
Switch:1#virtual-service tpvm install package var/lib/insight/packages/
TPVM_4900_8.2.0.0.img
Switch:1#configure terminal
Switch:1(config)#virtual-service tpvm vport eth0 connect-type sriov
Switch:1(config)#virtual-service tpvm vport eth0 vlan 10
Switch:1(config)#virtual-service tpvm enable
Switch:1(config)#remove /intflash/var/lib/insight/packages/TPVM_4900_8.1.5.0.img

```

## Virtual Services Configuration using EDM

Perform the procedures in this section to configure Extreme Integrated Application Hosting (IAH) virtual services on the switch using the Enterprise Device Manager (EDM).

### Viewing Virtual Services Resources

#### About This Task

Perform the following procedure to view the number of remaining virtual services resources on the switch.

#### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Virtual Service**.
3. Click the **Globals** tab.

#### *Globals* Field Descriptions

Use data in the following table to use the **Globals** tab.

| Name                  | Description                                                             |
|-----------------------|-------------------------------------------------------------------------|
| <b>DiskRemain</b>     | Shows the remaining disk space available, in Gigabytes (GB).            |
| <b>NumCoresRemain</b> | Shows the remaining number of CPU cores available.                      |
| <b>MemSizeRemain</b>  | Shows the remaining amount of memory size available, in Megabytes (MB). |

### Configure a Virtual Service

#### About This Task

Perform this procedure to configure a virtual service on the switch.

#### Before You Begin

You must configure at least one virtual port to enable the virtual service. For more information, see [Configure Virtual Ports](#) on page 871.

## Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Select **Virtual Service**.
3. Select the **Virtual Service** tab.
4. Select **Insert**.
5. In the **Name** field, enter a unique name.
6. (Optional) In the **NumCores** field, enter a value.
7. (Optional) In the **MemSize** field, enter a value.
8. Select **Insert**.
9. In the **Enable** field for the newly inserted row, change the value to true.
10. Select **Apply**.

### **Virtual Service** Field Descriptions

Use data in the following table to use the **Virtual Service** tab.

| Name                     | Description                                                                                                                     |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>              | Specifies the name of the virtual service. Every virtual service must have a unique name.                                       |
| <b>NumCores</b>          | Specifies the number of CPU cores assigned to the virtual service. The default is 1.                                            |
| <b>MemSize</b>           | Specifies the memory size (in Megabytes) assigned to the virtual service. The default value is 1024 Megabytes.                  |
| <b>Enable</b>            | Enables the virtual service.<br><br><b>Note:</b><br>You must configure at least one virtual port to enable the virtual service. |
| <b>PackageInfoName</b>   | Shows the package name used by the virtual service.                                                                             |
| <b>PackageAppName</b>    | Shows the application name used by the virtual service.                                                                         |
| <b>PackageAppVersion</b> | Shows the application version used by the virtual service.                                                                      |
| <b>UtilCpuAllot</b>      | Specifies the number of CPUs allocated to the virtual service.                                                                  |
| <b>UtilCpuUtil</b>       | Specifies the average percentage of CPU utilization over the past 30 seconds.                                                   |
| <b>UtilMemAllot</b>      | Specifies the memory (in Megabytes) allocated to the virtual service.                                                           |
| <b>UtilMemUsed</b>       | Specifies the memory used (in Megabytes) by the virtual service.                                                                |
| <b>UtilMemAvailable</b>  | Specifies the memory available (in Megabytes) for the virtual service.                                                          |

| Name          | Description                                             |
|---------------|---------------------------------------------------------|
| <b>State</b>  | Specifies the operational state of the virtual service. |
| <b>UpTime</b> | Specifies the operational time of the virtual service.  |

## Configuring Disks to be used by the Virtual Service

### About This Task

Perform the following procedure to configure the number of disks to be used by the virtual service configured on the switch.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Virtual Service**.
3. Click the **Disks** tab.
4. Click **Insert**.
5. In the **ServName** field, enter the virtual service name.
6. In the **Name** field, enter the disk name.
7. (Optional) In the **Size** field, enter a value.
8. Click **Insert**.

### *Disks* Field Descriptions

Use data in the following table to use the **Disks** tab.

| Name                 | Description                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ServName</b>      | Specifies the virtual service name.<br><br><b>Note:</b><br>The specified name must match the virtual service name configured on the switch. |
| <b>Name</b>          | Specifies the name of the disk used by the virtual service.                                                                                 |
| <b>Size</b>          | Specifies the disk size (in Gigabytes). The default is 10 Gigabytes.                                                                        |
| <b>SizeAllot</b>     | Shows the disk size (in Megabytes) allocated to the virtual service.                                                                        |
| <b>SizeAvailable</b> | Shows the available disk storage space (in Megabytes).                                                                                      |
| <b>SizeUsed</b>      | Shows the amount of disk storage space (in Megabytes) used by the virtual service.                                                          |

## Configure Virtual Ports

### About This Task

Perform the following procedure to configure virtual ports to be used by the virtual service configured on the switch.

#### Note

The names of Ethernet ports appearing in a specific Virtual Machine (VM) are not correlated to the configured virtual port names. Each VM renames the Ethernet ports as per its requirements, after they are discovered during the VM initialization.

By default, the system displays all virtual ports of OVS connection type first in the alphabetical order of their configured names, followed by the virtual ports of SR-IOV and VT-d connection types.

### Before You Begin

- You must enable trunking on the Extreme Integrated Application Hosting (IAH) port when you use SR-IOV and OVS connection types.
- Ensure the switch has the Ethernet drivers installed as per the SR-IOV standard, to support the VT-d and the SR-IOV connection type for the configured virtual ports.

### Procedure

- In the navigation pane, expand the **Configuration > Serviceability** folders.
- Select **Virtual Service**.
- Select the **VPorts** tab.
- Select **Insert**.
- In the **Virtual Service Name** field, enter the virtual service name.
- In the **Interface Name** field, enter a name for the virtual port.
- (Optional) In the **VlanIdList** field, enter a VLAN ID.
- (Optional) In the **ConnectType** field, select a connection type.

#### Note

Ensure the connection type you configure for the virtual port matches the connection type supported by the IAH port.

- Select **Insert**.

### *VPorts* Field Descriptions

Use data in the following table to use the **VPorts** tab.

| Name                        | Description                                                                                                                                 |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Virtual Service Name</b> | Specifies the virtual service name.<br><br><b>Note:</b><br>The specified name must match the virtual service name configured on the switch. |
| <b>Interface Name</b>       | Specifies the virtual port.                                                                                                                 |

| Name               | Description                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanIdList</b>  | Specifies the VLAN ID to which the virtual port is assigned.                                                                                                                                                                                                                               |
| <b>ConnectType</b> | Specifies the virtual port connect type. The default is VT-d. The switch supports the following maximums for virtual ports: <ul style="list-style-type: none"> <li>• OVS - 16</li> <li>• SR-IOV - 16</li> <li>• VT-d - 2</li> </ul>                                                        |
| <b>Port</b>        | Specifies the name of the Extreme Integrated Application Hosting port associated with the virtual port. Depending on hardware, the switch can support the following Extreme Integrated Application Hosting ports: <ul style="list-style-type: none"> <li>• 1/s1</li> <li>• 1/s2</li> </ul> |
| <b>NicType</b>     | Specifies the Virtual Port NIC type. The default is e1000. <ul style="list-style-type: none"> <li>• virtio</li> <li>• e1000</li> </ul> <p><b>Note:</b><br/>Configure this value only when the <b>ConnectType</b> field is ovs.</p>                                                         |

## Install a Virtual Service

### Before You Begin

- Use FTP or SFTP to transfer the OVA image to the `/var/lib/insight/packages/` directory on the switch.

### About This Task

Perform the following procedure to configure the package information to be used by the virtual service.

### Procedure

1. In the navigation pane, expand **Configuration > Serviceability**.
2. Select **Virtual Service**.
3. Select the **Application** tab.
4. Select **Insert**.
5. In the **Name** field, enter the virtual service name.
6. Next to the **PackageName** field, select the ellipsis, select the package to install, and then select **Ok**.
7. Select **Insert**.

**Application** Field Descriptions

Use data in the following table to use the **Application** tab.

| Name                     | Description                                                |
|--------------------------|------------------------------------------------------------|
| <b>Name</b>              | Specifies the name of the virtual service.                 |
| <b>PackageName</b>       | Specifies the name and location of the package.            |
| <b>InstallResult</b>     | Shows the status of the virtual service installation.      |
| <b>InstallStage</b>      | Shows the stages of a package installation.                |
| <b>PackageAppName</b>    | Shows the application name used by the virtual service.    |
| <b>PackageAppVersion</b> | Shows the application version used by the virtual service. |

## Viewing Virtual Services Package File Information

**About This Task**

Perform the following procedure to view information about the package files available in the `/var/lib/insight/packages` directory, which you can use to install a new virtual service.

**Procedure**

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Virtual Service**.
3. Click the **PackageFile** tab.

**PackageFile** Field Descriptions

Use data in the following table to use the **PackageFile** tab.

| Name        | Description                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b> | Shows the name and absolute path information for package files available in the <code>/var/lib/insight/packages</code> directory. |
| <b>Date</b> | Shows the date and time when the package file was added to the directory.                                                         |
| <b>Size</b> | Shows the size (in bytes) of the package file.                                                                                    |

## Fabric IPsec Gateway Configuration using CLI

Perform the procedures in this section to configure services like IPsec, fragmentation and reassembly, and to manage the Fabric IPsec Gateway Virtual Machine using the command line interface (CLI).

### Configure FTP Connection to an IP Address

Fabric IPsec Gateway Virtual Machine (VM) provides a File Transfer Protocol (FTP) CLI to copy the configuration files to the VM.

#### About This Task

Perform this procedure to configure an FTP connection to a specific IP Address.

#### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Configure FTP connection:

```
ftp {A.B.C.D}
```

#### Example

Configuring FTP connection to 192.0.2.50:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> ftp 192.0.2.50
```

#### Variable Definitions

The following table defines the variable for **ftp** command.

| Variable  | Value                                                          |
|-----------|----------------------------------------------------------------|
| {A.B.C.D} | Specifies the IP Address to establish the FTP connection with. |

### Display the Default Directory on Fabric IPsec Gateway VM

#### About This Task

Perform this procedure to display content in the default directory on the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

#### Note

Type **CTRL+Y** to exit the console.

2. Display the configured directory:  
ls

### Example

Displaying the configured directory on the VM.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> ls
coupled.cfg
```

## Load Configuration File to Fabric IPsec Gateway VM

### About This Task

Perform this procedure to load a configuration file to the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

#### Note

Type **CTRL+Y** to exit the console.

2. Load a specific configuration file to the VM :  
load WORD <1-255>

### Example

Loading a configuration file to the VM.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> load coupled.cfg
```

*Variable Definitions*

The following table defines the variable for **load** command.

| Variable            | Value                                  |
|---------------------|----------------------------------------|
| <i>WORD</i> <1-255> | Specifies the configuration file name. |

## Ping an IP Address on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to ping an IP Address on the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Ping an IP Address:  

```
ping {A.B.C.D}
```

### Example

Pinging an IP Address on the VM.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> ping 192.0.2.35
```

*Variable Definitions*

The following table defines parameters for the **ping** command.

| Variable  | Value                     |
|-----------|---------------------------|
| {A.B.C.D} | Specifies the IP address. |

## Configure Global Parameters on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to configure IPsec source IP address, Local Area Network (LAN ) interface IP and gateway IP address, maximum transmission unit (MTU) value, and so on globally, on the Fabric IPsec Gateway Virtual Machine (VM).

#### Note

You must perform this procedure only after the VM boots up.

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Configure IPsec source IP address for a Fabric Extend (FE) tunnel for IPsec in decoupled mode:

```
set global ipsec-tunnel-src-ip {A.B.C.D/X}
```

3. Assign VLAN ID to the configured IPsec source IP address:

```
set global ipsec-tunnel-src-vlan <2-4059>
```

4. Configure the LAN interface IP address on the first Ethernet interface (eth0) of Fabric IPsec Gateway VM:

```
set global lan-intf-ip {A.B.C.D/X}
```

5. Assign VLAN ID to the configured LAN interface IP address:

```
set global lan-intf-vlan <2-4059>
```

6. Configure the LAN interface gateway IP address on the VOSS switch:

```
set global lan-intf-gw-ip {A.B.C.D}
```

7. Configure the logical interface gateway IP address, to add routes for FE tunnels that need Fragmentation:

```
set global fe-tunnel-gw-ip {A.B.C.D}
```

8. Configure the logical interface source IP address for the FE tunnel:

```
set global fe-tunnel-src-ip {A.B.C.D}
```

#### Note

The logical interface source IP address must be same as the source IP address configured on the VOSS switch.

9. Configure the global MTU value:

```
set global mtu <mtu-value>
```

**Note**

- The switch applies the global MTU value, if you do not configure MTU during the IPsec tunnel configuration.
- If an IPsec tunnel is not using the fragmentation and reassembly capabilities, the default MTU value is 1950.

10. Configure the Wide Area Network (WAN) interface gateway IP address, which is the next hop for IPsec tunnels.

```
set global wan-intf-gw-ip {A.B.C.D}
```

11. Configure the virtual reassembly interface IP address:

```
set global virtual-reassembly-intf-ip {A.B.C.D/X}
```

**Note**

You must configure the virtual reassembly interface IP address to use the fragmentation and reassembly service.

12. Assign VLAN ID to the configured virtual reassembly interface IP address:

```
set global virtual-reassembly-intf-vlan <2-4059>
```

13. Disable IPsec on all configured tunnels:

```
set global ipsec-disable
```

14. Set IPsec log level:

```
set global ipsec-log-level <-1-5>
```

**Example**

Configuring global parameters on Fabric IPsec Gateway VM to configure an IPsec tunnel between two switches:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> set global ipsec-tunnel-src-ip 192.0.2.10/24
FIGW> set global ipsec-tunnel-src-vlan 101
FIGW> set global lan-intf-ip 192.0.2.20/24
FIGW> set global lan-intf-vlan 30
FIGW> set global lan-intf-gw-ip 192.0.2.30
FIGW> set global fe-tunnel-src-ip 192.0.2.40
FIGW> set global wan-intf-gw-ip 192.0.2.50
FIGW> set global mtu 1950
```

## Variable Definitions

The following table defines parameters for the **set global** command.

| Variable                                      | Value                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipsec-tunnel-src-ip</i><br>{A.B.C.D/X}     | Specifies the source IP address and subnet mask for IPsec tunnel.                                                                                                                                                                                                                                                                                                                  |
| <i>ipsec-tunnel-src-vlan</i> <2-4059>         | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <i>lan-intf-ip</i><br>{A.B.C.D/X}             | Specifies the IP address and subnet mask for Local Area Network (LAN) interface.                                                                                                                                                                                                                                                                                                   |
| <i>lan-intf-vlan</i><br><2-4059>              | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <i>lan-intf-gw-ip</i><br>{A.B.C.D}            | Specifies the gateway IP address for LAN interface.                                                                                                                                                                                                                                                                                                                                |
| <i>fe-tunnel-gw-ip</i><br>{A.B.C.D}           | Specifies the gateway IP address for Fabric Extend (FE) tunnel.                                                                                                                                                                                                                                                                                                                    |
| <i>fe-tunnel-src-ip</i><br>{A.B.C.D}          | Specifies the source IP address for FE tunnel.                                                                                                                                                                                                                                                                                                                                     |
| <i>mtu</i> <750-9000>                         | Specifies the Maximum Transmission Unit (MTU) value.<br><br><b>Note:</b><br>If an IPsec tunnel is not using the fragmentation and reassembly capabilities, the default MTU value is 1950.                                                                                                                                                                                          |
| <i>wan-intf-gw-ip</i><br>{A.B.C.D}            | Specifies the Wide Area Network (WAN) interface gateway IP address.                                                                                                                                                                                                                                                                                                                |
| <i>virtual-reassembly-intf-ip</i> {A.B.C.D/X} | Specifies the virtual-reassembly interface IP address and subnet mask on the Fabric IPsec Gateway (VM).<br><br><b>Note:</b><br>You must configure the virtual reassembly interface IP address to use the fragmentation and reassembly service.                                                                                                                                     |
| <i>virtual-reassembly-intf-vlan</i> <2-4059>  | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |

| Variable                               | Value                                                                                                                                                                                                              |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ipsec-disable</code>             | Disables IPsec operationally on all tunnels in the Fabric IPsec Gateway VM.                                                                                                                                        |
| <code>ipsec-log-level</code><br><-1-5> | Specifies the IPsec log levels on Fabric IPsec Gateway VM. Following are the three levels: <ul style="list-style-type: none"> <li>-1: Absolutely Silent</li> <li>0-4: Log levels</li> <li>5: Clear Logs</li> </ul> |

## Configure IPsec Tunnels on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to configure IPsec tunnels on Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Configure the Maximum Transmission Unit (MTU) value for the specific IPsec tunnel:

```
set ipsec <1-255> mtu <1300 - 9000>
```

#### Note

The MTU range <1300-9000> is applicable for FE tunnels with IPsec and fragmentation and reassembly capabilities.

3. Configure the ESP cipher suite for the IPsec tunnel:

```
set ipsec <1-255> esp <aes128gcm16-sha256 | aes256-sha256 |  
aes256gcm16-sha256>
```

4. Configure the authentication key for specific IPsec tunnel:

```
set ipsec <1-255> auth-key WORD <1-32>
```

#### Note

Do not use special characters ?, \, &, <, >, #.

5. Configure VXLAN destination IP address for IPsec tunnel:

```
set ipsec <1-255> fe-tunnel-dest-ip {A.B.C.D}
```

#### Note

The VXLAN destination IP address for IPsec tunnel must be the same as the VXLAN destination IP address for FE tunnel.

6. Configure the IPsec destination IP address for the specific tunnel deployed in decoupled mode:
 

```
set ipsec <1-255> ipsec-dest-ip {A.B.C.D}
```
7. Configure a name for the IPsec tunnel:
 

```
set ipsec <1-255> tunnel-name WORD <1-64>
```
8. Identify if the specific tunnel is a responder or initiator in Network Address Translation (NAT) cases:
 

```
set ipsec <1-255> responder-only <true | False>
```
9. Enable the IPsec on a specific tunnel:
 

```
set ipsec <1-255> admin-state enable
```

### Example

Configure parameters for IPsec tunnel on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> set ipsec 1 ipsec-dest-ip 192.0.2.5
FIGW> set ipsec 1 mtu 1950
FIGW> set ipsec 1 auth-key abcd
FIGW> set ipsec 1 tunnel-name Tunnel-to-BEB2
FIGW> set ipsec 1 fe-tunnel-dest-ip 192.0.2.15
FIGW> set ipsec 1 esp aes256gcm16-sha256
FIGW> set ipsec 1 admin-state enable
```

### Variable Definitions

The following table defines parameters for the **set ipsec** command.

| Variable                                                             | Value                                                                                                                                                                                                                                              |
|----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-255>                                                              | Specifies the unique ID for the IPsec tunnel.                                                                                                                                                                                                      |
| <i>admin-state</i> <enable   disable>                                | Enables or disables IPsec on the specific IPsec tunnel.                                                                                                                                                                                            |
| <i>auth-key</i> WORD<br><1-32>                                       | Specifies the pre-shared authentication key.<br><br><b>Note:</b><br>Do not use special characters ?, \, &, <, >, #.                                                                                                                                |
| <i>encryption-key-length</i> <128   256>                             | Specifies the encryption key length for the IPsec tunnel. The default encryption key length is 128. As a best practice, use the newer <i>esp</i> parameter instead; the <i>encryption-key-length</i> parameter remains for backward compatibility. |
| <i>esp</i> <aes128gcm16-sha256   aes256-sha256   aes256gcm16-sha256> | Specifies the ESP cipher suites for the IPsec tunnel. The default is aes128gcm16-sha256. aes256-sha256 is not supported in the current release.                                                                                                    |
| <i>fe-tunnel-dest-ip</i> {A.B.C.D}                                   | Specifies the destination IP address for Fabric Extend (FE) tunnel.                                                                                                                                                                                |

| Variable                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipsec-dest-ip</i><br>{A.B.C.D}       | Specifies the destination IP address for IPsec tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>mtu</i> <1300-9000                   | Specifies the Maximum Transmission Unit (MTU) value for the FE tunnel with both IPsec and fragmentation and assembly capabilities.                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>responder-only</i><br><true   false> | Specifies if the IPsec session in the FE tunnel will be in responder only mode or initiator mode. When in responder mode the FE tunnel will only respond to the incoming request and not initiate the IPsec connection. By default both sides of IPsec connection will be initiators in the FE tunnel. Configure the IPsec tunnel to be in responder only mode when there is Network Address Translation (NAT) between the IPsec connection. For more information about NAT, see <a href="#">IPsec NAT-T</a> on page 1749. |
| <i>tunnel-name</i> WORD<br><1-64>       | Specifies a name for the IPsec tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>egress-shaping-rate</i><br><1-1000>  | Specifies the egress shaper rate for the IPsec tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Enable Fragmentation Before Encryption on Fabric IPsec Gateway VM

Perform this procedure to fragment packets larger than the IPsec tunnel maximum transmission unit (MTU) before the packets are sent for encryption.

### Before You Begin

- Ensure IPsec is disabled on the tunnel. The administrative state must be disabled before you can enable or disable fragmentation before encryption.
- Configure the IPsec destination IP address or enable responder mode.

### About This Task

By default, fragmentation before encryption is disabled.

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Enable fragmentation before IPsec encryption:

```
set ipsec <1-255> fragment-before-encrypt enable
```

## Configure the Subject Identity on Fabric IPsec Gateway VM

### About This Task

Use this procedure to configure the subject parameters to identify the device.

## Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

### Note

Type **CTRL+Y** to exit the console.

2. Configure the distinguished name of the device:

```
set certificate subject <subject-label> DN <name>
```

3. (Optional) Configure the name of the generated key-pair:

```
set certificate subject <subject-label> key-label <key-label>
```

## Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>set certificate subject ExtremeLab DN "CN=subca5, OU=Test, O=Extreme, L=Town,
ST=State, E=email@extremenetworks.com"
FIGW>set certificate subject ExtremeLab key-label key1
```

## Variable Definitions

The following table defines parameters for the **set certificate subject** command.

| Variable                           | Value                                                                                                                                                                                                                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DN &lt;name&gt;</i>             | Specifies the distinguished name. You can create a comma-separated list.                                                                                                                                                                                                                     |
| <i>key-label &lt;key-label&gt;</i> | Specifies the key name of the generated key pair. This parameter is optional. If you do not configure one, the switch generates one the same as the subject-label.                                                                                                                           |
| <i>&lt;subject-label&gt;</i>       | Specifies the subject identity. You cannot use the following special characters: <ul style="list-style-type: none"> <li>• question mark (?)</li> <li>• backslash (\)</li> <li>• ampersand (&amp;)</li> <li>• less than (&lt;)</li> <li>• greater than (&gt;)</li> <li>• pound (#)</li> </ul> |

## Generate the Key Pair on Fabric IPsec Gateway VM

### About This Task

Use the following procedure to generate the private and public key pair. By default, VOSS generates a 2,048 RSA key when the system starts. You can use this procedure to generate a new key.

### Before You Begin

- Configure an EJBCA CA server.

- Configure a route from Fabric IPsec Gateway to the EJBCA CA server.

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Generate the key:

```
certificate generate key <type> <size> <key-label>
```

### Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>certificate generate key rsa 2048 key_rsa
fingerprint: 09ac0c64b9bf3ad04dc67f20942c674e
```

### Variable Definitions

The following table defines parameters for the **certificate generate key** command.

| Variable         | Value                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <i>key-label</i> | Specifies the key name of the generated key pair.                                                                                        |
| <i>size</i>      | Specifies the size of key-pair to be generated. The switch supports 2048.                                                                |
| <i>type</i>      | Specifies the type of cryptography algorithm used to generate the key-pair. The switch uses only rsa as the cryptography algorithm type. |

## Configure a Trustpoint CA on Fabric IPsec Gateway VM

### About This Task

Use this procedure to configure the certificate authority (CA) to use Simple Certificate Enrollment Protocol (SCEP) with a CA server for online certificate provisioning.

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Configure the trusted CA URL:

```
set certificate ca-trustpoint <ca-label> ca-url <ca-url>
```

3. Configure the common name of the CA:

```
set certificate ca-trustpoint <ca-label> caname <caname>
```

4. Configure the HTTP request type to support the type of CA:

```
set certificate ca-trustpoint <ca-label> get-method <post | get>
```

5. Configure the appropriate action:

- Configure the trustpoint, authenticate the trustpoint CA by getting the certificate of the CA, and store the CA certificate locally:

```
certificate ca <ca-trustpoint> caAuth
```

- Generate the certificate enrollment request, get the digital certificate, and store it locally, associating with the trustpoint CA:

```
certificate ca <ca-trustpoint> enroll <subject-label>
```

- Get the Certificate Revocation List (CRL) from the CDP and store into a file:

```
certificate get crl-from <A.B.C.D> <user> <file-path> <cacert-  
filename>
```

- Get the CA certificate obtained from the trustpoint CA:

```
certificate get cacert-from <A.B.C.D> <user> <file-path>
```

- Get the subject certificate obtained from the trustpoint CA:

```
certificate get signedcert-from <A.B.C.D> <user> <file-path>  
<subject-label>
```

- Release the locally stored certificate associated with the trustpoint CA after revocation:

```
certificate ca <ca-trustpoint> remove <subject-label>
```

- Remove all certificates from the CA trustpoint:

#### Note

You can clean the CA trustpoint only if the subject-label is not configured on an IPsec tunnel.

```
certificate ca <ca-trustpoint> clean
```

### Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>set certificate ca-trustpoint caExtremeEJBCA ca-url http://192.0.2.9:8080/ejbca/  
publicweb/apply/scep/test/pkiclient.exe
FIGW>set certificate ca-trustpoint caExtremeEJBCA caname subca5
FIGW>set certificate ca-trustpoint caExtremeEJBCA get-method post
```

### Variable Definitions

The following table defines parameters for the **set certificate ca-trustpoint** command.

| Variable                                   | Value                                                                                                                                                      |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;ca-label&gt;</code>              | Specifies the name of the certificate authority (CA). The name can use alphanumeric characters and is case-sensitive. The maximum length is 45 characters. |
| <code>ca-url &lt;ca-url&gt;</code>         | Specifies the trusted CA URL.                                                                                                                              |
| <code>caname &lt;caname&gt;</code>         | Specifies the name of the owner of the device or user.                                                                                                     |
| <code>get-method &lt;post   get&gt;</code> | Specifies the HTTP request style. You can use post for EJBCA or get for Win2012 CA. The default value is post.                                             |

The following table defines parameters for the **certificate ca** command.

| Variable                           | Value                                                                                                                                     |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;ca-trustpoint&gt;</code> | Specifies the name of the certificate authority. The name can be alphanumeric and is case-sensitive. The maximum length is 45 characters. |
| <code>&lt;subject-label&gt;</code> | Specifies the subject identity.                                                                                                           |

The following table defines parameters for the **certificate get** command.

| Variable                                                                                          | Value                                                                                                                                                         |
|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cacert-from &lt;A.B.C.D&gt; &lt;user&gt; &lt;file-path&gt;</code>                           | Specifies where to obtain the CA certificate. Specify the IP address, username, and remote file path.                                                         |
| <code>crl-from &lt;A.B.C.D&gt; &lt;user&gt; &lt;file-path&gt; &lt;cacert-filename&gt;</code>      | Specifies where to obtain the Certificate Revocation List. Specify the IP address, username, remote file path, and the CA certificate file to verify the CRL. |
| <code>signedcert-from &lt;A.B.C.D&gt; &lt;user&gt; &lt;file-path&gt; &lt;subject-label&gt;</code> | Specifies where to obtain the subject certificate. Specify the IP address, username, remote file path, and subject label.                                     |

## Generate the Certificate Signing Request on Fabric IPsec Gateway VM

### About This Task

Use this procedure to generate a certificate signing request (CSR) and store it into a file. This CSR is required to obtain the offline subject certificate.

## Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

### Note

Type **CTRL+Y** to exit the console.

2. Generate the CSR:

```
certificate generate csr <subject-label>
```

3. Configure where to send the CSR for signing:

```
certificate send-csr-to <A.B.C.D> <user> <remote-path> <subject-label>
```

## Variable Definitions

The following table defines parameters for the **certificate generate csr** command.

| Variable        | Value                           |
|-----------------|---------------------------------|
| <subject-label> | Specifies the subject identity. |

The following table defines parameters for the **certificate send-csr-to** command.

| Variable        | Value                                                   |
|-----------------|---------------------------------------------------------|
| <A.B.C.D>       | Specifies the IP address for the certificate authority. |
| <remote-path>   | Specifies the file path on the certificate authority.   |
| <subject-label> | Specifies the subject identity.                         |
| <user>          | Specifies the username for the certificate authority.   |

## Remove Keys and Certificates on Fabric IPsec Gateway VM

### Before You Begin

You can remove subject certificates from the certificate authority (CA) trustpoint only if the subject-label is not configured on an IPsec tunnel.

### About This Task

Use this procedure to remove keys or certificates from the certificate store.

## Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  

```
enable
```

```
virtual-service WORD<1-128> console
```

### Note

Type **CTRL+Y** to exit the console.

2. Remove a key:  

```
certificate remove key <key-label>
```
3. Remove a specific certificate from the store:  

```
certificate remove offline-cacert <filename>
```
4. Remove a Certificate Revocation List (CRL) certificate from the store:  

```
certificate remove offline-crl <filename>
```
5. Remove signed certificates for a specific subject label:  

```
certificate remove offline-subject-certs <subject-label>
```
6. Remove a specific identity certificate from the CA trustpoint:  

```
certificate ca <ca-trustpoint> remove <subject-label>
```
7. Remove all certificates from the CA trustPoint:  

```
certificate ca <ca-trustpoint> clean
```

### Variable Definitions

The following table defines parameters for the **certificate remove** command.

| Variable                                     | Value                                                                           |
|----------------------------------------------|---------------------------------------------------------------------------------|
| <i>key</i> <key-label>                       | Specifies the key name to remove.                                               |
| <i>offline-cacert</i><br><filename>          | Specifies the certificate filename to remove.                                   |
| <i>offline-crl</i><br><filename>             | Specifies the Certificate Revocation List (CRL) certificate filename to remove. |
| <i>offline-subject-certs</i> <subject-label> | Specifies the subject label for which to remove signed certificates.            |

The following table defines parameters for the **certificate ca** command.

| Variable        | Value                                                                                                                                     |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <ca-trustpoint> | Specifies the name of the certificate authority. The name can be alphanumeric and is case-sensitive. The maximum length is 45 characters. |
| <subject-label> | Specifies the subject identity.                                                                                                           |

## View the Certificate Details on Fabric IPsec Gateway VM

### About This Task

Use this procedure for the following tasks:

- Display the digital certificate for a certificate type or list all the certificate details from the local store.
- Display the certificate authority (CA) details for a trustpoint CA name or list all the CA details from the local store if the CA name is not specified.
- Display the configured key details for a key name.
- Display the configured subject details.

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Display all digital certificates:

```
show certificates all
```

3. Display the CA details:

```
show certificates cacert [<ca-label>]
```

4. Display Certificate Revocation List (CRL) certificate details:

```
show certificates crl [<ca-label>]
```

5. Display the certificate signing request (CSR) details:

```
show certificates csr [<ca-label>]
```

6. Display the name and public key of all the key-pairs:

```
show certificate keys
```

7. Display the details of signed certificates:

```
show certificate signed [<ca-label>]
```

### Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>show certificates keys key_rsa
Key Label:      key_rsa
private key with:
pubkey:        RSA 2048 bits
keyid:         ef:4c:1d:a7:cc:84:6f:87:da:e4:de:99:07:3d:96:fc:9a:d1:c9:f4
subjkey:       cb:d1:67:a0:da:9c:05:ce:c0:0d:a3:5c:1b:ba:ce:3f:ff:af:8f:77
```

### Variable Definitions

The following table defines parameters for the **show certificates** command.

| Variable      | Value                                                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| ca <ca-label> | Specifies the name of the certificate authority (CA).<br>If you do not specify the name, the command displays the details of all configured CAs. |

## View the Certificate Configuration on Fabric IPsec Gateway VM

### About This Task

Use this procedure to view the certificate configuration for the VM.

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Display all configured entries:

```
show running-config
```

3. Display the CA trustpoint configuration:

```
show certificate-config ca-trustpoint [<ca-label>]
```

4. Display the subject-related configuration:

```
show certificate-config subject [<subject-label>]
```

### Examples

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>show certificate-config ca-trustpoint
certificate {
  ca-trustpoint {
    ca-label a;
    caname subCaVpn;
    ca-url http://10.2.38.35:8080/ejbca/publicweb/apply/scep/test/pkiclient.exe;
    get-method post;
  }
}

Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>show certificate-config subject
certificate {
  subject {
    subject-label fig;
    DN CN=FIGW;
    key-label gigi;
  }
  subject {
    subject-label figv;
    DN CN=figvpn;
  }
}
```

## Configure Egress Shaping Rate for IPsec Tunnels on Fabric IPsec Gateway VM

### Before You Begin

Before you can configure the egress shaping rate for the IPsec tunnel on the VM, you must first disable the IPsec tunnel.

### About This Task

Perform this procedure to configure the egress shaping rate for IPsec tunnels on Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable

virtual-service WORD<1-128> console
```

**Note**  
Type **CTRL+Y** to exit the console.

2. Disable the IPsec tunnel:

```
delete ipsec <1-255> admin-state enable
```

3. Configure the egress shaping rate for the IPsec tunnel:

```
set ipsec <1-255> egress-shaping-rate <1-1000>
```

4. Enable the IPsec tunnel:

```
set ipsec <1-255> admin-state-enable
```

### Example

Configuring egress-shaping-rate for the IPsec tunnel on the Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> delete ipsec 1 admin-state enable
FIGW> set ipsec 1 egress-shaping-rate 200
FIGW> set ipsec 1 admin-state enable
```

### Variable Definitions

The following table defines parameters for the **set ipsec** command.

| Variable                              | Value                                                   |
|---------------------------------------|---------------------------------------------------------|
| <1-255>                               | Specifies the unique ID for the IPsec tunnel.           |
| <i>admin-state</i> <enable   disable> | Enables or disables IPsec on the specific IPsec tunnel. |
| <i>egress-shaping-rate</i> <1-1000>   | Specifies the egress shaping rate for the IPsec tunnel. |

## Configure Logical Interface Tunnel on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to configure a Fabric Extend (FE) tunnel with only fragmentation and reassembly capabilities, on the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Configure the logical interface destination IP address for the specific tunnel:

```
set logical-intf-tunnel <1-255> fe-tunnel-dest-ip {A.B.C.D}
```

3. Configure the Maximum Transmission Unit (MTU) value for the specific tunnel:

```
set logical-intf-tunnel <1-255> mtu <750-9000>
```

#### Note

The MTU range <750-9000> is applicable for FE tunnels with only fragmentation and reassembly capabilities.

4. Configure tunnel name:

```
set logical-intf-tunnel <1-255> tunnel-name WORD <1-64>
```

5. Configure the egress shaping rate for a specific tunnel:

```
set logical-intf-tunnel <1-255> egress-shaping-rate <1-1000>
```

### Example

Configuring logical interface tunnel on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> set logical-intf-tunnel 2 fe-tunnel-dest-ip 192.0.2.50
FIGW> set logical-intf-tunnel 2 mtu 1300
FIGW> set logical-intf-tunnel 2 egress-shaping-rate 5
FIGW> set logical-intf-tunnel 2 tunnel-name Tunnel-to-BEB2
```

## Variable Definitions

The following table defines parameters for the **set logical-intf-tunnel** command.

| Variable                               | Value                                                                                                                    |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <1-255>                                | Specifies the unique ID for the logical interface tunnel.                                                                |
| <i>fe-tunnel-dest-ip</i><br>{A.B.C.D}  | Specifies the FE tunnel destination IP address for the logical interface.                                                |
| <i>mtu</i> <750-9000>                  | Specifies the Maximum Transmission Unit (MTU) value for the FE tunnel with only fragmentation and assembly capabilities. |
| <i>tunnel-name</i> WORD<br><1-64>      | Specifies a name for the the logical interface tunnel.                                                                   |
| <i>egress-shaping-rate</i><br><1-1000> | Specifies the egress shaping rate for the logical interface tunnel.                                                      |

## Save Running Configuration to a File

### About This Task

Perform this procedure to save the current configuration on Fabric IPsec Gateway Virtual Machine (VM) to a specific file.

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Save configuration to the default configuration file:

```
save config [-y]
```

3. Save configuration to a specific file in the Fabric IPsec Gateway VM.

```
save config file WORD <1-255> [-y]
```

### Example

Save the Fabric IPsec Gateway configuration to file "test":

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW>save config file test.txt
File already exists, do you want to overwrite [y/n]: y
```

Save the Fabric IPsec Gateway configuration to file "test", forcing the switch to overwrite the file without confirmation:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> save config file test.txt -y
```

*Variable Definitions*

The following table defines parameters for the **save config** command.

| Variable                 | Value                                                                                |
|--------------------------|--------------------------------------------------------------------------------------|
| <i>file</i> WORD <1-255> | Specifies the name of file to save the configuration of the Fabric IPsec Gateway VM. |
| -y                       | Forces the switch to overwrite the configuration file without confirmation.          |

## Remove Configuration File from Fabric IPsec Gateway VM

### About This Task

Perform this procedure to remove a specific configuration file from Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**  
Type **CTRL+Y** to exit the console.

2. Remove the configuration file:  

```
remove WORD <1-255>
```

### Example

Remove configuration file "test" from Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> remove test
```

### Variable Definitions

The following table defines parameters for the **remove** command.

| Variable            | Value                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-255> | Specifies the configuration file name that the system removes from Fabric IPsec Gateway VM. |

## Delete Global Configuration on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to delete the global parameters that you configure on Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Delete configuration of specific global parameters:

```
delete global <fe-tunnel-gw-ip | fe-tunnel-src-ip | ipsec-disable |
ipsec-tunnel-src-ip | ipsec-tunnel-src-vlan | lan-intf-gw-ip | lan-
intf-ip | lan-intf-vlan | mtu | virtual-reassembly-intf-ip | virtual-
reassembly-intf-vlan | wan-intf-gw-ip>
```

### Example

Deleting the global Maximum Transmission Unit (MTU) configuration on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> delete global mtu
```

### Variable Definitions

The following table defines parameters for the **delete global** command.

| Variable                | Value                                                                |
|-------------------------|----------------------------------------------------------------------|
| <i>fe-tunnel-gw-ip</i>  | Deletes the global gateway IP address for Fabric Extend (FE) tunnel. |
| <i>fe-tunnel-src-ip</i> | Deletes the global source IP address for FE tunnel.                  |
| <i>ipsec-disable</i>    | Deletes the global IPsec configuration.                              |

| Variable                            | Value                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------|
| <i>ipsec-tunnel-src-ip</i>          | Deletes the global source IP address and subnet mask for IPsec tunnel.               |
| <i>ipsec-tunnel-src-vlan</i>        | Deletes the global source VLAN configuration for IPsec tunnel.                       |
| <i>lan-intf-gw-ip</i>               | Deletes the global gateway IP address on the Local Area Network (LAN) interface.     |
| <i>lan-intf-ip</i>                  | Deletes the global IP address and subnet mask on LAN interface.                      |
| <i>lan-intf-vlan</i>                | Deletes the global VLAN configuration on LAN interface.                              |
| <i>mtu</i>                          | Resets the Maximum Transmission Unit (MTU) value to its default, that is 1950 bytes. |
| <i>virtual-reassembly-intf-ip</i>   | Deletes the global virtual-reassembly interface IP address and subnet mask.          |
| <i>virtual-reassembly-intf-vlan</i> | Deletes the global virtual-reassembly interface VLAN configuration.                  |
| <i>wan-intf-gw-ip</i>               | Deletes the global gateway IP address on the Wide Area Network (WAN) interface.      |

## Delete IPsec Tunnel Configuration on Fabric IPsec Gateway VM

### Before You Begin

You must disable the IPsec administrative state on the tunnel before you can remove IPsec configuration.

### About This Task

Perform this procedure to delete the configuration of a specific IPsec tunnel on Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Delete the configuration of a specific tunnel:

```
delete ipsec <1-255> <admin-state enable | auth-key | encryption-key-length | fe-tunnel-dest-ip | fragment-before-encrypt enable | ipsec-dest-ip | mtu | responder-only | tunnel-name | egress-shaping-rate>
```

## Example

Delete configuration on IPsec tunnel ID 2:

```

Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW>delete ipsec 2 admin-state enable
FIGW>delete ipsec 2 auth-key
FIGW>delete ipsec 2 tunnel-name
FIGW>delete ipsec 2 fragment-before-encrypt enable

```

## Variable Definitions

The following table defines parameters for the **delete ipsec** command.

| Variable                              | Value                                                                                                                                 |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <1-255>                               | Specifies the unique ID of the configured IPsec tunnel.                                                                               |
| <i>admin-state enable</i>             | Disables the IPsec status on the specific IPsec tunnel.                                                                               |
| <i>auth-key</i>                       | Deletes the authentication key that you configure on the specific IPsec tunnel.                                                       |
| <i>encryption-key-length</i>          | Resets the encryption key length for the specific IPsec tunnel to its default value, that is 128 bit.                                 |
| <i>fe-tunnel-dest-ip</i>              | Deletes the destination IP address that you configure on the Fabric Extend (FE) tunnel.                                               |
| <i>fragment-before-encrypt enable</i> | Disables the fragmentation of packets before IPsec encryption on the tunnel. By default, fragmentation before encryption is disabled. |
| <i>ipsec-dest-ip</i>                  | Deletes the destination IP address that you configure on the IPsec tunnel.                                                            |
| <i>mtu</i>                            | Resets the Maximum Transmission Unit (MTU) value for the specific IPsec tunnel to the MTU value configured globally.                  |
| <i>responder-only</i>                 | Deletes the mode that you configure for the IPsec session in FE tunnel.                                                               |
| <i>tunnel-name</i>                    | Deletes the name that you configure for the IPsec tunnel.                                                                             |
| <i>egress-shaping-rate</i>            | Deletes the egress shaping rate for the IPsec tunnel.                                                                                 |

## Delete Logical Interface Tunnel Configuration on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to delete configuration of a specific logical interface tunnel on Fabric IPsec Gateway Virtual Machine (VM).

## Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

### Note

Type **CTRL+Y** to exit the console.

2. Delete configuration of specific logical interface tunnel:

```
delete logical-intf-tunnel <1-255> < fe-tunnel-dest-ip | mtu | egress-  
shaping-rate>
```

## Example

Deleting the destination IP address for Fabric Extend (FE) tunnel configured on the logical interface tunnel with ID 3.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> delete logical-intf-tunnel 3 fe-tunnel-dest-ip
```

### Variable Definitions

The following table defines parameters for the **delete logical-intf-tunnel** command.

| Variable                   | Value                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <i>&lt;1-255&gt;</i>       | Specifies the unique ID of the logical interface tunnel.                                                                         |
| <i>fe-tunnel-dest-ip</i>   | Deletes the destination IP address that you configure on the logical interface tunnel.                                           |
| <i>mtu</i>                 | Resets the Maximum Transmission Unit (MTU) value for the specific logical interface tunnel to the MTU value configured globally. |
| <i>egress-shaping-rate</i> | Deletes the egress shaping rate on the logical interface tunnel.                                                                 |

## Display Data in a File on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the data in a specific file on Fabric IPsec Gateway Virtual Machine (VM).

## Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

### Note

Type **CTRL+Y** to exit the console.

2. Display data in a file:  
more WORD <1-255>

## Example

Display the data from coupled.cfg file:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> more coupled.cfg
set global ipsec-tunnel-src-vlan 125
set global ipsec-tunnel-src-ip 192.0.2.10/24
set global lan-intf-vlan 30
set global lan-intf-ip 192.0.2.20/24
set global lan-intf-gw-ip 192.0.2.25
set global fe-tunnel-src-ip 192.0.2.45
set global wan-intf-gw-ip 192.0.2.11
set global mtu 1950
set ipsec 1 auth-key *****
set ipsec 1 fe-tunnel-dest-ip 192.0.2.50
set ipsec 1 encryption-key-length 128
set ipsec 1 admin-state enable
```

## Reboot Fabric IPsec Gateway VM

### About This Task

Perform this procedure to reboot the Fabric IPsec Gateway Virtual Machine (VM).

## Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

### Note

Type **CTRL+Y** to exit the console.

2. Reboot the VM:  
reboot

### Example

Rebooting Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> reboot
```

## Reset Current Configuration on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to reset the current configuration on Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Reset current configuration:

```
reset-config
```

#### Note

Reboot the Fabric IPsec Gateway VM after you reset the configuration.

### Example

Resetting current configuration on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> reset-config
```

## Traceroute to an IP address on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to traceroute to an IP address on Fabric IPsec Gateway Virtual Machine (VM).

**Procedure**

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

**Note**  
Type **CTRL+Y** to exit the console.

2. Traceroute to an IP address:  
traceroute {A.B.C.D}

**Example**

Traceroute to IP address.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> traceroute 192.0.2.100
```

*Variable Definitions*

The following table defines parameters for the **traceroute** command.

| Variable  | Value                                               |
|-----------|-----------------------------------------------------|
| {A.B.C.D} | Specifies the IP address to initiate traceroute to. |

Display the Default Configuration File on Fabric IPsec Gateway VM

**About This Task**

Perform this procedure to display the default configuration file on the Fabric IPsec Gateway Virtual Machine (VM).

**Procedure**

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

**Note**  
Type **CTRL+Y** to exit the console.

2. Display default configuration file:  
show default-config-file

**Example**

Displaying default configuration file on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show default-config-file
coupled.cfg
```

## Display IPsec Logs on Fabric IPsec Gateway

**About This Task**

Perform this procedure to display IPsec session logs on the Fabric IPsec Gateway Virtual Machine (VM).

**Procedure**

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**

Type **CTRL+Y** to exit the console.

2. Display IPsec session logs:

```
show ipsec-logs
```

**Example**

Displaying IPsec session logs on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show ipsec-logs
<<Month dd>> <<hh:mm:ss>> 15[IKE] <ipsec0-192.0.2.10|29> sending DPD request

--More-- (q = quit)
```

## Display IPsec Routes on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the IPsec routes configured on the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Display IPsec routes installed:

```
show ipsec-routes
```

### Example

Displaying the IPsec routes configured on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show ipsec-routes
192.0.2.30 via 192.0.2.20 dev eth0.125 mtu lock 1950
192.0.2.1/24 dev eth0.30 proto kernel scope link src 192.0.2.2
192.0.2.10 via 192.0.2.45 dev eth0.30
192.0.2.100/24 dev eth0.125 proto kernel scope link src 192.0.2.60
192.0.2.11/16 dev docker0 proto kernel scope link src 192.0.2.12 linkdown
```

## Display IPsec Encryption Statistics on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the IPsec encryption statistics on the Fabric IPsec Gateway Virtual Machine (VM).

## Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  

```
enable
```

```
virtual-service WORD<1-128> console
```

### Note

Type **CTRL+Y** to exit the console.

2. Display IPsec encryption statistics:  

```
show ipsec-stats
```

## Example

Displaying IPsec encryption statistics on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show ipsec-stats

## Display the Status of IPsec Tunnels on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the status of configured IPsec tunnel on the Fabric IPsec Gateway Virtual Machine (VM):

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Display the status of IPsec tunnels configured on the VM:

```
show ipsec-status
```

### Example

Displaying the status of configured IPsec tunnel on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show ipsec-status

## Displays the IPsec Configuration on the Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the IPsec configuration on the Fabric IPsec Gateway Virtual Machine (VM):

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

#### Note

Type **CTRL+Y** to exit the console.

2. Display the IPsec configuration on the configured on the VM:  
show ipsec-config <1-255>

### Example

Displaying the IPsec configuration on the configured on the VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

FIGW> show ipsec-config 2
ipsec {
    tunnel_id 2;
    encryption-key-length 128;
    fe-tunnel-dest-ip 10.10.10.10;
    ipsec-dest-ip 70.70.70.73;
    mtu 1950;
    responder-only false;
    tunnel-name ----;
    auth-method psk;
    cert-subject;
    auth-key *****;
    egress-shaping-rate 110;
    fragment-before-encrypt enable;
    admin-state enable
}
```

## Display the Logical Interface IPsec Configurations on the Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the logical interface IPsec configurations on the Fabric IPsec Gateway Virtual Machine (VM):

## Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

### Note

Type **CTRL+Y** to exit the console.

2. Display the logical interface IPsec configurations on the VM:  
show logical-intf-config <1-255>

## Example

Displaying the logical interface IPsec configurations on the on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW>
FIGW> show logical-intf-config 1
logical-intf-tunnel {
    tunnel_id 1;
    tunnel-name ----;
    fe-tunnel-dest-ip 20.20.20.20;
    mtu 1950;
    egress-shaping-rate 110;
```

## Display Current Configuration on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the parameters configured currently on the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

### Note

Type **CTRL+Y** to exit the console.

2. Display the parameters currently configured on the VM:  
show running-config

**Example**

Displaying the parameters configured on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show running-config
set global ipsec-tunnel-src-vlan 125
set global ipsec-tunnel-src-ip 192.0.2.1/24
set global lan-intf-vlan 30
set global lan-intf-ip 192.0.2.10/24
set global lan-intf-gw-ip 192.0.2.25
set global fe-tunnel-src-ip 192.0.2.55
set global wan-intf-gw-ip 192.0.2.11
set global mtu 1950
set ipsec 1 auth-key *****
set ipsec 1 fe-tunnel-dest-ip 192.0.2.70
set ipsec 1 encryption-key-length 128
set ipsec 1 admin-state enable
```

## Display Current Version of Fabric IPsec Gateway VM

**About This Task**

Display current version of the Fabric IPsec Gateway Virtual Machine (VM).

**Procedure**

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**

Type **CTRL+Y** to exit the console.

2. Display current version of the VM:

```
show version
```

**Example**

Displaying current version of the Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW>show version
FabricIPSecGW_VM_4.0.0.0
```

## Log Out of Fabric IPsec Gateway VM

### About This Task

Perform this procedure to log out of the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type **CTRL+Y** to exit the console.

2. Log out of VM:

```
exit
```

### Example

Logging out of the Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> exit
```

# Fabric Configuration Work Flow

---

The following section describes the generic work flow to configure SPBM and IS-IS infrastructure and services on your network.

## Note

This section is an overview. For further details on the SPBM and IS-IS infrastructure and configuration, see the sections described in the Documentation Sources section that follows.

### 1. Infrastructure configuration

As a first step, you must configure your basic infrastructure for Shortest Path Bridging MAC (SPBM).

### 2. Services configuration

After you complete the infrastructure configuration, you configure the appropriate services for your network to run on top of your base architecture. This includes:

- Layer 2 and Layer 3 VSNs
- IP Shortcuts
- Inter-VSN routing

### 3. Fabric interoperations

You can also configure Fabric gateway functionality like SPB-PIM Gateway and VXLAN Gateway.

### 4. Operations and Management

To debug connectivity issues and isolate network faults in the SPBM network, you can use Connectivity Fault Management (CFM).

## Documentation Sources

---

See the following documentation sources:

- For information on basic SPBM infrastructure and IS-IS configuration and Layer 2 services, see [Fabric Basics and Layer 2 Services](#) on page 912.

This section also contains information on configuring Fabric Extend, which enables your enterprise to extend Fabric Connect technology over Layer 2 or Layer 3 core networks.

- For information on Fabric Layer 3 services configuration, see [Fabric Layer 3 Services](#) on page 1338.
- For information on IP Multicast over Fabric Connect configuration and services, see [IP Multicast over Fabric Connect](#) on page 1652. [SPB-PIM Gateway configuration](#) on page 3172 also contains information about configuring the SPB-PIM Gateway (SPB-PIM GW), which provides multicast inter-domain communication between an SPB network and a PIM network. The SPB-PIM GW can also connect two independent SPB domains.

- For information on CFM, see [Connectivity Fault Management](#) on page 3481.
- For information on VXLAN Gateway configuration, see [VXLAN Gateway](#) on page 3895.

## SPBM and IS-IS Infrastructure Configuration

---

### SPBM and IS-IS Infrastructure Fundamentals

Shortest Path Bridging MAC (SPBM) is a next generation virtualization technology that revolutionizes the design, deployment, and operations of carriers and service providers, along with enterprise campus core networks and the enterprise data center. SPBM provides massive scalability while at the same time reducing the complexity of the network.

SPBM eliminates the need for multiple overlay protocols in the core of the network by reducing the core to a single Ethernet based link-state protocol that provides all virtualization services in an integrated model. In addition, by relying on endpoint service provisioning only, the idea of building your network once and not touching it again becomes a true reality. This technology provides all the features and benefits required by carrier-grade, enterprise and service provider deployments without the complexity of alternative technologies, for example, Multiprotocol Label Switching (MPLS).

SPBM simplifies deployments by eliminating the need to configure multiple points throughout the network. When you add new connectivity services to an SPBM network you do not need intrusive core provisioning. The simple endpoint provisioning is done where the application meets the network, with all points in between automatically provisioned through the robust link-state protocol, Intermediate-System-to-Intermediate-System (IS-IS).

Most Ethernet based networks use 802.1Q tagged interfaces between the routing switches. SPBM uses two Backbone VLANs (B-VLANs) that are used as the transport instance. A B-VLAN is not a traditional VLAN in the sense that it does not flood unknown, broadcast or multicast traffic, but only forwards based on IS-IS provisioned backbone MAC (B-MAC) tables. After you configure the B-VLANs and the IS-IS protocol is operational, you can map the services to service instances.

SPBM uses IS-IS to discover and advertise the network topology, which enables it to compute the shortest path to all nodes in the SPBM network. SPBM uses IS-IS shortest path trees to populate forwarding tables for the individual B-MAC addresses of each participating node.

To forward customer traffic across the core network backbone, SPBM uses IEEE 802.1ah Provider Backbone Bridging (PBB) MAC-in-MAC encapsulation, which hides the customer MAC (C-MAC) addresses in a backbone MAC (B-MAC) address pair. MAC-in-MAC encapsulation defines a B-MAC destination address (BMAC-DA) and a B-MAC source address (BMAC-SA). Encapsulating customer MAC addresses in B-MAC addresses improves network scalability (no end-user C-MAC learning is required in the core) and also significantly improves network robustness (loops have no effect on the backbone infrastructure.)

The SPBM B-MAC header includes a Service Instance Identifier (I-SID) with a length of 32 bits with a 24-bit ID. I-SIDs identify and transmit virtualized traffic in an encapsulated SPBM frame. You can use I-SIDs in a Virtual Services Network (VSN) for VLANs or VRFs across the MAC-in-MAC backbone:

- **Unicast**

- For a Layer 2 VSN, the device associates the I-SID with a customer VLAN, which the device then virtualizes across the backbone. Layer 2 VSNs associate one VLAN per I-SID.
- With Layer 3 VSN, the device associates the I-SID with a customer VRF, which the device virtualizes across the backbone. Layer 3 VSNs associate one VRF per I-SID.
- With Inter-VSN routing, Layer 3 devices, routers, or hosts connect to the SPBM cloud using the SPBM Layer 2 VSN service. The Backbone Core Bridge can transmit traffic between different VLANs with different I-SIDs.
- With IP shortcuts, no I-SID is required, forwarding for the Global Routing Table (GRT) is done using IS-IS based shortest path BMAC reachability.

For more information on Fabric Layer 3 services, see [Fabric Layer 3 Services](#) on page 1338.

- **Multicast**

- With Layer 2 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and the scope I-SID is based on the Layer 2 VSN I-SID.
- With Layer 3 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and the scope I-SID is based on the Layer 3 VSN I-SID.
- With IP Shortcuts with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream, but there is no I-SID for the scope, which is the Global Routing Table (GRT).

For more information on IP multicast over Fabric Connect, see [IP Multicast over Fabric Connect](#) on page 1652.

**Note**

Inter-VSN routing for IP multicast over Fabric Connect is not supported.

The switch supports the IEEE 802.1aq standard of SPBM, which allows for larger Layer 2 topologies and permits faster convergence.

### *Multiple tenants using different SPBM services*

The following figure shows multiple tenants using different services within an SPBM metro network. In this network, you can use some or all of the SPBM implementation options to meet the needs of the community while maintaining the security of information within VLAN members.

**Figure 55: Multi-tenant SPBM metro network**

To illustrate the versatility and robustness of SPBM even further, the following figure shows a logical view of multiple tenants in a ring topology. In this architecture, each tenant has its own domain where some users have VLAN requirements and are using Layer 2 VSNs and others have VRF requirements and are using Layer 3 VSNs. In all three domains, they can share data center resources across the SPBM network.

**Figure 56: SPBM ring topology with shared data centers**

*spbm-config-mode boot flag*

Shortest Path Bridging (SPB) and Protocol Independent Multicast (PIM) cannot interoperate with each other on the switch at the same time. The boot flag called **spbm-config-mode** ensures that SPB and PIM stay mutually exclusive.

- The **spbm-config-mode** boot flag is enabled by default. This enables you to configure SPB and IS-IS, but you cannot configure PIM either globally or on an interface.
- If you disable the boot flag, save the configuration and reboot with the saved configuration. After you enable the flag, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

**Important**

- Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.
- If you disable the boot flag, save the configuration and reboot with the saved configuration. After you disable the flag, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

For more information, see [IP Multicast](#) on page 1431.

*vxlan-gw-full-interworking-mode Boot Configuration Flag*

The VXLAN Gateway implementation is available in the following modes:

- **Base Interworking Mode** – This is the default mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments.
- **Full Interworking Mode** – This mode supports the Base mode communication between VXLAN and traditional VLAN environments as well as VXLAN-to-VXLAN communication and all SPB functionality including vIST and SMLT. To enter this mode, you must enable the **vxlan-gw-full-interworking-mode** boot configuration flag.

**Note**

Changing the mode requires a reboot for the change to take effect.

*MAC-in-MAC encapsulation*

To forward customer traffic across the core network backbone, SPBM uses IEEE 802.1ah Provider Backbone Bridging (PBB) MAC-in-MAC encapsulation, which hides the customer MAC (C-MAC) addresses in a backbone MAC (B-MAC) address pair. MAC-in-MAC encapsulation defines a B-MAC source address (BMAC-SA) and a B-MAC destination address (BMAC-DA) to identify the backbone source and destination addresses.

The originating node creates a MAC header that is used for delivery from end to end. As the MAC header stays the same across the network, there is no need to swap a label or do a route lookup at each node, allowing the frame to follow the most efficient forwarding path end to end.

Encapsulating customer MAC addresses in B-MAC addresses improves network scalability (no end-user C-MAC learning is required in the core) and also significantly improves network robustness (loops in access networks do not impact forwarding results in the backbone infrastructure.)

## I-SID

SPBM introduces a service instance identifier called I-SID. SPBM uses I-SIDs to separate services from the infrastructure. After you create an SPBM infrastructure, you can add additional services (such as VLAN extensions or VRF extensions) by provisioning the endpoints only. The SPBM endpoints are Backbone Edge Bridges (BEBs), which mark the boundary between the core MAC-in-MAC SPBM domain and the edge customer 802.1Q domain. I-SIDs are provisioned on the BEBs to be associated with a particular service instance. In the SPBM core, the bridges are Backbone Core Bridges (BCBs). BCBs forward encapsulated traffic based on the B-MAC-DA.

The SPBM B-MAC header includes a Service Instance Identifier (I-SID) with a length of 32 bits with a 24-bit ID. I-SIDs identify a service instance for virtualized traffic in an encapsulated SPBM frame. You can use I-SIDs in a Virtual Services Network (VSN) for VLANs or VRFs across the MAC-in-MAC backbone:

- For a Layer 2 VSN, the I-SID is associated with a customer VLAN, which is then virtualized across the backbone. Layer 2 VSNs offer an any-any LAN service type. Layer 2 VSNs associate one VLAN per I-SID.
- For a Layer 2 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and a scope I-SID that defines the scope as Layer 2 VSN. A multicast stream with a scope of Layer 2 VSN can only transmit a multicast stream for the same Layer 2 VSN.
- For a *Transparent Port UNI*, the I-SID is associated with a port or MLT, which is then virtualized across the backbone. *Transparent Port UNI* associates multiple ports or MLT to an I-SID.
- For a Layer 3 VSN, the I-SID is associated with a customer VRF, which is also virtualized across the backbone. Layer 3 VSNs are always full-mesh topologies. Layer 3 VSNs associate one VRF per I-SID.
- For a Layer 3 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and a scope I-SID that defines the scope as Layer 3 VSN. A multicast stream with a scope of Layer 3 VSN can only transmit a multicast stream for the same Layer 3 VSN.
- For IP Shortcuts with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and defines the scope as Layer 3 GRT. A multicast stream with a scope of Layer 3 GRT can only transmit a multicast stream for a Layer 3 GRT.

### Note

I-SID configuration is required only for virtual services such as Layer 2 VSN and Layer 3 VSN. With IP Shortcuts with unicast, no I-SID is required, forwarding for the Global Routing table is done using IS-IS based shortest path B-MAC reachability.

### Note

I-SID to VLAN binding is used to automatically determine the path between client and server in order to attach network devices to FA Zero touch services.

*BCBs and BEBs***Table 87: Fabric Mode product support**

| Feature         | Product         | Release introduced |
|-----------------|-----------------|--------------------|
| Fabric BCB mode | 5420 Series     | VOSS 8.4           |
|                 | 5520 Series     | VOSS 8.2.5         |
|                 | VSP 4450 Series | VSP 4000 4.0       |
|                 | VSP 4900 Series | VOSS 8.1           |

|                 | XA1400 Series   | VOSS 8.0.50        |

The boundary between the core MAC-in-MAC SPBM domain and the edge customer 802.1Q domain is handled by Backbone Edge Bridges (BEBs). I-SIDs are provisioned on the BEBs to be associated with a particular service instance.

In the SPBM core, the bridges are referred to as Backbone Core Bridges (BCBs). BCBs forward encapsulated traffic based on the BMAC-DA.

**Important**

SPBM separates the payload from the transport over the SPBM infrastructure. Configure all virtualization services on the BEBs at the edge of the network. There is no provisioning required on the core SPBM switches. This provides a robust carrier grade architecture where configuration on the core switches never needs to be touched when adding new services.

A BEB performs the same functionality as a BCB, but it also terminates one or more Virtual Service Networks (VSN). A BCB does not terminate any VSNs and is unaware of the VSN traffic it transports. A BCB simply knows how to reach any other BEB in the SPBM backbone.

### *VLANs without member ports*

If a VLAN is attached to an I-SID there must be another instance of that same I-SID in the SPBM network.

- If another instance of that I-SID exists, the device designates that VLAN as operationally up regardless of whether it has a member port or not.

When the VLAN is operationally up, the IP address of the VLAN will be in the routing table.

- If no matching instance of the I-SID exists in the SPBM network, then that VLAN has no reachable members and does not act as an NNI interface.

The VLAN does not act as a UNI interface because it does not have a member port.

Therefore, the device does not designate the VLAN as operationally up because the VLAN does not act as a UNI or an NNI interface.

If the device acts as a BCB with two VLANs configured and two I-SIDs, there must be a UNI side with the corresponding I-SID existing in the network.

If the device acts as both BEB and BCB, then there must be a member port in that VLAN to push out the UNI traffic.

### *Basic SPBM network topology*

The following figure shows a basic SPBM network topology, specifically a Layer 2 VSN. Switches A and D are the Backbone Edge Bridges (BEB) that provide the boundary between the customer VLANs (C-VLAN) and the Backbone. Switches B and C are the Backbone Core Bridges (BCB) that form the core of the SPBM network.

**Figure 57: SPBM L2 VSN**

SPBM uses IS-IS in the core so that all BEBs and BCBs learn the IS-IS System-ID (B-MAC) of every other switch in the network. For example, BEB-A uses IS-IS to build an SPBM unicast forwarding table containing the B-MAC of switches BCB-B, BCB-C, and BEB-D.

The BEBs provide the boundary between the SPBM domain and the virtualized services domain. For a Layer 2 VSN service, the BEBs map a C-VLAN to an I-SID based on local service provisioning. Any BEB in the network that has the same I-SID configured can participate in the same Layer 2 VSN.

In this example, BEB A and BEB D are provisioned to associate C-VLAN 20 with I-SID 100. When BEB A receives traffic from C-VLAN 20 that must be forwarded to the far-end location, it performs a lookup and determines that C-VLAN 20 is associated with I-SID 100 and that BEB D is the destination for I-SID 100. BEB A then encapsulates the data and C-MAC header into a new B-MAC header, using its own nodal B-MAC: A as the source address and B-MAC: D as the destination address. BEB A then forwards the encapsulated traffic to BCB B.

To forward traffic in the core toward the destination node D, BCB B and BCB C perform Ethernet switching using the B-MAC information only.

At BEB D, the node strips off the B-MAC encapsulation, and performs a lookup to determine the destination for traffic with I-SID 100. BEB D identifies the destination on the C-VLAN header as C-VLAN 20 and forwards the packet to the appropriate destination VLAN and port.

*E-Tree and Private VLAN topology***Table 88: E-Tree and Private VLANs product support**

| Feature                  | Product         | Release introduced |
|--------------------------|-----------------|--------------------|
| E-Tree and Private VLANs | 5420 Series     | VOSS 8.4           |
|                          | 5520 Series     | VOSS 8.2.5         |

|                          | XA1400 Series   | Not Supported      |

Ethernet Private Tree (E-Tree) extends Shortest Path Bridging MAC (SPBM) to Private VLANs (PVLAN).

Transport within the SPBM network is achieved by associating the private VLAN with an I-SID. Flooded traffic from both promiscuous and isolated devices is transported over the same I-SID multicast tree and suppression for spoke-to-spoke traffic is done on the egress SPB Backbone Edge Bridge (BEB). This means the Private VLAN IDs are globally significant and must be the same on all BEBs

The following list provides details for E-Tree and Private VLAN topology:

- E-Tree associates a Private VLAN with an I-SID.

**Note**

The same I-SID could be attached to a regular VLAN. In that case, all ports on the regular VLAN behave like Promiscuous ports on the PVLAN.

- Other SPB BEBs can associate a regular CVLAN to the same I-SID that E-Tree uses.

**Note**

The CVLAN ID must match the primary PVLAN ID.

- CVLAN devices assigned to the same I-SID that E-Tree uses have Promiscuous connectivity within the segment.

The following figure shows a basic E-Tree network topology consisting of groups of private VLANs connected by the SPBM core network.

**Figure 58: Sample E-Tree configuration**

### Private VLAN port types

The private VLAN port type is isolated, promiscuous, or trunk. If the port is a member of an MLT, then the port inherits the private VLAN type of the MLT.

In terms of network topology, the isolated port is considered a spoke. The isolated port, or spoke, does not communicate with any other isolated port in the network. The isolated port only communicates with the promiscuous ports, or hubs.

### E-Tree and Private VLAN limitations

The following limitations apply to E-Tree and Private VLAN topology:

- A port that is of Private VLAN type trunk must be tagged. Isolated and Promiscuous Private VLAN ports can be either tagged or untagged.
- When a port or MLT that has a Private VLAN type set to Isolated or Promiscuous is added to a private VLAN, if that port is used by other non private VLANs, then those non private VLANs are removed.
- A port which is Private VLAN type Isolated and is tagged can belong to only one Private VLAN.

IS-IS

**Table 89: IS-IS product support**

| Feature                               | Product         | Release introduced |
|---------------------------------------|-----------------|--------------------|
| IS-IS authentication with SHA-256     | 5420 Series     | VOSS 8.4           |
|                                       | 5520 Series     | VOSS 8.2.5         |
|                                       | VSP 4450 Series | VOSS 7.0           |
|                                       | VSP 4900 Series | VOSS 8.1           |
|                                       | VSP 7200 Series | VOSS 7.0           |

SPBM eliminates the need for multiple overlay protocols in the core of the network by reducing the core to a single Ethernet-based, link-state protocol (IS-IS). IS-IS provides virtualization services using a pure

Ethernet technology base. SPBM also uses IS-IS to discover and advertise the network topology, which enables it to compute the shortest path to all nodes in the SPBM network.

IS-IS is a link-state, interior gateway protocol that was developed for the International Organization for Standardization (ISO). ISO terminology refers to routers as Intermediate Systems (IS), hence the name Intermediate System-to-Intermediate System (IS-IS).

To provide a loop-free network and to learn and distribute network information, SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol. IS-IS is designed to find the shortest path from any one destination to any other in a dynamic fashion. IS-IS creates any-to-any connectivity in a network in an optimized, loop-free manner, without the long convergence delay experienced with the Spanning Tree Protocol. IS-IS does not block ports from use, but rather employs a specific path. As such, all links are available for use.

IS-IS dynamically learns the topology of a network and constructs unicast and multicast mesh connectivity. IS-IS parallel adjacency support allows you to configure multiple IS-IS links between the two nodes. Each node in the network calculates a shortest-path tree to every other network node based on System-IDs (B-MAC addresses). Only one adjacency with the shortest path is selected as an active adjacency.

**Note**

Only an active interface with an active adjacency is added into local SPF calculations. This mechanism ensures the local node selects the shortest path and has the same view as the rest of the SPB network.

In the SPBM environment for Layer 2 VSNs, IS-IS carries only pure Layer 2 information with no requirement for an underlying IP control plane or forwarding path. IS-IS runs directly over Layer 2.

**Note**

SPBM carries Layer 3 information for Layer 3 VSNs.

In SPBM networks, IS-IS performs the following functions:

- Discovers the network topology
- Builds shortest path trees between the network nodes:
  - Forwards unicast traffic
  - Determines the forwarding table for multicast traffic
- Communicates network information in the control plane:
  - Service Instance Identifier (I-SID) information

SPBM can distribute I-SID service information to all SPBM nodes, as the I-SIDs are created. SPBM includes I-SID information in the IS-IS Link State protocol data units (PDUs). When a new service instance is provisioned on a node, its membership is flooded throughout the topology using an IS-IS advertisement.

### *Standard TLVs*

IS-IS uses Type-Length-Value (TLV) encoding. SPBM employs IS-IS as the interior gateway protocol and implements additional TLVs to support additional functionality. The switch also supports Sub-TLVs. TLVs exist inside IS-IS packets and Sub-TLVs exist as additional information in TLVs.

The switch supports and is in full compliance with standard 802.1aq TLVs. The IEEE ratified the 802.1aq standard that defines SPBM and the Type-Length-Value (TLV) encoding that IS-IS uses to support SPBM services. The following table lists all the TLVs that the switch supports.

**Table 90: Standard TLVs**

| TLV | Description                                                                                                                                                          | Usage                                                                                                |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| 1   | Area addresses — The Area Addresses TLV contains the area addresses to which the IS-IS is connected.                                                                 | IS-IS area                                                                                           |
| 22  | Extended IS reachability — The Extended IS Reachability TLV contains information about adjacent neighbors.                                                           | IS-IS adjacencies<br>Sub-TLV 29: SPBM link metric is carried within this TLV.                        |
| 129 | Protocols supported — The Protocol supported TLV carries the Network Layer Protocol Identifiers (NLPID) for the Network Layer protocols where the IS-IS can be used. | SPBM in addition to existing NLPID (IPV4 0xCC, IPV6 0x*E.), IEEE 802.1aq defined SPBM NLPID as 0xC1. |
| 135 | Extended IP reachability — The Extended IP Reachability TLV 135 is used to distribution IP reachability between IS-IS peers.                                         | SPBM uses this existing IS-IS TLV to carry IP Shortcut routes in the Global Routing Table (GRT).     |

**Table 90: Standard TLVs (continued)**

| TLV | Description                                                                                                                                                                                                                                                                                                                                                                              | Usage                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 143 | <p>Multi-topology port aware capability (MT-Port-Capability) TLV</p> <p>This TLV carries the SPB instance ID in a multiple SPB instances environment. This TLV is carried within IS-IS Hello Packets (IIH), only when parallel links exist.</p>                                                                                                                                          | <p>This TLV carries the following SPBM Sub TLV:</p> <ul style="list-style-type: none"> <li>• Sub-TLV 6: SPB B-VID Sub TLV indicates the mapping between a VLAN and its equal cost tree (ECT) algorithm. To form an adjacency, both nodes must have a matching primary (B-VLAN, ECT) pair, and secondary (B-VLAN, ECT) pair, the number of B-VLANs must be equal, B-VLAN values must match, ECT values for the B-VLANs must match. Used in IS-IS Hellos only.</li> <li>• MCID Sub TLV: The MCID is a digest of the VLANs and MSTI. Neighboring SPBM nodes must agree on the MCID to form an adjacency. The MCID is set to all zeros (0).</li> </ul> <p>After the switch receives a non-zero MCID Sub TLV, it reflects content back to the neighbor.</p> <ul style="list-style-type: none"> <li>• Link L1 Metric Sub-TLV 7: Contains L1 metric of the link</li> </ul> |
| 144 | <p>Multi-topology Capability (MT-Capability) TLV.</p> <p>This TLV carries the SPB instance ID in a multiple SPB instance environment. This TLV is carried within LSPs.</p> <p>In multicast over Fabric Connect, TLV 144 on the BEB bridge, where the sender is located, has the transmit (Tx) bit set. On the BEB bridge, where the receiver is located the receive (Rx) bit is set.</p> | <p>TLV 144 is the service identifier TLV. TLV 144 advertizes B-MAC and I-SID information.</p> <p>This TLV carries the following Sub TLVs:</p> <p>Sub-TLV 1: SPB instance Sub TLV contains a unique SPSourceID (nickname) to identify the SPBM node within this SPB topology.</p> <p>Sub-TLV 3: SPB Service ID (I-SID) is stored in TLV 144 sub-TLV 3. Sub-TLV 3 carries service group membership (I-SIDs) for a particular SPBM B-VLAN.</p>                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 184 | <p>SPBM IP VPN reachability — IS-IS TLV 184 is used to advertise SPBM L3 VSN route information across the SPBM cloud.</p>                                                                                                                                                                                                                                                                | <p>IP reachability for Layer 3 VSNs</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 90: Standard TLVs (continued)**

| TLV | Description                                                                                                                                                                                                                                                    | Usage                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 185 | IPVPN multicast TLV with IPMC sub TLV — The IPVPN multicast TLV contains information about the scope I-SID.                                                                                                                                                    | TLV 185 on the BEB bridge, where the source is located, displays the multicast source and group addresses and has the transmit (Tx) bit set. Each multicast group has its own data I-SID that maps to the source and group addresses. As part of the IPVPN TLV, sub-TLVs define IPv4 unicast, IPv6 unicast and IPv4 multicast information. Layer 2 VSN IP multicast over Fabric Connect and Layer 3 VSN IP multicast over Fabric Connect (using VRF) use TLV 185. |
| 186 | IP multicast TLV (GRT) — TLV 186 on the BEB bridge, where the source is located, displays the multicast source and group addresses and has the transmit (Tx) bit set. Each multicast group has its own data I-SID that maps to the source and group addresses. | IP Shortcuts with IP multicast over Fabric Connect use TLV 186. All multicast streams are constrained within the level in which they originate, which is called the scope level.                                                                                                                                                                                                                                                                                  |
| 236 | IPv6 Reachability — The IPv6 reachability TLV 236 is used to distribute IPv6 network reachability between IS-IS peers.                                                                                                                                         | SPBM uses the existing IS-IS TLV to carry IPv6 shortcut routes through the SPBM core.                                                                                                                                                                                                                                                                                                                                                                             |

For more information on IP multicast over Fabric Connect, see [IP Multicast over Fabric Connect](#) on page 1652.

### IS-IS hierarchies

IS-IS is a dynamic routing protocol that operates within an autonomous system (or domain). IS-IS provides support for hierarchical routing, which enables you to partition large routing domains into smaller areas. When used separately from SPBM, IS-IS uses a two-level hierarchy, dividing the domain into multiple Level 1 areas and one Level 2 area. When used separately from SPBM, the Level 2 area serves as backbone of the domain, connecting to all the Level 1 areas. SPBM currently uses only Level 1 areas.

#### Important

The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled.

### IS-IS PDUs

Intermediate System to Intermediate System Hello (IIH) packets discover IS-IS neighbors and establish and maintain IS-IS adjacencies. An IIH is sent in every Hello-interval to maintain the established

adjacency. If a node has not heard IIHs from its neighbor for (hello-interval x hello-multiple) seconds, the node tears down the adjacency. IIH carries TLV 143 and SPB B-VLAN Sub-TLV (among other sub-TLVs). For two nodes to form an adjacency the B-VLAN pairs for primary B-VLAN and secondary B-VLAN must match.

Link State Packets (LSP) advertise link state information. The system uses the link state information to compute the shortest path. LSP also advertises MT-capability TLV 144 and SPB instance Sub-TLV, and SPB I-SIDs Sub-TLV.

Complete Sequence Number Packets (CSNP) contain the most recent sequence numbers of all LSPs in the database. CSNP notifies neighbors about the local LSDB. After a neighbor receives a CSNP, it compares the LSPs in the CSNP with the LSP in the local LSDB. If the neighbor is missing LSPs, it sends a Partial Sequence Number Packets (PSNP) to request the missing LSPs. This process synchronizes the LSDBs among neighbors. A synchronized LSDB among all nodes in the network is crucial to producing a loop-free shortest path.

### *IS-IS configuration parameters*

#### **IS-IS system identifiers**

The IS-IS system identifiers consist of three parts:

- System ID — The system ID is any 6 bytes that are unique in a given area or level. The system ID defaults to the baseMacAddress of the chassis but you can configure a non-default value. The system ID must use a unicast MAC address; do not use a multicast MAC address. A MAC address that has the low order bit 1 set in the highest byte is a multicast MAC address. For example, the following are multicast MAC addresses: x1xx.xxxx.xxxx, x3xx.xxxx.xxxx, x5xx.xxxx.xxxx, x7xx.xxxx.xxxx, x9xx.xxxx.xxxx, xBxx.xxxx.xxxx, xDxx.xxxx.xxxx, and xFxx.xxxx.xxxx.
- Manual area — The manual area or area ID is up to 13 bytes long. The first byte of the area number (for example, 49) is the Authority and Format Indicator (AFI). The next bytes are the assigned domain (area) identifier, which is up to 12 bytes (for example, 49.0102.0304.0506.0708.0910.1112). IS-IS supports a maximum of three manual areas, but the switch software only supports one manual area.
- NSEL — The last byte (00) is the n-selector. In this implementation, this part is automatically attached. There is no user input accepted.

The Network Entity Title (NET) is the combination of all three global parameters.

All routers have at least one manual area. Typically, a Level 1 router does not participate in more than one area.

The following are the requirements for system IDs:

- All IS-IS enabled routers must have one manual area and a unique system ID.
- All routers in the same area must have the same area ID.
- All routers must have system IDs of the same length (6 bytes).
- All IS-IS enabled routers must have a unique nickname.

#### **PSNP interval**

You can change the PSNP interval rate. A longer interval reduces overhead, while a shorter interval speeds up convergence.

### CSNP periodic and interval rate

You can configure the CSNP periodic and interval rate. A longer interval reduces overhead, while a shorter interval speeds up convergence.

### Parameters for the link state packet

Link state packets (LSPs) contain vital information about the state of adjacencies, which must be exchanged with neighboring IS-IS systems. Routers periodically flood LSPs throughout an area to maintain synchronization. You can configure the LSP to reduce overhead or speed up convergence.

The following list describes IS-IS parameters related to LSPs:

- The **max-lsp-gen-interval** is the time interval at which the generated LSP is refreshed. The default is 900 seconds with a range of 30 to 900.
- The **retransmit-lsp-interval** is the minimum amount of time between retransmission of an LSP. When transmitting or flooding an LSP an acknowledgement (ACK) is expected. If the ack is not received within **retransmit-lsp-interval**, the LSP is re-transmitted. The default is 5 seconds with a range of 1 to 300.

### Point-to-point mode

All SPBM links are point-to-point links. The switch does not support broadcast links.

### IS-IS interface authentication

Configure IS-IS interface authentication to improve security and to guarantee that only trusted routers are included in the IS-IS network. Interface level authentication only checks the IIH PDUs. If the authentication type or key in a received IIH does not match the locally-configured type and key, the IIH is rejected. By default, authentication is disabled.

You can use either one of the following authentication methods:

- Simple password authentication — Uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet.
- MD5 authentication — Creates a Message Digest (MD5) key.
- SHA-256 — Adds a Hash-based Message Authentication Code (HMAC) digest to each IS-IS Hello packet.

#### Important

If the `.isis_md5key.txt` and `.isis_simplekey.txt` are missing, IS-IS adjacencies cannot be established.

### Password considerations

To reset the authentication password type, you must set the type to none.

The switch software supports only interface level authentication. The switch software does not support area level or domain level authentication.

### SHA-256 considerations

IS-IS Hello packets are sent periodically to discover IS-IS neighbors, and to establish and maintain IS-IS adjacencies. If you enable SHA-256 authentication, the switch adds an HMAC-SHA256 digest to each Hello packet.

#### Note

The interfaces used to make the adjacencies must have SPBM configured.

The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet.

Directly connected switches must share the same key (secret), which can have a maximum length of 16 characters.

### Hellos

To update the identities of neighboring routers, you can configure the:

- IS-IS Interface Level 1 Hello interval
- IS-IS Interface Level 1 Hello multiplier

#### IS-IS Interface Level 1 Hello interval

IS-IS uses level 1 Hello packets to initialize and maintain adjacencies between neighboring routers.

You can configure the IS-IS interface level 1 Hello interval to change how often Hello packets are sent out from an interface level.

#### IS-IS Interface Level 1 Hello multiplier

You can configure the IS-IS interface level 1 Hello multiplier to specify how many Hellos the switch must miss before it considers the adjacency with a neighboring switch down. By default, the hold (wait) time is the Hello interval multiplied by the Hello multiplier. By default, if the Hello interval is 9 and the Hello multiplier is 3, the hold time is 27. If the Hello multiplier is increased to 10, the hold time is increased to 90.

#### IS-IS Interface Level 1 Link metric

You can configure the IS-IS interface level 1 link metric to overwrite the default metric value. By configuring the metric, you can specify a preferred path. Low cost reflects high-speed media, and high cost reflects slower media. For the wide metric, the value ranges from 1 to 16,777,215.

- The switch only supports the wide metric.
- The total cost of a path equals the sum of the cost of each link.

- The default value for wide metrics is 10.

**Note**

When multiple paths exist to reach a node, the path with the lowest sum of metrics of the individual links is chosen. If the sum of the paths are the same, the one with the lowest number of hops is chosen. If the number of hops is the same as well, then the tie-breaking is done by the system ID.

For the primary B-VLAN, the path that has a node with the lowest system ID is chosen.

Whereas, for the secondary B-VLAN, the path that has a node with the highest system ID is chosen.

**Disabling IS-IS**

You can disable IS-IS globally or at the interface level. If IS-IS is globally disabled, then all IS-IS functions stop. If IS-IS is enabled at the global level and disabled at one of the interface levels, then IS-IS continues on all other interfaces.

**Overload Bit**

A node sends the overload bit in LSP updates to inform other devices whether to use that node to pass transit traffic. For example, when a device receives an LSP with an overload bit, the device ignores that LSP in its Shortest Path First (SPF) calculation to avoid sending transit traffic through the overloaded node; however, the overloaded node can still receive traffic destined to itself.

The system activates the overload bit on bootup and clears it after 20 seconds. You can use the **overload-on-startup** parameter to control the time before the overload bit is cleared after bootup.

You can permanently configure the overload bit using the **overload** parameter. If you use this parameter, the system does not clear the overload bit after bootup and sends it in all LSP updates. If the overload bit is configured, other devices do not include this node for use as a transit node in IS-IS computations. By default, the **overload** parameter is set to false.

The **overload** and **overload-on-startup** parameters are configured under the `router isis` configuration mode in the CLI.

When IS-IS is enabled on a switch, the switch delays a reset by two seconds so that LSPs with the overload bit can be sent to all Backbone Edge Bridges (BEB) and Backbone Core Bridges (BCB) in the SPB domain.

**SPBM B-VLAN**

Each SPBM network instance is associated with at least one backbone VLAN (B-VLAN) in the core SPBM network.

**Note**

SPB internally uses spanning tree group (STG) 63 or Multiple Spanning Tree Instance (MSTI) 62. STG 63 or MSTI 62 cannot be used by another VLAN or MSTI. For non-SPB customer networks, if you use STG 63 or MSTI 62 in the configuration, you must delete STG 63 or MSTI 62 before you can configure SPBM.

This VLAN is used for both control plane traffic and dataplane traffic.

**Note**

Always configure two B-VLANs in the core to allow load distribution over both B-VLANs.

SPBM alters the behavior of the VLAN. When a B-VLAN is associated with an SPBM network the following VLAN attributes and behaviors are modified for the B-VLAN:

- Flooding is disabled
- Broadcasting is disabled
- Source address learning is disabled
- Unknown MAC discard is disabled

You cannot add ports to a B-VLAN manually, IS-IS enabled ports are automatically added to the B-VLAN.

Essentially the B-MAC addresses are programmed into the B-VLAN Forwarding Information Bases (FIBs) by IS-IS instead of the traditional VLANs flooding and learning approach.

Modification of the VLAN behavior is necessary to ensure proper control over the SPBM traffic.

### *Pre-populated FIB*

An Ethernet network usually learns MAC addresses as frames are sent through the switch. This process is called reverse learning and is accomplished through broadcast.

SPBM does not allow any broadcast flooding of traffic on the B-VLAN in order to prevent looping accomplished through flooding packets with unknown destinations (although multicast traffic is supported). As such, MAC addresses must be distributed within SPBM. This is accomplished by carrying the necessary B-MAC addresses inside the IS-IS link state database. To that end, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. This functionality enables the powerful end-point-provisioning of SPBM.

These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB) to maximize efficiency and to allow Reverse Path Forwarding Check (RPFC) to operate properly.

### *RPFC*

A loop prevention mechanism is required at Layer 2 to stop wayward traffic from crippling the network. Reverse Path Forwarding Check (RPFC) is the chosen method of suppressing loop traffic with SPBM. RPFC was originally designed for IP traffic at Layer 3 where it checks the source address of the packet against the routing entry in the routing table. The source address must match the route for the port it came in on otherwise the packet is illegitimate and therefore dropped.

With SPBM, the node matches the source B-MAC address against the ingress port to establish validity. If the frame is not supposed to come in that port, it is immediately suppressed imposing a guaranteed loop control. If there is no VLAN FDB entry to the source MAC address with the outgoing port as the ingress port, the frame will be dropped.

## SPBM Unicast FIB

### Unicast FIB

The unicast computation runs a single Dijkstra (unlike all pair Dijkstras for multicast). SPBM produces only one Shortest Path First (SPF) tree and the tree is rooted on the computing node.

The unicast computation generates an entry for each node in the network. The Destination Address (DA) for that entry is the system-id of the node. In addition, if a node advertises MAC addresses other than the system-id, each MAC address has an entry in the unicast FIB table, and the shortest path to that MAC should be exactly the same as the path to the node.

Unicast FIB entries are installed to the vlan-fdb table.

The following text shows an example of the unicast FIB.

```
Switch:1# show isis spbm unicast-fib

## SPBM Restrictions

### RSTP and MSTP

The following list identifies restrictions and limitations associated with RSTP and MSTP:

- RSTP mode does not support SPBM.
- A C-VLAN-level loop across SPBM NNI ports cannot be detected and needs to be resolved at the provisional level.
- SPBM NNI ports are not part of the Layer 2 VSN C-VLAN, and BPDUs are not transmitted over the SPBM tunnel. SPBM can only guarantee loop-free topologies consisting of the NNI ports. You should always use Simple Loop Prevention Protocol (SLPP) in an SMLT environment.

#### Note

Deploy SLPP on C-VLANs to detect loops created by customers in their access networks. However, SLPP is not required on B-VLANs, and it is not supported. The B-VLAN active topology is controlled by IS-IS that has loop mitigation and prevention capabilities built into the protocol.

- SPB internally uses spanning tree group (STG) 63 or Multiple Spanning Tree Instance (MSTI) 62. STG 63 or MSTI 62 cannot be used by another VLAN or MSTI. For non-SPB customer networks, if you use

STG 63 or MSTI 62 in the configuration, you must delete STG 63 or MSTI 62 before you can configure SPBM.

- You must configure SPBM B-VLANs on all devices in the same MSTP region. MSTP requires this configuration to generate the correct digest.
- Configure the SPBM B-VLANs to use matching VLAN IDs.

### Best Practices for SPB Regarding MSTP

Use NNI ports exclusively to transport traffic for SPB-based services and not be configured as members of any VLANs other than SPB B-VLANs. In releases that do not support `nmi-mstp`, when an SPBM IS-IS interface is created on an NNI port or an MLT, MSTP is automatically disabled for MSTI-62 on the port/MLT. However, MSTP is not automatically disabled on NNI ports for the CIST (default MSTI). In releases that support the `boot config flags nmi-mstp` command, the default behavior of the MSTP NNI ports is that CIST is disabled automatically on the NNI and the NNI ports cannot be members of any VLANs other than B-VLANs. The default `boot config flags nmi-mstp` must be set to false (which is the default). The following example shows the command to disable the MSTP on the NNI ports.

```
Switch:1(config)#interface gigabitEthernet 1/8
Switch:1(config-if)#no spanning-tree mstp
```

### Coexistence of MSTP and SPB-Based Services on NNI Ports

In releases that do not support `nmi-mstp` boot configuration, you can support the coexistence of non-SPB based services on the NNI ports, by adding NNI ports as members of VLANs, except for B-VLANs. These other VLANs rely on the use of MSTP for Loop prevention. The network operator must carefully consider the implications of keeping MSTP enabled on the NNI ports because any MSTP topology changes detected on the NNI ports impacts all services and causes most dynamically learned information on the UNI side to be flushed and relearned. This includes, but is not limited to, all customer MAC and ARP records. This can also cause all the UNI ports on a BEB to be temporarily put into a spanning-tree blocking state before transitioning to a forwarding state again. The net result is that MSTP topology changes on the NNI ports adversely impact traffic for SPB-based services. Therefore, the NNI ports be used exclusively for SPB traffic.

### SPBM IS-IS

The following list identifies restrictions and limitations associated with SPBM IS-IS:

- The switch does not support IP over IS-IS as defined by RFC 1195. IS-IS protocol is only to facilitate SPBM.
- The switch uses level 1 IS-IS. The switch does not support level 2 IS-IS. The CLI command `show isis int-l2-contl-pkts` is not supported because the IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1.
- The IS-IS standard defines wide (32bit ) metrics and narrow (8 bits) metrics. The switch supports the wide metric.
- To run IS-IS on an MLT, add the ports to the MLT, and then enable IS-IS on the MLT.

### SPBM NNI SMLT

The switch does not support NNI on SMLT links.

### VLACP

VLACP is generally used when a repeater or switch exists between connected switches to detect when a connection is down even when the link LED is lit. You can enable VLACP on Ethernet ports that are NNI interfaces, as well as Ethernet ports that are part of an NNI MLT.

### SNMP Traps

On each SPBM peer, if you configure the SPBM B-VLANs to use different VLAN IDs, for example, VLAN 10 and 20 on one switch, and VLAN 30 and 40 on the second, the system does not generate a trap message to alert of the mismatch because the two switches cannot receive control packets from one another. Configure the SPBM B-VLANs to use matching VLAN IDs.

### System MTU

Do not change the system MTU to less than the default value of 1950 bytes. The system MTU must be 1950 or jumbo because of the header size increase when transmitting packets over the SPBM cloud.

### IP Multicast over Fabric Connect

IP multicast over Fabric Connect cannot connect to existing Protocol Independent Multicast (PIM) networks that connect to SPB originated streams or that add PIM network streams into the SPB network. SPB-PIM Gateway (SPB-PIM GW), however, provides multicast interdomain communication between an SPB network and a PIM network. SPB-PIM GW accomplishes this interdomain communication across a special Gateway VLAN. The Gateway VLAN communicates with the PIM network through the PIM protocol messaging and translates the PIM network requirements into SPB language, and vice versa. For more information about SPB-PIM GW, see [SPB-PIM Gateway configuration](#) on page 3172.

### Other

The following list identifies other restrictions or considerations:

- You cannot use 3.33.33 as the SPB nickname because of a conflict with reserved IPv6 Ethernet multicast address 33:33:xx:xx:xx:xx.
- The software does not support I-SID filters.
- You cannot enable C-VLAN and B-VLAN on the same port.
- To ensure proper cleanup of MAC tables after you run the **no spbm** command, save the configuration, and then reboot the switch.

*Network Load Balancing (NLB)***Table 91: Network Load Balancing product support**

| Feature                                            | Product         | Release introduced |
|----------------------------------------------------|-----------------|--------------------|
| Network Load Balancing (NLB) - multicast operation | 5420 Series     | Not Supported      |
|                                                    | 5520 Series     | VOSS 8.2.5         |
|                                                    | VSP 4450 Series | Not Supported      |
|                                                    | VSP 4900 Series | VOSS 8.1           |
|                                                    | VSP 7200 Series | VOSS 6.0           |
|                                                    | VSP 7400 Series | VOSS 8.0           |
|                                                    | VSP 8200 Series | VOSS 6.0           |
|                                                    | VSP 8400 Series | VOSS 6.0           |
|                                                    | VSP 8600 Series | Not Supported      |
|                                                    | XA1400 Series   | Not Supported      |
| Network Load Balancing (NLB) - unicast operation   | 5420 Series     | Not Supported      |
|                                                    | 5520 Series     | VOSS 8.2.5         |
|                                                    | VSP 4450 Series | Not Supported      |
|                                                    | VSP 4900 Series | VOSS 8.1           |
|                                                    | VSP 7200 Series | VOSS 4.2.1         |
|                                                    | VSP 7400 Series | VOSS 8.0           |
|                                                    | VSP 8200 Series | VOSS 4.0           |
|                                                    | VSP 8400 Series | VOSS 4.2           |
|                                                    | VSP 8600 Series | VSP 8600 4.5       |
|                                                    | XA1400 Series   | Not Supported      |

SPBM supports Network Load Balancing (NLB) Unicast and Multicast modes.

NLB is a clustering technology available with Microsoft Windows 2000, Microsoft Windows 2003, Microsoft Windows 2008, and Microsoft Windows 2012 server family of operating systems. You can use NLB to share the workload among multiple clustering servers. NLB uses a distributed algorithm to load balance TCP/IP network traffic across a number of hosts, enhancing the scalability and availability of mission critical, IP based services, such as web, VPN, streaming media, and firewalls. NLB also provides high availability by detecting host failures and automatically redistributing traffic to remaining operational hosts.

SPBM Script

**Table 92: run spbm installation script product support**

| Feature                      | Product         | Release introduced |
|------------------------------|-----------------|--------------------|
| run spbm installation script | 5420 Series     | VOSS 8.4           |
|                              | 5520 Series     | VOSS 8.2.5         |
|                              | VSP 4450 Series | VOSS 4.1           |
|                              | VSP 4900 Series | VOSS 8.1           |
|                              | VSP 7200 Series | VOSS 4.2.1         |
|                              | VSP 7400 Series | VOSS 8.0           |
|                              | VSP 8200 Series | VOSS 4.1           |
|                              | VSP 8400 Series | VOSS 4.2           |
|                              | VSP 8600 Series | VSP 8600 8.0       |
|                              | XA1400 Series   | Not Supported      |

You can use a CLI script to quickly configure the SPB and IS-IS infrastructure to enable Fabric Connect on a switch. You can use the SPB script, rather than manually configure the minimum SPBM and IS-IS parameters.

You can use the command **run spbm** to quickly configure the following:

- Configure the SPB Ethertype.
- Create an SPB instance.
- Create an SPBM backbone VLAN and associate it to the SPB instance.
- Create an SPBM secondary backbone VLAN and associate it to the SPB instance.
- Add an SPB nickname.
- Create a manual area.
- Enable IS-IS on one of the switch interfaces.
- Enable IS-IS globally.
- Configure the IS-IS system name.
- Configure the IS-IS system ID.
- Configure SPBM port and MLT interfaces.
- Clean up any SPBM configuration.

The following table displays the default values applied if you use the **run spbm** command. The SPB script creates some of the default values based on the MAC address of the switch, including the nickname and System ID value.

| Parameter        | Default values |
|------------------|----------------|
| Ethertype        | 0x8100         |
| Primary B-VLAN   | 4051           |
| Secondary B-VLAN | 4052           |

| Parameter       | Default values                                                                       |
|-----------------|--------------------------------------------------------------------------------------|
| Manual area     | 49.0000                                                                              |
| Nickname        | Derived from the chassis MAC                                                         |
| System name     | Derived from the command line prompt                                                 |
| System ID value | Derived from the chassis MAC, using a different algorithm from that for the Nickname |

#### Note

The SPB script only creates the SPBM instance, VLAN, or other parameters if they do not already exist. For example, if the SPBM instance and VLAN already exist, the SPB script does not create them. If the SPB script cannot create one of the parameters because the parameter is already configured, the script stops and an error message displays.

### *Layer 2 Video Surveillance install script*

**Table 93: Layer 2 Video Surveillance install script product support**

| Feature                                   | Product         | Release introduced                                                                 |

|                                           | VSP 4450 Series | VOSS 6.1                                                                           |
|                                           | VSP 4900 Series | VOSS 8.1<br>To support this feature, VIM installation is mandatory in VSP4900-48P. |
|                                           | VSP 7200 Series | Not Supported                                                                      |
|                                           | VSP 7400 Series | Not Supported                                                                      |
|                                           | VSP 8200 Series | Not Supported                                                                      |
|                                           | VSP 8400 Series | Not Supported                                                                      |
|                                           | VSP 8600 Series | Not Supported                                                                      |
|                                           | XA1400 Series   | Not Supported                                                                      |

The Layer 2 Video Surveillance install script pre-configures configuration parameters for video surveillance solutions. With this script, a technician can quickly and easily deploy a typical video surveillance network that supports up to 2000 IP cameras, a recording solution, systems management, and viewing stations.

The install script uses best practices for converged solutions and provides redundant paths for all video traffic. The script configures the basic deployment of Shortest Path Bridging (SPB) and uses Layer 2 VSNs to enable full multicast capabilities between all IP subnets and VLANs.

## Configuration Parameters

The syntax of the install script command is **run vms layer-2 switch <5-99>** where the switch value (between 5 and 99) is a user-defined variable. The install script uses this switch value to configure the camera IP zone for the switch and to specify a unique SPB nickname, system-id, and IP source value.

The install script configures the following major parameters and populates the `xx` with the user-defined variable for the switch value:

- IP Loopback Interface Address: 192.168.0.xx (Management IP address on the switch.)
- IP-Source Address: 192.168.0.xx (IS-IS source IP address for the switch.)
- VLAN ID: 200 (On hardware platforms that only have NNI links, there is no need to create a surveillance VLAN.)
- System ID: 0011.0011.07xx (SPB system-id of switch)
- Nickname: 0.07.xx (SPB Nickname for switch)
- SPB Manual Area ID: 49.0001
- Backbone VLAN IDs: 4051 and 4052 (with 4051 as Primary)
- SPB Multicast: enabled
- SFP and SFP+ ports: (Define all ports as NNI links.)

### Note

The install script does not configure DHCP Relay parameters.

## Optional `syntax` Parameter

The install script requires that the switch be in the factory default state. The script prompts you to confirm this, but it does not check if you did so. The script continues running commands even if some of the commands in the script fail, and the failure of script commands is not evident by the script completion message.

The syntax of the install script command is: **run vms layer-2 switch <5-99> [syntax]**. The optional `syntax` parameter prints out all the commands run by the script onto the console. If you do not use the `syntax` parameter, you will not see an error message when a command fails to run.

### Important

Use the `syntax` parameter to display all the commands run by the script and show any errors that the script encounters. This is the only way to ensure that all configurations are configured without error.

## Configuration Filename

Upon successful completion of the install script, the switch configuration is saved with a filename based on the switch value used when the script was run. The switch primary boot config file flags are updated with the new filename.

For example, if you use 6 as the switch value, the command **run vms layer-2 switch 6** results in a switch configuration filename of `vms-layer2-switch-6.cfg`.

If you run the install script with the **syntax** parameter, you will see the pre-install command output:

- `save config file pre_vms_layer2_install.cfg`

- Save config to file /intflash/pre\_vms\_layer2\_install.cfg successful.
- and the completed install script output:
- save config file vms-layer2-switch-6.cfg
  - Save config to file /intflash/vms-layer2-switch-6.cfg successful.

### *IS-IS external metric*

The software supports the IS-IS external metric to differentiate between internal and external routes with Accept Policies.

With this feature you can use IS-IS to:

- change the external metric-type of a route when redistributing it from another protocol to IS-IS through route redistribution using a route-map.
- change the external metric-type of a route when accepting a remote IS-IS route with the help of IS-IS accept policies using a route-map.
- match the external metric-type when redistributing IS-IS routes into other protocols using the match option in the route-map.
- match the external metric-type when accepting a remote IS-IS route with the help of IS-IS accept policies by using a route-map
- process the external metric-type in the route selection process.

The IS-IS metric type can also be set using the base redistribute command without using the route-map.

### *SPB Ethertype*

The switch aligns the SPB ethertype to BCB's locally configured SPB ethertype. The BCBs mark the BTAG Ethertype of a transit MAC-in-MAC packet to match its locally configured value when it exits on a different NNI port, even if the BTAG Ethertype on the incoming packet (CFM or SPB) does not match its configured value.

#### **Note**

ISIS Hello packets are always marked with 0x8100 ethertype, and do not change according to the BCB's locally configured values.

*Equal Cost Multipath Pathlist with Fabric Connect***Table 94: ECMP Pathlist with Fabric Connect product support**

| Feature                                          | Product         | Release introduced |
|--------------------------------------------------|-----------------|--------------------|
| ECMP Pathlist with Fabric Connect (IS-IS routes) | 5420 Series     | VOSS 8.4           |
|                                                  | 5520 Series     | VOSS 8.2.5         |
|                                                  | VSP 4450 Series | VOSS 8.1.5         |
|                                                  | VSP 4900 Series | VOSS 8.1.5         |
|                                                  | VSP 7200 Series | VOSS 8.1.5         |
|                                                  | VSP 7400 Series | VOSS 8.1.5         |
|                                                  | VSP 8200 Series | VOSS 8.1.5         |
|                                                  | VSP 8400 Series | VOSS 8.1.5         |
|                                                  | VSP 8600 Series | Not Supported      |
|                                                  | XA1400 Series   | VOSS 8.1.5         |

If you use Equal Cost Multipath (ECMP) in a Shortest Path Bridging (SPB) scenario, the Intermediate System-to-Intermediate System (IS-IS) protocol sends multiple routes with the same destination to the routing manager. IS-IS can add up to eight equal cost routes with the same destination to the routing table and the router uses one route for traffic forwarding based on load management. Use the ECMP Pathlist feature to control how many equal-cost paths to add to the routing manager for the same destination.

**Note**

Different hardware platforms can support a different number of ECMP paths. For more information about the maximum number of ECMP paths supported on the switch, see the scaling information in [VOSS Release Notes](#).

For information about how to configure ECMP Pathlist, see [Configure ECMP](#) on page 1832 and [Configure ECMP](#) on page 1858.

*FAN Transit*

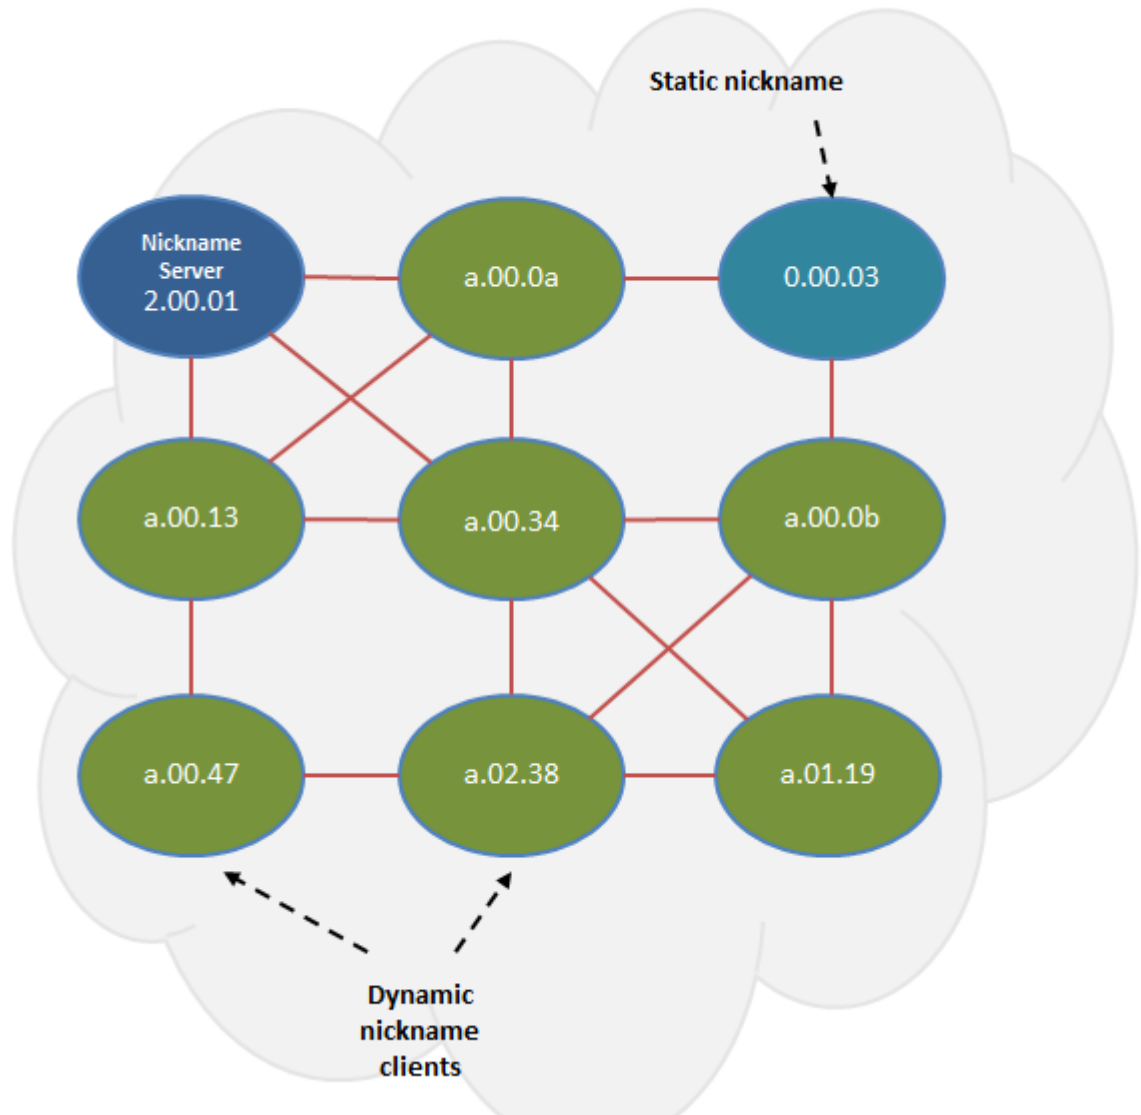

Fabric Area Network (FAN) transit refers to the ability of a switch to forward traffic between SPB nodes participating in a FAN. The switch is neither a part of the FAN nor does it originate or sink FAN traffic. It only forwards the traffic between the FAN end-points.

For information on how to verify the functioning of a transit switch within a FAN, see [Troubleshooting FAN Transit](#) on page 3669.

*Dynamic Nickname Assignment***Table 95: Dynamic Nickname Assignment product support**

| Feature                                                        | Product         | Release introduced |
|----------------------------------------------------------------|-----------------|--------------------|
| Dynamic Nickname Assignment                                    | 5420 Series     | VOSS 8.4           |

|                                                                | VSP 7200 Series | VOSS 8.3           |
|                                                                | VSP 7400 Series | VOSS 8.3           |
|                                                                | VSP 8200 Series | VOSS 8.3           |
|                                                                | VSP 8400 Series | VOSS 8.3           |
|                                                                | VSP 8600 Series | Not Supported      |
|                                                                | XA1400 Series   | Not Supported      |

Dynamic Nickname Assignment is a service that provides unique nicknames to compatible switches across a Fabric Area Network (FAN).

You can configure a node in a FAN as a nickname server. The nickname server cannot be started until you configure it with a static nickname. As a best practice, configure at least two nickname servers in a FAN to provide redundancy.

#### Note

Configure the nickname server with a static nickname that is outside any configured dynamic nickname server range in the network, or you can configure the nickname server with a static nickname from the first 10 values of the configured dynamic nickname server range in the network.

The nickname server interrogates FAN nodes that have been assigned a dynamic nickname to avoid nickname duplication.

A client joining the dynamic FAN in factory default mode initially does not have a nickname, and issues a broadcast soliciting a valid nickname assignment. The nickname server receives the request and

responds with a nickname assignment offer. The client then explicitly requests the particular nickname offered and the nickname server sends an acknowledgment.

The client maintains the nickname in persistent memory regardless of whether the active nickname server is the same server that originally provided the nickname. The client generates a trap and notifies the user if it is unable to receive a nickname from the server. When IS-IS starts, it issues a trap if a client does not have a nickname and clears the trap when the client receives a nickname from the nickname server.

A client rebooting or reconnecting to the FAN requests the same nickname assignment it had before reboot. If the requested nickname is within the nickname server's configured range of nicknames and is still available, the server acknowledges the nickname. If the requested nickname is outside of the nickname server's configured range or if the nickname has been assigned to another client, the request is denied by the nickname server and the client must request a new nickname.

### Static and Dynamic Nickname Servers

You can use static nickname assignment and Dynamic Nickname Assignment in the same FAN.

You can configure Dynamic Nickname Assignment using a range prefix that can use a range from 0.00.00 to F.FF.FF. This method provides 256 groups that cover the range of 0.00.00 to F.FF.FF.

#### Note

You can configure the nickname server with a static nickname from the first 10 values of the configured dynamic nickname server range in the network.

Do not use nicknames from the dynamic nickname range when you assign nicknames statically to non-server nodes. However, if there are existing nodes in the network with static nicknames in the dynamic nickname range, it is not a requirement to change their nickname assignment. If a node is assigned a dynamic nickname that is being used in the network, duplicate nickname protection is initiated. If the node that has the dynamic nickname loses the nickname election, it requests a different nickname from the nickname server. If a node with a static nickname loses the nickname election, IS-IS is disabled on that node and you must manually re-assign the nickname and re-enable IS-IS.

You can configure nicknames from a dynamic range if the nickname server is not started.

#### Note

You must disable Dynamic Nickname Assignment before you can change the nickname prefix.

### Debugging

A node must be a member of a FAN to host Dynamic Nickname Assignment applications. FAN connectivity enables the exchange of information between nickname clients and servers, such as nickname requests or nickname assignments. You can use Connectivity Fault Management (CFM) to debug connectivity issues or isolate faults. For more information about CFM, see [Connectivity Fault Management](#) on page 3481.

### Dynamic Nickname Assignment Considerations

Consider the following information when implementing this feature:

- You must configure a nickname server to assign unique nicknames to clients based on established policies.

- You can configure multiple nickname servers in a FAN to provide resiliency. If you configure multiple nickname servers, you must ensure that the ranges for nickname allocation do not overlap.
- Dynamic Nickname Assignment is not supported in a FAN that contains ERS 4900 or ERS 5900 products, or on products running VOSS releases prior to 7.0.

*MSTP-Fabric Connect Multi Homing*

**Table 96: MSTP-Fabric Connect Multi Homing product support**

| Feature                          | Product         | Release introduced |
|----------------------------------|-----------------|--------------------|
| MSTP-Fabric Connect Multi Homing | 5420 Series     | VOSS 8.4           |
|                                  | 5520 Series     | VOSS 8.2.5         |
|                                  | VSP 4450 Series | VOSS 7.0           |
|                                  | VSP 4900 Series | VOSS 8.1           |
|                                  | VSP 7200 Series | VOSS 7.0           |
|                                  | VSP 7400 Series | VOSS 8.0           |
|                                  | VSP 8200 Series | VOSS 7.0           |
|                                  | VSP 8400 Series | VOSS 7.0           |
|                                  | VSP 8600 Series | Not Supported      |
|                                  | XA1400 Series   | Not Supported      |

The MSTP-Fabric Connect Multi Homing feature allows MSTP or RSTP network to be multi-homed into a Fabric Connect network, providing a loop-free topology. MSTP-Fabric Connect Multi Homing enables an MSTP network to be multihomed into the SPB Fabric network through single node-to-multiple nodes or multiple nodes-to-multiple nodes.

**Important**

You must enable MSTP-Fabric Connect Multi Homing before you establish multihoming with an MSTP network.

MSTP-Fabric Connect Multi Homing uses I-SID 16777003. The switch creates this I-SID automatically and it cannot be modified.

MSTP-Fabric Connect Multi Homing is supported on SPBM mode only.

## Fabric Extend

**Table 97: Fabric Extend product support**

| Feature                                                               | Product         | Release introduced                    |

|                                                            | VSP 7400 Series | Not Supported                         |
|                                                            | VSP 8200 Series | Not Supported                         |
|                                                            | VSP 8400 Series | Not Supported                         |
|                                                            | VSP 8600 Series | Not Supported                         |
|                                                            | XA1400 Series   | VOSS 8.3.1                            |

Some hardware platforms support Fabric Extend natively. You can use these switches in a main office of a hub and spoke deployment or to connect one Data Center to another Data Center.

The VSP 4450 Series also supports Fabric Extend, but the switch must be connected to an Open Networking Adapter (ONA) because the VSP 4450 Series does not support Fabric Extend natively. The ONA enables the VSP 4450 Series to support Fabric Extend. The VSP 4450 Series uses the ONA to encapsulate Fabric Connect traffic. For example, you can use the VSP 4450 Series in a branch office of a hub and spoke deployment.

#### Note

In a Layer 2 core Fabric Extend solution, the VSP 4450 Series does not require an ONA because the tunnels are point-to-point VLAN connections, not VXLAN connections. Therefore, there is no need for an ONA to encapsulate a VXLAN header to SPB packets.

Fabric Extend enables Enterprises to extend the Fabric Connect technology over Layer 2 or Layer 3 core networks. The *logical IS-IS interface* is the mechanism that enables Fabric Extend to connect SPB fabric nodes. Logical IS-IS interfaces create virtual tunnels and encapsulate SPB traffic by adding a VXLAN header to SPB packets.

The following figure illustrates two Fabric Connect “islands” separated by a third-party core IP network. The IP network could be third-party equipment in an enterprise or a service provider’s infrastructure such as an MPLS VPN service.

**Figure 59: Fabric Connect networks connected by an IP network**

The following figure illustrates how Fabric Extend enables you to connect the fabric islands to create ONE Fabric Connect network. This figure shows a layer 3 core network where Fabric Extend uses IP tunneling by adding a VXLAN header to the SPBM packets. This can be over a third party IPv4 transport network such as MPLS IP-VPN or in a Campus IP backbones.

**Figure 60: Single Fabric Connect Domain realized using Fabric Extend**

The following figure shows a layer 2 core network where Fabric Extend can transport SPBM packets over a layer 2 MPLS VPLS or PBB E-LINE service by creating layer 3 tunnels over a layer 2 third party network.

**Figure 61: Fabric Extend over VLAN tunnels**

#### *Advantages of Fabric Extend*

**Fabric Connect** is an Ethernet-based, industry-standard (IEEE 802.1aq) networking virtualization solution. With Fabric Connect, you can have thousands of virtualized service instances at any point in the network. Other Fabric Connect advantages include rapid time to service, Layer 2 and Layer 3 Unicast and IP Multicast virtualization, and scalable IP multicast. But the most significant advantage of Fabric Connect is that you provision services at the network edge *only*, not the core.

The **Fabric Extend** feature enables you to *extend* the Fabric Connect model over Layer 2 and Layer 3 core networks. The interconnection of Fabric Connect deployments can be over any IP-based network whether it's a campus backbone, Data Center, or a MAN/WAN IP MPLS network.

#### *Fabric Extend and ONA*

Some hardware platforms support Fabric Extend natively on any of its physical ports. However, the VSP 4450 Series requires an Open Networking Adapter (ONA) to enable this functionality. The ONA is the Fabric Extend packet encapsulation engine for the VSP 4450 Series. The ONA / VSP 4450 Series combination can also provide enhanced features such as IP fragmentation and reassembly on Fabric Extend tunnels.

#### **Note**

In a Layer 2 core Fabric Extend solution, the VSP 4450 Series does not require an ONA because the tunnels are point-to-point VLAN connections, not VXLAN. Therefore, there is no need for an ONA to encapsulate a VXLAN header to SPB packets.

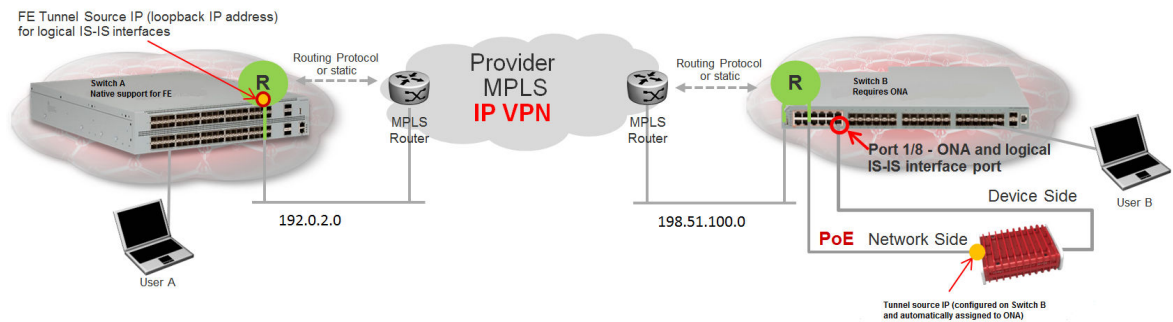

The VSP 4450 Series manages the ONA in the following ways:

- Controls and provisions the ONA.
- If PoE capable, the VSP 4450 Series supplies power to the ONA. (The ONA also supports an optional wall unit power adapter.)
- Transports traffic to and from the ONA over 1 GbE ports and sets QoS appropriately to the ONA's.
  - The ONA 1101GT can support basic Fabric Extend at line rate 1G traffic from the VSP 4450 Series at 1500 byte packet sizes.
  - Oversubscription of the ONA's packet engine may result if packets are smaller than 1500 bytes or if you enable enhanced features such as fragmentation and reassembly of packets. This results in

packet drop starting with lower QoS queued packets consistent with PCP and DSCP markings on packets received from the VSP 4450 Series. For more details on the ONA 1101GT forwarding performance, see [ONA Considerations](#) on page 965.

The ONA can operate in different modes. Fabric Extend is Operational Mode 1. To enable Fabric Extend, use the ONA's Manual Configuration menu to change the Operational Mode parameter to 1. For more information, refer to the manual that ships with the ONA.

In the following figure, the VSP 8200 Series is in a Fabric Connect network and is configured with Fabric Extend (FE). The VSP 4450 Series is also in a Fabric Connect network and is configured with SPB. The VSP 8200 Series and the VSP 4450 Series use industry-standard VXLAN tunnels to create a flow for FE traffic between the VSP 8200 Series and the ONA attached to the VSP 4450 Series.

**Figure 62: Fabric Extend traffic flow**

The following flow occurs when User A sends a packet to User B:

- The VSP 8200 Series receives the packet and encapsulates it with a MAC-in-MAC header.
- The VSP 8200 Series sends the MAC-in-MAC-encapsulated packet over the VXLAN tunnel to the VSP 4450 Series.
- The VSP 4450 Series receives the packet and sends it to the ONA network port.
- The ONA decapsulates the packet by removing the VXLAN header and sends the MAC-in-MAC packet header out the ONA device port back to the VSP 4450 Series.
- The VSP 4450 Series decapsulates the MAC-in-MAC header and forwards the packet to User B.

The following flow occurs when User B sends a packet to User A:

- The VSP 4450 Series receives the packet and sends it to the ONA over the ONA device port with MAC-in-MAC encapsulation.
- The ONA encapsulates the packet with a VXLAN header.
- The ONA then sends the packet out the ONA network port and back to the VSP 4450 Series.

- The VSP 4450 Series sends the VXLAN-encapsulated packet over the Routed IP network to the VSP 8200 Series.

**Note**

To interoperate with the VSP 8200 Series, you must set the MTU on the VSP 4450 Series/ONA combination to 1950 bytes.

- The VSP 8200 Series decapsulates the packet by removing the VXLAN header and the MAC-in-MAC header, and then forwards it to User A.

**Note**

Connect the ONA as shown with two ports to the VSP 4450 Series. You cannot connect the ONA directly to the IP core infrastructure.

*Logical IS-IS interface*

The logical IS-IS interface is the mechanism that enables Fabric Extend to connect SPB fabric nodes.

Logical IS-IS interfaces perform the following functions depending on the type of core network:

- In a Layer 3 core network, logical IS-IS interfaces create virtual IP tunnels and encapsulate SPB traffic by adding a Virtual Extensible LAN (VXLAN) header to SPB packets.
- In a Layer 2 core network, logical IS-IS interfaces do not use VXLAN. The tunnels are point-to-point VLAN connections so there is no need to encapsulate a VXLAN header to SPB packets. The logical IS-IS interfaces translate the Backbone VLAN IDs (B-VIDs) and maps them to each of the branch provider VLANs.

Fabric Extend uses virtual tunnels in Layer 3 core solutions to connect SPB fabric nodes. These nodes can stretch over IP routed campus networks, service provider Layer 2 core networks, or service provider Layer 3 core networks such as IP MPLS VPNs.

**Note**

VLACP cannot be used on logical IS-IS interface connections.

**Layer 2 core network**

If the service provider has a Layer 2 core network, note the following points:

- The syntax for configuring a logical interface is:

```
logical-intf isis <id> vid <list of vlans> primary-vid <vlanId> port
<slot/port> Mlt <mltId> [name <name>]
```

- `vid <list of vlans>` should have two VLANs, not more than two or less than two. The VID range is <2-4059>. You do not have to configure the VLANs as platform VLANs.
- `primary-vid` should be included in `vid <list of vlans>`.
- Each logical interface must have a unique set of VLANs for each port or MLT. The same VLANs however, can be reused across a different set of ports or MLTs.
- Logical interface VLANs and B-VLANs cannot be the same.
- Configuring the same VLANs as primary and secondary is not allowed.

- The `port/MLT` on which the Layer 2 core IS-IS logical interface is configured cannot be part of any other user configured VLANs.
- Cannot delete an MLT that is configured as a logical interface tunnel MLT.
- A logical interface consists of a port/MLT and a list of VLANs, where port/MLT is the physical connectivity to the Layer 2 core network and VLANs are the list of VLANs used to transport/bridge IS-IS control packets and Mac-in-Mac data traffic.
- VXLAN headers are not used in Layer 2 core Fabric Extend solutions.
- IS-IS control packets are not encapsulated before they are sent over a logical interface. Instead, the VLAN in the outer Ethernet header (SPB primary bvid) is replaced by the user configured logical interface VLAN.
- Spanning tree is disabled by default on **port/MLT** on which a Layer 2 core logical IS-IS interface is configured.

### Layer 3 core network

If the service provider has a Layer 3 core network, note the following points:

- The syntax for configuring a logical interface is:
 

```
logical-intf isis <id> dest-ip <destIpAddr> [name <name>]
```
- A logical IS-IS interface points to a remote BEB destination IP address.
- Port and VlanId are not needed to create a logical IS-IS interface, instead they can be retrieved from the next hop of destination IP address.
- IS-IS control packets (IS-IS hello, LSDB, CSNP, PSNP) are encapsulated with a VXLAN header and sent over a logical IS-IS interface.

### IPsec Compression

IPsec compression reduces the size of the IP datagram to improve the communication performance between hosts connected behind XA1400 Series Backbone Edge Bridges (BEB).

#### Tip

As a best practice, use IPsec compression only for Fabric Extend tunnels where latency is greater than 70ms.

The following list identifies how you can implement IPsec compression:

- You can configure IPsec compression for each logical-interface.
- You can configure multiple IPsec Fabric Extend (FE) adjacencies with or without compression simultaneously.
- You must enable IPsec compression on both BEBs to use IPsec compression for an FE adjacency.
- You cannot configure IPsec compression if fragmentation before encryption is already enabled on the logical interface.
- You can change the IPsec compression configuration for a logical interface only if IPsec is disabled on the logical interface.

For configuration information, see the following tasks:

- [Configure Fabric Extend Over IPsec](#) on page 1045 (using CLI)
- [Configure Fabric Extend Logical Interfaces for Native Support](#) on page 1163 (using EDM)

### *IS-IS Hello Padding*

To detect maximum transmission unit (MTU) mismatches, Intermediate System-to-Intermediate System (IS-IS) pads hello packets to the full interface MTU. All hello packets on Fabric Extend NNI links are padded. On non-Fabric Extend point-to-point NNI links, hello packets are padded until a hello packet is received from the other side.

#### **Note**

If you downgrade to a release that does not support this feature, you must disable the feature and save the configuration before you downgrade. You must have a compatible configuration file if you downgrade to an earlier release.

### *IPsec Fragmentation Before Encryption*

XA1400 Series, VSP 4900 Series, and VSP 7400 Series switches support IPsec fragmentation before encryption of Fabric Extend tunnels; VSP 4900 Series and VSP 7400 Series provide that support using Fabric IPsec Gateway.

The best practice is to enable fragmentation before encryption only for an IPsec adjacency over a WAN.

Configure IPsec fragmentation of the packets to occur before encryption and IPsec encapsulation. Packets are fragmented based on the tunnel maximum transmission unit (MTU) without the IPsec header so that the final packet does not exceed the tunnel MTU. The MTU value is a per tunnel configuration, which means packet fragmentation occurs per tunnel. For a tunnel with this functionality enabled, packets that egress the specific NNI port are encapsulating security payload (ESP) packets only.

The following list identifies how you can implement IPsec fragmentation before encryption:

- You can configure IPsec fragmentation before encryption for each logical-interface.
- You must configure IPsec over Fabric Extend in IPsec decoupled mode, which means the IPsec source and destination IP addresses are different than the Fabric Extend addresses.
- You cannot configure IPsec compression if fragmentation before encryption is already enabled on the logical interface.

#### **IPsec Coupled and Decoupled Mode**

A device is in IPsec decoupled mode when IPsec and Fabric Extend (FE) termination takes place on two different IP addresses. A device is in IPsec coupled mode when IPsec and Fabric Extend (FE) termination takes place on the same IP address.

The XA1400 Series devices, which use VOSS for Fabric Extend over IPsec, support both IPsec decoupled and coupled modes. The VSP 4900 Series and VSP 7400 Series devices, which use Fabric IPsec Gateway for Fabric Extend over IPsec, support IPsec in decoupled mode only. You must configure the IPsec tunnel in decoupled mode to enable IPsec termination in the Fabric IPsec Gateway VM. For more information about how to configure IPsec tunnels on the VM, see [Configure IPsec Tunnels on Fabric IPsec Gateway VM](#) on page 880.

For more information, see the following tasks:

- For XA1400 Series configuration using VOSS:
  - [Enable IPsec Fragmentation Before Encryption](#) on page 1053
  - [Disable IPsec Fragmentation Before Encryption](#) on page 1054

- For VSP 4900 Series and VSP 7400 Series configuration using Fabric IPsec Gateway, see [Enable Fragmentation Before Encryption on Fabric IPsec Gateway VM](#) on page 882.

### *Adjusting the TCP Maximum Segment Size*

You can adjust the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency.

#### **TCP MSS Overview**

When a client initiates a connection with a server, it uses TCP SYN packets to negotiate the MSS to avoid fragmentation. The client and server use the outgoing maximum transmission unit (MTU) to advertise the MSS.

If a tunnel exists between the client and server, the encapsulation consumes more room in the outer IP header. As a result, the router that performs the tunnel encapsulation fragments the packet to fit over the tunnel. Adjust the MSS to modify the value in the TCP SYN packet so the client and server negotiate a lower number and leave headroom for tunnel encapsulation.

This adjustment functionality applies to IPv4 only.

#### **Important**

If you enable this functionality and port mirroring simultaneously, the switch does not mirror CP-generated packets.

#### **VSP 4900 Series Support**

TCP MSS adjustment applies unidirectionally when a packet is forwarded from a UNI interface to any other interface. To use this functionality, you must enable TCP MSS adjustment on both sides of the FE tunnel.

#### **VSP 7400 Series Support**

TCP MSS adjustment applies unidirectionally when a packet is forwarded into an FE tunnel. To use this functionality, you must enable TCP MSS adjustment on both sides of the FE tunnel.

#### **XA1400 Series Support**

The MSS adjustment functionality only activates when at least one Fabric Extend (FE) tunnel with a MTU less than or equal to 1500 is configured. The functionality is inactive if no FE tunnels with MTU less than or equal to 1500 are configured. Deleting the last tunnel with MTU less than or equal to 1500 results in the functionality becoming inactive.

The switch can auto-derive the MSS value based of the tunnel MTUs or you can manually configure the MSS value. The formula for the auto-derived value is

$\text{min}(\text{Tunnels MTUs}) - 200\text{B}$  (size for VXLAN + MIM + IPSEC + IP+TCP headers)

If you configure multiple FE tunnels with MTU less than or equal to 1500, then the switch uses the lowest of all tunnel MTUs to auto-derive the TCP MSS adjust value. The same value applies bidirectionally, to all TCP syn packets that transmit NNI to UNI and UNI to NNI.

**Tip**

As a best practice, disable this enhancement on the head-end side and enable only at the branch side.

The switch does not support different TCP adjust MSS values if you configure different FE tunnel MTUs on different tunnels.

If you configure FE tunnels and regular NNIs on the same adjacency, then the TCP adjust MSS value applies to all TCP packets traversing across regular NNIs and FE tunnels.

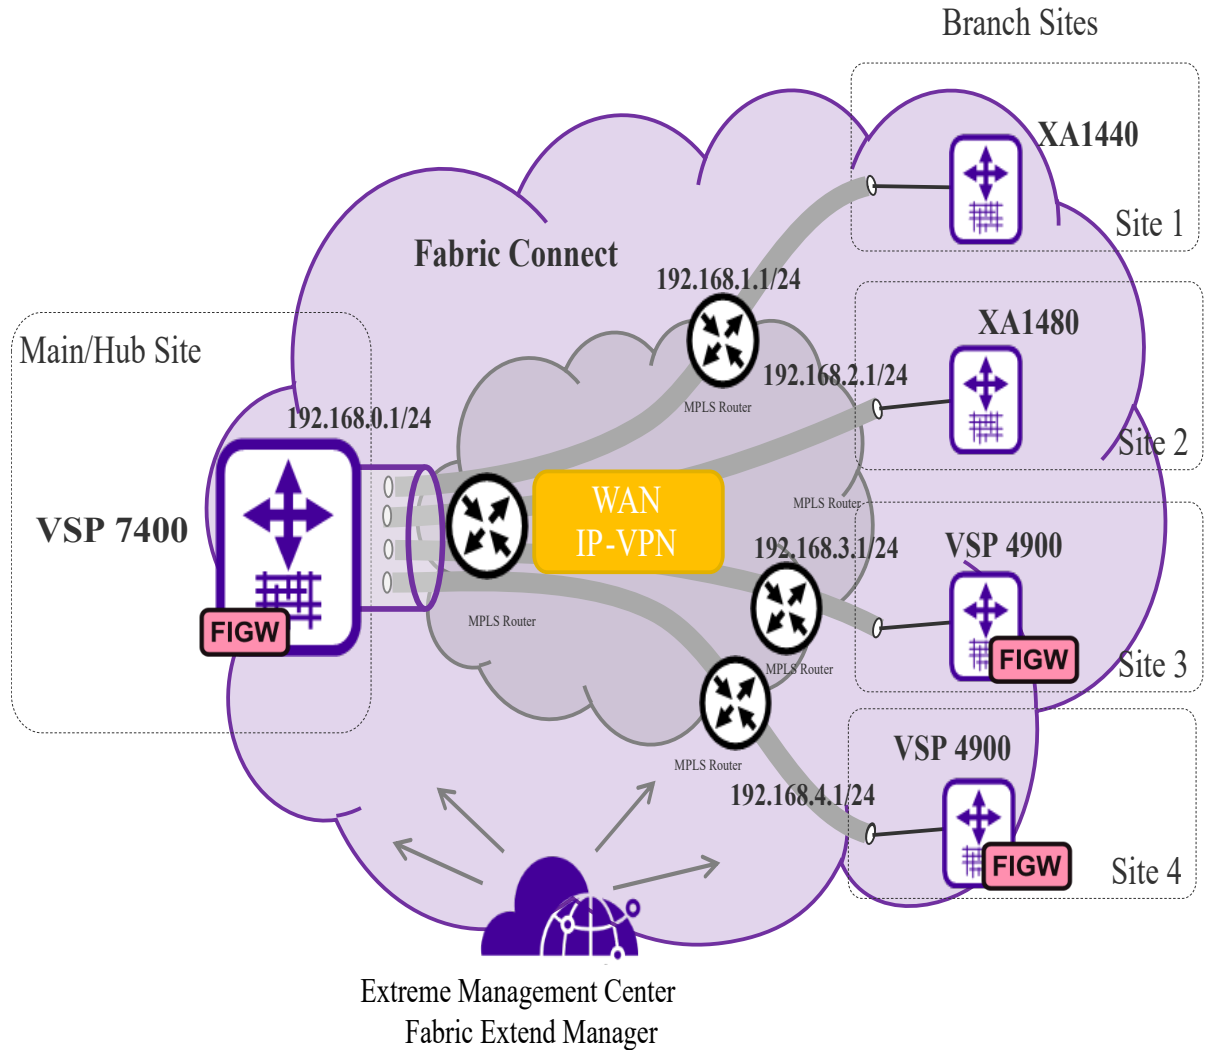

### *Types of Fabric Extend Deployments*

As the number of Fabric Connect networks increased, the need to connect those networks became more and more desirable. Fabric Extend solves the problem of going beyond the Ethernet Fabric Connect connections to include the following IP routed wide area network (WAN) and campus solutions:

1. Fabric Extend over an MPLS IP-VPN provider WAN
2. Fabric Extend over an MPLS Virtual Private LAN Service (VPLS) or Provider Backbone Bridging (PBB) Ethernet LAN (ELAN) provider network
3. Fabric Extend over an IP campus network
4. Fabric Extend over an MPLS Pseudo-Wire or Ethernet Virtual Private Line (E-Line) provider network
5. Fabric Extend over IPsec

#### **Fabric Extend over an MPLS IP-VPN provider WAN**

The most common Fabric Extend deployment is a hub and spoke topology that connects the Main office over a service provider's MPLS IP VPN to multiple Branch offices. The following figure illustrates how the hub device on the main site establishes virtual tunnels with all of the spoke devices in the same domain. In this scenario, the traffic flows are bidirectional: from hub-to-spoke and spoke-to-hub.

**Figure 63: Fabric Extend IP VPN Deployment Option**

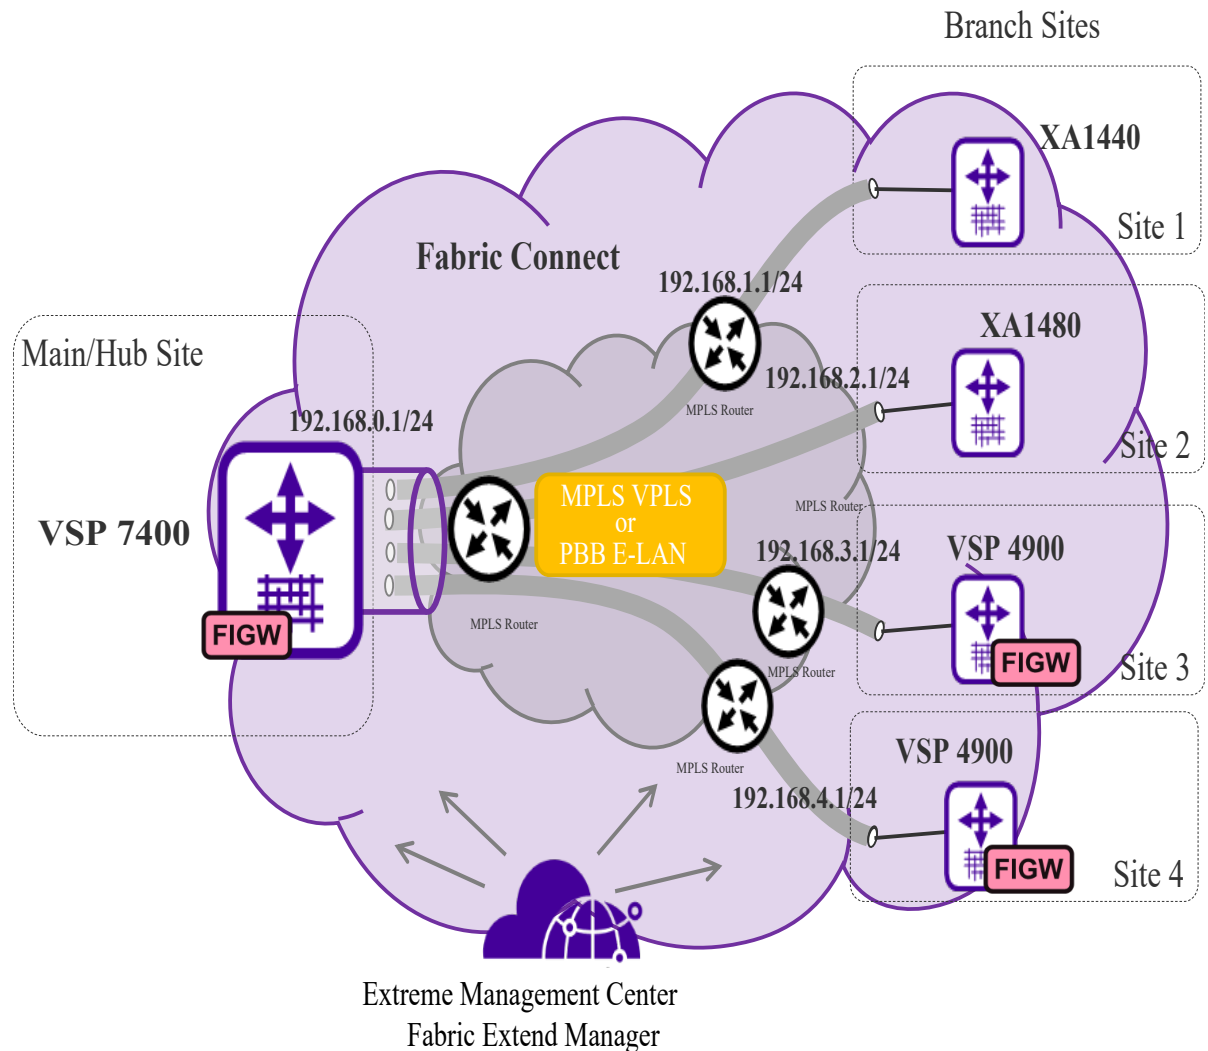

**Note**

If Fabric Extend with IPsec or fragmentation and reassembly is a requirement, depending on your requirements, you can use a mix of VSP 7400 Series or VSP 4900 Series with Fabric IPsec Gateway and XA1400 Series at the main and branch sites.

**Fabric Extend over an MPLS VPLS/P2P-VPLS/E-LINE/P2P-VLAN provider network**

Where the preceding hub and spoke deployment is over a Layer 3 MPLS IP-VPN, the following VPLS deployment is over a Layer 2 segment. This type of hub and spoke deployment extends the fabric over an MPLS Virtual Private LAN Service (VPLS) or Provider Backbone Bridging (PBB) Ethernet LAN (E-LINE) network. In this scenario, the SPB nodes are connected with a point-to-point Ethernet link.

**Figure 64: Fabric Extend VPLS Deployment Option**

#### Fabric Extend over an IP campus network

Some customers do not want to migrate their infrastructures to SPB immediately. They want to keep their existing IP core network and deploy SPB on the edge. In this scenario, Fabric Extend supports a fabric overlay on top of the existing campus infrastructure.

The following figure illustrates how this deployment supports any-to-any traffic with full-mesh tunnels between fabric nodes. The fabric nodes serve as campus switches, support routing into the IP infrastructure, and provide an overlay fabric that enables all fabric benefits.

**Figure 65: Fabric Extend Full Mesh Campus Deployment Option**

#### Fabric Extend over an MPLS PWE3/E-Line provider network

The following hub and spoke deployment over an MPLS Pseudowire or Ethernet Virtual Private Line (E-Line) uses service provider VLAN tunnels. Because you can map many (VID, port/mlt list) sets to an I-SID, this gives Service Providers the flexibility to let more than one customer use the same VLAN with different I-SIDs.

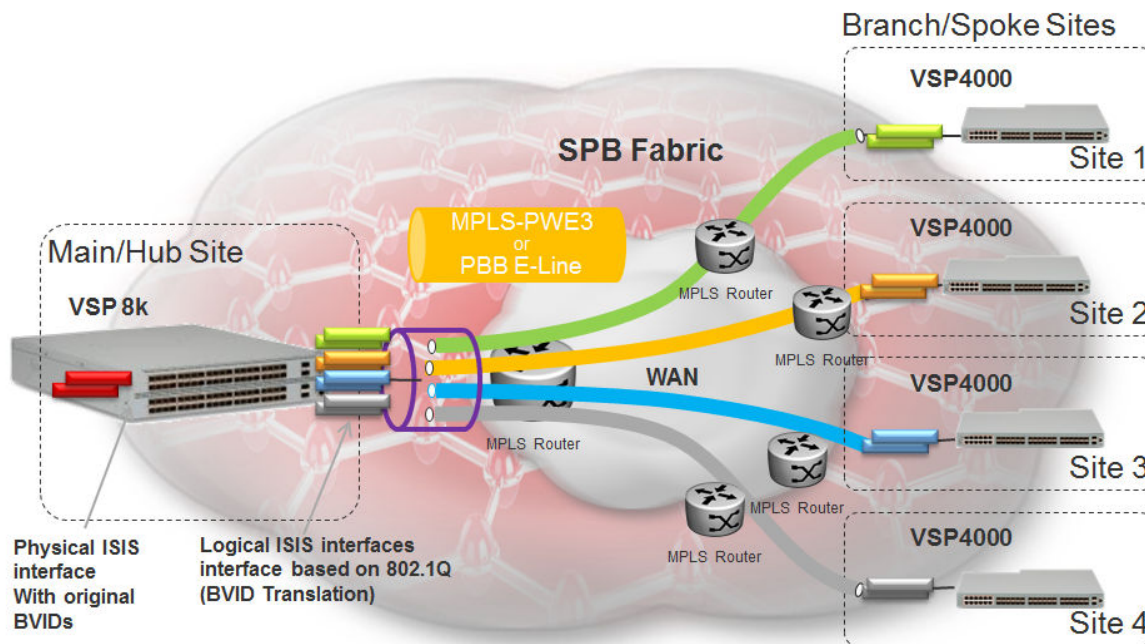

#### Note

The VSP 4450 Series switches in this type of deployment do not require an ONA because the tunnels are point-to-point VLAN connections, not VXLAN. Therefore, there is no need for an ONA to encapsulate a VXLAN header to SPB packets.

The following figure illustrates how two dedicated Backbone VLAN IDs (B-VIDs) are mapped from the hub to spoke sites. Logical IS-IS interfaces translate the B-VIDs and maps them to each of the branch provider VLANs.

For a detailed configuration example showing logical interfaces using B-VID translation to two different logical VLAN IDs, see *Shortest Path Bridging (802.1aq) Technical Configuration Guide*.

**Figure 66: Fabric Extend Pseudowire Deployment Option**

**Fabric Extend over IPsec**

The Fabric Extend over IPsec hub and remote deployment uses service provider VLAN tunnels and IPsec to provide permanent connections between locations. It is best used for site-to-site connections, such as connecting remote sites to the core network. Since IPsec works at the network layer, this type of configuration is not limited or dedicated to a particular application.

**Note** FE over IPsec connectivity requires an XA1400 Series device on each end of the FE tunnel.

The following figure illustrates how the FE over IPsec deployment supports the site-to-site connections. It shows a Layer 3 core network where Fabric Extend uses IP tunneling by adding a VXLAN header to the SPBM packets. This can be over a third party IPv4 transport network such as MPLS IP-VPN or in a Campus IP backbone.

**Figure 67: Fabric Extend over IPsec Deployment Option**

### *Fabric Extend Tunnel MTU*

You can configure a unique MTU value for each Fabric Extend (FE) tunnel on a XA1400 Series device. You can configure each ISIS logical interface with a unique MTU value for each FE tunnel in the VXLAN interface to improve fragmentation and reassembly in WAN connectivity over MPLS IP VPN and internet-based connections through a NAT router.

Fragmentation and reassembly is based on the MTU value configured for each FE tunnel. You can change the MTU configuration at any time for each FE tunnel. The supported MTU range is 750 to 9000, and the default MTU value is 1950.

**Note**

FE Tunnel MTU is an optional configuration.

For example, if you configure an FE tunnel with an MTU of 900, and a packet size of 1950 is received on UNI with the destination on the FE tunnel, the system fragments the original 1950-sized packet into the three packets (900, 900, 150) with a packet size equal to or less than 900. The system transmits the three fragmented packets over the ISIS logical interface of the FE tunnel. After the packets are received at the destination, the system performs the packet reassembly (900, 900, 150) into the 1950-sized packet.

**Fabric Extend Tunnel MTU Considerations**

Consider the following interactions between route MTU and FE Tunnel MTU configurations:

- If route MTU is not configured, the MTU value for each FE tunnel is applicable to ingress and egress traffic on the tunnel.
- If route MTU is configured, the MTU value for each FE tunnel is applicable for ingress traffic on the tunnel. The route MTU value applies to all egress traffic.

**Note**

System MTU maximum is a separate configuration. You can configure a system maximum MTU size of 1522, 1950, or 9022. The default value is 1950.

### *IPsec Source IP Address Per Tunnel Interface*

To deploy the XA1400 Series in an environment that includes more than one provider connection with IPsec, you require a source IP address for each IPsec tunnel.

When you connect to a broadband provider such as cable modem, DSL, or LTE, the only routable IP interface is the one that is assigned by the provider (either through DHCP or statically). As a result, the Internet can only route the assigned subnet. You cannot deploy a routing protocol between the branch device and the provider modem.

When you connect two different providers to a branch device, each provider uses a different subnet. The XA1400 Series must apply a different source IP address for each IPsec tunnel.

The following options are available to configure a specific source IP address for each IPsec tunnel:

- Statically configure a source IP address for each IPsec tunnel:
  - You must configure a VLAN, brouter, or CLIP IP address for the IPsec tunnel to use; this address must be in the same VRF as the tunnel.
  - You cannot delete the VLAN, brouter, or CLIP IP address if it is used as the static IPsec source IP.
  - You must disable IPsec on the logical interface before you configure an IPsec source IP.
  - The specified IP must be different than the global IPsec IP source address.
  - The specified IP can be the same as the management IP if you do not configure other logical IPsec interfaces with a source IP type of DHCP.
  - Multiple logical interfaces can use the same statically configured IPsec source IP.
- Dynamically obtain the source IP address for each IPsec tunnel from the management VLAN IP address assigned through DHCP:
  - You must enable DHCP on the management VLAN.
  - The co-existence mode, where both the management IP stack and the routing IP stack share the same IP address and default routes, must be present. For more information, see [VLAN](#) on page 70.
  - After you run the `ipsec tunnel-source-address type dhcp` command, the system imports the IP and VRF used by the management VLAN as the IPsec source IP on the logical interface.
  - The VRF can be different than the tunnel VRF.
  - You cannot delete the VLAN or modify its IP address if the IP address is used as the IPsec source IP.
  - The IPsec source IP type DHCP cannot be the same as the global IPsec source IP address or statically configured IP address.
  - After the system imports the DHCP IP address for use by IPsec, you can modify the management VLAN. For example, you can disable DHCP on the management VLAN, change the management VLAN ID, or delete the management VLAN.
  - After you save the configuration, the IP and VRF that the system imported for use by IPsec is saved to the configuration file using `ipsec tunnel-source-ip type dhcp <IP_address> vrf <vrf_name>`. After you reboot the switch, it loads the information from the configuration file and the IPsec tunnel IP address is no longer imported from the management VLAN.

### *Fabric Extend Considerations*

Review the following restrictions, limitations, and behavioral characteristics that are associated with Fabric Extend.

#### **Note**

If your Fabric Extend configuration includes a VSP 4450 Series/ONA combination, see [ONA Considerations](#) on page 965 for more information.

#### **Tunnel Source IP**

Fabric Extend supports the tunnel source IP address using a brouter port interface, a CLIP IP, or a VLAN IP.

The following table shows the product support.

| Product         | Tunnel source IP |               |               |
|-----------------|------------------|---------------|---------------|
|                 | Brouter port     | CLIP IP       | VLAN IP       |
| 5420 Series     | Yes              | Yes           | Yes           |
| 5520 Series     | Yes              | Yes           | Yes           |
| VSP 4450 Series | Yes              | Yes           | Yes           |
| VSP 4900 Series | Yes              | Yes           | Yes           |
| VSP 7200 Series | Yes              | Yes           | Yes           |
| VSP 7400 Series | Yes              | Yes           | Yes           |
| VSP 8200 Series | Yes              | Yes           | Yes           |
| VSP 8400 Series | Yes              | Yes           | Yes           |
| VSP 8600 Series | Not supported    | Not supported | Not supported |
| XA1400 Series   | Yes              | Yes           | Yes           |

### Tunnel Failover Time

With IS-IS interface default values, tunnel failure detection can take up to 27 seconds. You can reduce the IS-IS interface hello timers to speed up logical link failure detection, but be careful to avoid link flapping due to values that are too low.

#### Note

If the number of IS-IS interfaces on a node is greater than 100, it is a good practice to set the hello timer not lower than 5 seconds.

### ACL Filters over VXLAN

IP filters configured to match IP header fields in the headers of VXLAN encapsulated packets, work only when the switch acts as a transit router and does not participate in the initiation or termination of VXLAN traffic.

### VLACP

VLACP is not supported over logical IS-IS interfaces.

### CFM CCM

CFM Continuity Check Messages are not supported over logical IS-IS interfaces.

### CFM traceroute and tracemroute

If CFM packets transit over a layer 3 tunnel (that is the CFM packets ingress a Fabric Extend layer 3 core tunnel and egress through another layer 3 core tunnel), the transit SPBM nodes do not display as intermediate hops in the output for CFM **12 traceroute** and **12 tracemroute**.

This is because the CFM packets are encapsulated in the outer layer 3 header as part of VXLAN encapsulation, and the transit SPBM nodes cannot look into the payload of the VXLAN packet and send a copy of the CFM packet to local CPU for processing.

**CFM L2 Ping**

CFM Layer 2 ping to MCoSPB source mac is not supported and can fail if they are reachable via Fabric Extend tunnel.

**MACsec**

Switch-based MAC Security (MACsec) encryption is Layer 2 so it cannot be used with Fabric Extend IP, which is Layer 3.

**MTU Minimum in Layer 2 Pseudowire Core Networks**

Service provider Layer 2 connections must be at least 1544 bytes. In this type of deployment the tunnels are point-to-point VLAN connections that do not require VXLAN encapsulation. The default MTU value is 1950.

**Logical IS-IS Interfaces**

Layer 2 core and Layer 3 core logical IS-IS interfaces are not supported on the same switch at the same time.

**Fragmentation and Reassembly**

There is no fragmentation and reassembly support in Layer 2 core solutions.

If a tunnel was initially UP between a VSP 4450 Series and another VOSS switch with MTU 1950 and then the VSP 4450 Series was later configured for fragmentation, the following behavior occurs:

- If the ONA MTU is less than 1594, the tunnel to the VOSS switch will go DOWN.
- If the ONA MTU is 1594 and above, the tunnel will stay UP, but any fragmented packets received from the VSP 4450 Series will be lost at the VOSS switch site.

**RFC4963 and RFC4459 Considerations**

The ONA 1101GT provides for the IP MTU of the Network port to be reduced from the default setting of 1950 bytes to 1500 bytes or lower. The MTU reduction feature with Fabric Extend is provided to facilitate the connection of two Fabric Connect networks over an IP network with any MTU without requiring end stations on the networks to reduce their MTU. The ONA 1101GT with the IP MTU of the network port set to 1500 bytes will fragment Fabric Extend VXLAN tunnel packets exceeding 1500 bytes. The ONA 1101GT will also reassemble fragmented Fabric Extend VXLAN tunnel packets at the tunnel termination point. The IP fragmentation and reassembly RFC 791 describes the procedure for IP fragmentation, and transmission and reassembly of datagrams and RFC4963 and RFC4459 detail limitations and network design considerations when using fragmentation to avoid out of order packets and performance degradation.

The following list identifies factors that can impact performance:

- The link speed per VXLAN IP address should be slower than 1G to avoid reassembly context exhaustion.
- ECMP and link aggregation algorithms in the IP core should be configured not to use UDP port hashing that could send IP fragments after the first fragment on different paths causing out of order packets. This is due to the fact that subsequent fragments do not have UDP port information.

**Important**

Different MTU sizes on each end can result in traffic drops.

### Layer 2 Logical IS-IS Interfaces

Layer 2 logical IS-IS interfaces are created using VLANs. Different Layer 2 network Service Providers can share the same VLAN as long as they use different ports or MLT IDs.

#### Note

Exception: Layer 2 logical IS-IS interfaces are not supported on XA1400 Series.

### MTU Minimum in Layer 3 Core Networks

Service provider IP connections must be at least 1594 bytes to establish IS-IS adjacency over FE tunnels. The 1594 bytes includes the actual maximum frame size with MAC-in-MAC and VXLAN headers. If this required MTU size is not available, a log message reports that the IS-IS adjacency was not established. MTU cannot be auto-discovered over an IP tunnel so the tunnel MTU will not be automatically set. The default MTU value is 1950.

If the maximum MTU size has to be fewer than 1594 bytes, then you require fragmentation and reassembly of packets. The XA1400 Series and VSP 4450 Series/ONA combination supports fragmentation and reassembly, but you must have either an XA1400 Series or VSP 4450 Series with ONAs at BOTH ends of the IP WAN connection.

### IP Shortcuts

The tunnel destination IP cannot be reachable through an IP Shortcuts route.

#### Important

If you enable IP Shortcuts and you are using the GRT as the tunnel source VRF, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.

If you enable IP Shortcuts and you are using a VRF as the tunnel source VRF, this is not an issue.

### Layer 3 over Layer 2 Limitation

- The VOSS switches require a single next hop (default gateway) for all tunnels.
  - Over a layer 3 core network, on a given outgoing port or MLT, there is no issue as the one router next hop can support multiple VXLAN tunnels to one or more remote sites.
  - For layer 3 tunneling over a layer 2 core, the VOSS switch without any specific configuration supports only one Fabric Extend tunnel to one remote site. The workaround for this single next hop issue is to create an additional VRF, VLAN, and loopback interface.

For a configuration example of this workaround, see *Shortest Path Bridging (802.1aq) Technical Configuration Guide*.

#### Note

This limitation does not apply to VSP 4450 Series.

- You cannot establish a Virtual IST (vIST) session over a logical IS-IS interface. IST hellos cannot be processed or sent over a logical IS-IS interface if that is the only interface to reach BEBs in vIST pairs.

Assume that vIST is established over a regular NNI interface and the NNI interface goes down. If the vIST pairs are reachable through a logical IS-IS interface, then the vIST session goes down in up to

240 seconds (based on the IST hold down timer). During this time, the error message `IST packets cannot be sent over Fabric Extend tunnels, vist session may go down` is logged.

**Caution**

Expect traffic loss when the vIST session is down or when the error message is being logged.

**Port Mirroring Resources**

Port mirroring resources are limited to four ports simultaneously (where each mirroring direction counts as one). For example, if two mirroring ports are designated to mirror both ingress and egress traffic then all four mirroring ports are consumed.

Port mirroring shares these four resources with other applications such as port mirroring RSPAN, Fabric Extend, Application Telemetry, IPFIX, and ACL with mirror action. Each one of these applications consumes at least one port mirroring resource. (port mirroring RSPAN consumes two if you configure both Ingress and Egress modes.)

**Important**

- To enable any one of the above applications, you must have at least one free mirroring resource. If all four port mirroring resources are already in use, the switch displays a `Resource not available` error message when you try to enable the application.
- The VSP 8600 uses the four reserved resources for port mirroring and ACLs that have a mirroring action. For the other applications, this restriction does not apply because the VSP 8600 uses mirroring resources that do not come out of the four reserved port mirroring resources.

**Fabric Extend over IPsec Limitations**

- Fabric Extend over IPsec is only supported on XA1400 Series devices or on VSP 4900 Series and VSP 7400 Series using Fabric IPsec Gateway.
- Only pre-shared authentication key IPsec parameters are user configurable. Other, third-party solutions are not configurable.
- IKEv2 protocol key exchange only.
- IPsec support is only added for Fabric Extend tunnels.
- IPsec is not supported for regular Layer 3 routed packets.

*ONA Considerations*

Review the following restrictions, limitations, and behavioral characteristics that are associated with the ONA.

**ONA Network port requirements**

The following are **Network** port mandatory requirements for configuring Fabric Extend on the VSP 4450 Series:

- The ONA Network port should not be part of any static/LACP MLT configurations.
- The ONA Network port should be part of a VLAN that belongs to the GRT.

- The ONA Network port that is configured on the switch cannot be tagged. It must be an Access port.

### ONA Device port requirements

The following are **Device** port mandatory requirements for configuring Fabric Extend on the VSP 4450 Series:

- The ONA Device port should not be part of any static/LACP MLT, VLAN, or brouter configurations.
- The ONA Device port should not be configured as an access port. It is automatically configured as a trunk port when the **ip-tunnel-source-address** command is configured.
- The ONA Device port has to be connected directly to the VSP 4450 Series node where the FE tunnels originate.

### Layer 3 and Layer 2 ONA requirements

An ONA is required for Fabric Extend Layer 3 core solutions. An ONA is *not* required in Layer 2 core solutions because the tunnels are point-to-point VLAN connections, not VXLAN. Therefore, there is no need for an ONA to encapsulate a VXLAN header to SPB packets.

### DHCP server

ONAs require access to a local DHCP server to automatically configure IP addresses. Configure an untagged ONA management VLAN to where the ONA is connected with its network side interface. If DHCP is used, a DHCP relay configuration needs to be added to the ONA network side port in order for the ONA to get an IP address assigned from a DHCP server. Alternatively, you can manually configure its IP address and other required settings with the ONA Manual Configuration menu.

### IP tunnel source address

Before the ONA can get an IP tunnel source address from the VSP 4450 Series, the following steps must be taken:

- Connect the Device and Network ports on the ONA to the VSP 4450 Series.
- Make sure that the ONA is connected to a DHCP server. If a DHCP server is unavailable, statically configure an IP tunnel source address on the ONA.
- Create a Management VLAN on the ONA that includes the Network port.
- Designate the Device port for the IP tunnel source address in the configuration file.

The syntax for the IP tunnel source address is: **ip-tunnel-source-address <A.B.C.D> port <slot/port> [mtu <mtu\_value>] [vrf WORD<1-16>]**.

### Automatic routing of VXLAN packets on the VSP 4450 Series

If you configure an IP tunnel source address in a VRF instead of a GRT, then the VSP 4450 Series automatically routes VXLAN packets from the ONA network port into the VRF configured as part of the IP tunnel source. Although the ONA network port is a part of the management VLAN that is in the GRT, for VXLAN encapsulated packets, the VSP 4450 Series automatically routes the packets into the VRF in which the tunnel source IP address is configured. This is done using a filter rule that the VSP 4450 Series software automatically sets up that filters based on whether the incoming port is equal to the ONA network port and the packet has a VXLAN header.

The Management VLAN on the VSP 4450 Series that is used to communicate with the ONA must always be in a GRT and must not be a part of the IP tunnel source VRF.

**Figure 68: Autorouting between GRT and VRF**

### ONA Gateway

The ONA gateway has to be a local IP address on the ONA Management VLAN. The ONA gateway IP address must be the same as the local IP address of the VSP 4000 connected to the ONA.

#### Note

Extreme does not support ONA gateway IP addresses that are not local to the VSP 4450 Series. For example, you cannot use a VRRP IP address configured in a switch cluster for the ONA gateway.

### Maximum MTU

The ONA supports a maximum transmission unit (MTU) size of 1950 bytes. For the VSP 4450 Series to work with a switch that supports Fabric Extend natively, the MTU size must be left at the default setting of 1950. If the core network does not support jumbo frames, the VSP 4450 Series with ONA must be used on all sites.

### Fragmentation and reassembly

If the maximum MTU size has to be fewer than 1594 bytes, then you require fragmentation and reassembly of packets. The VSP 4450 Series with ONAs support fragmentation and reassembly, but you must have VSP 4450 Series switches with ONAs at BOTH ends of the IP WAN connection.

### QoS priority queues

The ONA 1101GT implements both Layer 2 and Layer 3 QoS. Specifically, it implements IEEE 802.1Q VLAN TCI PCP (Priority Code Point) and IETF IPv4 DSCP (Differentiated Services Code Point). These are implemented in hardware with the limitation that there are four Weighted Random Early Detection (WRED) priority queues, numbered 4 (highest) to 7 (lowest). The following tables show the mappings from the PCP and DSCP values in the packet to the priority queue.

The hardware puts each packet in 1 of the 4 HW queues in the following order:

1. If a packet is a tagged VLAN packet, the PCP field determines the priority queue. (Ethertypes 0x8100 and 0x88a8 identify tagged VLAN packets.)
2. If the packet is an IPv4 packet, the DSCP field determines the priority queue.
3. Use the highest priority queue (4).

The HW QoS is always enabled, and the CP to priority queue mappings are static.

The following table defines the 3 bit VLAN PCP value to queue number mapping. The queues are numbered 4..7 with 4 being the highest priority and 7 the lowest priority.

**Table 98: VLAN PCP to queue mapping**

| VLAN PCP | Queue Number |
|----------|--------------|
| 0        | 7            |
| 1        | 7            |
| 2        | 6            |
| 3        | 6            |
| 4        | 5            |
| 5        | 5            |
| 6        | 4            |
| 7        | 4            |

The following table defines the 6 bit IPv4 DSCP value to queue number mapping. The queues are numbered 4..7 with 4 being the highest priority and 7 the lowest.

**Table 99: IPv4 DSCP to queue mapping**

| IPv4 DSCP | VLAN PCP | Queue Number |
|-----------|----------|--------------|
| 0         | 1        | 7            |
| 1         | 1        | 7            |
| 2         | 1        | 7            |
| 3         | 1        | 7            |
| 4         | 1        | 7            |
| 5         | 1        | 7            |
| 6         | 1        | 7            |
| 7         | 1        | 7            |
| 8         | 2        | 6            |
| 9         | 1        | 7            |
| 10        | 2        | 6            |
| 11        | 1        | 7            |
| 12        | 2        | 6            |

**Table 99: IPv4 DSCP to queue mapping (continued)**

| IPv4 DSCP | VLAN PCP | Queue Number |
|-----------|----------|--------------|
| 13        | 1        | 7            |
| 14        | 2        | 6            |
| 15        | 1        | 7            |
| 16        | 3        | 6            |
| 17        | 1        | 7            |
| 18        | 3        | 6            |
| 19        | 1        | 7            |
| 20        | 3        | 6            |
| 21        | 1        | 7            |
| 22        | 3        | 6            |
| 23        | 1        | 7            |
| 24        | 4        | 5            |
| 25        | 1        | 7            |
| 26        | 4        | 5            |
| 27        | 4        | 5            |
| 28        | 4        | 5            |
| 29        | 1        | 7            |
| 30        | 4        | 5            |
| 31        | 1        | 7            |
| 32        | 5        | 5            |
| 33        | 1        | 7            |
| 34        | 5        | 5            |
| 35        | 5        | 5            |
| 36        | 5        | 5            |
| 37        | 1        | 7            |
| 38        | 5        | 5            |
| 39        | 1        | 7            |
| 40        | 6        | 4            |
| 41        | 5        | 5            |
| 42        | 1        | 7            |
| 43        | 1        | 7            |
| 44        | 1        | 7            |
| 45        | 1        | 7            |
| 46        | 6        | 4            |

**Table 99: IPv4 DSCP to queue mapping (continued)**

| IPv4 DSCP | VLAN PCP | Queue Number |
|-----------|----------|--------------|
| 47        | 6        | 4            |
| 48        | 7        | 4            |
| 49        | 1        | 7            |
| 50        | 1        | 7            |
| 51        | 1        | 7            |
| 52        | 1        | 7            |
| 53        | 1        | 7            |
| 54        | 1        | 7            |
| 55        | 1        | 7            |
| 56        | 7        | 4            |

| 60        | 1        | 7            |
| 61        | 1        | 7            |
| 62        | 1        | 7            |
| 63        | 1        | 7            |

## Fabric Attach

**Table 100: Fabric Attach product support**

| Feature              | Product         | Release introduced |
|----------------------|-----------------|--------------------|
| Fabric Attach Server | 5420 Series     | VOSS 8.4           |
|                      | 5520 Series     | VOSS 8.2.5         |
|                      | VSP 4450 Series | VOSS 5.0           |
|                      | VSP 4900 Series | VOSS 8.1           |
|                      | VSP 7200 Series | VOSS 5.0           |
|                      | VSP 7400 Series | VOSS 8.0           |
|                      | VSP 8200 Series | VOSS 5.0           |
|                      | VSP 8400 Series | VOSS 5.0           |
|                      | VSP 8600 Series | VSP 8600 6.3       |
|                      | XA1400 Series   | Not Supported      |

With Fabric Attach, network edge devices that do not support Shortest Path Bridging (SPB), MAC-in-MAC encapsulation (802.1ah) or service identifiers (I-SIDs) can take advantage of SPB infrastructure. To

attach to an SPB network, edge devices signal an SPB-aware FA Server to automatically configure the I-SIDs. The edge devices can then utilize existing SPB features across the fabric and leverage SPB infrastructure capabilities without manual configuration. Fabric Attach uses the IEEE 802.1AB Logical Link Discovery Protocol (LLDP) to signal a desire to join the SPB network.

FA uses the client-server model. An initial handshake occurs between the FA Server and the FA Client. After the discovery phase is complete, the FA Server accepts requests (from FA Clients) to add the C-VID (VLAN ID) and I-SID elements in the SPB network, and also automatically configures the necessary C-VID and I-SID. The FA Server then responds with an acknowledgement of whether the request succeeded. FA Clients can also be aggregated into a proxy device that handles the handshakes and requests on behalf of many clients, to the server. All of the discovery handshakes and I-SID mapping requests are then transferred using LLDP Type, Length, Value (TLV) fields.

FA leverages LLDP to discover directly connected FA peers and to exchange information associated with FA between those peers. Based on the LLDP standard, FA information is transmitted using organizational TLVs within LLDP Protocol Data Units (PDU).

### *FA Zero Touch Client Attachment*

**Table 101: Fabric Attach Zero Touch Client Attachment product support**

| Feature                                    | Product         | Release introduced |
|--------------------------------------------|-----------------|--------------------|
| Fabric Attach Zero Touch Client Attachment | 5420 Series     | VOSS 8.4           |
|                                            | 5520 Series     | VOSS 8.2.5         |
|                                            | VSP 4450 Series | VOSS 6.0           |
|                                            | VSP 4900 Series | VOSS 8.1           |
|                                            | VSP 7200 Series | VOSS 6.0           |
|                                            | VSP 7400 Series | VOSS 8.0           |
|                                            | VSP 8200 Series | VOSS 6.0           |
|                                            | VSP 8400 Series | VOSS 6.0           |
|                                            | VSP 8600 Series | VSP 8600 6.3       |
|                                            | XA1400 Series   | Not Supported      |

FA Zero Touch Client Attachment eases the configuration process on FA-capable devices by automating specific configuration tasks required for FA functionality.

**Note**

Only the base functionality of Zero Touch Client Attachment is supported.

After you initially configure Zero Touch Client Attachment on the FA Server, the settings are exported to receiving FA devices, where the required configuration tasks are automatically performed.

Base Zero Touch Client Attachment operation is tightly coupled with FA operation. Although you can enable or disable Zero Touch Client Attachment separately from FA, the feature is dependant on data that is only available during exchanges between the FA Server and FA Proxies, after a primary FA Server has been selected. By default, base Zero Touch Client Attachment support is enabled.

Base Zero Touch Client Attachment operation, when enabled, extracts management VLAN data from the primary FA Server advertisements and uses this data to update the in-use management VLAN if applicable. An FA Client can also utilize FA-provided management VLAN data after the FA Proxy or Server is discovered.

Zero Touch is active when the following criteria are met:

- On an FA Proxy:
  - Zero Touch Client Attachment is enabled
  - Fabric Attach is enabled
  - A primary FA Server is discovered and selected
- On an FA Server:
  - Zero Touch Client Attachment is enabled
  - FA is enabled
  - FA Proxies or FA Clients are discovered

The switch supports configurable VLANs in the range of 1 to 4059. VLAN 0 is invalid. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs on the switch range from 2 to 4094 but, by default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.

#### Note

You must enable Base Zero Touch **auto-client attach** and define the target Fabric Attach client in order to initiate Zero Touch Client Attachment processing.

FA Signaling generated by an FA Proxy or Server contains management VLAN data. If the management VLAN advertised by the primary FA Server differs from the management VLAN currently configured on the FA Proxy, Zero Touch Client Attachment initiates the following:

- VLAN creation — If the FA Server-specified management VLAN does not exist on the FA Proxy, Zero Touch Client Attachment creates a port-based VLAN.
- Management VLAN update — The created port-based VLAN becomes the designated management VLAN for the FA Proxy. No operations related to the previous management VLAN, such as port membership updates or VLAN deletion, are performed.
- Port VLAN membership update (FA Proxy/Server) — If required, Zero Touch Client Attachment updates the port VLAN membership to ensure that the uplink port through which the primary FA Server is accessed is a member of the management VLAN, for network accessibility.
- Port Default VLAN (PVID) update — The port-based PVID is automatically updated based on the VLAN ID value.

- Port Default Priority update — The default 802.1p user priority for the port is updated based on the specified port priority value of the Zero Touch client (range is 0–7).
- Zero Touch Client Specification removal — All Zero Touch client-related settings are updated based on the FA client discovery. Deleting a Zero Touch client specification or disabling any related Zero Touch option does not result in the immediate removal of any previously applied settings.

**Note**

The FA Proxy does not update the acquired management VLAN if the primary FA Server is lost. This data is updated if the management VLAN advertised by the current primary FA Server changes or if another primary FA Server is selected and new management VLAN data is advertised by the server.

Management VLAN and port membership updates performed by Zero Touch are maintained in non-volatile storage and are restored following a system reset. You must remove or update these configuration settings if they are deemed unnecessary at a later time.

- IP Address Source Mode Update — Updates the IP address source mode of the receiving device to DHCP-When-Needed, to initiate DHCP-based IP address acquisition if necessary.
- Automation of the FA Client Port Mode — Automates the configuration of EAP port modes based on the type of discovered FA Clients. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports.
- ZTC Installation — Initiates ZTC installation on applicable ports on the receiving device. Applies to FA Proxy and, in a limited manner, to FA Server devices. Automated configuration is applied only to FA-enabled ports.
- Auto Trusted FA Client Port Mode — Initiates automatic QoS interface class update based on the type of discovered FA clients. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports.
- Auto PVID FA Client Port Mode — Initiates automatic port PVID, port management VLAN membership and port tagging mode based on the type of discovered FA device. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports. This configuration is incompatible with the automatic FA Client Port Mode and ZTC Automatic attach options.

### *Fabric Attach Components*

FA components dynamically communicate with each other using FA signaling.

**FA Signaling**

FA has defined organizational specific TLVs within the standard LLDP protocol, to exchange messages and data amongst components of an FA solution. The FA TLVs facilitate handshaking and authentication, processing of requests for the creation of services, and providing responses on whether the requests succeeded. In addition, these services are deleted when the service requests are terminated, or when the authentication criteria are no longer valid. All components that participate in FA must be able to send, receive, and interpret the FA TLVs.

**FA Components**

FA includes the following network elements as components:

- FA Server:

An SPB-capable switch at the edge of a Fabric Connect cloud.

An FA Server receives requests from FA Clients or FA Proxies to create services with specific I-SID-to-VLAN bindings. The FA Server completes the association between conventional networks and fabric-based virtual service networks. For more details on the operation of an FA Server, see [Fabric Attach Server](#) on page 974.

- FA Proxy:

A network switch that supports the definition of I-SID-to-VLAN assignments and has the ability to advertise these assignments for possible use by an FA Server. FA Proxy switches also support the client mode for directly attached users or end devices. Typically, FA Proxies support downstream FA Client devices, while being directly connected to an upstream FA Server device.

- FA Client:

A network attached end-point device that advertises I-SID-to-VLAN binding requests for service creation, to an FA Proxy or an FA Server. FA Clients use FA signaling to automatically attach to fabric services.

### *Fabric Attach Server*

#### **FA Server operation**

In an FA solution, the FA Server performs the role of connecting FA Clients and FA Proxies to the SPB fabric, with minimal configuration. As part of the discovery handshake between the FA Server and client or proxy devices, LLDP PDUs are exchanged. Using standard LLDP, the FA Server learns neighbors, that include the proxy and client devices. In addition, the FA Server transmits organizational-specific element-discovery TLVs that are used by the client or proxy device to recognize its attachment to the FA Server.

**Figure 69: Fabric Attach Server connecting client or proxy devices to the Fabric network**

After the initial discovery handshake is complete, the client or proxy device transmits I-SID-to-VLAN assignment mapping requests to the FA Server to join the SPB fabric. These requests include the C-VID (VLAN ID) and the I-SID that the client or proxy device needs to join. The FA Server then creates the requested C-VID and I-SID on its device. It then responds with a PDU (containing the FA-specific TLV) to indicate whether the request succeeded. The I-SID thus created is a ELAN I-SID with endpoints of type Switched UNI. After I-SID creation, the I-SID is also advertised to the SPB network by IS-IS.

The traffic that is sent to or received from the SPB cloud is MAC-in-MAC (MiM) encapsulated. The FA Server, being SPB-capable, decapsulates the MiM traffic. If the I-SID matches the I-SID created on behalf of the client or proxy, the FA Server sends the traffic to that client or proxy and passes it on the C-VID that it expects.

### FA Server configuration

An FA Server can be configured at two levels—global and interface.

Configuration at the global level enables or disables FA on the entire switch. However, for attachment of clients or proxy devices, you must also configure FA at the interface level. Interfaces can be ports (including channelized ports), MLTs, SMLT or LACP MLTs. Enabling FA on an interface also enables transmission of LLDP packets that contain the FA-specific TLVs.

When you disable FA on an interface, LLDP transmission automatically stops on that interface.

#### Caution

Disabling FA or IS-IS triggers a flush of FA information on the switch. Disabling FA at the global level flushes all FA element-discovery information and mappings. Disabling at the interface level flushes element-discovery information and mappings associated with that interface.

#### Important

The only provisioning mode supported on the FA Server is SPB.

### *FA Proxies and FA Clients*

The configuration mode of FA Proxies and FA Clients is not supported. However, in an FA solution, the FA Server interacts with FA Proxies and FA Clients by accepting LLDP PDUs (containing FA TLVs) and using them to automatically create Switched UNI I-SIDs and endpoints, based on the mapping requests contained in those TLVs. For more information, see [FA TLVs](#) on page 975.

### *Fabric Attach operation*

The following sections detail FA operation.

## FA TLVs

FA leverages LLDP to discover directly connected FA peers and to exchange information associated with FA amongst those peers. FA information is transmitted using company-specific proprietary organizational Type, Length, Value (TLV) fields within LLDP Protocol Data Units (PDU). The following section describes the TLVs for FA.

FA uses two TLVs:

- FA Element TLV
- FA Assignment TLV

### FA Element TLV

The FA Element TLV is used by FA elements to advertise Fabric Attach capabilities. This data forms the basis for FA element discovery and is used in the initial handshake between the FA Server and a client or proxy device.

| TLV Type<br>[127] | TLV Length<br>[50 octets] | OUI<br>[00-04-0D] | Subtype<br>[11] | HMAC-SHA<br>Digest | Element<br>Type | State  | Mgmt<br>VLAN | Rsvd    | System ID |

**Table 102: FA Element TLV field descriptions**

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TLV Type        | Indicates whether the discovered element is a client or a proxy device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| OUI and Subtype | The information in these fields is used in LLDP packet handling.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| HMAC-SHA Digest | <p>Data integrity and source validation is supported through the use of the HMAC-SHA256 message authentication. This field supports a digest exchange between the source and destination devices. Symmetric private keys are used for digest generation. The HMAC-SHA256 generated digest size is 32 octets.</p> <p>The HMAC-SHA256 digest is computed starting with the Element Type data, that is, it starts at zero-based byte 38 of the TLV. The digest is then placed in the HMAC-SHA256 Digest field in the TLV prior to transmission. Upon receipt, the digest is again computed and the resulting digest is compared against the received digest. If the received digest is the same as the newly computed digest, the TLV is considered valid and processing commences. If the comparison fails, the TLV is discarded and processing is terminated.</p> <p><b>Caution:</b><br/>If FA communication occurs between non-secure systems, the HMAC-SHA256 Digest data must always be zero. If one system operates in secure mode and the other operates in non-secure mode, the FA Element TLV is discarded before it is processed by the system operating in secure mode.</p> |

**Table 102: FA Element TLV field descriptions (continued)**

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Element Type | <p>Indicates the supported element type. The primary element types are the FA Server, FA Proxy and FA Client.</p> <p>An FA Server is an SPB capable device that accepts externally generated I-SID-to-VLAN assignments. An FA Proxy is a non-SPBM device that supports I-SID-to-VLAN assignment definitions and advertises these assignments for possible use by an FA Server. An FA Client, also a non-SPBM device, advertises I-SID-to-VLAN assignments to a directly connected FA Proxy or an FA Server. Both tagged and untagged FA Client connections are supported.</p> <p>The list of supported element types and their values are:</p> <ul style="list-style-type: none"> <li>• FA Element Type - Other (1)</li> <li>• FA Server (2)</li> <li>• FA Proxy (3)</li> <li>• FA Server No Authentication (4)</li> <li>• FA Proxy No Authentication (5)</li> <li>• FA Client - Wireless Access Point Type 1, which directly attaches to the SPBM network.</li> <li>• FA Client - Wireless Access Point Type 2, which is tunneled to a controller.</li> <li>• FA Client - Switch (8)</li> <li>• FA Client - Router (9)</li> <li>• FA Client - IP Phone (10)</li> <li>• FA Client - IP Camera (11)</li> <li>• FA Client - IP Video (12)</li> <li>• FA Client - Security Device (13)</li> <li>• FA Client - Virtual Switch (14)</li> <li>• FA Client - Server/Endpoint (15)</li> </ul> |
| State        | <p>Indicates the link tagging requirements in FA Client-sourced frames. This field also indicates the current provisioning mode.</p> <p>The Link VLAN Tagging bit (bit 1) has one of the following values:</p> <ul style="list-style-type: none"> <li>• 0 – indicates that all traffic on the link is tagged. In this case, all discovered FA Clients are treated as tagged.</li> <li>• 1 – indicates that traffic on the link is either tagged or untagged. Here, all discovered FA Clients are treated as untagged.</li> </ul> <p>The automatic provisioning mode bits (bits 2 and 3) always have the value 1 for SPB provisioning. The switch only supports the SPB provisioning mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Mgmt VLAN    | <p>When you configure a management VLAN on the FA Server, it is included in this field in FA Server or FA Proxy sourced frames, and is used to support management VLAN auto-configuration on the downstream proxy and client devices.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| System ID    | <p>This field contains connection information that a TLV recipient can use to enforce connectivity restrictions.</p> <p>It contains the system MAC address (6 octets) for MLT configurations and the virtual BMAC address for vIST and SMLT configurations. It also contains information on the connection type such as MLT or SMLT.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Limitations**

- The FA Element TLV exists only once in an LLDP PDU and is included in all PDUs when the FA service is enabled.

- The maximum length of the FA Element TLV is 56 bytes.

#### FA I-SID-to-VLAN Assignment TLV

The FA I-SID-to-VLAN Assignment TLV is used by FA Clients to distribute I-SID-to-VLAN assignments that need to be supported by an FA Proxy or an FA Server.

| TLV Type<br>[127] | TLV Length<br>[41-506 octets] | OUI<br>[00-04-0D] | Subtype<br>[12] | HMAC-SHA Digest | Assignment Status | VLAN    | I-SID    |
|-------------------|-------------------------------|-------------------|-----------------|-----------------|-------------------|---------|----------|
| 7 bits            | 9 bits                        | 3 octets          | 1 octet         | 32 octets       | 4 bits            | 12 bits | 3 octets |

**Figure 71: FA Assignment TLV format**

#### FA I-SID-to-VLAN Assignment TLV fields

Some fields are common to both the FA Element and FA Assignment TLVs. The following fields are specific only to the FA Assignment TLV.

| TLV Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HMAC-SHA Digest   | <p>The HMAC-SHA256 digest is computed for the series 1 to 94 of I-SID-to-VLAN assignments, that is, the data for the digest computation starts at zero-based byte 38 of the TLV. The digest is then placed in the HMAC-SHA256 Digest field in the TLV prior to transmission. Upon receipt, the digest is again computed for the series 1 to 94 of I-SID-to-VLAN assignments in the received TLV and the resulting digest is compared against the received digest. If the received digest is the same as the newly computed digest, the TLV is considered valid and processing can commence. If the comparison fails, the TLV is discarded and processing is terminated.</p> <p><b>Caution:</b><br/>If FA communication occurs between non-secure systems, the HMAC-SHA256 Digest data must always be zero. If one system operates in secure mode and the other operates in non-secure mode, the FA I-SID-to-VLAN Assignment TLV is discarded before it is processed by the system operating in secure mode.</p> |
| Assignment status | Indicates whether the FA Server accepted or rejected the I-SID-to-VLAN mapping request from a client or proxy device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| VLAN              | Indicates the C-VID value advertised by the client or proxy device in the FA I-SID-to-VLAN mapping request.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| I-SID             | <p>Indicates the I-SID that is advertised by a client or proxy device in the FA I-SID-to-VLAN mapping request. This I-SID is used to create a Switched UNI (ELAN) I-SID.</p> <p><b>Note:</b><br/>This I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or Transparent Port UNI.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

#### Limitations

- The FA I-SID-to-VLAN Assignment TLV is included in an LLDP PDU only if the FA Server and proxy or client devices are directly connected to each other.
- This TLV can exist only once in an LLDP PDU.

- The size limit of this TLV is 511 bytes. This limits the maximum number of I-SID-to-VLAN assignments supported in an LLDP PDU to 94.
- For an FA I-SID-to-VLAN Assignment TLV to be processed, the FA Element TLV must also be present in the LLDP PDU.

### FA Element Discovery

The first stage of establishing FA connectivity is element discovery.

On an FA Server, FA is enabled globally by default. However, you must explicitly enable FA on a desired port or MLT interface. After FA is enabled, the FA Server begins transmitting LLDP PDUs that contain the element discovery TLVs. This information is received by FA Client and FA Proxy devices which in turn also transmit their FA capabilities and settings. After the element handshake completes, the FA Server receives I-SID-to-VLAN assignment mappings from the connected client or proxy devices.

An FA Server can communicate with multiple different FA Client and FA Proxy devices.

### FA data processing

In the following FA deployment, a client device (Client 1) attaches to the FA Server (FA Server 1) using a proxy device. Another client device (Client 2) attaches to the FA Server (FA Server 2) at the other edge of the network. The following section describes how data is processed when data traffic is transmitted from Client 1 to Client 2.

When Client 1 successfully attaches to FA Server 1, FA Server 1 creates a unique I-SID-to-VLAN mapping for Client 1 on its device. This mapping contains the I-SID and C-VID advertised by Client 1, using the FA Assignment TLV. For example, assume that Client 1 advertises I-SID 200 and C-VID 250.

Similarly, when Client 2 attaches to FA Server 2, FA Server 2 creates an I-SID-to-VLAN mapping for Client 2 on its device with, for example, I-SID 200 and C-VID 100. This is depicted in the following figure.

**Figure 72: Learning of I-SID-to-VLAN mappings**

When data traffic ingresses FA Server 1 at the FA-enabled port 1/1, it contains the C-VID of Client 1, which is, 250. The data is VLAN-encapsulated at this stage. As traffic egresses FA Server 1 into the SPB cloud, it is encapsulated with the ELAN I-SID created on FA Server 1 on behalf of Client 1, that is I-SID 200. The traffic is now MiM encapsulated with I-SID 200.

The following figure depicts VLAN encapsulation of data traffic from the FA Client to the FA Server (at either end of the SPB cloud) and its MiM encapsulation as it traverses the SPB cloud.

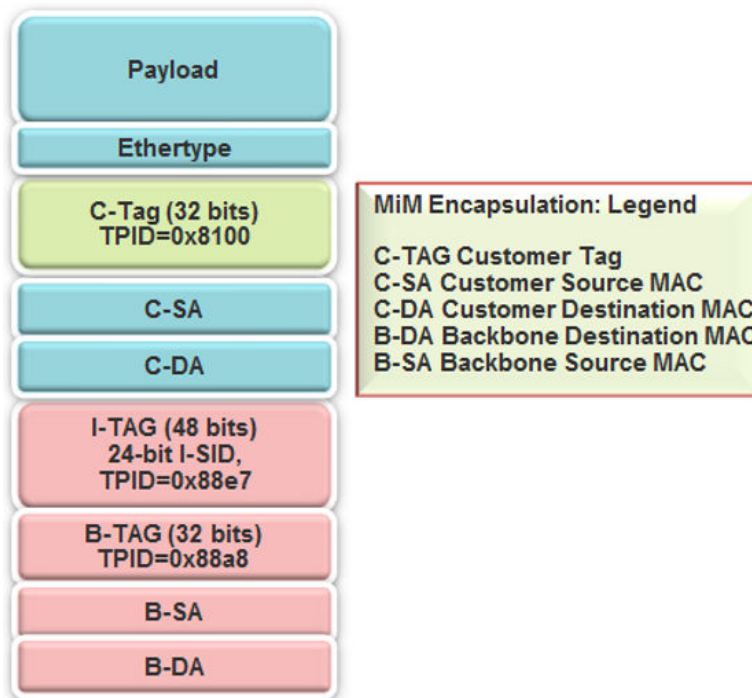

**Figure 73: Data encapsulation – VLAN encapsulation and MiM encapsulation**

As traffic exits the SPB cloud and ingresses the remote FA Server 2, it continues to be MiM encapsulated with I-SID 200.

At FA Server 2, the MiM traffic is decapsulated. Since the I-SID in the data packet matches the I-SID created on its device on behalf of Client 2, FA Server 2 prepares to send traffic to Client 2. At this stage, to successfully transmit the data traffic to Client 2, FA Server 2 must additionally know the C-VID that Client 2 expects traffic on. This information is obtained from the I-SID-to-VLAN mapping on FA Server 2 created on behalf of Client 2, which is C-VID 100. Thus FA Server 2 translates the C-VID in its data packets to this VLAN ID, and then passes it on to Client 2.

The following figure depicts the typical MiM encapsulation of a data packet. The B-DA and B-SA components indicated the system ID of the FA Server running SPB.

**Figure 74: MiM encapsulation**

## FA Server and I-SID-to-VLAN Assignments

FA Client or FA Proxy devices advertise I-SID-to-VLAN assignments to be supported on the FA Server. These assignments can be accepted or rejected by the FA Server. All communication between FA Proxies or Clients and the FA Server is using LLDP. Successful assignments result in the creation of a Switched UNI I-SIDs and endpoints based on the mapping requests.

The FA Server rejects I-SID-to-VLAN assignment requests if:

- FA is not configured properly on the port or MLT.
- Router IS-IS is disabled.

### Note

For Fabric Attach to operate properly and for the FA Server to accept I-SID-to-VLAN assignment requests, IS-IS must be enabled.

The following error message is logged immediately after IS-IS is disabled, and displays the error message only once in the log file. The system does not display it again when an assignment request is made from the FA Proxy.

```
CP1 [12/04/15 00:33:49.733:UTC] 0x00374589 00000000
GlobalRouter FA INFO Fabric Attach Assignments will be rejected
since ISIS is disabled.
```

- The C-VID and I-SID are not within the supported range.

Different hardware platforms support different customer C-VID ranges. The value 4095 is not supported. The value 4096 indicates that the port is untagged. An I-SID value of 0 is not supported on the FA Server.

- The I-SID is already assigned to an IP VPN.

The system displays the error message `I-SID is already assigned to an IPVPN`.

- The I-SID is already in use for SPB multicast.

The system displays the error message `SPB Multicast is enabled, ISID 16000000 and greater reserved for dynamic data-isid's used to carry Multicast traffic over SPB`.

- The I-SID has a value that is reserved for internal use.
- The I-SID cannot be used in an IS-IS accept policy.
- The I-SID is associated with a platform VLAN and that VLAN is used as a private VLAN (that is, has a secondary VLAN specified).
- The I-SID is already in use for Transparent Port UNI.
- The port that receives the I-SID-to-VLAN assignment is a member of an MLT, but FA is not successfully enabled on that MLT interface.
- There is a resource error on the FA Server system, such as lack of memory.
- The number of I-SID-to-VLAN assignments on a port exceeds the maximum limit which is 94.
- The number of I-SIDs on the switch exceeds the maximum limit.
- The same endpoint is configured on more than one I-SID.
- The port or MLT is associated with more than one C-VID in the same I-SID.

When the FA Server rejects I-SID-to-VLAN assignments, aside from viewing the log file, you can use trace to troubleshoot the cause of rejection.

For an example on troubleshooting rejection of I-SID-to-VLAN assignments on the FA Server and for more information on using trace, see [Troubleshooting Fabric Attach](#) on page 3659.

## FA management

You can configure a management I-SID on an FA-enabled port or MLT. This I-SID includes an optional C-VID parameter, which is a VLAN ID that is locally significant to the port or MLT and does **not** represent a platform VLAN.

Depending on whether the C-VID value is specified, the behavior is as follows:

- If the C-VID value is specified, the FA Server transmits this VLAN ID as the management VLAN in the FA Element TLV. A client or proxy receiving this TLV uses this VLAN ID for management traffic on the FA Server uplink.

Different hardware platforms support different customer C-VID ranges.

- If the C-VID value is not specified, the FA Server transmits a management VLAN with a VLAN ID value of 4095 in the FA Element TLV. A client or proxy receiving this TLV uses **untagged** traffic for network management on the FA Server uplink.

If you do not configure a management I-SID, the FA Server transmits a management VLAN ID value of 0 in the FA Element TLV. A client/proxy that receives the FA Element TLV retains the initial management configuration (if any) on its device.

Limitations of FA management I-SIDs

- A management I-SID value of 0 is not supported on the FA Server.
- You cannot enable BPDU on a management I-SID.

FA management configuration considerations

A Switched UNI I-SID that is created when an FA assignment is learned on a port or MLT, is uniquely identified by a tuple comprising of one of the combinations of (port, I-SID and C-VID) or (MLT ID, I-SID and C-VID). When you configure FA management, similar tuples are used. You can configure FA management on an FA-enabled port or MLT on which FA assignment mappings are learned, as long as the FA management tuple exactly matches the tuple created by the learned FA mapping.

The following scenarios describe the behavior when you configure FA management on a port or MLT that also receives learned FA mappings, but the tuples do not match.

- **Scenario 1:** You attempt to configure FA management on a port or MLT where an FA assignment mapping is already learned.

For example, consider an FA-enabled port 1/1 on which an assignment mapping is learned, with I-SID 100 and C-VID 20. You can configure FA management on port 1/1 as long as the I-SID and C-VID values exactly match that of the learned FA mapping. However, if you attempt to configure FA management on the port with a different I-SID and C-VID value, the configuration is not successful and an error message displays.

- **Scenario 2:** An FA assignment mapping is learned on a port or MLT that already has FA management configured.

For example, consider that FA management is configured on port 1/1. If an FA assignment mapping is learned on the port with the same I-SID and C-VID values as that of the FA management configuration, then the mapping is accepted. Otherwise the mapping is rejected.

### FA message authentication and integrity protection

For the security of FA communication in terms of data integrity and authenticity, a keyed-hash message authentication code can be transmitted within every FA TLV.

It protects the I-SID-to-VLAN assignment exchanges between the FA Server and FA Proxy. The standard HMAC-SHA256 algorithm calculates the message authentication code (digest) involving a cryptographic hash function (SHA-256) in combination with a shared secret key. The key is symmetric, that is, it is known by both the source and destination parties.

By default, on the FA Server, message authentication is enabled at the interface level and a default key is defined to provide secure communication.

You can configure a different authentication key on an interface (port or MLT) on the FA Server, to authenticate a client on that interface. The authentication key is stored in encrypted form when you save configuration on the FA Server. For an FA Client to authenticate and attach to the FA Server, the authentication key must match on both the client and the server. In general, the FA authentication key must match between two FA components exchanging FA TLVs through LLDP.

When you enable FA message authentication, the message authentication key (default or configured) generates a Hash-based Message Authentication Code (HMAC) digest that is included in FA I-SID-to-VLAN Assignment TLV. Upon receipt, the HMAC digest is recomputed for the TLV data and compared against the digest included in the TLV. If the digests are the same, the data is valid. If the digests are not the same, the data is considered invalid and is ignored.

The FA secure communication setting (enabled/disabled) and the symmetric key data are maintained across resets and restored during FA initialization.

### *Fabric Attach and Switched UNI*

With the C-VLAN UNI feature, I-SID-to-VLAN mappings must be unique across the network. With the Transparent Port UNI (ELAN Transparent) feature, you can map an entire port or MLT to an I-SID.

With the Switched UNI feature, you can associate many different C-VID/port or C-VID/MLT list combinations to a single I-SID.

### Switched UNI and FA

FA brings the capability of automatically creating Switched UNI I-SIDs on a switch, without manual intervention. The I-SIDs thus created are ELAN I-SIDs with endpoints of type Switched UNI, and are by default for Layer 2. MAC learning takes place and there is an any-to-any relationship. For Layer 3 participation, you must configure a platform VLAN with the same I-SID value as that of the I-SID in a learned FA mapping.

#### Note

The number of Switched UNI I-SIDs created are different for different product families. For more information, see [VOSS Release Notes](#).

### Limitations of FA-created Switched UNI I-SIDs

- An FA-created Switched UNI I-SID is always ELAN.
- You cannot enable BPDU on an FA-created Switched UNI I-SID.
- The ELAN I-SIDs created are by default for Layer 2. For Layer 3 participation, you must manually configure a platform VLAN with the same I-SID value as that of the I-SID in a learned FA mapping. You can configure the platform VLAN with the same VLAN ID as that of the C-VID, or use a different value.
- The Switched UNI (ELAN) I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or a T-UNI.
- You cannot change from one UNI type to another dynamically. The I-SID must be deleted and created with the new UNI type (Customer VLAN (C-VLAN), Transparent Port user-network-interface (T-UNI), ELAN).
- If the port is a member of an MLT, you must add the entire MLT to the C-VID.
- The port is always in the forwarding state.
- You cannot associate a port or MLT with more than one C-VID in the same I-SID.
- The same C-VID, port or MLT cannot be a member of more than one I-SID. Different hardware platforms support different customer C-VID ranges. The value 4095 is not supported and cannot be configured. The value 4096 indicates that the port is untagged.
- An I-SID value of 0 is not supported on the FA Server.

### *Fabric Attach Deployment Scenarios*

Fabric Attach is typically deployed in the access layer(s) of a Fabric Connect network.

Fabric Attach, when used with a Fabric Connect solution, provides the same capabilities at the access layer, but those services and policies are now mapped across the entire network end-to-end. FA makes user and end device attachment simple and creates network configuration and sets up resources only when needed.

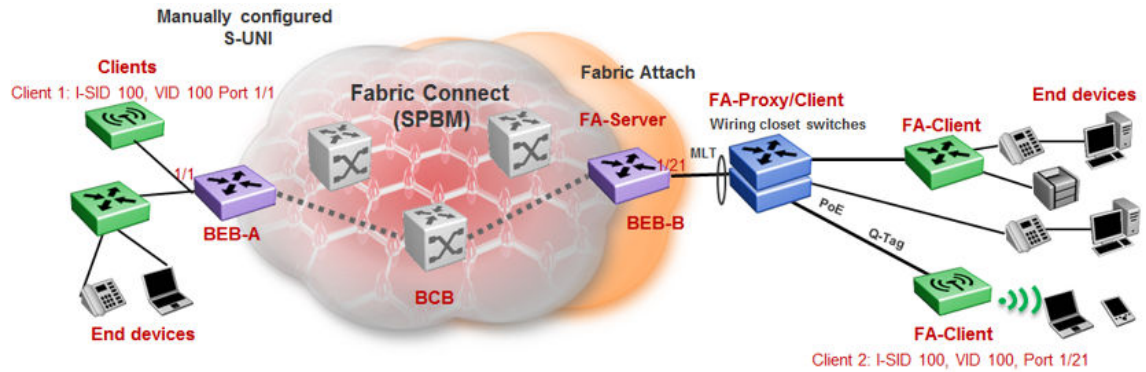

An FA Server can be connected to FA Client or FA Proxy devices on three types of interfaces, namely, a port, MLT or an SMLT. The following sections discuss FA in SMLT and non-SMLT deployments.

### **FA and Switched UNI in non-SMLT deployments**

The following deployment shows an SPBM network in which one edge has manually configured Switched UNI I-SIDs and the other edge has Fabric Attach (FA). At the FA edge, the I-SIDs are learned using FA TLVs and are automatically created on the FA Server as ELAN I-SIDs with Switched UNI endpoints.

This deployment demonstrates that the FA-created I-SIDs can communicate with any other I-SID (manually created Switched UNI or a C-VLAN with an I-SID), on the local switch or across the SPBM fabric, as long as the I-SID values are the same.

BEB-B is a switch acting as the FA Server with an NNI interface to the SPBM cloud. FA Client and FA Proxy devices send I-SID-to-VLAN mapping requests to the FA Server on the respective FA-enabled ports, using LLDP TLVs. This enables the I-SID endpoints to communicate with the SPB cloud.

If several clients are aggregated in an MLT, at least one of the ports must send the mapping requests for the FA Server to create the I-SID endpoints for that MLT. For example, let Client 2 be a wireless FA Client (such as a WLAN 9100 AP device) on port 1/21, that sends an FA mapping request for I-SID 100 and C-VID (VLAN ID) 100. The FA Server (BEB-B) creates the requested I-SID 100 on its device, and advertises it to the SPB cloud.

BEB-A has manually configured Switched UNI endpoints, one of which is Client 1 (connected at port 1/1) using the same I-SID value 100.

With this setup, data traffic can freely flow between Client 1 and Client 2 through the two BEBs and the BCB.

Thus the Switched UNI I-SIDs learned using FA TLVs on one edge of the Fabric Connect (SPBM) network can communicate with the manually created I-SIDs on the other edge, as long as they both have the same value.

### FA and Switched UNI in SMLT deployments

The following examples discuss FA in dual-homed and single-homed SMLT deployments.

#### Fabric Attach in a dual-homed SMLT deployment

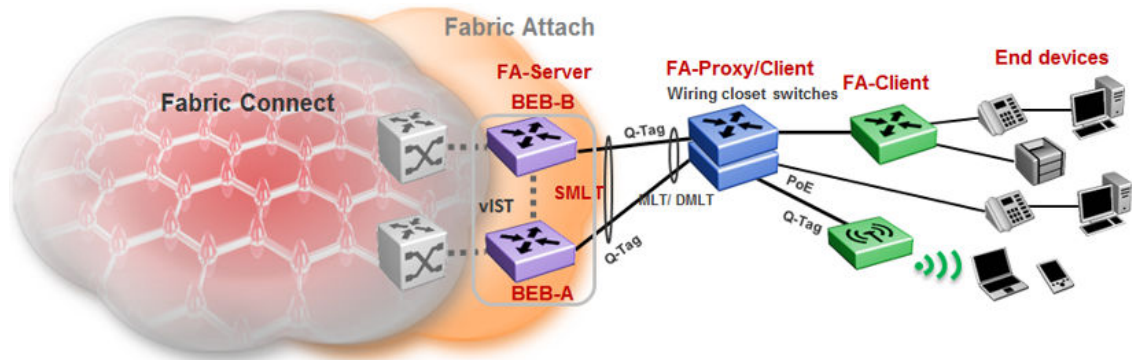

The following section describes FA in a dual-homed SMLT deployment. A pair of switches that operate as IST peers act as the FA Server. An FA Proxy (typically a wiring closet switch or an access switch) is connected to FA Clients and in turn to end devices. The FA Clients or FA Proxies advertise I-SID-to-VLAN mappings namely the interface C-VID and the I-SID to the FA Server switches. Both switches receive the mapping information using LLDP TLVs. The switch that learns the mapping first from the LLDP TLV considers the I-SID endpoint to be discovered locally, and creates the I-SID on its device. It then sends the mapping information to its peer switch. When the peer switch receives the mapping

across IST in a new SMLT message, it too creates the I-SID and endpoint on its device. This I-SID however, is considered to be discovered remotely, because the data was synchronized from its peer.

#### Note

- For the peer switches acting as the FA Server to transmit the same FA System ID (based on the virtual MAC), SMLT configuration must be the same on both peers.
- For successful FA operation, configuration of FA message authentication and the authentication key must be the same on both peers.
- For successful operation in Layer 3, a platform VLAN must be configured on both peers. This is necessary for proper MAC learning.

**Figure 75: FA in a dual-homed SMLT deployment**

In the above example deployment, BEB-A and BEB-B are IST peers collectively acting as the FA Server. FA TLVs sent from the clients (through the proxy) are learned on FA-enabled ports on BEB-A and BEB-B. When BEB-A learns the mapping for the first time on its port, it creates an I-SID on its device. This is considered locally discovered. In addition, it sends an SMLT message to its peer BEB-B, which also creates the I-SID on its device. This time, the I-SID is considered remotely discovered. Similarly, if BEB-B receives a mapping from a client for the first time, it creates an I-SID (locally discovered) and also sends an IST message to its peer to create an I-SID (remotely discovered).

Irrespective of whether the I-SID creation on the FA peers is triggered by a local TLV event or by messaging from the IST peer, they can both receive data traffic. Thus in a dual-homed SMLT deployment, any I-SID can be learned irrespective of whether it is discovered locally, discovered remotely or both.

#### Note

- On the IST peers, if an FA TLV is learned on a port or normal MLT (instead of the admin SMLT), only the I-SID is sent to the peer switch.

### Fabric Attach in a single-homed SMLT deployment

In the single-homed SMLT, as shown in the following deployment, the FA Server creates either a locally discovered I-SID (if received from a client using FA TLVs) or a remotely discovered I-SID (if synchronized from its IST peer), but not both.

**Figure 76: Fabric Attach in a single-homed SMLT deployment**

### *Fabric Attach Considerations*

Review the following restrictions, limitations, and behavioral characteristics for Fabric Attach.

- IS-IS and FA must be globally enabled on the FA Server, for FA to operate successfully.
- Static MAC, Static ARP and configuration of a static IGMP group are not supported on FA-enabled ports.
- An FA port cannot be a BROUTER port.
- You cannot enable FA on an existing Transparent Port UNI or a C-VLAN UNI port.
- On VSP 8600 Series, you also cannot enable FA on an existing Switched UNI.
- FA I-SID-to-VLAN assignment mapping requests from a client or proxy device can be accepted or rejected by the FA Server.
- On an FA-enabled port or MLT, you must first disable LACP before you change the LACP key.
- You can only enable VLACP on an FA enabled MLT; VLACP is not supported on FA enabled non-MLT ports.
- On VLACP enabled ports, FA and LLDP signaling run independent of the VLACP state. Therefore, requests and responses are exchanged between the FA Server and client or proxy devices even if VLACP is operationally down. However, forwarding of data traffic is dependent on VLACP being operationally up on the port.

For example, if VLACP is enabled on the FA Server side of the link but not on the proxy or the client side, the FA Server learns the I-SID-to-VLAN assignment mappings and creates the required I-SIDs on its device. However, data traffic is not forwarded on the port until VLACP is operationally up.

- On VSP 4450 Series, you cannot use a port designated as a Fabric Extend tunnel source, configured using the command **ip-tunnel-source-address**, for Fabric Attach.
- FA uses the virtual MAC to create the FA system ID when the FA is on an SMLT. If you delete the SPBM instance, then this information is no longer available. Therefore, you must delete the FA on SMLT before deleting the SPBM instance.

- You cannot enable FA and Endpoint Tracking simultaneously on the same interface.
- On VSP 8600 Series, dynamically learned Fabric Attach announced VLAN:ISID bindings and manually configured Switched-UNI end-points are not supported on the same interface.

## Endpoint Tracking

**Table 103: Endpoint Tracking product support**

| Feature           | Product         | Release introduced |
|-------------------|-----------------|--------------------|
| Endpoint Tracking | 5420 Series     | Not supported      |
|                   | 5520 Series     | VOSS 8.2.5         |
|                   | VSP 4450 Series | Not Supported      |
|                   | VSP 4900 Series | Not Supported      |
|                   | VSP 7200 Series | VOSS 8.1.1         |
|                   | VSP 7400 Series | VOSS 8.1.1         |
|                   | VSP 8200 Series | VOSS 8.1.1         |
|                   | VSP 8400 Series | VOSS 8.1.1         |
|                   | VSP 8600 Series | Not Supported      |
|                   | XA1400 Series   | Not Supported      |

### *Endpoint Tracking Overview*

Endpoint Tracking provides dynamic assignment of virtual machines (VMs) to IP subnets as they attach to a Shortest Path Bridging (SPB) cloud. Deployment scenarios include VMs connecting to DvR Leaf nodes, or regular SPBM deployments.

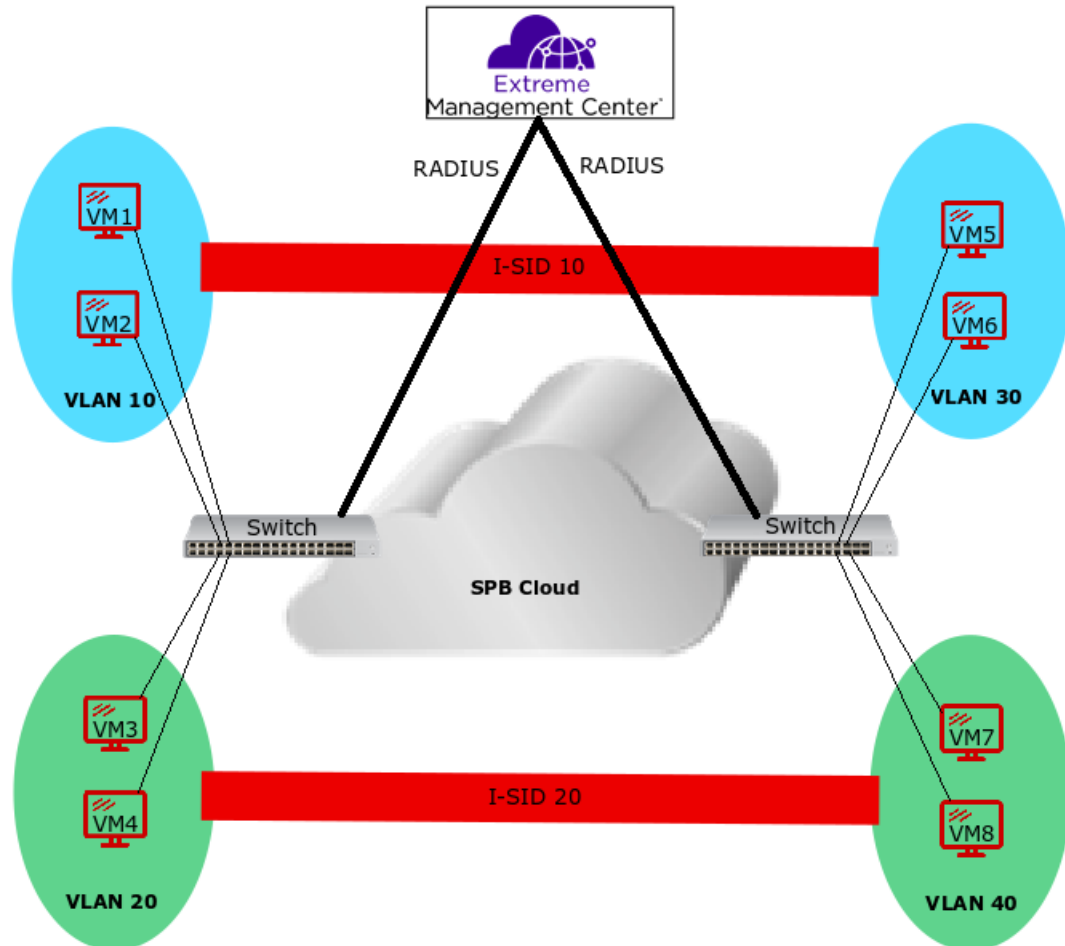

Extreme Management Center or ExtremeCloud IQ - Site Engine is integral to the Endpoint Tracking solution. Extreme Management Center or ExtremeCloud IQ - Site Engine delivers automation; there is no need to manually configure server VLANs on data center access switches. Additionally, Extreme Management Center or ExtremeCloud IQ - Site Engine) provides the ability to see what VM MACs exist, and where they are located.

Extreme Management Center or ExtremeCloud IQ - Site Engine's ExtremeConnect module integrates with third-party virtualization software (such as VMware or Microsoft HyperV) and communicates with the ExtremeControl module to automatically extract all of the VM MACs (including VLAN assignment for each MAC) and then automatically create all of the necessary authentication profiles, rules and mappings.

When the switch detects a new VM on a port, it sends a RADIUS request to Extreme Management Center or ExtremeCloud IQ - Site Engine. ExtremeConnect checks with VCenter for the Port Group, VLAN ID, and I-SID information that corresponds with the VM, communicates with the ExtremeControl module for the RADIUS authentication, and sends the RADIUS response back to the switch with the VLAN:ISID binding information. Based on the binding, the switch then automatically creates a dynamic Switched UNI (S-UNI). Dynamic S-UNIs are not saved into the configuration file.

### Typical Endpoint Tracking Implementation Example

The following example shows a typical implementation of Endpoint Tracking and the dynamic I-SID assignment process, as provisioned in Extreme Management Center or ExtremeCloud IQ - Site Engine.

**Figure 77: Endpoint Tracking Example**

The sequence within and among the four example VLANs in this configuration is as follows:

1. The RADIUS server authenticates VM1, and the switch automatically creates a Switched UNI with VLAN 10 and I-SID 10 binding, (using the outbound attributes received from the RADIUS server). Subsequently, the server authenticates VM2, which uses the same Switched UNI.
2. Similarly, on the other side of the SPB cloud, the RADIUS server authenticates VM5 and the switch automatically creates a Switched UNI with VLAN 30 and I-SID 10 binding, (using the outbound attributes received from the RADIUS server). Subsequently, the server authenticates VM6, which uses the same Switched UNI.
3. The same sequence occurs for VMs 3 and 4, and PCs 7 and 8, with the first authentication in each VLAN providing the outbound RADIUS attributes needed for the creation of a Switched UNI for that VLAN.
4. The final result is that VMs 1, 2, 5, and 6 can access each other on I-SID 10, and VMs 3, 4, 7, and 8 can access each other on I-SID 20.

### *Static S-UNIs and Visibility Mode*

Endpoint Tracking can also be used in cases where static S-UNIs are configured on Endpoint Tracking-enabled ports. In this case, the MACs are allowed by default on the static S-UNI. However, by default, the MACs learned on a static S-UNI are not learned at the Endpoint Tracking level. Endpoint Tracking Visibility Mode allows tracking of MACs that are learned on static S-UNIs. This implies that a binding is created for these MACs, but these bindings do not create dynamic S-UNIs, they are used for tracking purposes only.

### *Interface Support*

Endpoint Tracking is supported on Ethernet ports, MLTs, and SMLTs.

If the switch is a Virtual IST (vIST) peer, the dynamic Switched UNI is synchronized to its vIST peer as follows:

- If the MAC is learned on an SMLT UNI interface, all Switched UNI information is synchronized to the vIST peer.
- If the MAC is learned on a non-SMLT UNI interface, only the I-SID is synchronized to the vIST peer.

### *VM Moves and VLAN:ISID Bindings*

When a VM moves to a new switch within a network (with no change to the VLAN segment), the new switch triggers a new RADIUS authentication, which points that VM MAC to the new switch, and new bindings are applied on the new switch. The old switch detects that the VM MAC is moved and automatically deletes the old binding, if the old binding has not already aged out.

However, if a VM remains attached to the same (previously authenticated) switch, but the VLAN segment is changed, you must push a reauthentication request from Extreme Management Center or ExtremeCloud IQ - Site Engine to force the required binding updates. For more information about managing binding updates using RADIUS Change-of-Authorization (CoA) functionality, see [Extreme Management Center or ExtremeCloud IQ - Site Engine Integration](#) on page 990.

### *Operational Considerations*

Consider the following when implementing Endpoint Tracking:

- A RADIUS server used for Endpoint Tracking provides authorization only; no accounting processes are supported. Although accounting is enabled by default for all RADIUS servers, it is not currently supported for use with Endpoint Tracking, even if left enabled.
- Fabric Attach is not supported on ports or MLT/SMLTs that have Endpoint Tracking enabled.

### *Extreme Management Center or ExtremeCloud IQ - Site Engine Integration*

Endpoint Tracking integrates with Extreme Management Center or ExtremeCloud IQ - Site Engine ExtremeConnect and ExtremeControl modules. The ExtremeConnect module offers API integration with third party products, such as VMware or Microsoft HyperV, from which VM endpoint information is extracted and automatically converted into usable policies for use in the ExtremeControl module, which acts as a RADIUS server for authorizing Endpoint Tracking MACs.

The following diagram illustrates an example of Extreme Management Center or ExtremeCloud IQ - Site Engine interaction with a switch for Endpoint Tracking:

**Figure 78: Extreme Management Center or ExtremeCloud IQ - Site Engine Endpoint Tracking Interaction Example**

### RADIUS Server Attributes

The RADIUS attributes to configure in either standard or custom Extreme Management Center or ExtremeCloud IQ - Site Engine RADIUS profiles for Endpoint Tracking depend on your deployment and traffic type:

- For tagged traffic, if the RADIUS server provides both the VLAN ID and I-SID value, use only the **FA-VLAN-ISID** attribute.
- For tagged traffic, if the RADIUS server provides only the VLAN ID (and you are therefore using an I-SID offset value), use only the **Tunnel-Private-Group-ID** attribute.
- For untagged traffic, if the RADIUS server provides both the VLAN ID and I-SID value, use the **FA-VLAN-ISID** and **Egress-VLANID** or **Egress-VLAN-name** attributes.
- For untagged traffic, if the RADIUS server provides only the VLAN ID (and you are therefore using an I-SID offset value), use the **Tunnel-Private-Group-ID** and **Egress-VLANID** or **Egress-VLAN-name** attributes.
- Use the **Session-Timeout** attribute to override the default timeout period of 24 hours, which is amount of time, in seconds, between a MAC address authentication and the deletion of that MAC address from the Endpoint Tracking binding table.

All other RADIUS attributes are ignored.

### Managing Binding Updates using RADIUS Change-of-Authorization

Endpoint Tracking uses RADIUS RFC 5176 Change-of-Authorization (CoA) functionality to enable forced VLAN:ISID binding updates.

For example, when a VLAN segment is changed on a VM that resides on a previously authenticated switch, that VM requires a new VLAN:ISID binding to reflect the new VLAN segment. Because the switch has previously been authenticated, you must force a new authentication request to update the binding information.

Using ExtremeControl, you can manually push a reauthentication request for the VM MAC. This action sends a disconnect-request from the RADIUS server to the switch, which deletes the old binding. When the switch detects the VM again, a new RADIUS authentication request is sent from the switch to the RADIUS server, resulting in updated binding information upon successful authentication.

For more information about RADIUS Dynamic Session Change Support (RFC 5176), see [RFC 5176 – Dynamic Session Change](#) on page 2706.

Deployment Examples

Endpoint Tracking deployment scenarios include Distributed Virtual Routing (DvR) deployments, or regular SPBM deployments.

The following example illustrates a DvR deployment:

**Figure 79: DvR Topology Example**

The following example illustrates a regular SPBM deployment:

**Figure 80: SPBM Cloud Example**

### Configuration Fundamentals

#### Extreme Management Center or ExtremeCloud IQ - Site Engine Configuration

To configure Endpoint Tracking, you must perform the following:

- Using the ExtremeConnect component, configure and manage your third-party virtualization platform.
- Using the ExtremeControl component, configure and manage the RADIUS server used for Endpoint Tracking authentication.

For information about configuring Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.

#### Switch Configuration

To configure Endpoint Tracking, you must perform the following:

- Add, configure, and enable the RADIUS server host as configured in the Extreme Management Center or ExtremeCloud IQ - Site Engine to function as the switch authentication server for Endpoint Tracking. Ensure that you select **endpoint-tracking** for the **used-by** variable. Add, configure

and enable the RADIUS dynamic-server client. For information about adding a RADIUS server host and a RADIUS dynamic-server client to the switch, see [RADIUS](#) on page 2697.

- Optionally configure a global I-SID offset value.

When you provision the Endpoint Tracking RADIUS server in Extreme Management Center or ExtremeCloud IQ - Site Engine, you choose which outbound attributes the RADIUS server includes in each authentication response. If you always include an I-SID value in those outbound attributes, you do not need to configure an I-SID offset value on the switch.

For MACs that do not receive an I-SID attribute from the RADIUS server, use Auto-ISID-Offset functionality. The configured I-SID offset value is used to calculate an I-SID value for a switched UNI when no I-SID value is provided by the RADIUS server in the outbound attributes. In that case, the I-SID value is calculated as follows:

$I-SID = \text{VLAN ID} + \text{configured I-SID offset value}$ .

- After optionally configuring a global I-SID offset value, enable Endpoint Tracking globally on the switch.
- Create and enable Endpoint Tracking on each interface. Ensure that you have deleted any existing VLAN bindings on the interfaces, as the Endpoint Tracking bindings are dynamic.

CLI commands provide the functionality to separate the creation, deletion, enabling, and disabling of Endpoint Tracking on interfaces. For example, if you want to flush all VLAN:ISID bindings on a port, you can disable (but not delete) Endpoint Tracking on that port, keeping the port distinct from other ports where Endpoint Tracking is not yet created.

## Multi-area SPB

**Table 104: Multi-area SPB**

| Feature                      | Product         | Release introduced |
|------------------------------|-----------------|--------------------|
| Multi-area SPB Boundary Node | 5420 Series     | Not Supported      |
|                              | 5520 Series     | Not Supported      |
|                              | VSP 4450 Series | Not Supported      |
|                              | VSP 4900 Series | Not Supported      |
|                              | VSP 7200 Series | Not Supported      |
|                              | VSP 7400 Series | VOSS 8.4           |
|                              | VSP 8200 Series | Not Supported      |
|                              | VSP 8400 Series | Not Supported      |
|                              | VSP 8600 Series | Not Supported      |
|                              | XA1400 Series   | Not Supported      |

The Multi-area SPB feature enables building a scalable Shortest Path Bridging (SPB) network, consisting of multiple Intermediate System-to-Intermediate System (IS-IS) areas that connect to each other through the boundary nodes. The Multi-area SPB feature provides flexible network design through which you can group the nodes in the areas on a need basis.

Each area in the Multi-area SPB network contains the interior nodes and the boundary nodes.

**Figure 81: Boundary nodes in the Multi-area SPB network**

Each boundary node runs two Intermediate-System-to-Intermediate-System (IS-IS) instances, representing the home area and the remote area. Each IS-IS instance runs the Shortest Path First (SPF) computation and uses its own Link State Database (LSDB). The boundary nodes support Backbone Edge Bridge (BEB) functionality in addition to the Backbone Control Bridge (BCB) configuration and the UNIs belong only to the home area. You can configure IS-IS interfaces on each instance.

**Note**

The boundary nodes do not support Auto-sense, you must manually configure all network-to-network interfaces (NNI) on the boundary nodes.

The multiple areas in the Multi-area SPB network connect in various patterns, for example, the hub and spoke topology and the daisy chain topology.

*Designated and Non-designated Boundary Nodes*

Among the boundary nodes in the Multi-area SPB network, the system elects the designated boundary node on basis of the unique chassis MAC value of the node. The nodes in the SPB area advertise their chassis MAC value using the link state packet (LSP) and the system elects the node with the smallest chassis MAC value as the designated boundary node. Each node in the network detects the designated boundary node on basis of the LSDB information.

The functions of the boundary nodes in the Multi-area SPB network are:

- Designated boundary node:
  - Creates the area virtual node LSPs on each IS-IS instance.
  - Configures the virtual node's adjacency with the other boundary node on basis of the reachability of the node.

- Advertises the services on the area virtual node on basis of the redistribution policies that you configure.
- Non-designated boundary node:
  - Connects to the area virtual node and the system uses it to forward the traffic on basis of the IS-IS computation.
  - Takes over as the designated boundary node if the designated boundary node is no longer available in any area.

For more information about the area virtual node, see [Area Virtual Node](#) on page 996.

#### Minimum Requirements

The minimum requirements for the Multi-area SPB to function are:

- Two boundary nodes to provide redundancy.
- Multi-area SPB redistribution policies between areas, like layer 2 redistribution, layer 3 unicast redistribution, multicast redistribution, Distributed Virtual Routing (DvR) backbone redistribution and so on. For more information, see [Multi-area SPB Redistribution and Policies](#) on page 997.

#### Area Virtual Node

The designated boundary node in the Multi-area SPB network creates the area virtual node. The area virtual node sums up an entire network topology in a single virtual node representing all the services from the represented area.

**Figure 82: Representation of area virtual node**

When considering the shortest path between two nodes in different areas in the Multi-area SPB network, the area virtual node logically connects the shortest path within one area to the shortest path within another area. The area virtual nodes help the Multi-area SPB network to visualize any external area as a single IS-IS entity.

The boundary nodes in the Multi-area SPB network exposes one virtual node in each of two connected areas, to represent a collection of nodes from the other area. On the basis of the policies that you configure on the boundary nodes, you can control the services that the system exports from a home area to the remote area as the system includes the configuration in the Link State Packets (LSP) of the corresponding area virtual node.

You can configure the area virtual node parameters on both home and remote IS-IS instances. For more information about configuring the area virtual node, see [Configure IS-IS Multi-area SPB Virtual Node](#) on page 1102.

### *Remote IS-IS Instance*

The Multi-area SPB feature introduces the remote Intermediate-System-to-Intermediate-System (IS-IS) instance. You can configure the manual area, system ID, nickname, and area virtual node parameters on the remote IS-IS instance. When enabling Remote IS-IS Instance, make sure that the physical node nickname, virtual node nickname and system ID are different. To configure the remote IS-IS instance on the switch, you must:

- Configure manual area and nickname manually on the switch.
- Enable IS-IS and remote IS-IS instances on the switch, globally.
- Configure Shortest Path Bridging MAC (SPBM) instance on both home and remote IS-IS instances.
- Configure Backbone-VLANs (B-VLANs) globally on both home and remote instances.

For more information, see [Enable Remote IS-IS Router Configuration Globally](#) on page 1110.

### *Multi-area SPB Redistribution and Policies*

The Multi-area SPB redistribution and policies govern the process of importing routes in the Multi-area SPB network across the boundary nodes, that is from the home area to the remote area or vice versa. The traffic flow between the areas within the Multi-area SPB network is the same as the packet flow between the source and destination in a flat SPB network. If more than one boundary node connects to same two areas then the redistribution configuration on the boundary nodes must be consistent, that is the system must permit or deny the same routes to the cross area boundaries. With Multi-area SPB you can configure layer 2 redistribution, layer 3 unicast redistribution, multicast over SPB redistribution, and Distributed Virtual Routing backbone redistribution on the switch.

## **Layer 2 Redistribution**

In the Multi-area SPB network the layer 2 redistribution identifies the services that the system transports from the home area to the remote area and the I-SIDs that the system extends across the boundary nodes in an area. The destination area permits or denies the services on basis of the layer 2 redistribution policies that you configure.

You can configure the layer 2 I-SID redistribution on the switch globally. The layer 2 redistribution policies are bidirectional, which means only one redistribution filter applies to both the home area and the remote area.

### **Note**

Any changes in the layer 2 I-SIDs in the home area will trigger updates to the I-SIDs in the remote area or vice versa.

For more information about configuring Multi-area SPB layer 2 redistribution, see:

- [Configure Multi-area SPB Layer 2 I-SID Redistribution](#) on page 1111
- [Configure Multi-area SPB Layer 2 I-SID List](#) on page 1111

### Layer 3 Unicast Redistribution

The layer 3 VSN functionality within the Multi-area SPB network is same as the layer 3 VSN functionality in the flat SPB network. In the Multi-area SPB network, for the layer 3 services to pass the area boundary, you must explicitly configure them on the boundary nodes. Inter-VRF routes on the boundary node will not be redistributed across area boundaries. You can configure redistribution unidirectionally on the boundary nodes. You can also apply different policies from home to remote and remote to home.

The configuration guidelines for the layer 3 Multi-area SPB redistribution are:

- To redistribute inter-area routes in GRT, configure IPSC on the boundary nodes.
- To redistribute inter-area routes in a specific VRF, configure IPSC and layer 3 VSN for that VRF.

#### Note

The system does not redistribute inter-vrf routes on the boundary nodes across the area boundaries.

For information about configuring layer 3 unicast redistribution, see:

- [Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution](#) on page 1113
- [Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution on a VRF Instance](#) on page 1116
- [Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution](#) on page 1114
- [Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution on a VRF Instance](#) on page 1117

### Multicast over SPB Redistribution

Multicast over Shortest Path Bridging (SPB) redistribution manages filtering of the IP multicast streams that the system transports from one area to another. The IP multicast services pass through to the other area on the boundary node depending on the policy that you configure specific to the sender IP address, the multicast group IP address and the Virtual Router Forwarding (VRF) ID.

Multicast over SPB policy is a unidirectional solution, the system filters the IP multicast streams from the area that they originate to the other area or vice versa, independently. Each IP multicast stream that the system advertises in one area will also be advertised on the corresponding area virtual node after it passes the multicast over SPB policy.

Following are the configuration guidelines for the multicast over SPB redistribution:

- Enable multicast on the boundary nodes.
- For layer 3 VSNs, configure Multiprotocol Label Switching Virtual Private Network (MVPN) on the boundary nodes.
- For layer 2 multicast, the scope I-SID must pass the layer 2 VSN policy.
- Configure the same policies as the boundary node on the peer boundary nodes.

For information about configuring Multi-area SPB multicast redistribution, see:

- [Configure Multi-area SPB IPv4 Routed Multicast Redistribution](#) on page 1122

- [Configure IS-IS Multi-area SPB IPv4 Routed Multicast Redistribution on a VRF Instance](#) on page 1123

### Distributed Virtual Routing Backbone Redistribution

The Distributed Virtual Routing (DvR) functionality within the Multi-area SPB network is same as the DvR functionality in the flat SPB network. For more information, see [Distributed Virtual Routing \(DvR\) Fundamentals](#) on page 681. To configure Multi-area SPB DvR backbone redistribution, the boundary node must be a functional DvR controller in a domain in the home area or a non-DvR Backbone Edge Bridge.

#### Note

DvR domains can only be a part of one area, you must not configure the same DvR domain in multiple areas.

When you enable the Multi-area SPB DvR backbone redistribution the system extends the DvR backbone across the area boundaries. The boundary node in the Multi-area SPB network performs the DvR controller functions to receive and propagate the hosts in the DvR domain. Since the interior nodes in one area of the Multi-area SPB network are not visible to the interior nodes in other areas, the system sends the area virtual nodes representing the specific area as a gateway in the DvR route TLV. When the system sends the DvR traffic to another DvR domain in a specific destination area, the system sends the traffic to the destination area's boundary nodes and the boundary nodes perform the route lookup and forward the traffic to the correct DvR domain in the destination area.

For information about configuring Multi-area SPB DvR backbone redistribution, see [Configure Multi-area SPB DvR Backbone Redistribution](#) on page 1119.

### *Multi-area SPB Considerations and Restrictions*

The following list identifies the restrictions and considerations that apply to the Multi-area SPB feature:

- You must not connect the same Protocol Independent Multicast (PIM) domain to the SPB-PIM Gateway nodes that are in different Intermediate-System-to-Intermediate-System (IS-IS) areas, to avoid the inter-area redistribution of the same multicast information.
- You can enable the Dynamic Nickname server on the boundary nodes in the home area, but the boundary nodes cannot be clients in any of the two areas. The boundary nodes do not support the Dynamic Nickname server in the remote area.
- The virtual node MAC address does not support CFM layer 2 ping and layer 2 traceroute.
- You must manually configure the backbone VLANs (B-VLAN) on the boundary nodes, so the system does not learn the dynamic values that it receives through the Link Layer Discovery Protocol (LLDP). However, the system sends the manually configured B-VLANs on the BN through LLDP, so that other neighbors can learn them (both in home and remote areas).
- If you enable Auto-sense on a port and it receives a Fabric Connect TLV through LLDP then the port transitions to the NNI pending state and the system logs a message. In this state the system does not enable IS-IS (including home and remote area), and no IS-IS adjacency forms. For more information, see [Auto-sense Port States](#) on page 19.
- If the system forms an adjacency between two boundary nodes that are part of the home and remote area, the hello packets in the home area will use the home manual area and the hello packets in the remote area use the remote manual area.

- If the system forms a home and a remote adjacency on the same port then the Multi-area SPB feature uses different Backbone VLAN IDs (B-VIDs) for each adjacency, the home adjacency uses the primary B-VID and the remote adjacency uses the secondary B-VID.
- If the system forms an IS-IS adjacency in both the home and remote areas on a boundary node, of the same port then the remote adjacency stays up only with another boundary node that also has IS-IS configured on both the home and remote areas of the same port.
- If a boundary node connects to a Backbone Edge Bridge (BEB) in the remote area and if you configure IS-IS in the home area on the same interface, then the remote adjacency goes down.
- On the boundary node, to install a route from a remote area in the routing table manager (RTM), the route must pass the accept policy and the Multi-area SPB redistribution policy that you configure on the specific Virtual Router Forwarding (VRF) instance.
- On the boundary node, to install an inter-VRF route from a remote area in the routing table manager (RTM), the inter-VRF route must pass the accept policy and the Multi-area SPB redistribution policy that you configure on both the source and destination VRF instances.
- Nickname for the physical node and virtual node must be different.
- When enabling Remote IS-IS Instance, make sure that the physical node nickname, virtual node nickname and system ID are different.

## SPBM and IS-IS infrastructure configuration using CLI

This section provides procedures to configure SPBM and IS-IS using Command Line Interface (CLI).

### Important

The **spbm-config-mode** boot flag must be enabled (default) before you can configure SPBM or IS-IS. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

### *Running the SPBM script*

Use the following procedure to run the SPBM script to automate the minimum required SPBM and IS-IS parameters to allow Fabric Connect to operate on the switch.

### **Before You Begin**

- Enable SPBM before running the SPBM script.
- Delete existing IS-IS interfaces before running this script. See [Removing specific IS-IS and MLT interfaces](#) on page 1004 for information on removing IS-IS interfaces.

### **About This Task**

You can use this procedure to quickly configure the minimum SPBM and IS-IS parameters. However, a manual procedure is available instead of using this script. The default values are given in square brackets. You may input your values at the prompt or if you wish to accept the default values, press

Enter. This command first accepts all values and then removes existing SPBM configurations before configuring the entered values.

#### Note

This process causes the SPBM traffic to flap temporarily.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Run the SPBM script:

```
run spbm
```

#### Note

If the script causes a configuration conflict or cannot execute a command, an error message displays and the script stops.

### Example

Run the SPBM script:

```
Switch:1(config)# run spbm
```

```
*****
*** This script will guide you through configuring the          ***
*** switch for optimal operation SPB.                          ***
*** -----  ***
*** The values in [] are the default values, you can           ***
*** input alternative values at any of the prompts.            ***
*** If you wish to terminate or exit this script              ***
*** enter ^C <control-C> at any prompt.                        ***
*** NOTE: THE COMMAND WILL TEMPORARILY FLAP IS-IS,SPBM        ***
*****
SPB Ethertype <0x8100,0x88a8> [0x8100]:
SPB primary BVLAN 2-4059 [4051]:300
SPB secondary BVLAN 2-4059 [4052]:400

ISIS MLT interface <MLT ID LIST>[:]:1
Enable CFM SPBM (y/n) [n]:y
Enter CFM SPBM MEPID <1-8191> [1]:2
Enter CFM SPBM level <0-7> [4]:4

****CONFIGURATION IN PROGRESS****
*SPBM enabled globally*
*SPBM instance 1 configured*
*SPBM BVLANS configured*
```

```
*SPBM SMLT configured*
*SPBM multicast enabled globally*
*IP shortcuts configured*
*SPBM SMLT configured*
*IS-IS enabled*
*IS-IS on port 1/5 configured*
*IS-IS on port 1/6 configured*
*IS-IS on MLT 1 configured*
*CFM SPBM configured*
****SCRIPT EXECUTION COMPLETE****
```

### Remove Existing SPBM Configuration

Use the following procedure to remove existing SPBM configurations, disable CFM, and return the CFM MEP-ID and level configurations to default values.

#### Before You Begin

- Enable SPBM before running this script.
- If the switch uses Zero Touch Fabric Configuration, you must run the following commands before you perform this procedure:
  - **no auto-sense onboarding i-sid**
  - **no vlan i-sid <1-4059>**

#### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```

2. Run the script:

```
run spbm clean
```

#### Note

If the script causes a configuration conflict or cannot run a command, an error message displays and the script stops.

3. To ensure proper cleanup of MAC tables, save the configuration, and then reboot the switch.

#### Example

Run the script:

```
Switch:1(config)#no auto-sense onboarding i-sid
Switch:1(config)#no vlan i-sid
Switch:1(config)#run spbm clean
The following will delete all SPBM and interfaces and default the CFM configurations. Do
you want to continue? <y/n>[n]:y

Switch:1(config)#no router isis enable
Switch:1(config)#interface gigabitethernet 1/10
Switch:1(config-if)#no isis
Switch:1(config-if)#interface gigabitethernet 1/11
Switch:1(config-if)#no isis
Switch:1(config-if)#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no vlan 4051
```

```

Switch:1(config)#no vlan 4052
Switch:1(config)#router isis
Switch:1(config-isis)#no spbm 1
Switch:1(config-isis)#router isis
Switch:1(config-isis)#no ip-source-address
Switch:1(config-isis)#no system-id
Switch:1(config-isis)#no manual-area 49.0000
Switch:1(config-isis)#no cfm spbm enable
Switch:1(config)#cfm spbm level 4
Switch:1(config)#cfm spbm mepid 1
Switch:1(config)#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#

**SPBM configurations have been removed**

```

### Configuring the IS-IS port interfaces using SPBM script

Use the following procedure to run the SPBM script to configure the IS-IS port interfaces. As this command does not flap IS-IS or SPBM, it is particularly effective to use this command when SPBM is already configured and you require to configure additional ports or MLTs. Running the run spbm interface command does not alter existing IS-IS or SPBM configurations.

#### About This Task

You can use this procedure to quickly configure the minimum SPBM and IS-IS parameters. However, a manual procedure is available instead of using this script.

#### Note

You must enable SPBM before running the SPBM script.

#### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Run the SPBM script:  
run spbm interface

#### Note

If the script causes a configuration conflict or cannot execute a command, an error message displays and the script stops.

#### Example

Run the SPBM script:

```
Switch:1(config)# run spbm interface
```

```

*****
*** This script will guide you through configuring the          ***
*** switch for optimal operation SPB.                          ***
*** -----  ***
*** The values in [] are the default values, you can          ***
*** input alternative values at any of the prompts.           ***

```

```

*** If you wish to terminate or exit this script          ***
*** enter ^C <control-C> at any prompt.                 ***
*****
ISIS port interfaces <a/b,c/d> []:1/2,1/4,1/8
ISIS MLT interface <MLT ID LIST> []:1
*IS-IS on port 1/2 configured*
*IS-IS on port 1/4 configured*
*IS-IS on port 1/8 configured*
*IS-IS on MLT-1 configured*

```

### Removing specific IS-IS and MLT interfaces

Use the following procedure to remove specific IS-IS ports and MLT interfaces when you get the error IS-IS SPBM interfaces have been configured. Please delete these interfaces.

#### About This Task

This procedure removes existing IS-IS ports and MLT interfaces. You can choose which port and MLT interfaces need to be removed. This command does not alter the other SPBM or IS-IS configurations.

#### Note

You must enable SPBM before running the SPBM script.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Run the script:
 

```
run spbm interface clean
```

#### Note

If the script causes a configuration conflict or cannot execute a command, an error message displays and the script stops.

#### Example

Run the spbm interface clean script:

```

Switch:1(config)# run spbm interface clean

*****
*** This script will guide you through deleting the      ***
*** IS-IS SPBM interfaces.                               ***
*** -----   ***
*** The values in [] are the default values.            ***
*** If you wish to terminate or exit this script        ***
*** enter ^C <control-C> at any prompt.                 ***
*****
ISIS port interfaces to be deleted <a/b,c/d>[]:1/2,1/4,1/8
ISIS MLT interface <MLT ID LIST> []:1
IS-IS port 1/2 deleted
IS-IS port 1/4 deleted
IS-IS port 1/8 deleted

```

```
** 3 IS-IS port interfaces deleted **
MLT 1 deleted
** 1 IS-IS MLTs deleted **
```

### Configure Minimum SPBM and IS-IS Parameters

Use the following procedure to configure the minimum required SPBM and IS-IS parameters to enable SPBM operation on the switch.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable SPBM globally:  

```
spbm
```
3. Enter IS-IS Router Configuration mode:  

```
router isis
```
4. Create the SPBM instance (only one SPBM instance is supported):  

```
spbm <1-100>
```
5. Add the SPBM B-VLAN to the SPBM instance:  

```
spbm <1-100> b-vid {<vlan-id [-vlan-id] [,...]} [primary <1-4059>]
```
6. Configure the system nickname (2.5 bytes in the format <x.xx.xx>):  

```
spbm <1-100> nick-name <x.xx.xx>
```

#### Note

Although it is not strictly required for SPBM operation, you should change the IS-IS system ID from the default B-MAC value to a recognizable address to easily identify a switch (Log on to IS-IS Router configuration mode and use the `system-id <xxxx.xxxx.xxxx>` command). This helps to recognize source and destination addresses for troubleshooting purposes.

7. Configure an IS-IS manual area (1-13 bytes in the format <xx.xxxx.xxxx...xxx>, only one manual area is supported.):  

```
manual-area <xx.xxxx.xxxx...xxx>
```
8. Exit IS-IS Router Configuration mode to Global Configuration mode:  

```
exit
```
9. Create the SPBM backbone VLAN (B-VLAN):  

```
vlan create <2-4059> type spbm-bvlan
```
10. Enter Interface Configuration mode, by specifying the ports or MLTs that are going to link to the SPBM network:  

```
interface {GigabitEthernet {slot/port [/sub-port] [-slot/port [/sub-port]] [,...]} | mlt <1-512> }
```
11. Configure an IS-IS interface on the selected ports or MLTs:
  - a. Create an IS-IS circuit and interface on the selected ports or MLTs:  

```
isis
```

- b. Enable the SPBM instance on the IS-IS interfaces:  

```
isis spbm <1-100>
```
- c. Enable the IS-IS circuit/interface on the selected ports or MLTs:  

```
isis enable
```
12. Enable interface.
13. Exit Interface Configuration mode:  

```
exit
```
14. Enable IS-IS globally:  

```
router isis enable
```
15. Display the SPBM configurations:  

```
show isis spbm
```
16. Display the global IS-IS configuration:  

```
show isis
```
17. Display the interface IS-IS configuration:  

```
show isis interface
```

### Examples

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spbm
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 b-vid 4051,4052 primary 10
Switch:1(config-isis)#spbm 1 nick-name 1.11.16
Switch:1(config-isis)#manual-area c0.2000.000.00
Switch:1(config-isis)#exit
Switch:1(config)#interface GigabitEthernet 1/21
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-if)#exit
Switch:1(config)#vlan create 4051 type spbm-vlan
Switch:1(config)#vlan create 4052 type spbm-vlan
Switch:1(config)#router isis enable

Switch:1(config)#show isis spbm
```

```

## Variable definitions

The following table defines parameters for the **isis** command.

| Variable                  | Value                                                                                                                                                                 |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>             | Enables or disables the IS-IS circuit/interface on the specified port or MLT. The default is disabled. Use the no option to disable IS-IS on the specified interface. |
| <i>spbm &lt;1-100&gt;</i> | Enable the SPBM instance on the IS-IS interfaces.                                                                                                                     |

The following table defines parameters for the **manual-area** command.

| Variable           | Value                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <xx.xxx.xxx...xxx> | Specifies the IS-IS manual-area (1-13 bytes in the format <xx.xxx.xxx...xxx>). Only one manual area is supported. For IS-IS to operate, you must configure at least one area.<br>Use the no option to delete the manual area. |

The following table defines parameters for the **spbm** command.

| Variable                                   | Value                                                                                                                                                                 |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-100>                                    | Creates the SPBM instance. Only one SPBM instance is supported.                                                                                                       |
| <i>b-vid</i> {<vlan-id [-vlan-id] [,...]}> | Sets the IS-IS SPBM instance data VLANs. Use the no option to remove the specified B-VLAN from the SPBM instance.                                                     |
| <i>nick-name</i> <x.xx.xx>                 | Specifies a nickname for the SPBM instance globally. The value is 2.5 bytes in the format <x.xx.xx>. Use the no or default options to delete the configured nickname. |
| <i>primary</i> <1-4059>                    | Sets the IS-IS instance primary data B-VLAN.                                                                                                                          |

The following table defines parameters for the **vlan create** command.

| Variable                                         | Value                                                                                                                                                                                                                     |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <2-4059>                                         | Specifies the VLAN ID. Creates an SPBM Backbone VLAN (B-VLAN). You can optionally specify a name for the SPBM B-VLAN.                                                                                                     |
| <i>type</i> {port-mstp protocol-mstp spbm-bvlan} | Specifies the type of VLAN created. <ul style="list-style-type: none"> <li>port-mstp — Create a VLAN by port.</li> <li>protocol-mstp — Create a VLAN by protocol.</li> <li>spbm-bvlan — Create an SPBM B-VLAN.</li> </ul> |

## Job aid

### Important

After you have configured the SPBM nickname and enabled IS-IS. To maintain the same nickname with a different system ID, perform the following steps:

1. Disable IS-IS.
2. Change the system ID.
3. Change the nickname to a temporary one.
4. Enable IS-IS.
5. Wait up to 20 minutes for the LSPs with the original system ID to age out.

### Note

To check the age out time, use the **show isis lsdb sysid <original-sys-id>** command on any of the other SPB nodes in the network. When there is no output from this command, proceed to the next step. The time left (in seconds) for the LSPs to age out is shown under the column **LIFETIME**.

6. Disable IS-IS.
7. Change the nickname to the original nickname.
8. Enable IS-IS.

### Configure Minimum SPBM and IS-IS Parameters using `auto-nni` Command

Use the following procedure to configure the minimum required SPBM and IS-IS parameters using the `auto-nni` command to have the node create an IS-IS interface, attach the interface to an SPBM instance, and then enable IS-IS on the port interface.

This procedure is only for the port interface. The `auto-nni` command is not supported on the MLT interface and the Fabric Extend Logical Interface.

#### About This Task

The `auto-nni` command provides a quick and simple way to configure the IS-IS interface. You can use the `auto-nni` command instead of the following existing IS-IS commands on the physical (port) interface:

- `isis`
- `isis spbm instance`
- `isis enable`

The existing commands are still available and you have the option to use the new command or the three existing commands. If you need to modify any of the default parameters under `isis` or `isis spbm instance`, use `isis` and `isis spbm instance` constructs even if you created the interface with the `auto-nni` command.

#### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable SPBM globally:  
`spbm`
3. Enter IS-IS Router Configuration mode:  
`router isis`
4. Create the SPBM instance (only one SPBM instance is supported):  
`spbm <1-100>`
5. Add the SPBM B-VLAN to the SPBM instance:  
`spbm <1-100> b-vid {<vlan-id [-vlan-id] [,...]} [primary <1-4059>]`
6. Configure the system nickname (2.5 bytes in the format <x.xx.xx>):  
`spbm <1-100> nick-name <x.xx.xx>`

#### Note

Although it is not strictly required for SPBM operation, you should change the IS-IS system ID from the default B-MAC value to a recognizable address to easily identify a switch (Log on to IS-IS Router configuration mode and use the `system-id <xxxx.xxxx.xxxx>` command). This helps to recognize source and destination addresses for troubleshooting purposes.

- Configure an IS-IS manual area (1-13 bytes in the format <xx.xxxx.xxxx...xxx>. Only one manual area is supported.):

```
manual-area <xx.xxxx.xxxx...xxx>
```

- Exit IS-IS Router Configuration mode to Global Configuration mode:

```
exit
```

- Create the SPBM backbone VLAN (B-VLAN):

```
vlan create <2-4059> type spbm-bvlan
```

- Enter Interface Configuration mode, by specifying the ports or MLTs that are going to link to the SPBM network:

```
interface {GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | mlt <1-512> }
```

- Configure an IS-IS interface on the selected ports.

```
auto-nni
```

- Enable interface.

- Exit Interface Configuration mode:

```
exit
```

- Enable IS-IS globally:

```
router isis enable
```

- Display the SPBM configurations:

```
show isis spbm
```

- Display the global IS-IS configuration:

```
show isis
```

- Display the interface IS-IS configuration:

```
show isis interface
```

## Examples

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spbm
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 b-vid 10,20 primary 10
Switch:1(config-isis)#spbm 1 nick-name 1.11.16
Switch:1(config-isis)#manual-area c0.2000.000.00
Switch:1(config-isis)#exit
Switch:1(config)#interface gigabitethernet 1/21
Switch:1(config-if)#auto-nni
Switch:1(config-if)#exit
Switch:1(config)#vlan create 10 type spbm-vlan
Switch:1(config)#vlan create 20 type spbm-vlan
Switch:1(config)#router isis enable
Switch:1(config)#show isis spbm

Switch:1(config)#show isis spbm
```

Configure I-SIDs for Private VLANs

### Before You Begin

- A private VLAN must be created. For more information about creating private VLANs, see [Create a Private VLAN](#) on page 3750.

## About This Task

Assign one I-SID for each private VLAN.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Assign the I-SID to the primary and secondary VLAN.
 

```
vlan i-sid <1-4059> <0-16777215> [force]
```

## Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#vlan i-sid 5 75
Switch:1(config)#show vlan private-vlan

## Variable Definitions

The following table defines parameters for the **vlan i-sid** command.

| Variable     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>     | Specifies the VLAN ID.<br>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <0-16777215> | Specifies the service instance identifier (I-SID). You cannot use I-SID 0x00ffffff. The system reserves this I-SID to advertise the virtual BMAC in an SMLT dual-homing environment.<br>This value is the same for the primary and secondary VLANs.                                                                                                                                                                                                  |
| <i>force</i> | Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.                                                                                                                                                                                                                                                                                                                                                               |

### Displaying global SPBM parameters

Use the following procedure to verify the proper global SPBM configuration.

**Procedure**

1. Display the SPBM configuration:  

```
show isis spbm
```
2. You can also use the following command to identify SPBM VLANs. For `spbm-bvlan`, the attribute `TYPE` displays `spbm-bvlan` instead of `byport`. For private VLANs, the attribute `TYPE` displays `private` instead of `byport`.  

```
show vlan basic
```

**Example**

```
Switch# show isis spbm
```

```

```

### Configuring SMLT parameters for SPBM

Use the following procedure to configure the required Split MultiLink Trunking (SMLT) parameters to allow SPBM to interoperate with SMLT on the switch.

#### Note

- The assignment of primary and secondary roles to the vIST peers is automatic. The switch with the lower system ID (between the two vIST peers) is primary, and the switch with the higher system ID is secondary when default system-id values are being used.
- SMLT peer system ID is part of the required configuration. You must configure the SMLT peer system ID as the nodal MAC of the peer device. In the IS-IS network, the nodal MAC of devices should be eight apart from each other.
- When using the default hardware assigned system-id value, the SMLT Virtual B-MAC is automatically derived by comparing the system-id values of the two vIST peers. A value of 0x01 plus the lower of the two system-id values is used as the SMLT Virtual B-MAC.

When using a manually configured system-id value, the SMLT Virtual B-MAC must also be manually configured.

- An I-SID must be assigned to every VLAN that is a member of a Layer 2 VSN. Also, if a Layer 2 VSN is created on one vIST Peer, it must also be created on the other vIST peer.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Disable IS-IS on the switch:
 

```
no router isis enable
```
3. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
4. Specify the system ID of the vIST peer, so that if it goes down, the local peer can take over forwarding for the failed peer:
 

```
spbm <1-100> smlt-peer-system-id <xxxx.xxxx.xxxx>
```
5. Configure the virtual B-MAC, which is shared and advertised by both peers:
 

```
spbm <1-100> smlt-virtual-bmac <0x00:0x00:0x00:0x00:0x00:0x00>
```
6. Exit to Global Configuration mode:
 

```
exit
```

7. Enable IS-IS on the switch:  

```
router isis enable
```
8. Display the SPBM SMLT configuration:  

```
show isis spbm
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
```

Disable IS-IS on the switch:

```
Switch:1(config)#no router isis enable
```

Enter the IS-IS Router Configuration mode:

```
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 smlt-peer-system-id 0018.b0bb.b3df
Switch:1(config-isis)#spbm 1 smlt-virtual-bmac 00:14:c7:e1:33:e0
Switch:1(config-isis)#router isis enable

Switch:1(config-isis)#show isis spbm

**Variable definitions**

The following table defines parameters for the **spbm** command.

| Variable                                                          | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>smlt-peer-system-id</code><br><xxxx.xxxx.xxxx>              | Specifies the IS-IS SPBM peer system ID. SMLT peer system ID is part of the required configuration. You must configure the SMLT peer system ID as the nodal MAC of the peer device. In the IS-IS network, the nodal MAC of devices should be eight apart from each other.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>smlt-virtual-bmac</code><br><0x00:0x00:0x00:0x00:0x00:0x00> | Specifies a virtual MAC address that can be used by both peers. SMLT virtual B-MAC is an optional configuration.<br><br><b>Note:</b> <ul style="list-style-type: none"> <li>If SMLT virtual B-MAC is not configured, the system derives SMLT virtual B-MAC from the configured SMLT peer system ID and the nodal MAC of the device (IS-IS system ID). The system compares the nodal MAC of the device with the SMLT peer system ID configured and takes the small one, plus 0x01, as the SMLT virtual B-MAC.</li> <li>The system also derives SMLT split BEB from the SMLT peer system ID and nodal MAC of the device. The device with the lower system ID is primary, the device with the higher system ID is secondary.</li> </ul> |

### Configuring optional SPBM parameters

Use the following procedure to configure optional SPBM parameters.

#### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Configure the SPBM ethertype:
 

```
spbm ethertype {0x8100 | 0x88a8}
```
- Configure the optional link-state database (LSDB) trap global parameter. To configure this parameter, you must globally disable IS-IS on the switch:
  - Disable IS-IS on the switch:
 

```
no router isis enable
```
  - Enter IS-IS Router Configuration mode:
 

```
router isis
```
  - Enable a trap when the SPBM LSDB changes:
 

```
spbm <1-100> lsdb-trap enable
```
  - Enable IS-IS on the switch:
 

```
router isis enable
```
  - Exit IS-IS Router Configuration mode:
 

```
exit
```

4. Configure the optional SPBM interface parameters. To configure these parameters, you must disable IS-IS on the interface:
  - a. Specify an SPBM interface to configure:

```
interface {GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]][,...]} | mlt <mltid> }
```
  - b. Disable IS-IS on the interface:

```
no isis enable
```
  - c. Configure SPBM instance interface-type on IS-IS interface. SPBM supports only pt-pt:

```
isis spbm <1-100> interface-type {broadcast|pt-pt}
```
  - d. Configure the IS-IS Interface level 1 metric:

```
isis spbm <1-100> ll-metric <1-16777215>
```
  - e. Enable IS-IS on the switch:

```
isis enable
```

### Example

```
Switch> enable
Switch# configure terminal
Switch(config)# spbm ethertype 0x8100
Switch(config-isis)# no router isis enable
Switch(config)# router isis
Switch(config-isis)# spbm 1 lsdB-trap enable
Switch(config-isis)# router isis enable
Switch(config-isis)# exit
Switch(config)# interface gigabitEthernet 1/7
Switch(config-if)# no isis enable
Switch(config-if)# isis spbm 1 interface-type pt-pt
Switch(config-if)# isis spbm 1 ll-metric 500
Switch(config-if)# isis enable
```

### Variable definitions

The following table defines parameters for the **spbm** command.

| Variable                                    | Value                                                                                                                                                                  |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ethertype {0x8100   0x88a8}</code>    | Configures the SPBM ethertype. The default value is 0x8100.                                                                                                            |
| <code>&lt;1-100&gt; lsdb-trap enable</code> | Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disabled. Use the <b>no</b> or <b>default</b> options to disable LSDB traps. |

The following table defines parameters for the **isis spbm** command.

| Variable                                                    | Value                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-100&gt; interface-type {broadcast pt-pt}</code> | Configures the SPBM instance interface-type on the IS-IS interface located on the specified port or MLT. SPBM only supports the point-to-point (pt-pt) interface type. The default is pt-pt. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of pt-pt. |
| <code>&lt;1-100&gt; ll-metric &lt;1-16777215&gt;</code>     | Configures the IS-IS interface level 1 metric on the specified port or MLT. The default value is 10. Use the <b>no</b> or <b>default</b> options to set this parameter to the default.                                                                                                        |

### Configuring optional IS-IS global parameters

Use the following procedure to configure optional IS-IS global parameters.

#### Procedure

1. Enter IS-IS Router Configuration mode:
 

```
enable
configure terminal
router isis
```
2. Configure optional IS-IS global parameters:
  - a. Specify the Complete Sequence Number Packet (CSNP) interval in seconds:
 

```
csnp-interval <1-600>
```
  - b. Configure the router type globally:
 

```
is-type {l1|l12}
```
  - c. Configure the maximum level, in seconds, between generated LSPs by this Intermediate System:
 

```
max-lsp-gen-interval <30-900>
```
  - d. Configure the IS-IS metric type:
 

```
metric {narrow|wide}
```
  - e. Set or clear the overload condition:
 

```
overload
```
  - f. Configure the overload-on-startup value in seconds:
 

```
overload-on-startup <15-3600>
```

- g. Configure the Partial Sequence Number Packet (PSNP) in seconds:  
psnp-interval <1-120>
- h. Configure the minimum time between retransmission of an LSP:  
retransmit-lsp-interval <1-300>
- i. Configure the SPF delay in milliseconds:  
spf-delay <0-5000>
- j. Configure the name for the system:  
sys-name WORD<0-255>
- k. Configure the IS-IS system ID for the switch:  
system-id <xxxx.xxxx.xxxx>

**Example**

```
Switch> enable

Switch# configure terminal

Switch(config)# router isis

Switch(config-isis)# csnp-interval 10

Switch(config-isis)# is-type 11

Switch(config-isis)# max-lsp-gen-interval 800

Switch(config-isis)# metric wide

Switch(config-isis)# overload

Switch(config-isis)# overload-on-startup 30

Switch(config-isis)# psnp-interval 10

Switch(config-isis)# retransmit-lsp-interval 10

Switch(config-isis)# default sys-name

Switch(config-isis)# spf-delay 200

Switch(config-isis)# default system-id
```

## Variable definitions

The following table defines parameters for the **csnp-interval** command.

| Variable | Value                                                                                                                                                                                                                                                                                                                                              |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-600>  | Specifies the CSNP interval in seconds. This is a system level parameter that applies for level 1 CSNP generation on all interfaces. A longer interval reduces overhead, while a shorter interval speeds up convergence.<br>The default value is 10. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 10. |

The following table defines parameters for the **is-type** command.

| Variable | Value                                                                                                                                                                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {l1 l12} | Sets the router type globally: <ul style="list-style-type: none"> <li>l1: Level-1 router type</li> <li>l12: Not valid.</li> </ul> The default value is l1. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of l1. |

The following table defines parameters for the **max-lsp-gen-interval** command.

| Variable | Value                                                                                                                                                                                                                               |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <30-900> | Specifies the maximum interval, in seconds, between generated LSPs by this Intermediate System.<br>The default value is 900 seconds. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 900. |

The following table defines parameters for the **metric** command.

| Variable      | Value                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {narrow wide} | Specifies the IS-IS metric type. Only wide is supported.<br>The default value is wide. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of wide. |

The following table defines parameters for the **overload** command.

| Variable | Value                                                                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| overload | Sets or clears the overload condition.<br>The default value is disabled. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of disabled. |

The following table defines parameters for the **overload-on-startup** command.

| Variable  | Value                                                                                                                                                                                                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <15–3600> | Specifies the IS-IS overload-on-startup value in seconds. The overload-on-startup value is used as a timer to control when to send out LSPs with the overload bit cleared after IS-IS startup.<br>The default value is 20. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 20. |

The following table defines parameters for the **psnp-interval** command.

| Variable | Value                                                                                                                                                                                                                                                                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1–120>  | Specifies the PSNP interval in seconds. This is a system level parameter that applies for level 1 PSNP generation on all interfaces. A longer interval reduces overhead, while a shorter interval speeds up convergence.<br>The default value is 2. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 2. |

The following table defines parameters for the **retransmit-lsp-interval** command.

| Variable | Value                                                                                                                                                                                                                                                                                                                                |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1–300>  | Specifies the minimum time between retransmission of an LSP. This defines how fast the switch resends the same LSP. This is a system level parameter that applies for Level1 retransmission of LSPs.<br>The default value is 5 seconds. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 5. |

The following table defines parameters for the **spf-delay** command.

| Variable | Value                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0–5000> | Configures the delay, in milliseconds, to pace successive Shortest Path First (SPF) runs. The timer prevents more than two SPF runs from being scheduled back-to-back. The mechanism for pacing SPF allows two back-to-back SPF runs.<br>The default value is 100 milliseconds. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 100 milliseconds. |

The following table defines parameters for the **sys-name** command.

| Variable    | Value                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<0–255> | Specifies a name for the system. This may be used as the host name for dynamic host name exchange in accordance with RFC 2763.<br>By default, the system name comes from the host name configured at the system level.<br>Use the <b>no</b> or <b>default</b> options to set this parameter to the default value (host name).<br><br><b>Note:</b><br>The system does not display any consistency checks when you edit sys-name. |

The following table defines parameters for the **system-id** command.

| Variable          | Value                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <xxxxx.xxxx.xxxx> | Specifies the IS-IS system ID for the switch.<br>Use the <b>no</b> or <b>default</b> options to set this parameter to the default value (node BMAC). |

## Job aid

### Important

After you have configured the SPBM nickname and enabled IS-IS. To maintain the same nickname with a different system ID, perform the following steps:

1. Disable IS-IS.
2. Change the system ID.
3. Change the nickname to a temporary one.
4. Enable IS-IS.
5. Wait up to 20 minutes for the LSPs with the original system ID to age out.

### Note

To check the age out time, use the **show isis lsdb sysid <original-sys-id>** command on any of the other SPB nodes in the network. When there is no output from this command, proceed to the next step. The time left (in seconds) for the LSPs to age out is shown under the column **LIFETIME**.

6. Disable IS-IS.
7. Change the nickname to the original nickname.
8. Enable IS-IS.

## Configuring Optional IS-IS Interface Level 1 Parameters

Use the following procedure to configure optional IS-IS interface level 1 parameters.

### Important

Save your configuration using **save config** for the updates to be available after reboot. Saving the configuration also ensures that any authentication keys (passwords) specified during the configuration are properly encrypted.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure optional IS-IS interface level 1 parameters:

- a. Specify the authentication type used for IS-IS hello packets on the interface:

```
isis hello-auth type {none|simple|hmac-md5|hmac-sha-256}
```

- b. If you select `simple` as the `hello-auth` type, you must also specify a key value but the key-id is optional:

```
isis hello-auth type simple key WORD<1-16> [key-id <1-255>]
```

- c. If you select `hmac-md5` or `hmac-sha-256`, you must also specify a key value. The key-id is optional:

```
isis hello-auth type hmac-md5 key WORD<1-16> [key-id <1-255>]]
```

```
isis hello-auth type hmac-sha-256 key WORD<1-16> [key-id <1-255>]]
```

- d. Configure the IS-IS Interface level 1 designated router priority:

```
isis [l1-dr-priority <0-127>]
```

### Note

This parameter is not used for SPBM because SPBM only runs on point-to-point interfaces. This parameter is for designated router election on a broadcast LAN segment, which is not supported.

- e. Configure the IS-IS Interface level 1 hello interval:

```
isis [l1-hello-interval <1-600>]
```

- f. Configure the IS-IS Interface level 1 hello multiplier:

```
isis [l1-hello-multiplier <1-600>]
```

## Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch(config):1# interface gigabitethernet 1/1
```

```
Switch(config-if):1# isis
```

```
Switch(config-if):1# isis hello-auth type hmac-md5 key test
```

```
Switch(config-if):1# isis l1-dr-priority 100
Switch(config-if):1# isis l1-hello-interval 20
Switch(config-if):1# isis l1-hello-multiplier 10
Switch(config):1# save config
```

### Variable Definitions

The following table defines parameters for the **isis** command.

| Variable                                                                                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>hello-auth type {none  simple hmac-md5 hmac- sha-256}} [key [key WORD&lt;1- 16&gt;] [key-id &lt;1-255&gt;]</pre> | <p>Specifies the authentication type used for IS-IS hello packets on the interface. <b>type</b> can be one of the following:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• simple: If selected, you must also specify a key value but the key id is optional. Simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet.</li> <li>• hmac-md5: If selected, you must also specify a key value but the key-id is optional. MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. There is an optional key ID.</li> <li>• hmac-sha-256: If selected, you must also specify a key value but the key-id is optional. With SHA-256 authentication, the switch adds an hmac-sha-256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet. There is an optional key ID.</li> </ul> <p><b>Note:</b><br/>Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate IS-IS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key.<br/>This feature is in full compliance with RFC 5310.</p> <p>The default is none. Use the <b>no</b> or <b>default</b> options to set the hello-auth type to none.</p> |
| <pre>ll-dr-priority &lt;0-127&gt;</pre>                                                                               | <p>Configures the IS-IS Interface level 1 designated router priority to the specified value. The default value is 64. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 64.</p> <p><b>Note:</b><br/>This parameter is not used for SPBM because SPBM only runs on point-to-point interfaces. This parameter is for designated router election on a broadcast LAN segment, which is not supported.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Variable                                       | Value                                                                                                                                                                                            |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>l1-hello-interval &lt;1-600&gt;</code>   | Configures the IS-IS interface level 1 hello interval. The default value is 9 seconds.<br>Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 9 seconds.   |
| <code>l1-hello-multiplier &lt;1-600&gt;</code> | Configures the IS-IS interface level 1 hello multiplier. The default value is 3 seconds.<br>Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 3 seconds. |

### Display IS-IS Interface Parameters

Use the following procedure to display the IS-IS interface parameters.

#### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Display IS-IS interface configuration and status parameters (including adjacencies):  
`show isis interface [l1|l2|l12] [home|remote]`
3. Display IS-IS interface authentication configuration:  
`show isis int-auth [home|remote]`
4. Display IS-IS interface timers:  
`show isis int-timers [home|remote]`
5. Display IS-IS circuit level parameters:  
`show isis int-ckt-level [home|remote]`

#### Example

```
Switch:1# show isis interface
=====
ISIS Interfaces
=====

**Variable Definitions**

The following table defines parameters for the **show isis interface** command.

| Variable      | Value                                                                                   |
|---------------|-----------------------------------------------------------------------------------------|
| <i>home</i>   | Displays the IS-IS interface information that the system configures in the home area.   |
| <i>l1</i>     | Displays the interface information for Level 1.                                         |
| <i>l2</i>     | Displays the interface information for Level 2.                                         |
| <i>l12</i>    | Displays the interface information for Level 1 and Level 2.                             |
| <i>remote</i> | Displays the IS-IS interface information that the system configures in the remote area. |

The following table defines parameters for the **show isis ini-auth** command.

| Variable      | Value                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------|
| <i>home</i>   | Displays the IS-IS interface authentication information that the system configures in the home area.   |
| <i>remote</i> | Displays the IS-IS interface authentication information that the system configures in the remote area. |

The following table defines parameters for the **show isis ini-timer** command.

| Variable      | Value                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------|
| <i>home</i>   | Displays the IS-IS interface timer information that the system configures in the home area.   |
| <i>remote</i> | Displays the IS-IS interface timer information that the system configures in the remote area. |

The following table defines parameters for the **show isis ini-ckt-level** command.

| Variable      | Value                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------|
| <i>home</i>   | Displays the IS-IS interface circuit level parameters that the system configures in the home area.   |
| <i>remote</i> | Displays the IS-IS interface circuit level parameters that the system configures in the remote area. |

*Display the IP Unicast FIB, Unicast FIB, and Unicast Tree*

### About This Task

In SPBM, Backbone MAC (B-MAC) addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS Type-Length-Value (TLV) that advertises the Service Instance Identifier (I-SID) and B-MAC information across the network. Each node has a System ID, which also serves as B-MAC of the switch. These B-MAC addresses are populated into the SPBM Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are never exchanged in the network as IP Shortcuts allow Global Routing Table (GRT) IP networks to be transported across IS-IS.

The **show isis spbm ip-unicast-fib** or **show isis spbm ipv6-unicast-fib** command displays all of the IS-IS routes in the IS-IS LSDB. The IP ROUTE PREFERENCE column in the show output displays the IP route preference.

Routes within the same VSN are added to the LSDB with a default preference of 7. Inter-VSN routes are added to the LSDB with a route preference of 200. IS-IS accept policies enable you to change the route preference for incoming routes. If the same route is learned from multiple sources with different route preferences, then the routes are not considered equal cost multipath (ECMP) routes. The route with the lowest route preference is the preferred route. In Layer 2, in the event of a tie-break between routes from multiple sources, the tie-breaking is based on cost and hop count.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display the SPBM IP unicast FIB:

- For IPv4:

```
show isis spbm ip-unicast-fib [all] [id <1-16777215] [spbm-nh-as-  
mac] [home|remote]
```

- For IPv6:

```
show isis spbm ipv6-unicast-fib [all] [id <1-16777215] [spbm-nh-as-  
mac] [home|remote]
```

3. Display the SPBM unicast FIB:

```
show isis spbm unicast-fib [b-mac <0x00:0x00:0x00:0x00:0x00:0x00>]
[vlan <1-4059>] [summary] [home|remote]
```

4. Display the SPBM unicast tree:

```
show isis spbm unicast-tree <1-4059> [destination <xxxx.xxxx.xxxx>]
```

**Examples**

```
Switch# show isis spbm ip-unicast-fib

**Variable Definitions**

The following table defines parameters for the **show isis spbm ip-unicast-fib** command.

| Variable                     | Value                                                                                                                                                                                                                                                                                                      |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>all</i>                   | Displays entries for the Global Routing Table (GRT) and all Virtual Routing and Forwarding (VRF) instances.<br><br><b>Note:</b><br>If you use the command <b>show isis spbm ip-unicast-fib</b> the device displays only GRT entries. The command shows IP routes from remote Backbone Edge Bridges (BEBs). |
| <i>home</i>                  | Displays the IS-IS SPBM IP unicast Forwarding Information Base (FIB) information that the system configures in the home area.                                                                                                                                                                              |
| <i>id &lt;1-16777215&gt;</i> | Displays IS-IS SPBM IP unicast FIB information by Service Instance Identifier (I-SID) ID.                                                                                                                                                                                                                  |

| Variable              | Value                                                                                             |
|-----------------------|---------------------------------------------------------------------------------------------------|
| <i>remote</i>         | Displays the IS-IS SPBM IP unicast FIB information that the system configures in the remote area. |
| <i>spbm-nh-as-mac</i> | Displays the next hop B-MAC of the IP unicast FIB entry.                                          |

The following table defines parameters for the **show isis spbm ipv6-unicast-fib** command.

| Variable               | Value                                                                                                                                                                                                                                                                                                          |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>all</i>             | Displays entries for the Global Routing Table (GRT) and all Virtual Routing and Forwarding (VRF) instances.<br><br><b>Note:</b><br>If you use the command <b>show isis spbm ipv6-unicast-fib</b> the device displays only GRT entries. The command shows IPv6 routes from remote Backbone Edge Bridges (BEBs). |
| <i>home</i>            | Displays the IS-IS SPBM IPv6 unicast Forwarding Information Base (FIB) information that the system configures in the home area.                                                                                                                                                                                |
| <i>id</i> <1-16777215> | Displays IS-IS SPBM IPv6 unicast FIB information by Service Instance Identifier (I-SID) ID.                                                                                                                                                                                                                    |
| <i>remote</i>          | Displays the IS-IS SPBM IPv6 unicast FIB information that the system configures in the remote area.                                                                                                                                                                                                            |
| <i>spbm-nh-as-mac</i>  | Displays the next hop as MAC of the IPv6 unicast FIB entry.                                                                                                                                                                                                                                                    |

The following table defines parameters for the **show isis spbm unicast-fib** command.

| Variable                                        | Value                                                                                                                      |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>b-mac</i><br><0x00:0x00:0x00:0x00:0x00:0x00> | Displays the FIB for the specified BMAC.                                                                                   |
| <i>home</i>                                     | Displays the IS-IS SPBM unicast Forwarding Information Base (FIB) information that the system configures in the home area. |
| <i>remote</i>                                   | Displays the IS-IS SPBM unicast FIB information that the system configures in the remote area.                             |
| <i>vlan</i> <1-4059>                            | Displays the FIB for the specified SPBM VLAN.                                                                              |
| <i>summary</i>                                  | Displays a summary of the FIB.                                                                                             |

The following table defines parameters for the **show isis spbm unicast-tree** command.

| Variable                            | Value                                                    |
|-------------------------------------|----------------------------------------------------------|
| <1-4059>                            | Specifies the SPBM B-VLAN ID.                            |
| <i>destination</i> <xxxx.xxxx.xxxx> | Displays the unicast tree for the specified destination. |

*Display IS-IS LSDB and Adjacencies*

Use the following procedure to display the IS-IS LSDB and adjacencies.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS LSDB:  

```
show isis lsdb [level {l1|l2|l12}] [sysid <xxxx.xxxx.xxxx>] [lspid
<xxxx.xxxx.xxxx.xx-xx>] [tlv <1-236>] [detail] [home|remote]
```
3. Display IS-IS adjacencies:  

```
show isis adjacencies [home|remote]
```
4. Clear IS-IS LSDB:  

```
clear isis lsdb
```

**Example**

```
Switch:1# show isis lsdb

### Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

| Variable                                  | Value                                                                              |
|-------------------------------------------|------------------------------------------------------------------------------------|
| <i>detail</i>                             | Displays detailed information.                                                     |
| <i>home</i>                               | Displays the IS-IS LSDB information that the system configures in the home area.   |
| <i>level {l1 l2 l12}}</i>                 | Displays the LSDB for the specified level: l1, l2, or l12.                         |
| <i>local</i>                              | Displays IS-IS local LSDB information.                                             |
| <i>remote</i>                             | Displays the IS-IS LSDB information that the system configures in the remote area. |
| <i>sysid &lt;xxxx.xxxx.xxxx&gt;</i>       | Displays the LSDB for the specified system ID.                                     |
| <i>lspid &lt;xxxx.xxxx.xxxx.xx-xx&gt;</i> | Displays the LSDB for the specified LSP ID.                                        |
| <i>tlv &lt;1-236&gt;</i>                  | Displays the LSDB by TLV type.                                                     |

The following table defines parameters for the **show isis adjacencies** command.

| Variable      | Value                                                                         |
|---------------|-------------------------------------------------------------------------------|
| <i>home</i>   | Displays the IS-IS adjacencies that the system configures in the home area.   |
| <i>remote</i> | Displays the IS-IS adjacencies that the system configures in the remote area. |

The following table defines parameters for the **clear isis** command.

| Variable    | Value                                                                                                                                                                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Isdb</i> | Clears the IS-IS Link State Database (LSDB). The command clears learned LSPs only. The command does not clear local generated LSPs. As soon as the platform clears the LSDB the LSP synchronization process starts immediately and the LSDB synchronizes with its neighbors. |

### Display IS-IS Statistics and Counters

Use the following procedure to display the IS-IS statistics and counters.

#### Procedure

1. Display IS-IS system statistics:  
`show isis statistics`
2. Display IS-IS interface counters:  
`show isis int-counters [home|remote]`
3. Display IS-IS level 1 control packet counters:  
`show isis int-l1-ctrl-pkts [home|remote]`

#### Note

The switch uses level 1 IS-IS. The switch does not support level 2 IS-IS. The command **show isis int-l2-ctrl-pkts** is not supported because the IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1.

4. Clear IS-IS statistics:  
`clear isis stats [error-counters] [packet-counters]`

#### Example

```
Switch:1# show isis statistics
=====
ISIS System Stats
=====
LEVEL   CORR  AUTH  AREA  MAX SEQ  SEQ NUM  OWN LSP  BAD ID  PART  LSP DB  AREA  AREA-NAME

| Port1/21 | Received    | 13335 | 226 | 1 | 227 | HOME | area-9.00.02 |

## Variable Definitions

The following table defines parameters for the **show isis int-counters** command.

| Variable      | Value                                                                                |
|---------------|--------------------------------------------------------------------------------------|
| <i>home</i>   | Displays the IS-IS interface counters that the system configures in the home area.   |
| <i>remote</i> | Displays the IS-IS interface counters that the system configures in the remote area. |

The following table defines parameters for the **show isis int-l1-ctrl-pkts** command.

| Variable      | Value                                                                                        |
|---------------|----------------------------------------------------------------------------------------------|
| <i>home</i>   | Displays the IS-IS L1 control packet counters that the system configures in the home area.   |
| <i>remote</i> | Displays the IS-IS L1 control packet counters that the system configures in the remote area. |

The following table defines parameters for the **clear isis stats** command.

| Variable               | Value                               |
|------------------------|-------------------------------------|
| <i>error-counters</i>  | Clears IS-IS stats error-counters.  |
| <i>packet-counters</i> | Clears IS-IS stats packet-counters. |

### Run the Layer 2 Video Surveillance install script

Use the following procedure to run the Layer 2 Video Surveillance install script.

#### Before You Begin

The switch must be in the factory default state. When you start the install script, the switch displays a prompt to remind you to do this.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Run the install script:
 

```
run vms layer-2 switch <5-99> [syntax]
```

The script uses the value that you assign to the switch number (between 5 and 99) to seed unique values in the configuration script.

## Examples

The following example shows the complete output of the install script without the `syntax` parameter. As you can see, there is no indication that the script encountered any errors.

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)# run vms layer-2 switch 6

Do you want to execute the run vms layer-2 script? Device needs to be in factory default
state. (y/n) ? y

**Previous configurations stored in pre_vms_layer2_install.cfg**
**New VMS configurations stored in new primary config file vms-layer2-switch-6.cfg**
*** VMS Layer-2 script execution complete ***
Switch:1(config)#boot config choice primary config-file /intflash/vms-layer2-switch-6.cfg
```

The following example displays the output of the script using the `syntax` parameter. This example is only a small sample of the output, but it shows how the script reports warnings and errors it encounters.

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)# run vms layer-2 switch 6 syntax

Do you want to execute the run vms layer-2 script? Device needs to be in factory default
state. (y/n) ? y

Switch:1(config)# save config file pre_vms_layer2_install.cfg
File [/intflash/pre_vms_layer2_install.cfg] already existing,CP-1: Save config to file /
intflash/pre_vms_layer2_install.cfg successful.
WARNING: Choice Primary Node Config file is "/intflash/vms-layer2-switch-6.cfg".

Switch:1(config)# spbm
Switch:1(config)# spbm ethertype 0x8100
Switch:1(config)# router isis
Switch:1(config-isis)# spbm 1

Error: ISIS - IS-IS is enabled, runtime change not allowed.

Switch:1(config)# exit

Switch:1(config)# save config file vms-layer2-switch-6.cfg
File [/intflash/vms-layer2-switch-6.cfg] already existing,CP-1: Save config to file /
intflash/vms-layer2-switch-6.cfg successful.

Switch:1(config)# boot config choice primary config-file /intflash/vms-layer2-switch-6.cfg
Switch:1(config)#
**Previous configurations stored in pre_vms_layer2_install.cfg**
**New VMS configurations stored in new primary config file vms-layer2-switch-6.cfg**
*** VMS Layer-2 script execution complete ***
Switch:1(config)#boot config choice primary config-file /intflash/vms-layer2-switch-6.cfg
```

## Variable Definitions

The following table defines parameters for the `run vms layer-2 switch` command.

| Variable      | Value                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <5-99>        | Specifies a switch value, which is then used as a common element to configure switch parameters such as nickname, VLAN ID, SPB and IP parameters.<br>This switch value is also used in the name of the saved configuration file. For example, <b>6</b> is the switch value in <code>vms-layer2-switch-6.cfg</code>                                                      |
| <i>syntax</i> | Species that the switch displays all the commands run by the script on the console. Use this parameter to see errors that the script encounters.<br><br><b>Note:</b><br>The script does not stop if it encounters errors. To verify that the script runs without errors, use the <i>syntax</i> parameter to display errors or conflicting configurations on the switch. |

### *Suspend Duplicate System ID Detection When Replacing a Switch*

When a switch is replaced and the original system ID and nickname is used, you must wait up to 20 minutes for the LSPs with the original system to age out. This is due to duplicate system ID and nickname detection. However, you can suspend duplicate detection on the replacement switch so that you can bring the switch into the network immediately.

#### **About This Task**

To temporarily disable duplicate detection on the replacement switch, perform the following steps:

#### **Procedure**

1. Copy the configuration file of the original switch to the replacement switch.
2. Power up the replacement switch while it is not connected to the SPB network, that is, NNI ports are not connected.
3. Disable IS-IS on the original switch, or remove the switch from the network.
4. On the replacement switch, enter the following Global Configuration command to suspend duplicate detection for up to 21 minutes:  

```
isis dup-detection-temp-disable
```
5. To check the remaining time, use the `show isis dup-detection-temp-disable remaining time` command.
6. Remove the original switch from the network.
7. Connect the replacement switch to the network.

### *Configure Dynamic Nickname Assignment*

#### **About This Task**

Use this procedure to specify a nickname prefix for Dynamic Nickname Assignment.

#### **Note**

You must disable Dynamic Nickname Assignment before you can change the nickname prefix.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the Dynamic Nickname Assignment nickname allocation:
 

```
spbm nick-name server prefix x.xx.xx
```
3. Enable Dynamic Nickname Assignment:
 

```
spbm nick-name server
```
4. Verify the configuration:
 

```
show spbm
```

## Examples

Configure a nickname allocation prefix and enable Dynamic Nickname Assignment:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spbm nick-name server prefix C.30.00
Switch:1(config)#spbm nick-name server
```

Dynamic Nickname Assignment configuration values and their associated behavior are shown in the following output from the **show spbm** command:

```
Switch:1>show spbm
                    spbm : enable
                    ethertype : 0x8100
                    nick-name server : enable
                    nick-name allocation : static
                    nick-name server range : C.30.00-C.3F.FF
```

## Variable Definitions

The following table defines parameters for the **spbm nick-name server** command.

| Variable              | Value                                                                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>prefix x.xx.xx</i> | Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default nickname allocation range is A.00.00-A.0F.FF. |

### *Display Dynamic Nickname Assignment*

#### About This Task

Use this procedure to display the current status and values for Dynamic Nickname Assignment.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display Dynamic Nickname Assignment configuration values:
 

```
show spbm
```

**Example**

```
Switch:1>show spbm
                spbm : enable
                ethertype : 0x8100
                nick-name server : disable
                nick-name allocation : static
                nick-name server range : A.00.00-A.0F.FF
```

*Enabling MSTP-Fabric Connect Multi Homing***Note**

This procedure does not apply to VSP 8600 Series or XA1400 Series.

**About This Task**

Perform this procedure to enable MSTP-Fabric Connect Multi Homing for a specific SPBM instance.

**Before You Begin**

You must configure a nickname for the specific SPBM instance on which you enable MSTP-Fabric Connect Multi Homing.

**Procedure**

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
2. Enable MSTP-Fabric Connect Multi Homing on a specified SPBM instance:
 

```
spbm <1-100> stp-multi-homing enable
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 stp-multi-homing enable
```

**Variable definitions**

The following table defines parameters for the **spbm** command.

| Variable                       | Value                                                                                            |
|--------------------------------|--------------------------------------------------------------------------------------------------|
| <i>&lt;1-100&gt;</i>           | Specifies the IS-IS SPBM instance ID to create an SPBM instance.                                 |
| <i>stp-multi-homing enable</i> | Enables MSTP-Fabric Connect Multi Homing on the specific SPBM instance. The default is disabled. |

### Determine the Root Bridge in an MSTP-Fabric Connect Multi Homing Configuration

Identify the root bridge by determining where the Common and Internal Spanning Tree (CIST) regional root MAC address is learned for the STP-reserved I-SID. Check which MAC address has the same first five octets as the CIST regional root MAC address.

#### About This Task

When you enable MSTP-Fabric Connect Multi Homing, you can use the following two commands to determine which BEB is the root bridge:

- **show spanning-tree mstp status**
- **show i-sid mac-address-entry 16777003**

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Determine the CIST regional root:
 

```
show spanning-tree mstp status
```
3. Determine which MAC address has the same first five octets as seen in the CIST regional root MAC address:
 

```
show i-sid mac-address-entry 16777003
```

#### Example

In the following example, bold text identifies the relevant information in the command output. In the output of the second command, the DEST-MAC shows 10:cd:ae:6e:d8:84, which is the system ID of the CIST regional root BEB, and the system name is BEB-1000.

```
Switch:1>show spanning-tree mstp status
```

```

## Fabric Extend configuration using the CLI

The following sections provide procedural information you can use to configure Fabric Extend (FE) using the Command Line Interface (CLI).

### *Configure Fabric Extend*

Use the following procedure to configure Fabric Extend (FE) between a Main office to a Branch office. This is a typical deployment. However, if your deployment creates tunnels between two switches that support Fabric Extend natively, then repeat those steps and ignore the steps for switches that require an ONA.

#### Note

VRF is an optional parameter. If a VRF is not configured, then FE uses the GRT.

### **Before You Begin**

The tunnel source IP address can be a brouter port IP, a CLIP IP, or a VLAN IP.

#### Note

Product Notice: Except VSP 8600 Series, all product series support a VLAN IP as the Fabric Extend tunnel source IP address.

For information about product support, see [Fabric Extend Considerations](#) on page 961.

If using the tunnel originating address on the **GRT**, Fabric Extend has the following requirements:

- The tunnel source IP address must be on the GRT, not on a VRF.

#### Note

A best practice is to use separate IP addresses for the SPBM IP Shortcuts **ip-source-address** command and the Fabric Extend **ip-tunnel-source-address** command. However, if you want these IP addresses to be the same, you **MUST** exclude the **ip-source-address** address with an IS-IS accept policy. You cannot use the redistribute command with a route map exclusion.

Specify a CLIP interface to use as the source address for SPBM IP shortcuts.

- If IP Shortcuts is enabled, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.

If you are using the tunnel originating address on a **VRF**, Fabric Extend has the following requirements:

- Configure a CLIP and tunnel source IP address on the VRF.
- Remote management of the VSP 4450 Series is only possible after establishing IP Shortcut over IS-IS. (Alternatively, you can enable GRT-VRF redistribution locally.)

### **About This Task**

Configuring Fabric Extend consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

Note that the VSP 4450 Series source address command is different than other platforms. Also note that the logical interface commands are different between Layer 2 and Layer 3 networks.

## Procedure

The following steps are for platforms that support FE natively:

1. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

2. Configure the IP tunnel source address:

```
ip-tunnel-source-address <A.B.C.D> [vrf WORD<1-16>]
```

3. Enter Global Configuration mode:

```
exit
```

4. Use one of the following commands to create a logical IS-IS interface:

- In a network with a Layer 3 Core, enter `logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>] [mtu <750-9000>]`
- In a network with a Layer 2 Core, enter `logical-intf isis <1-255> vid <list of vids> primary-vid <2-4059> port <slot/port> mlt <mltId> [name WORD<1-64>] [mtu <750-9000>]`

### Note

The primary VLAN ID (**primary-vid** must be one of the VLANs in the **vid <list of vids>**.

The following steps are for platforms that require an ONA to support FE:

### Note

The interface VLAN connecting to the ONA network port is always in the GRT and the member port that the VLAN is part of is always an access port.

5. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

6. Configure the IP tunnel source address on the port that connects to the Device side of the ONA:

```
ip-tunnel-source-address <A.B.C.D> port <slot/port> [mtu <mtu_value>]  
[vrf WORD<1-16>]
```

7. Exit back into Global Configuration mode:

```
exit
```

8. Use one of the following commands to create a logical IS-IS interface:

- In a network with a Layer 3 Core, enter:

```
logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>]
```

- In a network with a Layer 2 Core, enter:

```
logical-intf isis <1-255> vid <list of vids> primary-vid <2-4059>  
port <slot/port> mlt <mltId> [name WORD<1-64>]
```

#### Note

The primary VLAN ID (**primary-vid**) must be one of the VLANs in the **vid <list of vids>**.

## Variable Definitions

The following table defines parameters for the **ip-tunnel-source-address** command.

To delete an IS-IS IP tunnel source address, use the **no ip-tunnel-source-address** option.

#### Note

The **port** parameter is for the VSP 4450 Series only.

| Variable         | Value                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <A.B.C.D>        | Specifies the IS-IS IPv4 tunnel source address, which can be a brouter interface IP, a CLIP IP, or a VLAN IP.                                                                                                                                      |
| port <slot/port> | Specifies the port that is connected to the ONA's Device port.                                                                                                                                                                                     |
| vrf WORD<1-16>   | Specifies the VRF name associated with the IP tunnel.                                                                                                                                                                                              |
| mtu <mtu_value>  | Specifies the Maximum Transmission Unit (MTU) size for each packet. Different hardware platforms support different MTU ranges. Use the CLI Help to see the available range for the switch.<br>This parameter only applies to an ONA configuration. |

The following table defines parameters for the **logical-intf isis** command, depending on whether you have a Layer 2 or Layer 3 core.

To delete a logical IS-IS interface, use the **no logical-intf isis** option.

**Table 105: Layer 2 core**

| Variable                                                         | Value                                                                                        |
|------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| <1-255>                                                          | Specifies the index number that uniquely identifies this logical interface.                  |
| port {slot/port[/sub-port]<br>[-slot/port[/sub-port]]<br>[,...]} | Specifies the physical port that the logical interface is connected to in a Layer 2 network. |
| vid <list of vids>                                               | Specifies the list of VLANs that are associated with this logical interface.                 |

**Table 105: Layer 2 core (continued)**

| Variable                                                                             | Value                                                                                                     |
|--------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <i>primary-vid</i> <2-4059>                                                          | Specifies the primary tunnel VLAN ID associated with this Layer 2 IS-IS logical interface.                |
| <i>mlt</i> < <i>mltId</i> >                                                          | Specifies the MLT ID that the logical interface is connected to in a Layer 2 network.                     |
| <i>name</i> WORD<1-64>                                                               | Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters. |
| <i>mtu</i> <750-9000><br><b>Note:</b><br>Exception: only supported on XA1400 Series. | Specifies the Maximum Transmission Unit (MTU) size of each packet. The default MTU value is 1950.         |

**Table 106: Layer 3 core**

| Variable                                                                             | Value                                                                                                     |
|--------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <1-255>                                                                              | Specifies the index number that uniquely identifies this logical interface.                               |
| <i>dest-ip</i> <A.B.C.D>                                                             | Specifies the tunnel destination IP address of the remote BEB.                                            |
| <i>name</i> WORD<1-64>                                                               | Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters. |
| <i>mtu</i> <750-9000><br><b>Note:</b><br>Exception: only supported on XA1400 Series. | Specifies the Maximum Transmission Unit (MTU) size of each packet. The default MTU value is 1950.         |

*Configure Fabric Extend Over IPsec***Note**

This procedure only applies to XA1400 Series.

Use the following procedure to configure Fabric Extend (FE) over IPsec.

**Before You Begin**

The tunnel source IP address can be a router port IP, a CLIP IP, or a VLAN IP.

**About This Task**

Configuring Fabric Extend over IPsec consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

For information about how to configure an IPsec NAT-T Responder, see [IPsec configuration using CLI](#) on page 1753.

## Procedure

### Switch A Steps

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```

2. Configure the IP tunnel source address:

```
ip-tunnel-source-address <A.B.C.D> [vrf WORD<1-16>]
```

3. Enter Global Configuration mode:

```
exit
```

4. Use one of the following commands to create a logical IS-IS interface:

- In a network with a Layer 3 Core, enter `logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>] [mtu <750-9000>]`

5. Configure an IS-IS interface on the selected ports or MLTs:

- a. Create an IS-IS circuit and interface on the selected ports or MLTs:

```
isis
```

- b. Enable the SPBM instance on the IS-IS interfaces:

```
isis spbm <1-100>
```

- c. Enable the IS-IS circuit/interface on the selected ports or MLTs:

```
isis enable
```

6. Configure the IPsec authentication method:

```
ipsec auth-method <pre-share |rsa-sig>
```

7. Create the authentication key, if using a pre-shared key:

```
auth-key WORD<1-32>
```

8. Configure IPsec encryption key length for FE tunnel.

```
ipsec encryption-key-length <128 | 256>
```

#### Note

- You cannot change the encryption key length when IPsec is enabled on the FE tunnel.

9. (Optional) Enable IPsec compression on the logical interface:

```
ipsec compression
```

By default, IPsec compression is disabled. If you enable it, you must enable it on both ends of the adjacency.

10. Enable IPsec on the logical interface:

```
ipsec
```

11. Exit interface configuration mode:

```
exit
```

### Switch B Steps

12. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

13. Configure the IP tunnel source address:

```
ip-tunnel-source-address <A.B.C.D> [vrf WORD<1-16>]
```

14. Enter Global Configuration mode:

```
exit
```

15. Use one of the following commands to create a logical IS-IS interface:

- In a network with a Layer 3 Core, enter `logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>] [mtu <750-9000>]`

16. Configure an IS-IS interface on the selected ports or MLTs:

- a. Create an IS-IS circuit and interface on the selected ports or MLTs:

```
isis
```

- b. Enable the SPBM instance on the IS-IS interfaces:

```
isis spbm <1-100>
```

- c. Enable the IS-IS circuit/interface on the selected ports or MLTs:

```
isis enable
```

17. Configure the IPsec authentication method:

```
ipsec auth-method <pre-share |rsa-sig>
```

18. Create the authentication key, if using a pre-shared key:

```
auth-key WORD<1-32>
```

19. Configure IPsec encryption key length for FE tunnel.

```
ipsec encryption-key-length <128 | 256>
```

### Note

- You cannot change the encryption key length when IPsec is enabled on the FE tunnel.

20. (Optional) Enable IPsec compression on the logical interface:

```
ipsec compression
```

By default, IPsec compression is disabled. If you enable it, you must enable it on both ends of the adjacency.

21. Enable IPsec on the logical interface:

```
ipsec
```

22. Exit interface configuration mode:

```
exit
```

## Variable Definitions

The following table defines parameters to configure Fabric Extend (FE) over IPsec on a device.

The following table defines parameters for the **ip-tunnel-source-address** command.

| Variable       | Value                                                                                              |
|----------------|----------------------------------------------------------------------------------------------------|
| <A.B.C.D>      | Specifies the IS-IS IPv4 tunnel source address, which can be a router IP, a CLIP IP, or a VLAN IP. |
| vrf WORD<1-16> | Specifies the VRF name associated with the IP tunnel.                                              |

**Table 107: Layer 3 core**

| Variable        | Value                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------------|
| <1-255>         | Specifies the index number that uniquely identifies this logical interface.                               |
| <A.B.C.D>       | Specifies the IS-IS IPv4 tunnel source address, which can be either a router interface IP or a CLIP IP.   |
| name WORD<1-64> | Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters. |
| mtu <750-9000>  | Specifies the Maximum Transmission Unit (MTU) size of each packet. The default MTU value is 1950.         |

The following table defines parameters for the **isis** command.

| Variable     | Value                                                                                                                                                                 |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enable       | Enables or disables the IS-IS circuit/interface on the specified port or MLT. The default is disabled. Use the no option to disable IS-IS on the specified interface. |
| spbm <1-100> | Enable the SPBM instance on the IS-IS interfaces.                                                                                                                     |

The following table defines parameters for the **auth-key** command.

| Variable   | Value                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<1-32> | Specifies the authentication key on the assigned logical interface if using a pre-shared key. Use the no option to disable the authentication key on the specified interface. |

The following table defines parameters for the **ipsec** command.

| Variable                                             | Value                                                                                                                                                      |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>auth-method &lt;pre-share   rsa-sig&gt;</code> | Configures the authentication method for IPsec. The default is a pre-shared key. Use <code>rsa-sig</code> to use an installed digital certificate instead. |
| <code>encryption-key-length &lt;128   256&gt;</code> | Specifies the IPsec encryption key length for FE tunnel, which is 128 bit or 256 bit. The default IPsec encryption key length value is 128 bit.            |

### Configure Static Source IP Address for IPsec Tunnel

#### Note

This procedure only applies to XA1400 Series.

Perform this procedure to configure a specific source IP address for the IPsec tunnel when you deploy the XA1400 Series in an environment that requires more than one provider connection with IPsec.

#### Before You Begin

- Configure a VLAN, brouter, or CLIP IP address for the IPsec tunnel to use; this address must be in the same VRF as the tunnel.
- Disable IPsec on the logical interface.

#### About This Task

The static source IP address for the IPsec tunnel cannot be the same as the global or dynamically configured source IP address.

#### Procedure

1. Enter Logical IS-IS Interface Configuration mode:
 

```
enable
configure terminal
logical-intf isis <1-255>
```
2. Configure the IP address to use as the source IP address for IPsec tunnel:
 

```
ipsec tunnel-source-address type static {A.B.C.D}
```
3. Enable IPsec on the logical interface:
 

```
ipsec
```

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#logical-intf isis 3
Switch:1(config-isis-3-198.51.100.1)#ipsec tunnel-source-address type static 20.20.20.20
Switch:1(config-isis-3-198.51.100.1)#ipsec
```

## Variable Definitions

The following table defines parameters for the **ipsec tunnel-source-address type static** command.

| Variable  | Value                                                                                                                                                               |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D} | Specifies the manually configured source IP address for the IPsec tunnel. The source IP address must be on the same VRF as the source IP address for the IP tunnel. |

### Configure DHCP Source IP Address for IPsec Tunnel

#### Note

This procedure only applies to XA1400 Series.

Perform this procedure to dynamically obtain the source IP address for the IPsec tunnel from DHCP when you deploy the XA1400 Series in an environment that requires more than one provider connection with IPsec.

### Before You Begin

- Disable IPsec on the logical interface.
- Ensure that the DHCP client is enabled for the Management Instance VLAN interface.
- Ensure that there is coexistence between the VOSS routing stack and the Management Instance VLAN interface. Use the **propagate-to-routing** command from the mgmt VLAN level to move to the coexistence mode automatically. For more information, see [VLAN](#) on page 70.

### About This Task

The static source IP address for the IPsec tunnel cannot be the same as the global or dynamically configured source IP address.

### Procedure

1. Enter Logical IS-IS Interface Configuration mode:
 

```
enable

configure terminal

logical-intf isis <1-255>
```
2. Import the source IP address from DHCP:
 

```
ipsec tunnel-source-address type dhcp
```
3. Enable IPsec on the logical interface:
 

```
ipsec
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#logical-intf isis 3
Switch:1(config-isis-3-198.51.100.1)#ipsec tunnel-source-address type dhcp
Switch:1(config-isis-3-198.51.100.1)#ipsec
```

*Configure ESP Cipher Suite for IPsec***Note**

This procedure only applies to XA1400 Series.

**Before You Begin****About This Task**

Configure the Encapsulating Security Payload (ESP) cipher suite for IPsec.

**Procedure**

1. Enter Logical IS-IS Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
logical-intf isis <1-255>
```

2. Configure the ESP cipher suite for IPsec:

```
ipsec esp [<aes128gcm16-sha256 | aes256-sha256 | aes256gcm16-sha256 >]
```

**Variable Definitions**

The following table defines parameters for the **ipsec esp** command.

| Variable             | Value                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------|
| <aes128gcm16-sha256> | Specifies the AES cipher with a 128-bit encryption key and GCM block mode.                            |
| <aes256-sha256>      | Specifies the AES cipher with a 256-bit encryption key and CBC block mode (for QAT performance mode). |
| <aes256gcm16-sha256> | Specifies the AES cipher with a 256-bit encryption key and GCM block mode.                            |

*Disable IPsec Compression***Note**

If you downgrade to an earlier release that does not support this feature, you must disable the feature and save the configuration. Downgrading to an earlier release will require a compatible configuration file.

**Procedure**

1. Enter Logical IS-IS Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
logical-intf isis <1-255>
```

2. Disable IPsec:
 

```
no ipsec
```
3. Disable IPsec compression:
 

```
no ipsec
```
4. Enable IPsec:
 

```
ipsec
```
5. Save the configuration.
6. Verify the configuration:
 

```
show isis logical-interface ipsec
```

### Example

```
Switch:1(config-isis-2-192.0.2.10)# no ipsec
Switch:1(config-isis-2-192.0.2.10)# no ipsec compression
Switch:1(config-isis-2-192.0.2.10)# ipsec
Switch:1(config-isis-2-192.0.2.10)#show isis logical-interface ipsec
=====
                                     ISIS Logical Interface IPsec
=====

### Configure IS-IS Hello Padding

#### Note

This procedure does not apply to VSP 8600 Series.

Perform this procedure to dynamically configure IS-IS hello padding on all IS-IS NNI links. IS-IS hello padding is enabled by default.

### About This Task

Disable hello padding if the WAN-line MTU is less than 1596 bytes and fragmentation and reassembly functionality is enabled.

### Procedure

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```

2. Perform one of the following actions:
  - Disable hello padding: `no hello-padding`
  - Enable hello padding, if previously disabled: `hello-padding`
3. Verify the configuration:
 

```
show isis
```

### Example

Verify IS-IS hello padding status:

```
Switch:1>show isis
=====

```

### Enable IPsec Fragmentation Before Encryption

#### Note

This procedure only applies to XA1400 Series.

Configure IPsec fragmentation before encryption to avoid possible throughput penalty for sending fragmented packets over the Internet.

### Before You Begin

- Configure the IPsec tunnel source address globally.
- Disable IPsec on the logical interface.
- IPsec over Fabric Extend must be in IPsec decoupled mode. For more information, see [Fabric IPsec Gateway Fundamentals](#) on page 852.
- Configure one of the following:
  - the IPsec tunnel destination IP

- IPsec NAT-T responder only mode
- IPsec responder remote NAT IP address

### Procedure

1. Enter Logical IS-IS Interface Configuration mode:  
enable  
  
configure terminal  
  
logical-intf isis <1-255>
2. Enable IPsec fragmentation before encryption on the logical interface:  
ipsec fragment-before-encrypt
3. Enable IPsec on the logical interface:  
ipsec
4. Verify the configuration:  
show isis logical-interface ipsec

### Example

Enable IPsec fragment before encryption and verify the configuration:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#logical-intf isis 2
Switch:1(config-isis-2-192.0.2.24)#ipsec fragment-before-encrypt
Switch:1(config-isis-2-192.0.2.24)#ipsec
Switch:1>show isis logical-interface ipsec
```

```

### Disable IPsec Fragmentation Before Encryption

#### Note

This procedure only applies to XA1400 Series.

If you downgrade to an earlier release that does not support this feature, you must disable the feature and save the configuration. You must have a compatible configuration file if you downgrade to an earlier release.

## Before You Begin

### Procedure

1. Enter Logical IS-IS Interface Configuration mode:  
enable  
  
configure terminal  
  
logical-intf isis <1-255>
2. Disable IPsec on the logical interface:  
no ipsec
3. Disable IPsec fragmentation before encryption on the logical interface:  
no ipsec fragment-before-encrypt
4. Enable IPsec on the logical interface:  
ipsec
5. Verify the configuration:  
show isis logical-interface ipsec

### Example

Disable IPsec and IPsec fragmentation before encryption and verify the configuration:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#logical-intf isis 2
Switch:1(config-isis-2-192.168.20.1)#no ipsec
Switch:1(config-isis-2-192.168.20.1)#no ipsec fragment-before-encrypt
Switch:1(config-isis-2-192.168.20.1)#ipsec
Switch:1(config-isis-2-192.168.20.1)#show isis logical-interface ipsec

Adjust the TCP Maximum Segment Size

#### Note

This procedure only applies to VSP 4900 Series, VSP 7400 Series, and XA1400 Series.

Adjust the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency.

### About This Task

#### Note

If you downgrade to an earlier release that does not support this feature, you must disable the feature and save the configuration. Downgrading to an earlier release requires a compatible configuration file.

The default varies depending on hardware platform:

- For XA1400 Series, this functionality is enabled when at least one Fabric Extend (FE) tunnel with a MTU less than or equal to 1500 is configured, and the value is auto-derived.
- For VSP 4900 Series and VSP 7400 Series, this functionality is disabled. The default value, when enabled, is 1300.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Use one of the following commands to configure the MSS adjustment functionality as required:

- a. Configure an explicit MSS adjust value:

```
ip tcp adjust-mss mss <max-segment-size> [enable]
```

- b. Disable MSS adjustment explicitly:

```
no ip tcp adjust-mss
```

- c. Disable a configured MSS adjustment value and return to the auto-derived value:

#### Note

This step only applies to XA1400 Series.

```
no ip tcp adjust-mss mss
```

3. Verify the configuration:

```
show ip tcp adjust-mss
```

### Examples

Configure an MSS value of 1100 and verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip tcp adjust-mss mss 1100
Switch:1>show ip tcp adjust-mss
```

```
=====
                        IP TCP Adjust MSS
=====
ENABLE          STATUS          TCP MSS          TCP MSS
                        TYPE          VALUE
```

```
-----
TRUE                ACTIVE                MANUAL-CONFIG                1100
-----
```

Disable the configured MSS adjustment value on XA1400 Series and verify the configuration:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no ip tcp adjust-mss mss
Switch:1(config)#show ip tcp adjust-mss
=====
                IP TCP Adjust MSS
=====
ENABLE        STATUS        TCP MSS        TCP MSS
                TYPE                VALUE
-----
TRUE          ACTIVE        AUTO-DERIVED   1300
-----
```

### Displaying Fabric Extend over IPsec tunnel status

Use the following procedure to display the Fabric Extend over IPsec tunnel status on the switch.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Fabric Extend over IPsec tunnel status:

```
show io logical-intf-ipsec
```

Example of a Fabric Extend over IPsec tunnel status.

```
Switch:1> show io logical-intf-ipsec
bash-4.3# ipsec status | grep ESTABLISHED
ipsec1-192.0.2.192[12]: ESTABLISHED 13 hours ago,
192.0.2.193[192.0.2.193]...192.0.2.192[192.0.2.192]
ipsec0-192.0.2.182[11]: ESTABLISHED 13 hours ago,
192.0.2.193[192.0.2.193]...192.0.2.182[192.0.2.182]
```

### Configure BFD on a Fabric Extend Tunnel

#### About This Task

Use the following procedure to configure BFD on a Fabric Extend Tunnel.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Enable BFD:
 

```
router bfd enable
```
3. In the VLAN Interface Configuration mode, you can enable BFD:
 

```
ip bfd enable
```
4. In the Loopback Interface Configuration mode, you can enable BFD:
 

```
ip bfd enable
```

5. Enable BFD on an IS-IS Logical Interface:

```
logical-intf isis <1-255> bfd enable
```

### Example

Enable BFD on a Fabric Extend tunnel:

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bfd enable
Switch:1(config)#interface loopback 1
Switch:1(config-if)#ip bfd enable
Switch:1(config-if)#logical-intf isis 1
Switch:1(config-isis-1-1.2.3.5)#bfd enable
```

### Display IS-IS Logical Interfaces

Use the following procedure to display the Intermediate-System-to-Intermediate-System (IS-IS) logical interfaces configured on the switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS logical interfaces:

```
show isis logical-interface [name | ipsec | shaper | mtu]
```

### Examples

Example of a Layer 2 Core

```

## Variable Definitions

The following table defines parameters for the **show isis logical-interface** command.

| Variable | Value                                                                                                                               |
|----------|-------------------------------------------------------------------------------------------------------------------------------------|
| name     | Displays the full name of the IS-IS logical interface (up to a maximum of 64 characters).                                           |
| ipsec    | Displays the IS-IS logical interface ID and IPsec authentication key.                                                               |
| shaper   | Displays the IS-IS logical interface egress shaping rate values. Only interfaces that have egress shaping rates configured display. |

## Display BFD Fabric Extend Neighbor Information

### About This Task

Use this procedure to display BFD Fabric Extend neighbors.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the BFD configurations:
 

```
show ip bfd neighbors vrf WORD<1-16>
```

**Example**

```
Switch:1>show ip bfd neighbors vrf vrf30
=====
BFD Session - VRF vrf30

UP          ISIS      ISIS
-----
1 out of 1 BFD session displayed
-----
```

*Configure Global Source IP Address for IPsec Tunnel***About This Task**

Perform this procedure to configure the global source IP address for IPsec tunnel on the switch.

**Note**

Product Notice: This procedure only applies to XA1400 Series switches.

**Procedure**

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
2. Configure the source IP address for IPsec tunnel:
 

```
ipsec tunnel-source-address {A.B.C.D}
```

**Note**

You must configure the source IP address for IPsec tunnel on the same VRF as the source address for IP tunnel.

**Example**

Configuring source IP address for IPsec tunnel.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#ipsec tunnel-source-address 192.0.2.10
```

## Variable Definitions

The following table defines the variable for **ipsec tunnel-source-address** command.

| Variable  | Value                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D} | Specifies the global IP address for IPsec tunnel, which is configured on the same VRF as the source address for IP tunnel. |

### Configure Destination IP Address for IPsec Tunnel

#### About This Task

Perform this procedure to configure the destination IP address for the IPsec tunnel on a specific IS-IS logical interface on the switch.

#### Note

Product Notice: This procedure only applies to XA1400 Series switches.

#### Procedure

1. Enter Logical IS-IS Interface Configuration mode:
 

```
enable

configure terminal

logical-intf isis <1-255>
```
2. Configure destination IP address for IPsec tunnel:
 

```
ipsec tunnel-dest-ip {A.B.C.D}
```

#### Example

Configuring destination IP address for IPsec tunnel.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#logical-intf isis 1
Switch:1(config-isis-1-192.0.2.25)ipsec tunnel-dest-ip 192.0.2.30
```

## Variable Definitions

The following table defines the variable for **ipsec tunnel-dest-ip** command.

| Variable  | Value                                                                                        |
|-----------|----------------------------------------------------------------------------------------------|
| {A.B.C.D} | Specifies destination IP address for the IPsec tunnel on a specific IS-IS logical interface. |

## Fabric Attach Configuration using the CLI

The following sections provide procedural information you can use to configure Fabric Attach (FA) and Logical Link Discovery Protocol (LLDP) using the Command Line Interface (CLI). For information about LLDP related to FA, see [Link Layer Discovery Protocol configuration using CLI](#) on page 2185.

*Configure Fabric Attach Globally*

For proper operation, FA must be enabled at both the global level and at the interface level on the FA Server. By default, FA is globally enabled. However, FA is disabled by default at the interface level and must be explicitly enabled on each interface.

Use this procedure to enable Fabric Attach globally on a switch.

**Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable FA:

```
fa enable
```

3. (Optional) Disable FA:

```
no fa enable
```

**Caution**

Disabling FA flushes all FA element discovery and mappings.

4. View the FA configuration status. Use one of the following commands:

- show fa
- show fa agent

**Example**

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#fa enable

Switch:1>show fa

=====
Fabric Attach Configuration
=====
FA Service : enabled
FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
FA Provision Mode : spbm

Switch:1>show fa agent

=====
Fabric Attach Configuration
=====
FA Service : enabled
FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
FA Provision Mode : spbm
```

### Configuring Fabric Attach discovery timeout

Use this procedure to configure the Fabric Attach discovery time-out.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the FA discovery time-out in seconds:  

```
fa discovery-timeout <45-480>
```

#### Note

The discovery time-out must be greater than or equal to the assignment time-out.

3. (Optional) Configure the default FA discovery time-out:

```
default fa discovery-timeout
```

#### Example

Configure the FA discovery time-out.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#fa discovery-timeout 50
```

Verify the configuration.

```
Switch:1(config)#show fa

=====
                        Fabric Attach Configuration
=====

                FA Service : enabled
                FA Element Type : server
FA Assignment Timeout : 45
FA Discovery Timeout : 50
                FA Provision Mode : spbm
```

#### Variable definitions

The following table defines parameters for the **fa discovery-timeout** command.

| Variable | Value                                                                                        |
|----------|----------------------------------------------------------------------------------------------|
| <45-480> | Specifies the Fabric Attach discovery time-out in seconds. The default value is 240 seconds. |

### Configuring Fabric Attach assignment timeout

Use this procedure to configure the Fabric Attach assignment time-out.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the FA assignment time-out in seconds:  

```
fa assignment-timeout <45-480>
```

### Note

The assignment time-out must be less than or equal to the discovery time-out.

3. (Optional) Configure the default FA assignment time-out value:  

```
default fa assignment-timeout
```

## Example

Configure the FA assignment time-out:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#fa assignment-timeout 50
```

Verify the configuration:

```
Switch:1(config)#show fa

=====
                          Fabric Attach Configuration
=====

          FA Service : enabled
          FA Element Type : server
          FA Assignment Timeout : 50
          FA Discovery Timeout : 240
          FA Provision Mode : spbm
```

## Variable definitions

The following table defines parameters for the **fa assignment-timeout** command.

| Variable | Value                                                                                            |
|----------|--------------------------------------------------------------------------------------------------|
| <45-480> | Specifies the Fabric Attach assignment time-out in seconds.<br>The default value is 240 seconds. |

### *Enabling Fabric Attach on an interface*

Use this procedure to enable Fabric Attach on an interface (port, static MLT or LACP MLT). Enabling FA on an MLT enables FA on all ports of the MLT. If your platform supports channelization, FA can also be enabled on channelized ports.

## Before You Begin

Verify that FA is enabled globally on the switch.

## About This Task

Enabling FA on a port or MLT is necessary for element discovery.

On the FA Server, FA is enabled globally by default. However, you must explicitly enable FA on the desired port or MLT interface. FA is successfully enabled on an MLT only if all ports of the MLT have FA successfully enabled. Enabling FA automatically configures LLDP on all ports. Tagging is configured and spanning tree is disabled.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable FA on the interface:

```
fa enable
```

3. (Optional) Disable FA on the interface:

```
no fa enable
```

### Caution

Disabling FA flushes all FA element discovery and I-SID-to-VLAN mappings associated with the interface.

4. View the FA configuration status:

```
show fa interface [disabled-auth] [enabled-auth] [mlt <1-512>] [port
<{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}>]
```

## Example

Enable FA on a port:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#fa enable
Switch:1(config-if)#exit
Switch:1(config)#
```

Enable FA on an MLT:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#fa enable
```

```
Switch:1(config-mlt)#exit
Switch:1(config)#
```

Verify that FA is enabled on the interfaces.

### Note

When FA is enabled, message authentication is enabled by default. The authentication key is set to the default value and displays encrypted on the output.

```
Switch:1>show fa interface
```

```
=====
                        Fabric Attach Interfaces
=====
INTERFACE      SERVER  MGMT   MGMT   MSG AUTH  MSG AUTH  ORIGIN

| enabled-auth                                               | Displays the FA interfaces (port or MLT) that have authentication enabled.                                                                                                                                                                                                                                                                                                                                        |
| <1-512>                                                    | The valid range for MLT ID.<br>Displays FA configuration on the specified MLT interface.                                                                                                                                                                                                                                                                                                                          |
| port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.<br>Displays FA configuration on the specified port. |

### Configuring FA message authentication on an interface

Use this procedure to configure FA message authentication on an interface (port or MLT).

#### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure FA message authentication on a port or MLT:

```
[default] [no] fa message-authentication
```

#### Note

When FA is enabled, message authentication is enabled by default. The authentication key is set to the default value and displays encrypted on the output.

#### Example

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#
```

Enable message authentication on a port.

```
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#fa message-authentication
Switch:1(config-if)#show fa interface port 1/2
```

```
=====

-----
```

*Configuring the FA authentication key on an interface*

On the FA Server, you can configure an authentication key on an interface (port, static MLT or LACP MLT), to authenticate a client or proxy device on that interface. The authentication key is stored in encrypted form when you save configuration on the FA Server.

**Before You Begin**

Ensure that:

- On the FA Server, FA is enabled globally and also on the interface.
- FA message authentication is enabled on the interface.

**Note**

By default, enabling FA enables message authentication. The authentication key is set to the default value and the system displays the encrypted authentication key on the output.

**About This Task**

Use this procedure to configure an FA authentication key on a specified port or on all ports of an MLT, on the switch. If you do not configure an authentication key, the default value is used. If you specify a key, the default value is overridden and is stored in encrypted format in a separate file other than the configuration file, when you execute the `save config` command.

**Caution**

For an FA Client or an FA Proxy device to successfully authenticate and attach to the FA Server, the authentication key must match on both the client and the server. If the authentication key is changed on the FA Server switch, it must correspondingly be changed on the FA Client or Proxy attached to it, for FA to operate properly.

**Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface mlt <1-512>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the FA authentication key:

```
fa authentication-key WORD<0-32>
```

3. (Optional) Configure the default FA authentication key:

```
default fa authentication-key
```

**Example**

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
```

Enable FA and message authentication on a port. Configure the authentication key `phone-network` on the port.

```
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#fa enable
Switch:1(config-if)#fa message-authentication
Switch:1(config-mlt)#fa authentication-key phone-network
Switch:1(config-if)#exit
Switch:1(config)#
```

Enable FA and message authentication on an MLT. Configure the authentication key `client-network` on the MLT.

```
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#fa enable
Switch:1(config-mlt)#fa message-authentication
Switch:1(config-mlt)#fa authentication-key client-network
```

Verify configuration of the FA authentication key. The system displays the encrypted authentication key on the output.

```
Switch:1(config-if)#show fa interface

```

**Variable Definitions**

The following table defines parameters for the **fa authentication-key** command.

| Variable   | Value                                                |
|------------|------------------------------------------------------|
| WORD<0-32> | Specifies the authentication key on the port or MLT. |

*Configure FA Management on a Port or MLT*

Use this procedure to configure a management I-SID on a Fabric Attach (FA)-enabled port or MLT.

To configure an FA management I-SID for Auto-sense-enabled ports, see [Configure a Management I-SID for Auto-sense Fabric Attach Proxy Switches](#) on page 39.

**Before You Begin**

Ensure that the port or MLT is enabled for FA.

## About This Task

This command applies to all traffic sent or received on a port or MLT, carrying the VLAN ID specified using the `c-vid` parameter. This parameter is optional.

Depending on whether the `c-vid` parameter is specified or not, the behavior is as follows:

- If you specify the `c-vid` parameter, the FA Server transmits this VLAN ID as the management VLAN in the FA Element TLV. A client or proxy receiving this TLV uses this VLAN-ID for management traffic on the FA Server uplink.
- If you do not specify the `c-vid` parameter, the FA Server transmits a management VLAN with a VLAN ID value of 4095 in the FA Element TLV. A client or proxy receiving this TLV uses untagged traffic for network management on the FA Server uplink.

An FA management I-SID can have a platform VLAN associated with it. For Layer 3 support on the management I-SID, you must create a platform VLAN by port and associate the platform VLAN with the management I-SID. The C-VID can be of the same value or of a different value than that of the platform VLAN.

If the management I-SID matches one of the FA Switched UNI (ELAN) I-SIDs (as displayed by the command `show i-sid elan`), then the platform VLAN is automatically associated with the FA-enabled interface (port or MLT).

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

2. Configure the FA management I-SID:

```
fa management i-sid <i-sid><c-vid>
```

### Important

If you do not specify a C-VID value, the port or MLT is untagged.

3. Verify configuration of FA management on the port or MLT, using the following commands:

- `show i-sid <i-sid>`
- `show interfaces gigabitEthernet i-sid [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show mlt i-sid [<1-512>]`

## Examples

Configure FA management on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal

| <code>&lt;c-vid&gt;</code>       | Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch.<br><br><b>Important:</b><br>If you do not specify a C-VID value, the port or MLT is <b>untagged</b> . |

### View Fabric Attach Global Configuration Status

Use this procedure to display the Fabric Attach global configuration status on a switch.

#### Procedure

- To enter User EXEC mode, log on to the switch.
- Display the FA configuration status using one of the following commands:
  - `show fa`
  - `show fa agent`

#### Example

Sample output for the **show fa** command:

```
Switch:1>show fa

=====
Fabric Attach Configuration
=====
FA Service : enabled
FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
FA Provision Mode : spbm
```

Sample output for the **show fa agent** command:

```
Switch:1>show fa agent

=====
Fabric Attach Configuration
=====
FA Service : enabled
FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
FA Provision Mode : spbm
```

### Viewing Fabric Attach interface configuration

Use this procedure to view FA interface configuration.

#### Procedure

1. To enter User EXEC mode, log on to the switch.

2. View all FA interfaces (ports and MLTs):

```
show fa interface
```

3. To view FA interface configuration on ports, use one of the following commands:

- View FA configuration on all ports:

```
show fa interface port
```

- View FA configuration on a specific port, enter:

```
show fa interface port [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

4. To view FA interface configuration on MLTs, use one of the following commands:

- View FA configuration on all MLTs:

```
show fa interface mlt
```

- View FA configuration on a specific MLT:

```
show fa interface mlt [<1-512>]
```

#### Example

The following example displays sample outputs for the **show fa interface** command.

```
Switch:1>show fa interface

=====
Fabric Attach Interfaces

### Variable definitions

The following table defines parameters for the `show fa interface port` command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

The following table defines parameters for the `show fa interface mlt` command.

| Variable                   | Value                       |
|----------------------------|-----------------------------|
| <code>&lt;1-512&gt;</code> | The valid range for MLT ID. |

### Viewing Fabric Attach Discovered Elements

Use this procedure to view Fabric Attach discovered elements.

#### About This Task

When FA is enabled on an FA Server switch, LLDP PDUs are exchanged between the FA Server and FA Clients or FA Proxies. Standard LLDPs allow neighbors to be learned. With the help of organizational-specific element discovery TLVs, the client or proxy recognizes that it has attached to the FA Server. Only after the discovery handshake is complete, an FA Client or FA Proxy can transmit I-SID-to-VLAN assignments to join the SPB Fabric network through the FA Server.

#### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```

2. Display FA discovered elements:

```
show fa elements
```

3. Display FA discovered elements on a specific port:

```
show fa elements [{slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]]
```

### Example

The following example displays the sample output for the `show fa elements` command.

```
Switch:1#show fa elements

=====
Fabric Attach Discovery Elements
=====

```

### Variable definitions

The following table defines parameters for the `show fa elements` command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

### Viewing Fabric Attach I-SID-to-VLAN Assignments

Use this procedure to display the I-SID-to-VLAN assignments advertised by an FA Client or an FA Proxy, to be supported on the FA Server. These assignments can be accepted or rejected by the FA Server. An

assignment that is successfully accepted by the FA Server results in the creation of a Switched UNI I-SID on the interface.

### Before You Begin

Verify that IS-IS and SPBM are properly configured on the FA Server switch.

- Verify SPBM configuration using the command **show running-config module spbm**.
- Verify IS-IS configuration using one of the following commands:
  - **show isis**
  - **show isis interface**
  - **show isis adjacency**
  - **show isis lsdb**

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display FA I-SID-to-VLAN assignments:

```
show fa assignment
```

3. Display FA I-SID-to-VLAN assignments on specific ports:

```
show fa assignment [{slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]]
```

### Example

The following example displays a sample output for the `show fa assignment` command.

#### Note

The state of I-SID-to-VLAN assignments on a client or proxy device is pending until it is changed by the FA Server to `active` or `reject`.

```
Switch:>en
Switch:1#show fa assignment
=====
                          Fabric Attach Assignment Map
=====
Interface  I-SID      Vlan      State      Origin
-----
1/1         2          2         active     proxy
1/2         3          3         active     proxy
1/2         4          4         active     proxy
1/3         5          5         reject     proxy
-----
4 out of 4 Total Num of fabric attach assignment mappings displayed
-----
```

## Variable definitions

The following table defines parameters for the **show fa assignment** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

### Viewing Fabric Attach Statistics

If FA discovery fails, use this procedure to display FA statistics to determine if FA discovery TLVs were processed. You can also view the FA assignment statistics to determine the number of FA assignments that were accepted or rejected by the FA Server.

You can view the statistics at either the global level or at the port (interface) level.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View global level FA statistics:  
show fa statistics [summary]
3. View FA statistics at the slot/port level:  
show fa statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]

#### Note

If a slot is removed from the switch chassis, the FA statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

4. (Optional) Clear FA statistics:  
clear fa statistics [summary] [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]

### Examples

Viewing FA discovery and assignment statistics:

```
Switch:1>en
Switch:1#show fa statistics
```

## Variable Definitions

The following table defines parameters for the **show fa statistics** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| summary                                                      | Displays a summary of Fabric Attach element discovery and assignment statistics at the global level.                                                                                                                                                                                                                                                          |
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Display Learned LLDP Neighbors

Use this procedure to verify details of the LLDP neighbors learned.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Verify details of LLDP neighbors learned:  
show lldp neighbor
3. Verify details of LLDP neighbors learned on a specific port:  
show lldp neighbor port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*

### Example

The following example shows how two switches—an FA Server and an FA Proxy discover each other as LLDP neighbors. Switch A, which is the FA Server is a VSP 7200 Series switch (model VSP 7254XSQ) and switch B which is the proxy device is an ERS 4826GTS switch.

The following examples shows neighbor discovery on non-channelized and channelized ports (if your platform supports channelization).

On the non-channelized port 1/1 on the FA Server, verify neighbor discovery of the proxy switch.

```

SwitchA:1>en
SwitchA:1#show lldp neighbor
-----

```

```

                                LLDP Neighbor

## Variable Definitions

The following table defines parameters for the **show lldp neighbor** command.

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.<br>Displays LLDP neighbor information on the specified port. |

### Display Switched UNI (ELAN) I-SID Information

Use this procedure to display information on FA-created Switched UNI (ELAN) I-SIDs.

#### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Display all Switched UNI (ELAN) I-SIDs:
 

```
show i-sid elan
```

3. Display ELAN I-SID information on an MLT:

```
show mlt i-sid [<1-512>]
```

#### Note

Viewing ELAN I-SID information on an MLT is useful to understand the origin of the I-SID when multiple client or proxy devices connecting to the FA Server using SMLT MLT advertise the same I-SID-to-VLAN mappings. In the event of a link failure on an MLT, the origin of the I-SID helps determine on which MLT, and thereby from which proxy or client device, the mappings were successfully learnt.

4. Display ELAN I-SID information on ports:

```
show interfaces gigabitEthernet i-sid [{slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]]
```

#### Examples

Display information on all Switched UNI (ELAN) I-SIDs.

The following sample output displays, for example, the I-SID information on one of the peer switches of the FA Server, in a dual-homed SMLT configuration.

```
Switch:1>enable
Switch:1#show i-sid elan

All 6 out of 6 Total Num of Elan i-sids displayed

ORIGIN Legend:
C: manually configured; D: discovered by FA or EPT
M: FA management; E: discovered by EAP; A: auto-sense
```

```
l: discover by local switch  r: discover by remote VIST switch
```

### Note

The I-SID TYPE field displays once for each I-SID. The I-SID TYPE of an I-SID that is either learned through FA mapping assignments or configured as an FA management I-SID, is always ELAN. If a platform VLAN has the same I-SID value as that of the I-SID in an FA mapping assignment or in an FA management I-SID configuration, then the platform VLAN is associated with the I-SID endpoint and displays in the VLANID column.

Display MLT I-SID information for MLT 1.

In this sample output, the ORIGIN field indicates the origin of the I-SID endpoint.

```
Switch:1>show mlt i-sid

### Variable Definitions

The following table defines parameters for the **show i-sid** command.

| Variable | Value                     |
|----------|---------------------------|
| elan     | Displays all ELAN I-SIDs. |

The following table defines parameters for the **show mlt i-sid** command.

| Variable | Value                       |
|----------|-----------------------------|
| <1-512>  | The valid range for MLT ID. |

The following table defines parameters for the **show interfaces gigabitEthernet i-sid** command.

| Variable                                                    | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {slot/port[/sub-port]<br>[-slot/port[/sub-port]]<br>[,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

### Enabling or disabling FA Zero Touch Client Attachment

Use this procedure to enable or disable the global FA Zero Touch Client Attachment feature on an FA Proxy or Server. By default, FA Zero Touch Client Attachment support is enabled.

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable an FA Zero Touch client:

```
fa zero-touch-client standard <camera|ona-sdn|ona-spb-over-ip|phone|  
router|security-device|srvr-endpt|switch|video|virtual-switch|wap-  
type1|wap-type2> i-sid <1-15999999>
```

3. Disable an FA Zero Touch client:

```
no fa zero-touch-client standard <camera|ona-sdn|ona-spb-over-ip|  
phone|router|security-device|srvr-endpt|switch|video|virtual-switch|  
wap-type1|wap-type2>
```

#### Example

```
Switch:1(config)# fa zero-touch-client standard camera i-sid 1003  
Switch:1(config)# no fa zero-touch-client standard camera
```

## Variable definitions

The following table defines parameters for the **fa zero-touch-client standard** command.

| Variable               | Value                                          |
|------------------------|------------------------------------------------|
| <i>camera</i>          | Specify element type to match camera.          |
| <i>ona-sdn</i>         | Specify element type to match ona-sdn.         |
| <i>ona-spb-over-ip</i> | Specify element type to match ona-spb-over-ip. |
| <i>phone</i>           | Specify element type to match phone.           |
| <i>router</i>          | Specify element type to match router.          |
| <i>security-device</i> | Specify element type to match security-device. |
| <i>svr-endpt</i>       | Specify element type to match svr-endpt.       |
| <i>switch</i>          | Specify element type to match switch.          |
| <i>video</i>           | Specify element type to match video.           |
| <i>virtual-switch</i>  | Specify element type to match virtual-switch.  |
| <i>wap-type1</i>       | Specify element type to match wap-type1.       |
| <i>wap-type2</i>       | Specify element type to match wap-type2.       |

## Displaying FA Zero Touch Client Attachment

Use this procedure to display the Zero Touch Client Attachment data you have configured on an FA Server.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display Zero Touch Client Attachment data:  
show fa zero-touch-client

### Example

The following example displays sample output for the **show fa zero-touch-client** command.

```
Switch:1#show fa zero-touch-client
=====

## Configure Endpoint Tracking Using CLI

The following sections provide procedural information to configure Endpoint Tracking using CLI.

### *Configure Endpoint Tracking Interfaces*

Create and enable Endpoint Tracking on ports and MLT/SMLT interfaces. Creating, deleting, enabling, and disabling Endpoint Tracking on interfaces can be accomplished as separate steps using this procedure.

#### **Before You Begin**

- In Extreme Management Center or ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center or ExtremeCloud IQ - Site Engine.

#### **About This Task**

Configure ports and MLT/SMLT interfaces to function as Switched UNI interfaces, and then create and enable Endpoint Tracking on those interfaces.

#### **Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface mlt <1-512>
```

#### **Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Flex UNI on the interface:

```
flex-uni enable
```

3. Create and enable Endpoint Tracking:

- Create Endpoint Tracking on the interface:

```
endpoint-tracking
```

- Create and enable Endpoint Tracking on the interface:

```
endpoint-tracking enable
```

#### **What to Do Next**

Configure Endpoint Tracking globally on the switch.

## Configure Endpoint Tracking Globally

Configure Endpoint Tracking globally on the switch.

### Before You Begin

- In Extreme Management Center or ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center or ExtremeCloud IQ - Site Engine.
- Create and enable Endpoint Tracking on interfaces.

### About This Task

Optionally, if the RADIUS outbound attributes do not include an I-SID value, configure an I-SID offset value, and globally enable I-SID offset for Endpoint Tracking. The I-SID offset value is used to calculate an I-SID value for a switched UNI if no I-SID value is provided by the RADIUS server. In that case, the I-SID value is calculated as follows: I-SID = VLAN ID + configured I-SID offset value.

After optionally configuring an I-SID offset value, enable Endpoint Tracking globally on the switch.

#### Note

If you have previously enabled Endpoint Tracking globally and want to change the currently configured I-SID offset value, you must disable Endpoint Tracking globally, change the I-SID value, and then re-enable Endpoint Tracking globally.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. (Optional) Configure an I-SID offset value, and enable I-SID offset globally on the switch:
 

```
endpoint-tracking auto-isid-offset <0-15995903>
endpoint-tracking auto-isid-offset enable
```
3. Enable Endpoint Tracking globally on the switch:
 

```
endpoint-tracking enable
```

### Variable Definitions

The following table defines parameters for the **endpoint-tracking auto-isid-offset** command.

| Variable                        | Value                                                                                   |
|---------------------------------|-----------------------------------------------------------------------------------------|
| <code>&lt;0-15995903&gt;</code> | The I-SID offset value. The default is 15990000.                                        |
| <code>enable</code>             | Enables or disables I-SID offset value globally on the switch. The default is disabled. |

### Configure Endpoint Tracking Visibility Mode

Configure Endpoint Tracking visibility mode on the switch.

#### Before You Begin

- In Extreme Management Center or ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center or ExtremeCloud IQ - Site Engine.
- Create and enable Endpoint Tracking on interfaces.
- Enable Endpoint Tracking globally on the switch.

#### About This Task

Enable visibility mode to allow MAC learning on static S-UNIs for Endpoint Tracking.

#### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable Endpoint Tracking visibility mode on the switch:  
`endpoint-tracking visibility-mode`

### Display Endpoint Tracking Configuration Information

Perform this procedure to display configuration information for Endpoint Tracking.

#### About This Task

Perform this procedure to display global, interface and binding information for Endpoint Tracking.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the global status of Endpoint Tracking on the switch, and the configured I-SID offset value, if applicable:  
`show endpoint-tracking`
3. Display the status of all interfaces that have Endpoint Tracking created:  
`show endpoint-tracking interfaces [gigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] | [mlt <1-512>]`
4. Display a summary of the VLAN:ISID binding information for all ports, or MLT/SMLT interfaces:  
`show endpoint-tracking bindings summary`
5. Display the VLAN:ISID binding information for the switch, for ports, or for MLT/SMLT interfaces:  
`show endpoint-tracking bindings [gigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] | [mlt <1-512>]`

## Example

The following example displays all of the Endpoint Tracking configuration information for a switch.

```
Switch:1>show endpoint-tracking
=====
Endpoint Tracking Configuration
=====

endpoint tracking status : ENABLED
auto-isid-offset value : 15990000
auto-isid-offset enabled : ENABLED
visibility-mode status : ENABLED

Switch:1>show endpoint-tracking interfaces
=====

1/10      201    00:00:00:00:1b:03  accept  27       15990027  autoconfig  0 day(s), 00:01:40  0 day(s), 00:00:00
1/10      201    00:00:00:00:1b:04  accept  27       15990027  autoconfig  0 day(s), 00:01:40  0 day(s), 00:00:00
1/10      201    00:00:00:00:1b:05  accept  27       15990027  autoconfig  0 day(s), 00:01:40  0 day(s), 00:00:00

5 out of 5 Total Num of Endpoint Tracking bindings displayed.
```

## Variable Definitions

The following table defines parameters for the **show endpoint-tracking bindings** command.

| Variable                                                              | Value                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| MLT <1-512>                                                           | Specifies the MLT ID.                                                                                                                                                                                                                                                                                                                                         |
| summary                                                               | Provides a summary of the total number and status of bindings for all interfaces.                                                                                                                                                                                                                                                                             |

## IS-IS external metric configuration using the CLI

This section provides procedures for IS-IS external metric configuration.

### Matching metric type for IS-IS routes

#### About This Task

Use this procedure to match the external metric-type by using a route-map for any of the following cases:

- accepting a remote IS-IS route with the help of IS-IS accept policies.
- redistributing IS-IS routes into other protocols.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must log on to the route-map configuration mode in the CLI.

#### Procedure

1. Enter Route-Map Configuration mode:
 

```
enable

configure terminal

route-map WORD<1-64> <1-65535>
```
2. Match IS-IS metric type:
 

```
match metric-type-isis {any|internal|external}
```
3. Permit the route policy action:
 

```
permit
```
4. Enable the route policy
 

```
enable
```

## Example

Match metric type for IS-IS routes:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
```

Match metric type for IS-IS routes in accept policies:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# accept route-map rol
Switch:1(config-isis)# exit
Switch:1(config)# isis apply accept
```

Match metric type to redistribute IS-IS routes into some other protocol (OSPF,RIP,BGP)

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router bgp
Switch:1(router-bgp)# redistribute isis route-map rol
Switch:1(router-bgp)# exit
Switch:1(config)# ip bgp apply redistribute
```

## Variable definitions

The following table defines parameters for the **match metric-type-isis** command.

| Variable                                    | Value                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| metric-type-isis<br>{any internal external} | <p>Specifies the IS-IS metric type.</p> <ul style="list-style-type: none"> <li>• internal – permits or denies routes that are internal to the IS-IS domain.</li> <li>• external – permits or denies routes that originate from an external routing protocol domain.</li> <li>• any – permits or denies both internal routes as well as external routes.</li> </ul> |

## Setting metric type for IS-IS routes

### About This Task

Use this procedure to set the IS-IS external metric-type by using a route-map for any of the following cases:

- accepting a remote IS-IS route with the help of IS-IS accept policies.
- redistributing routes from other protocols into IS-IS.

## Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must log on to the route-map configuration mode in the CLI.

## Procedure

1. Enter Route-Map Configuration mode:  

```
enable

configure terminal

route-map WORD<1-64> <1-65535>
```
2. Set IS-IS metric type:  

```
set metric-type-isis {any|internal|external}
```
3. Permit the route policy action:  

```
permit
```
4. Enable the route policy  

```
enable
```

## Example

Set metric type for IS-IS routes:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# set metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
```

Set metric type for IS-IS routes in accept policies:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# set metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# accept route-map rol
Switch:1(config-isis)# exit
Switch:1(config)# isis apply accept
```

Set metric type to redistribute routes from other protocols into IS-IS:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# redistribute bgp route-map rol
Switch:1(config-isis)# exit
Switch:1(config)# isis apply redistribute
```

## Variable definitions

The following table defines parameters for the **set metric-type-isis** command.

| Variable                                    | Value                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| metric-type-isis<br>{any internal external} | Specifies the IS-IS metric type. <ul style="list-style-type: none"> <li>internal – permits or denies routes that are internal to the IS-IS domain.</li> <li>external – permits or denies routes that originate from an external routing protocol domain.</li> <li>any – permits or denies both internal routes as well as external routes.</li> </ul> |

*Setting metric type for IS-IS routes using global redistribute command*

### About This Task

Use this procedure to set the IS-IS external metric-type using the global redistribute command for the following cases redistributing routes from other protocols into IS-IS.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must log on to the IS-IS router configuration mode in the CLI.

### Procedure

- Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
- Set IS-IS metric type using global redistribute command:

```
redistribute direct metric-type {internal|external}
```
- Enable the route policy

```
redistribute direct enable
```

### Example

Set metric type for IS-IS routes using global redistribute command:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# router isis
Switch:1(config-isis)# redistribute direct metric-type internal
Switch:1(config-isis)# redistribute direct enable
```

### Variable definitions

The following table defines parameters for the **redistribute direct metric-type** command.

| Variable                        | Value                                                                                                                                                                                                                                                                   |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| metric-type {internal external} | Specifies the IS-IS metric type. <ul style="list-style-type: none"> <li>• internal – permits or denies routes that are internal to the IS-IS domain.</li> <li>• external – permits or denies routes that originate from an external routing protocol domain.</li> </ul> |

## Multi-area SPB Configuration using CLI

Perform the procedures in this section to configure Multi-area SPB parameters like virtual node, router remote Intermediate-System-to-Intermediate-System (IS-IS), layer 2 unicast and multicast redistribution, and IPv4 and IPv6 route redistribution on the switch using the Command Line Interface (CLI).

### Multi-area SPB Configuration Flow

#### Note

This procedure only applies to the VSP 7400 Series.

Perform the following procedures in sequence to configure the Multi-area SPB feature on the switch.

#### Procedure

1. [Configure Remote IS-IS Multi-area SPB Nickname for an SPBM Instance](#) on page 1099.
2. [Display the Remote IS-IS SPBM Nickname Configuration](#) on page 1125.
3. [Configure Remote IS-IS Manual Area](#) on page 1100.
4. [Configure Remote IS-IS System ID](#) on page 1101.
5. [Configure an IS-IS Area Name](#) on page 1101
6. [Display IS-IS Remote Area Configuration](#) on page 1126.
7. [Display IS-IS Area Configuration](#) on page 1126.
8. [Configure IS-IS Multi-area SPB Virtual Node](#) on page 1102.
9. [Display IS-IS Area Virtual Node Configuration](#) on page 1127.
10. [Configure Remote IS-IS Hello Authentication on a Port](#) on page 1104.
11. [Configure Remote IS-IS Layer 1 Designated Router Priority on a Port](#) on page 1105.
12. [Configure Remote IS-IS Hello Interval on a Port](#) on page 1106.
13. [Configure Remote IS-IS Hello Multiplier on a Port](#) on page 1107.
14. [Configure Remote IS-IS SPBM Parameters on a Port](#) on page 1108.
15. [Enable Remote IS-IS on a Port](#) on page 1109.
16. [Enable Remote IS-IS Router Configuration Globally](#) on page 1110.
17. [Display IS-IS Remote Area Configuration](#) on page 1126.
18. [Configure Multi-area SPB Layer 2 I-SID List](#) on page 1111.
19. [Display IS-IS Multi-area SPB Layer 2 I-SID List Information](#) on page 1127.
20. [Configure Multi-area SPB Layer 2 I-SID Redistribution](#) on page 1111.
21. [Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution](#) on page 1113.
22. [Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution](#) on page 1114.

23. [Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution on a VRF Instance](#) on page 1116.
24. [Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution on a VRF Instance](#) on page 1117.
25. [Configure Multi-area SPB DvR Backbone Redistribution](#) on page 1119.
26. [Display IS-IS Multi-area SPB DvR Configuration](#) on page 1130.
27. [Configure Multi-area SPB Layer 2 Multicast Snooping Redistribution](#) on page 1120.
28. [Configure Multi-area SPB IPv4 Routed Multicast Redistribution](#) on page 1122.
29. [Configure IS-IS Multi-area SPB IPv4 Routed Multicast Redistribution on a VRF Instance](#) on page 1123.

### *Configure Remote IS-IS Multi-area SPB Nickname for an SPBM Instance*

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to configure remote IS-IS Multi-area SPB nickname for a specific SPBM instance on the switch.

### Procedure

1. Enter IS-IS Router Remote Configuration mode:  
`enable`  
  
`configure terminal`  
  
`router isis remote`
2. Configure IS-IS Multi-area SPB nickname:  
`spbm <1-100> nick-name <x.xx.xx>`

### Example

Configuring remote IS-IS Multi-area SPB nickname for SPBM instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote
Switch:1(config-remote)spbm 4 nick-name 1.11.16
```

### What to Do Next

To verify the configuration, see [Display the Remote IS-IS SPBM Nickname Configuration](#) on page 1125.

## Variable Definitions

The following table defines parameters for the **spbm** command.

| Variable                   | Value                                                                                                                   |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <1-100>                    | Specifies the SPBM instance on the remote IS-IS interface.                                                              |
| <i>nick-name</i> <x.xx.xx> | Specifies a nickname for the remote IS-IS SPBM Multi-area SPB instance. The value is 2.5 bytes in the format <x.xx.xx>. |

### Configure Remote IS-IS Manual Area

#### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to configure the remote Intermediate System-to-Intermediate System (IS-IS) manual area.

## Procedure

1. Enter IS-IS Router Remote Configuration mode:

```
enable

configure terminal

router isis remote
```

2. Configure the manual-area:

```
manual-area xx.xxxx.xxxx...xxxx
```

## Example

Configuring remote IS-IS manual area:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote
Switch:1(config-isis-remote)manual-area c1.1000.000.00
```

## What to Do Next

To verify the configuration, see [Display IS-IS Remote Area Configuration](#) on page 1126 and [Display IS-IS Area Configuration](#) on page 1126.

## Variable Definitions

The following table defines parameters for the **manual-area** command.

| Variable                  | Value                                                                 |
|---------------------------|-----------------------------------------------------------------------|
| <xx.xxxx.xxxx...xxx<br>x> | Specifies the remote IS-IS manual-area in the range of 1 to 13 bytes. |

*Configure Remote IS-IS System ID***Note**

This procedure only applies to the VSP 7400 Series.

**About This Task**

Perform this procedure to configure the remote Intermediate System-to-Intermediate System (IS-IS) system ID on the switch.

**Procedure**

1. Enter IS-IS Router Remote Configuration mode:
 

```
enable

configure terminal

router isis remote
```
2. Configure the remote IS-IS system ID:
 

```
system-id xxxx.xxxx.xxxx
```

**Example**

Configuring the remote IS-IS system ID:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote
Switch:1(config-isis-remote)#system-id 0017.c6ed.44df
```

**What to Do Next**

To verify the configuration, see [Display IS-IS Remote Area Configuration](#) on page 1126 and [Display IS-IS Area Configuration](#) on page 1126.

**Variable Definitions**

The following table defines parameters for the **system-id** command.

| Variable       | Value                                                |
|----------------|------------------------------------------------------|
| xxxx.xxxx.xxxx | Specifies the remote IS-IS system ID for the switch. |

*Configure an IS-IS Area Name***Note**

This procedure only applies to the VSP 7400 Series.

**Before You Begin**

- You must disable IS-IS or remote IS-IS.

## About This Task

Perform this procedure to configure the area name for home and remote areas.

## Procedure

1. Enter either IS-IS Router Configuration or IS-IS Router Remote Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis OR router isis remote
```

2. Configure the area name:

```
area-name WORD<0-255>
```

3. Enable IS-IS or remote IS-IS:

```
router isis enable OR router isis remote enable
```

## Example

Configure the home and remote area names:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router isis
Switch:1(config-isis)#area-name 30
Switch:1(config)#router isis remote
Switch:1(config-isis-remote)# area-name 50
```

## Variable Definitions

The following table defines parameters for the **area-name** command.

| Variable            | Value                                                                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <0-255> | Specifies the area name. The default value is area-manual-area, where manual-area represents the IS-IS or remote IS-IS manual-area value that you configure. |

*Configure IS-IS Multi-area SPB Virtual Node*

### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to configure the IS-IS Multi-area SPB virtual node parameters like nick-name, system ID, and system name in the home or remote area.

## Procedure

1. Enter either IS-IS Router Configuration or IS-IS Router Remote Configuration mode:

```
enable

configure terminal

router isis Or router isis remote
```

2. Configure the nick-name for the IS-IS Multi-area SPB virtual node:

```
area-vnode nick-name <x.xx.xx>
```

3. Configure the system name for the IS-IS Multi-area SPB virtual node:

```
area-vnode sys-name WORD<0-255>
```

4. Configure the system ID for the IS-IS Multi-area SPB virtual node:

```
area-vnode system-id xxxx.xxxx.xxxx
```

## Example

Configuring the IS-IS Multi-area SPB virtual node in the home area:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#area-vnode nick-name 0.82.40
Switch:1(config-isis)#area-vnode sys-name SwitchC
Switch:1(config-isis)#area-vnode system-id 1222.3300.0000
```

Configuring the IS-IS Multi-area SPB virtual node in the remote area:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote
Switch:1(config-isis)#area-vnode nick-name 0.82.60
Switch:1(config-isis)#area-vnode sys-name SwitchA
Switch:1(config-isis)#area-vnode system-id 1222.3311.2222
```

## What to Do Next

To verify the configuration, see [Display IS-IS Area Virtual Node Configuration](#) on page 1127.

## Variable Definitions

The following table defines parameters for the **area-vnode** command.

| Variable                           | Value                                                                                                          |
|------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <i>nick-name</i> x.xx.xx           | Specifies a nickname for the IS-IS SPBM Multi-area SPB instance. The value is 2.5 bytes in the format x.xx.xx. |
| <i>sys-name</i><br>WORD<0-255>     | Specifies the name of the system.                                                                              |
| <i>system-id</i><br>xxxx.xxxx.xxxx | Specifies the IS-IS Multi-area SPB virtual node system ID.                                                     |

### Configure Remote IS-IS Hello Authentication on a Port

**Note**

This procedure only applies to the VSP 7400 Series.

**About This Task**

Perform this procedure to configure authentication type used for remote Intermediate-System-to-Intermediate-System (IS-IS) hello packets on the interface. The type can be one of the following: none, simple, hmac-md5, or hmac-sha-256.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the hello authentication type:

```
isis remote hello-auth type {none | simple | hmac-md5 | hmac-sha-256}  
[key WORD<1-16>] [key-id <1-255>]
```

**Example**

Configuring the simple authentication type for remote IS-IS hello packets on port 1/2:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface gigabitEthernet 1/2  
Switch:1(config-if)#isis remote hello-auth type simple key Test key-id 125
```

## Variable Definitions

The following table defines parameters for the **isis remote hello-auth** command.

| Variable                                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>key WORD&lt;1-16&gt;</code>                           | Specifies the authentication key (password) that the receiving router uses to verify the packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>key-id &lt;1-255&gt;</code>                           | Specifies the optional key ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>type {none   simple   hmac-md5   hmac-sha-256}</code> | <p>Specifies the authentication type used for remote IS-IS hello packets on the interface. The type can be one of the following:</p> <ul style="list-style-type: none"> <li>Simple - Simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet. You can also specify a key value.</li> <li>hmac-md5 - MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. You can also specify a key value and key-id.</li> <li>hmac-sha-256 - With SHA-256 authentication, the switch adds an HMAC-SHA256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet. You can also specify a key value and key-id.</li> </ul> <p>The default type is none.</p> |

### Configure Remote IS-IS Layer 1 Designated Router Priority on a Port

#### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to configure the Level 1 remote Intermediate-System-to-Intermediate-System (IS-IS) designated router priority to the specified value.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Level 1 remote IS-IS designated router priority:

```
isis remote ll-dr-priority <0-127>
```

## Example

Configuring the remote IS-IS designated router priority for port 1/4:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#isis remote l1-dr-priority 1
```

## Variable Definitions

The following table defines parameters for the **isis remote l1-dr-priority** command.

| Variable | Value                                                                                                                                      |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <0-127>  | Specifies the level 1 remote Intermediate-System-to-Intermediate-System (IS-IS) designated router priority value. The default value is 64. |

*Configure Remote IS-IS Hello Interval on a Port*

### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to configure the remote hello interval to change how often hello packets are sent out from an interface level.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the remote hello interval:

```
isis remote l1-hello-interval <1-600>
```

## Example

Configuring the remote hello interval on port 1/3:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/3
Switch:1(config-if)#isis remote l1-hello-interval 1
```

## Variable Definitions

The following table defines parameters for the **isis remote l1-hello-interval** command.

| Variable | Value                                                                         |
|----------|-------------------------------------------------------------------------------|
| <1-600>  | Configures the Level 1 remote hello interval. The default value is 9 seconds. |

### Configure Remote IS-IS Hello Multiplier on a Port

#### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to configure the remote hello multiplier to specify how many hellos the switch must miss before it considers the adjacency with a neighboring switch down.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the level 1 hello multiplier:

```
isis remote l1-hello-multiplier <1-600>
```

## Example

Configuring the remote hello multiplier on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#isis remote l1-hello-multiplier 1
```

## Variable Definitions

The following table defines parameters for the **isis remote l1-hello-multiplier** command.

| Variable | Value                                                                    |
|----------|--------------------------------------------------------------------------|
| <1-600>  | Configures the Level 1 hello multiplier. The default value is 3 seconds. |

*Configure Remote IS-IS SPBM Parameters on a Port***Note**

This procedure only applies to the VSP 7400 Series.

**About This Task**

Perform this procedure to configure the remote Intermediate-System-to-Intermediate-System (IS-IS) Shortest Path Bridging MAC (SPBM) parameters on a specific port.

**Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the remote IS-IS SPBM interface type:

```
isis remote spbm <1-100> interface-type {broadcast | pt-pt}
```

3. Configure the cost of the remote SPBM instance:

```
isis remote spbm <1-100> ll-metric <1-16777215>
```

**Example**

Configuring the remote IS-IS SPBM interface type and layer 1 metric on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#isis remote spbm 2 interface-type broadcast
Switch:1(config-if)#isis remote spbm 2 ll-metric 2
```

**Variable Definitions**

The following table defines parameters for the **isis remote spbm** command.

| Variable                                                     | Value                                                                                         |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <1-100>                                                      | Specifies the SPBM instance.                                                                  |
| <i>interface-type</i><br>{ <i>broadcast</i>   <i>pt-pt</i> } | Specifies the IS-IS SPBM interface type as broadcast or point-to-point (pt-pt).               |
| <i>ll-metric</i><br><1-16777215>                             | Specifies the SPBM instance layer 1 metric on the IS-IS interface located on a specific port. |

*Enable Remote IS-IS on a Port***Note**

This procedure only applies to the VSP 7400 Series.

**Before You Begin**

- Configure manual-area in both home and remote area.
- Configure the Shortest Path Bridging MAC (SPBM) instance and backbone VLANs (B-VLAN) manually.
- Configure the nickname in both home and remote area manually.
- Disable Auto-sense on the port.
- Make sure that the physical node nickname, virtual node nickname and system ID are different.

**About This Task**

Perform this procedure to enable remote Intermediate-System-to-Intermediate-System (IS-IS) interface on the selected port(s).

**Note**

When the switch receives a Fabric Connect TLV through LLDP on a port that has remote IS-IS enabled on it, the port transitions to the Auto-sense NNI pending state. For more information, see [Auto-sense Port States](#) on page 19.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable remote IS-IS interface:

```
isis remote enable
```

**Example**

Enabling remote IS-IS interface on port 1/2:

```
Switch:1>enable
Switch:1#confiure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)isis remote enable
```

## Variable Definitions

The following table defines parameters for the **isis remote** command.

| Variable      | Value                                                   |
|---------------|---------------------------------------------------------|
| <i>enable</i> | Enables a remote IS-IS interface on the selected ports. |

### Enable Remote IS-IS Router Configuration Globally

#### Note

This procedure only applies to the VSP 7400 Series.

## Before You Begin

- Configure manual-area in both home and remote area.
- Configure the Shortest Path Bridging MAC (SPBM) instance and backbone VLANs (B-VLAN) manually.
- Configure the nickname in both home and remote area manually.

## About This Task

Perform this procedure to enable remote IS-IS router configuration on the switch, globally.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable IS-IS router remote configuration:
 

```
router isis remote [enable]
```

## Example

Enabling IS-IS router remote configuration globally:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote enable
```

## What to Do Next

To verify the configuration, see [Display IS-IS Remote Area Configuration](#) on page 1126.

## Variable Definitions

The following table defines parameters for the **router isis remote** command.

| Variable      | Value                                                             |
|---------------|-------------------------------------------------------------------|
| <i>enable</i> | Enables router IS-IS remote configuration globally on the switch. |

*Configure Multi-area SPB Layer 2 I-SID List***Note**

This procedure only applies to the VSP 7400 Series.

**About This Task**

Perform this procedure to configure the Multi-area SPB layer 2 I-SID list.

**Procedure**

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
2. Configure the Multi-area SPB layer 2 I-SID list:
 

```
multi-area 12 isid-list WORD<1-32> WORD<1-1024>
```

**Example**

Configuring the Multi-area SPB layer 2 I-SID list that includes specific I-SID values:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area 12 isid-list testlist 1,3,5,100-200
```

**What to Do Next**

To verify the configuration, see [Display IS-IS Multi-area SPB Layer 2 I-SID List Information](#) on page 1127.

**Variable Definitions**

The following table defines parameters for the **multi-area 12 isid-list** command.

| Variable                  | Value                                 |
|---------------------------|---------------------------------------|
| <i>WORD&lt;1-32&gt;</i>   | Specifies the name of the I-SID list. |
| <i>WORD&lt;1-1024&gt;</i> | Specifies the list of I-SID values.   |

*Configure Multi-area SPB Layer 2 I-SID Redistribution***Note**

This procedure only applies to the VSP 7400 Series.

**About This Task**

Perform this procedure to configure Multi-area SPB layer 2 I-SID redistribution.

## Procedure

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
2. Configure the Multi-area SPB layer2 I-SID redistribution:
 

```
multi-area l2 redistribute i-sid {deny-all | permit-all} [except-isid-
list WORD<1-32>]
```
3. Verify the Multi-area SPB layer2 I-SID redistribution configuration:
 

```
show isis multi-area l2 redistribute i-sid
```
4. Apply the layer 2 I-SID redistribution:
 

```
isis multi-area l2 apply redistribute i-sid
```

## Example

Configuring Multi-area SPB layer 2 I-SID redistribution and exclude the I-SID values specified in the I-SID list:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area l2 redistribute i-sid permit-all except-isid-list
testlist
Switch:1(config-isis)#show isis multi-area l2 redistribute i-sid
=====
MULTI AREA L2 ISID REDIST POLICY
=====
Permit          Except List Name
-----
permit-all     testlist
-----
Switch:1(config-isis)#isis multi-area l2 apply redistribute i-sid
```

## Variable Definitions

The following table defines parameters for the **multi-area l2 redistribute i-sid** command.

| Variable                                           | Value                                                                                                   |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <i>deny-all</i>                                    | Denies the Multi-area SPB IPv6 unicast redistribution configuration for the specified I-SID list name.  |
| <i>except-isid-list</i><br><i>WORD&lt;1-32&gt;</i> | Specifies the name of the I-SID list.                                                                   |
| <i>permit-all</i>                                  | Permits the Multi-area SPB IPv6 unicast redistribution configuration for the specified I-SID list name. |

*Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution***Note**

This procedure only applies to the VSP 7400 Series.

**Before You Begin**

Configure IP Shortcuts on the boundary nodes.

**About This Task**

Perform this procedure to configure Multi-area SPB IPv4 unicast redistribution on the switch.

**Procedure**

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```

2. Create the Multi-area SPB IPv4 unicast redistribution instance:

```
multi-area ip redistribute unicast [home-to-remote | remote-to-home]
```

**Note**

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
multi-area ip redistribute unicast [home-to-remote | remote-to-home]
route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv4 unicast redistribution instance:

```
multi-area ip redistribute unicast [home-to-remote | remote-to-home]
enable
```

5. Verify the Multi-area SPB IPv4 unicast redistribution configuration:

```
show isis multi-area ip redistribute unicast [home-to-remote | remote-to-home]
```

6. Apply the Multi-area SPB IPv4 unicast redistribution:

```
isis multi-area ip apply redistribute unicast [home-to-remote |
remote-to-home]
```

**Example**

Configuring Multi-area SPB IPv4 unicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area ip redistribute unicast home-to-remote
Switch:1(config-isis)#multi-area ip redistribute unicast home-to-remote route-map test
Switch:1(config-isis)#multi-area ip redistribute unicast home-to-remote enable
```

```

Switch:1(config-isis)#show isis multi-area ip redistribute home-to-remote
=====
                ISIS Multiarea Redistribute List for ip unicast - GlobalRouter
=====
DIRECTION          ENABLE      RPOLICY
-----
home-to-remote     TRUE       test
-----
Switch:1(config-isis)#isis multi-area ip apply redistribute unicast home-to-remote

```

## Variable Definitions

The following table defines parameters for the **multi-area ip redistribute unicast** and the **isis multi-area ip apply redistribute unicast** commands.

| Variable                                    | Value                                                                                 |
|---------------------------------------------|---------------------------------------------------------------------------------------|
| <i>enable</i>                               | Enables Multi-area SPB IPv4 unicast redistribution.                                   |
| <i>home-to-remote</i>                       | Specifies the IPv4 unicast redistribution configuration for home to remote direction. |
| <i>remote-to-home</i>                       | Specifies the IPv4 unicast redistribution configuration for remote to home direction. |
| <i>route-map</i><br><i>WORD&lt;1-64&gt;</i> | Specifies the name of the route policy.                                               |
| <i>vrf WORD&lt;1-16&gt;</i>                 | Specifies the unicast redistribution configuration for specific VRF instance.         |

### Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution

#### Note

This procedure only applies to the VSP 7400 Series.

## Before You Begin

Configure IP Shortcuts on the boundary nodes.

## About This Task

Perform this procedure to configure Multi-area SPB IPv6 unicast redistribution on the switch.

## Procedure

1. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

2. Create the Multi-area SPB IPv6 unicast redistribution:

```
multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home]
```

#### Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home]
route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv6 unicast redistribution instance:

```
multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home]
enable
```

5. Verify the Multi-area SPB IPv6 unicast redistribution configuration:

```
show isis multi-area ipv6 redistribute unicast [home-to-remote |
remote-to-home]
```

6. Apply the Multi-area SPB IPv6 unicast redistribution:

```
isis multi-area ipv6 apply redistribute unicast [home-to-remote |
remote-to-home]
```

### Example

Configuring Multi-area SPB IPv6 unicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area ipv6 redistribute unicast home-to-remote
Switch:1(config-isis)#multi-area ipv6 redistribute unicast home-to-remote route-map test
Switch:1(config-isis)#multi-area ipv6 redistribute unicast home-to-remote enable
Switch:1(config-isis)#show isis multi-area ipv6 redistribute home-to-remote
=====
          ISIS Multiarea Redistribute List for ipv6 unicast - GlobalRouter
=====
DIRECTION          ENABLE          RPOLICY
-----
home-to-remote     TRUE           test
-----
Switch:1(config-isis)#isis multi-area ipv6 apply redistribute unicast home-to-remote
```

### Variable Definitions

The following table defines parameters for the **multi-area ipv6 redistribute unicast** and the **isis multi-area ipv6 apply redistribute unicast** commands.

| Variable              | Value                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------|
| <i>enable</i>         | Enables Multi-area SPB IPv6 unicast redistribution on the switch.                     |
| <i>home-to-remote</i> | Specifies the IPv6 unicast redistribution configuration for home to remote direction. |

| Variable                                | Value                                                                                 |
|-----------------------------------------|---------------------------------------------------------------------------------------|
| <code>remote-to-home</code>             | Specifies the IPv6 unicast redistribution configuration for remote to home direction. |
| <code>route-map WORD&lt;1-64&gt;</code> | Specifies the name of the route policy.                                               |
| <code>vrf WORD&lt;1-16&gt;</code>       | Specifies the IPv6 unicast redistribution configuration for a specific VRF instance.  |

### Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution on a VRF Instance

#### Note

This procedure only applies to the VSP 7400 Series.

### Before You Begin

Configure IP Shortcuts and layer 3 VSN on the Virtual Router Forwarding (VRF) instance.

### About This Task

Perform this procedure to configure IS-IS Multi-area SPB IPv4 unicast redistribution on a specific VRF instance on the switch.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Create the IS-IS Multi-area SPB IPv4 unicast redistribution instance on the VRF:

```
isis multi-area ip redistribute unicast [home-to-remote | remote-to-home]
```

#### Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
isis multi-area ip redistribute unicast [home-to-remote | remote-to-home] route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv4 unicast redistribution instance on the VRF:

```
isis multi-area ip redistribute unicast [home-to-remote | remote-to-home] enable
```

5. Verify the Multi-area SPB IPv4 unicast redistribution configuration on the VRF:

```
show isis multi-area ip redistribute unicast [home-to-remote | remote-to-home] vrf WORD<1-16>
```

6. Exit to Global Configuration mode:

```
exit
```

7. Apply the Multi-area SPB IPv4 unicast redistribution on the VRF:

```
isis multi-area ip apply redistribute unicast [home-to-remote |
[remote-to-home] vrf WORD<1-16>
```

### Example

Configuring IS-IS Multi-area SPB IPv4 unicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf VRF1
Switch:1(router-vrf)#isis multi-area ip redistribute unicast home-to-remote
Switch:1(router-vrf)#isis multi-area ip redistribute unicast home-to-remote route-map test
Switch:1(router-vrf)#isis multi-area ip redistribute unicast home-to-remote enable
Switch:1(router-vrf)#show isis multi-area ip redistribute unicast home-to-remote vrf VRF1
=====
                ISIS Multiarea Redistribute List for ip unicast - VRF VRF1
=====
DIRECTION          ENABLE          RPOLICY
-----
home-to-remote     TRUE           test
-----
Switch:1(router-vrf)#exit
Switch:1(config)#isis multi-area ip apply redistribute unicast home-to-remote vrf VRF1
```

### Variable Definitions

The following table defines parameters for the **isis multi-area ip redistribute unicast** and the **isis multi-area ip apply redistribute unicast** commands.

| Variable                                    | Value                                                                                 |
|---------------------------------------------|---------------------------------------------------------------------------------------|
| <i>enable</i>                               | Enables IPv4 unicast redistribution on the VRF instance.                              |
| <i>home-to-remote</i>                       | Specifies the IPv4 unicast redistribution configuration for home to remote direction. |
| <i>remote-to-home</i>                       | Specifies the IPv4 unicast redistribution configuration for remote to home direction. |
| <i>route-map</i><br><i>WORD&lt;1-64&gt;</i> | Specifies the name of the route policy.                                               |
| <i>vrf WORD&lt;1-16&gt;</i>                 | Specifies the IPv4 unicast redistribution configuration for specific VRF instance.    |

### Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution on a VRF Instance

#### Note

This procedure only applies to the VSP 7400 Series.

### Before You Begin

Configure IP Shortcuts and layer 3 VSN on the Virtual Router Forwarding (VRF) instance.

## About This Task

Perform this procedure to configure IS-IS Multi-area SPB IPv6 unicast redistribution on a specific Virtual Router Forwarding (VRF) instance on the switch.

## Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Create the IS-IS Multi-area SPB IPv6 unicast redistribution instance on the VRF:

```
isis multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home]
```

### Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
isis multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home] route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv6 unicast redistribution instance on the VRF:

```
isis multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home] enable
```

5. Verify the Multi-area SPB IPv6 unicast redistribution configuration on the VRF:

```
show isis multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home] vrf WORD<1-16>
```

6. Exit to Global Configuration mode:

```
exit
```

7. Apply the Multi-area SPB IPv6 unicast redistribution on the VRF:

```
isis multi-area ipv6 apply redistribute unicast [home-to-remote | remote-to-home] vrf WORD<1-16>
```

## Example

Configuring IS-IS Multi-area SPB IPv6 unicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf VRF1
Switch:1(router-vrf)#isis multi-area ipv6 redistribute unicast home-to-remote
Switch:1(router-vrf)#isis multi-area ipv6 redistribute unicast home-to-remote route-map test
Switch:1(router-vrf)#isis multi-area ipv6 redistribute unicast home-to-remote enable
Switch:1(router-vrf)#show isis multi-area ipv6 redistribute unicast home-to-remote vrf VRF1
=====
```

```

=====
ISIS Multiarea Redistribute List for ipv6 unicast - VRF VRF1
=====
DIRECTION          ENABLE      RPOLICY
-----
home-to-remote     TRUE       test
-----
Switch:1(router-vrf)#exit
Switch:1(config)#isis multi-area ipv6 apply redistribute unicast home-to-remote vrf VRF1

```

## Variable Definitions

The following table defines parameters for the **isis multi-area ipv6 redistribute unicast** and the **isis multi-area ipv6 apply redistribute unicast** commands.

| Variable                                    | Value                                                                                 |
|---------------------------------------------|---------------------------------------------------------------------------------------|
| <i>enable</i>                               | Enables IPv6 unicast redistribution on the VRF instance.                              |
| <i>home-to-remote</i>                       | Specifies the IPv6 unicast redistribution configuration for home to remote direction. |
| <i>remote-to-home</i>                       | Specifies the IPv6 unicast redistribution configuration for remote to home direction. |
| <i>route-map</i><br><i>WORD&lt;1-64&gt;</i> | Specifies the name of the route policy.                                               |
| <i>vrf WORD&lt;1-16&gt;</i>                 | Specifies the IPv6 unicast redistribution configuration for a specific VRF instance.  |

## Configure Multi-area SPB DvR Backbone Redistribution

### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to configure Multi-area SPB Distributed Virtual Routing (DvR) backbone redistribution on the switch.

## Procedure

- Enter IS-IS Router Configuration mode:
 

```
enable
configure terminal
router isis
```
- Configure IS-IS Multi-area SPB DvR backbone redistribution:
 

```
multi-area dvr redistribute backbone
```

## Example

Configuring Multi-area SPB DvR backbone redistribution:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#router isis
Switch:1(config-isis)multi-area dvr redistribute backbone
```

## What to Do Next

To verify the configuration, see [Display IS-IS Multi-area SPB DvR Configuration](#) on page 1130.

### Configure Multi-area SPB Layer 2 Multicast Snooping Redistribution

#### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to configure Multi-area SPB layer 2 multicast snooping redistribution for specific I-SID values or a specific I-SID list.

## Procedure

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
2. Create the Multi-area SPB layer 2 snooping multicast redistribution for a specific I-SID or I-SID list:
 

```
multi-area l2 redistribute snoop-multicast {home-to-remote | remote-to-home} {i-sid <1-16777215> | isid-list WORD<1-32>}
```
3. (Optional) Configure a route policy to govern the redistribution:
 

```
multi-area l2 redistribute snoop-multicast {home-to-remote | remote-to-home} {i-sid <1-16777215> | isid-list WORD<1-32>} route-map WORD<1-64>
```
4. Enable the Multi-area SPB layer 2 snooping multicast redistribution instance:
 

```
multi-area l2 redistribute snoop-multicast {home-to-remote | remote-to-home} {i-sid <1-16777215> | isid-list WORD<1-32>} enable
```
5. Verify the Multi-area SPB layer 2 snooping multicast redistribution configuration:
 

```
show isis multi-area l2 redistribute snoop-multicast
```
6. Apply the Multi-area SPB layer 2 snooping multicast redistribution:
 

```
isis multi-area l2 apply redistribute snoop-multicast [home-to-remote | remote-to-home]
```

## Example

Configuring Multi-area SPB layer 2 home to remote multicast snooping redistribution:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
```

Configuring Multi-area SPB layer 2 home to remote multicast snooping redistribution for I-SID 1100:

```
Switch:1(config-isis)#multi-area 12 redistribute snoop-multicast home-to-remote i-sid 1100
Switch:1(config-isis)#multi-area 12 redistribute snoop-multicast home-to-remote i-sid
1100
route-map test
Switch:1(config-isis)#multi-area 12 redistribute snoop-multicast home-to-remote i-sid
1100
enable
```

Configuring Multi-area SPB layer 2 home to remote multicast snooping redistribution for I-SID list List1:

```
Switch:1(config-isis)#multi-area 12 redistribute snoop-multicast home-to-remote isid-list
List1
Switch:1(config-isis)#multi-area 12 redistribute snoop-multicast home-to-remote isid-list
List1 route-map test
Switch:1(config-isis)#multi-area 12 redistribute snoop-multicast home-to-remote isid-list
List1 enable
```

Verifying the Multi-area SPB layer 2 home to remote multicast snooping redistribution configuration:

```
Switch:1(config-isis)#show isis multi-area 12 redistribute snoop-multicast
=====
MULTI-AREA L2 SNOOP MULTICAST REDISTRIBUTE BY ISID
=====
ISID      DIRECTION      ENABLE      RPOLICY
-----
1100     home-to-remote  TRUE       test
=====
MULTI-AREA L2 SNOOP MULTICAST REDISTRIBUTE BY ISID LIST
=====
ISID LIST      DIRECTION      ENABLE      RPOLICY
-----
List1         home-to-remote  TRUE       test
-----
```

Applying the Multi-area SPB layer 2 home to remote multicast snooping redistribution:

```
Switch:1(config-isis)#isis multi-area 12 apply redistribute snoop-multicast home-to-remote
```

## Variable Definitions

The following table defines parameters for the **multi-area 12 redistribute snoop-multicast** and the **isis multi-area 12 apply redistribute snoop-multicast** commands.

| Variable                               | Value                                                                                               |
|----------------------------------------|-----------------------------------------------------------------------------------------------------|
| <i>enable</i>                          | Enables Multi-area SPB layer 2 multicast snooping redistribution.                                   |
| <i>i-sid</i> <1-16777215>              | Specifies the I-SID value.                                                                          |
| <i>isid-list</i><br><i>WORD</i> <1-32> | Specifies the name of the I-SID list.                                                               |
| <i>home-to-remote</i>                  | Specifies the layer 2 multicast snooping redistribution configuration for home to remote direction. |

| Variable                                                | Value                                                                                               |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>remote-to-home</code>                             | Specifies the layer 2 multicast snooping redistribution configuration for remote to home direction. |
| <code>route-map</code><br><code>WORD&lt;1-64&gt;</code> | Specifies the name of the route policy.                                                             |

### Configure Multi-area SPB IPv4 Routed Multicast Redistribution

#### Note

This procedure only applies to the VSP 7400 Series.

#### Before You Begin

- Enable multicast on the boundary nodes.
- Configure Multiprotocol Label Switching Virtual Private Network (MVPN) on the boundary nodes, for layer 3 VSN.
- Configure the same policies as the boundary node on the peer boundary nodes.

#### About This Task

Perform this procedure to configure Multi-area SPB IPv4 routed multicast redistribution on the switch.

#### Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```

2. Create the Multi-area SPB IPv4 routed multicast redistribution instance:

```
multi-area ip redistribute routed-multicast [home-to-remote | remote-to-home]
```

#### Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
multi-area ip redistribute routed-multicast [home-to-remote | remote-to-home] route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv4 routed multicast redistribution instance:

```
multi-area ip redistribute routed-multicast [home-to-remote | remote-to-home] enable
```

5. Verify the Multi-area SPB IPv4 routed multicast redistribution configuration:

```
show isis multi-area ip redistribute routed-multicast [home-to-remote | remote-to-home]
```

6. Apply the Multi-area SPB IPv4 routed multicast redistribution:

```
isis multi-area ip apply redistribute routed-multicast [home-to-remote
| remote-to-home]
```

### Example

Configuring Multi-area SPB IPv4 routed multicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area ip redistribute routed-multicast home-to-remote
Switch:1(config-isis)#multi-area ip redistribute routed-multicast home-to-remote route-
map test
Switch:1(config-isis)#multi-area ip redistribute routed-multicast home-to-remote enable
Switch:1(config-isis)#show isis multi-area ip redistribute routed-multicast home-to-remote
=====
      ISIS Multiarea Redistribute List for routed multicast - GlobalRouter
=====
DIRECTION          ENABLE          RPOLICY
-----
home-to-remote     TRUE           test
-----
Switch:1(config-isis)#isis multi-area ip apply redistribute routed-multicast home-to-
remote
```

### Variable Definitions

The following table defines parameters for the **multi-area ip redistribute routed-multicast** and the **isis multi-area ip apply redistribute routed-multicast** command.

| Variable                                    | Value                                                                                          |
|---------------------------------------------|------------------------------------------------------------------------------------------------|
| <i>enable</i>                               | Enables Multi-area SPB IPv4 routed multicast redistribution.                                   |
| <i>home-to-remote</i>                       | Specifies the IPv4 routed multicast redistribution configuration for home to remote direction. |
| <i>remote-to-home</i>                       | Specifies the IPv4 routed multicast redistribution configuration for remote to home direction. |
| <i>route-map</i><br><i>WORD&lt;1-64&gt;</i> | Specifies the name of the route policy.                                                        |
| <i>vrf WORD&lt;1-16&gt;</i>                 | Specifies the multicast routing redistribution configuration for specific VRF instance.        |

Configure IS-IS Multi-area SPB IPv4 Routed Multicast Redistribution on a VRF Instance

#### Note

This procedure only applies to the VSP 7400 Series.

### Before You Begin

- Enable multicast on the boundary nodes.
- Configure Multiprotocol Label Switching Virtual Private Network (MVPN) on the boundary nodes, for layer 3 VSN.

- Configure the same policies as the boundary node on the peer boundary nodes.

### About This Task

Perform this procedure to configure IS-IS Multi-area SPB IPv4 routed multicast redistribution on a specific Virtual Router Forwarding (VRF) instance on the switch.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Create the IS-IS Multi-area SPB IPv4 routed multicast redistribution instance on the VRF:

```
isis multi-area ip redistribute routed-multicast [home-to-remote |
remote-to-home]
```

#### Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
isis multi-area ip redistribute routed-multicast [home-to-remote |
remote-to-home] route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv4 routed multicast redistribution instance on the VRF:

```
isis multi-area ip redistribute routed-multicast [home-to-remote |
remote-to-home] enable
```

5. Verify the Multi-area SPB IPv4 routed multicast redistribution configuration on the VRF:

```
show isis multi-area ip redistribute routed-multicast [home-to-remote
| remote-to-home] [vrf WORD<1-16> | vrfids WORD<0-512>]
```

6. Exit to Global Configuration mode:

```
exit
```

7. Apply the Multi-area SPB IPv4 routed multicast redistribution on the VRF:

```
isis multi-area ip apply redistribute routed-multicast [home-to-remote
| [remote-to-home] vrf WORD<1-16>
```

### Example

Configuring IS-IS Multi-area SPB IPv4 routed multicast redistribution for home to remote direction on VRF VRF1:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf VRF1
Switch:1(router-vrf)#isis multi-area ip redistribute routed-multicast home-to-remote
Switch:1(router-vrf)#isis multi-area ip redistribute routed-multicast home-to-remote
route-map test
Switch:1(router-vrf)#isis multi-area ip redistribute routed-multicast home-to-remote
enable
```

```

Switch:1(router-vrf)#show isis multi-area ip redistribute routed-multicast home-to-remote
vrf VRF1
=====
                ISIS Multiarea Redistribute List for routed multicast - VRF VRF1
=====
DIRECTION          ENABLE      RPOLICY
-----
home-to-remote     TRUE       test
-----
Switch:1(router-vrf)#exit
Switch:1(config)#isis multi-area ip apply redistribute routed-multicast home-to-remote
vrf VRF1

```

## Variable Definitions

The following table defines parameters for the **isis multi-area ip redistribute routed-multicast** and the **isis multi-area ip apply redistribute routed-multicast** commands.

| Variable                                    | Value                                                                                          |
|---------------------------------------------|------------------------------------------------------------------------------------------------|
| <i>enable</i>                               | Enables IPv4 routed multicast redistribution on the VRF instance.                              |
| <i>home-to-remote</i>                       | Specifies the IPv4 routed multicast redistribution configuration for home to remote direction. |
| <i>remote-to-home</i>                       | Specifies the IPv4 routed multicast redistribution configuration for remote to home direction. |
| <i>route-map</i><br><i>WORD&lt;1-64&gt;</i> | Specifies the name of the route policy.                                                        |
| <i>vrf</i> <i>WORD&lt;1-16&gt;</i>          | Specifies the multicast routing redistribution configuration for specific VRF instance.        |

## Multi-area SPB Verification using CLI

Perform the procedures in this section to verify the Multi-area SPB configuration on the switch using the Command Line Interface (CLI).

### Display the Remote IS-IS SPBM Nickname Configuration

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to display the remote Intermediate-System-to-Intermediate-System (IS-IS) Shortest Path Bridging MAC (SPBM) nickname configuration on the switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the remote IS-IS SPBM nickname configuration:

```
show isis spbm nick-name remote
```

## Example

Displaying the remote IS-IS SPBM nickname configuration:

```
Switch:1>show isis spbm nick-name remote
=====
ISIS SPBM NICK-NAME

*Display IS-IS Multi-area SPB IPv4 Redistribution Configuration*

**Note**

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to display the IS-IS Multi-area SPB IPv4 redistribution configuration for home to remote, remote to home, unicast, routed multicast, specific Virtual Router Forwarding (VRF) instance, and VRF IDs on the switch.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS Multi-area SPB IPv4 home to remote redistribution configuration:  

```
show isis multi-area ip redistribute [home-to-remote [vrf WORD<1-16> | vrfids WORD<0-512>]]
```
3. Display the IS-IS Multi-area SPB IPv4 remote to home redistribution configuration:  

```
show isis multi-area ip redistribute [remote-to-home [vrf WORD<1-16> | vrfids WORD<0-512>]]
```
4. Display the IS-IS Multi-area SPB IPv4 routed multicast redistribution configuration:  

```
show isis multi-area ip redistribute routed-multicast [home-to-remote [vrf WORD<1-16> | vrfids WORD<0-512>] | remote-to-home [vrf WORD<1-16> | vrfids WORD<0-512>] | vrf WORD<1-16> | vrfids WORD<0-512>]]
```
5. Display the IS-IS Multi-area SPB IPv4 unicast redistribution configuration:  

```
show isis multi-area ip redistribute unicast [home-to-remote [vrf WORD<1-16> | vrfids WORD<0-512>] | remote-to-home [vrf WORD<1-16> | vrfids WORD<0-512>] | vrf WORD<1-16> | vrfids WORD<0-512>]]
```
6. Display the IS-IS Multi-area SPB IPv4 redistribution configuration for VRF instance:  

```
show isis multi-area ip redistribute vrf WORD<1-16>
```
7. Display the IS-IS Multi-area SPB IPv4 redistribution configuration for VRF ID:  

```
show isis multi-area ip redistribute vrfids WORD<0-512>
```

## Example

Displaying the IS-IS Multi-area SPB IPv4 unicast redistribution configuration on the switch:

```
Switch:1>show isis multi-area ip redistribute unicast
=====
                ISIS Multiarea Redistribute List for ip unicast - GlobalRouter
=====
DIRECTION          ENABLE      RPOLICY
-----
home-to-remote     TRUE
remote-to-home     TRUE
```

*Display IS-IS Multi-area SPB IPv6 Redistribution Configuration*

### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to display the IS-IS Multi-area SPB IPv6 redistribution configuration for home to remote, remote to home, unicast, specific Virtual Router Forwarding (VRF) instance, and VRF IDs on the switch.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS Multi-area SPB IPv6 home to remote redistribution configuration:  

```
show isis multi-area ipv6 redistribute [home-to-remote [vrf WORD<1-16>
| vrfids WORD<0-512>]]
```
3. Display the IS-IS Multi-area SPB IPv6 remote to home redistribution configuration:  

```
show isis multi-area ipv6 redistribute [remote-to-home [vrf WORD<1-16>
| vrfids WORD<0-512>]]
```
4. Display the IS-IS Multi-area SPB IPv6 unicast redistribution configuration:  

```
show isis multi-area ipv6 redistribute unicast [home-to-remote [vrf
WORD<1-16> | vrfids WORD<0-512>] | remote-to-home [vrf WORD<1-16> |
vrfids WORD<0-512>] | vrf WORD<1-16> | vrfids WORD<0-512>]]
```
5. Display the IS-IS Multi-area SPB IPv6 redistribution configuration for VRF instance:  

```
show isis multi-area ipv6 redistribute [vrf WORD<1-16>]
```
6. Display the IS-IS Multi-area SPB IPv6 redistribution configuration for VRF ID:  

```
show isis multi-area ipv6 redistribute [vrfids WORD<0-512>]
```

## Example

Displaying the IS-IS Multi-area SPB IPv6 unicast redistribution configuration:

```
Switch:1>show isis multi-area ipv6 redistribute unicast
=====
                ISIS Multiarea Redistribute List for ipv6 unicast - GlobalRouter
=====
DIRECTION                ENABLE      RPOLICY
-----
home-to-remote            TRUE       Test1
remote-to-home            TRUE       Test2
```

*Display IS-IS Multi-area SPB DvR Configuration*

### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to display the IS-IS Multi-area SPB Distributed Virtual Routing (DvR) redistribution configuration on the switch.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS Multi-area SPB DvR redistribution configuration:  

```
show isis multi-area dvr redistribute
```

## Example

Displaying the IS-IS Multi-area SPB DvR redistribution configuration on the switch:

```
Switch:1>show isis multi-area dvr redistribute
```

```

=====

### Display IS-IS Multi-area SPB Layer 2 Multicast Snooping Redistribution Configuration

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to display the IS-IS Multi-area SPB layer 2 multicast snooping redistribution configuration on the switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the multicast snooping redistribution configuration:
 

```
show isis multi-area l2 redistribute snoop-multicast
```

### Example

Displaying the IS-IS Multi-area SPB layer 2 multicast snooping redistribution configuration on the switch:

```

Switch>show isis multi-area l2 redistribute snoop-multicast
=====
MULTI-AREA L2 SNOOP MULTICAST REDISTRIBUTE BY ISID
=====
ISID      DIRECTION      ENABLE      RPOLICY
-----
1100     home-to-remote  TRUE       test
=====
MULTI-AREA L2 SNOOP MULTICAST REDISTRIBUTE BY ISID LIST
=====
ISID LIST  DIRECTION      ENABLE      RPOLICY
-----
List1     home-to-remote  TRUE       test
=====

```

## SPBM and IS-IS infrastructure configuration using EDM

This section provides procedures to configure basic SPBM and IS-IS infrastructure using Enterprise Device Manager (EDM).

#### Important

The **EnableSpbmConfigMode** boot flag must be enabled (default) before you can configure SPBM or IS-IS. To verify the setting, navigate to **Configuration > Edit > Chassis** and click on the **Boot Config** tab.

## Configuring required SPBM and IS-IS parameters

### About This Task

Use the following procedure to configure the minimum required SPBM and IS-IS parameters to allow SPBM to operate on the switch. SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

### Procedure

1. Configure SBPM B-VLANs:

#### Note

Always configure two B-VLANs in the core to allow load distribution over both B-VLANs.

- a. In the navigation pane, expand **Configuration > VLAN > VLANs**.
  - b. Click the **Basic** tab.
  - c. Click **Insert**.
  - d. In the **type** field, click **spbm-bvlan**.
  - e. Click **Insert**.
2. Enable SPBM globally:
    - a. In the navigation pane, expand **Configuration > IS-IS**.
    - b. Click **SPBM**.
    - c. Click the **Globals** tab.
    - d. In the **GlobalEnable** field, select **enable** to enable SPBM globally.
    - e. Click **Apply**.
  3. Create an SPBM instance:

#### Note

Only one SBPM instance is supported.

- a. In the navigation pane, expand **Configuration > IS-IS > SPBM**.
  - b. Click the **SPBM** tab.
  - c. Click **Insert** to create an SPBM instance.
  - d. In the **Id** field, specify the SPBM instance ID.
  - e. In the **NodeNickName** field, specify the node nickname (valid value is 2.5 bytes in the format <x.xx.xx>).
  - f. In the **Vlans** field, specify the IDs of the SPBM B-VLANs to add to the SPBM instance.
  - g. In the **PrimaryVlan** field, specify which of the SPBM B-VLANs specified in the previous step is the primary B-VLAN.
  - h. Click **Insert**.
4. Create a manual area:

#### Note

Only one manual area is supported.

- a. In the navigation pane, expand **Configuration > IS-IS > IS-IS**.
  - b. Click the **Manual Area** tab.
  - c. Click **Insert**.
  - d. Specify the Manual Area address (a valid value is 1-13 bytes in the format <xx.xxxx.xxxx...xxxx>).
  - e. Click **Insert**.
5. Update the default IS-IS system ID to a recognizable address:
- a. In the navigation pane, expand **Configuration > IS-IS > IS-IS**.
  - b. Click the **Globals** tab.
  - c. In the **SystemId** field, update the default B-MAC value to a recognizable address.

**Note**

Although it is not strictly required for SPBM operation, you must change the IS-IS system ID from the default B-MAC value to a recognizable address to easily identify a switch. This helps to recognize the source and destination addresses for troubleshooting purposes.

- d. In the **AdminState** field, click **on**.
  - e. Click **Apply**.
6. Create an IS-IS circuit and enable SPBM on the circuit:
- a. In the navigation pane, expand **Configuration > IS-IS**.
  - b. Click the **Interfaces** tab.
  - c. Click **Insert** to create an IS-IS circuit.
  - d. In the **IfIndex** field, specify the port or MLT on which to create the IS-IS circuit.
  - e. Click **Insert**.
  - f. Select the newly created IS-IS circuit entry, and click **SPBM**.
  - g. In the **Interfaces SPBM** tab, click **Insert**.
  - h. In the **State** field, select **enable**.
  - i. Click **Insert**. This enables the SPBM instance on the IS-IS circuit.
  - j. Navigate back to the **Interfaces** tab.
  - k. In the **AdminState** field for the IS-IS circuit entry, select **on** to enable the IS-IS circuit.
  - l. Click **Apply**.

**SPBM Field Descriptions****Note**

The following tables list the minimum required SPBM and IS-IS parameters to allow SPBM to operate on the switch. For more detailed information on all of the parameters see the procedures that follow. For more information on how to configure VLANs, see [VLAN Configuration using EDM](#) on page 3780.

Use the data in the following table to use the **VLANs Basic** tab.

| Name        | Description                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Type</b> | Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul> |

Use the data in the following table to use the **SPBM Globals** tab.

| Name                                                                                                                    | Description                                                                                                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GlobalEnable</b>                                                                                                     | Enables or disables SPBM globally. The default is disabled.<br>To ensure proper cleanup of MAC tables after you disable SPBM, save the configuration, and then reboot the switch.               |
| <b>GlobalEtherType</b>                                                                                                  | Specifies the global ethertype value as 0x8100 or 0x88a8. The default value is 0x8100.                                                                                                          |
| <b>NicknameServerEnable</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series.            | Enables or disables the nickname server. The default is disabled.                                                                                                                               |
| <b>NicknameDynamicAllocationStatus</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series. | Displays the Dynamic Nickname Allocation service operational status.                                                                                                                            |
| <b>NicknameServerPrefix</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series.            | Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default is A.00.00. |

Use the data in the following table to use the **SPBM** tab.

| Name                | Description                                                                                            |
|---------------------|--------------------------------------------------------------------------------------------------------|
| <b>Id</b>           | Specifies the SPBM instance ID. Only one SPBM instance is supported.                                   |
| <b>NodeNickName</b> | Specifies a nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>. |
| <b>PrimaryVlan</b>  | Specifies the primary SPBM B-VLANs to add to the SPBM instance.                                        |

| Name                                                                                                     | Description                                                                                                                                                                                       |
|----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Vlans</b>                                                                                             | Specifies the SPBM B-VLANs to add to the SPBM instance.                                                                                                                                           |
| <b>LsdbTrap</b>                                                                                          | Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disable.                                                                                                |
| <b>IpShortcut</b>                                                                                        | Enables or disables SPBM IP shortcut state. The default is disable.                                                                                                                               |
| <b>SmltSplitBEB</b>                                                                                      | Specifies whether the switch is the primary or secondary v1ST peer. The default is primary.                                                                                                       |
| <b>SmltVirtualBmac</b>                                                                                   | Specifies a virtual MAC address that can be used by both peers.                                                                                                                                   |
| <b>SmltPeerSysId</b>                                                                                     | Specifies the system ID of the SPBM SMLT for this SPBM instance.                                                                                                                                  |
| <b>Mcast</b>                                                                                             | Specifies if IP multicast over SPBM is enabled. The default is disabled.                                                                                                                          |
| <b>McastFwdCacheTimeout</b>                                                                              | Specifies the global forward cache timeout in seconds. The default is 210 seconds.                                                                                                                |
| <b>Ipv6Shortcut</b>                                                                                      | Enables or disables SPBM IPv6 shortcut state. The default is disable.                                                                                                                             |
| <b>McastSpbPimGwControllerEnable</b>                                                                     | Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default.                                                                                                          |
| <b>McastSpbPimGwGatewayEnable</b>                                                                        | Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default.                                                                                                                     |
| <b>StpMultiHoming</b>                                                                                    | Enables or disables MSTP-Fabric Connect Multi Homing.<br>The default is disabled (false).                                                                                                         |
| <b>BVlanOrigin</b><br><br><b>Note:</b><br>Exception: not supported on XA1400 Series and VSP 8600 Series. | Shows how the B-VLAN was created. The values can be config for manual configuration using CLI or SNMP, or dynamic through Zero Touch Fabric Configuration and Auto-sense. The default is dynamic. |

Use the data in the following table to use the **IS-IS Manual Area** tab.

| Name            | Description                                                                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AreaAddr</b> | Specifies the IS-IS manual area. Valid value is 1-13 bytes in the format <xx.xxxx.xxxx...xxxx>. Only one manual area is supported. Use the same manual area across the entire SPBM cloud. For IS-IS to operate, you must configure at least one manual area. |

Use the data in the following table to use the **IS-IS Globals** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminState</b> | Specifies the global status of IS-IS on the switch: on or off. The default is off.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SystemId</b>   | <p>Specifies the IS-IS system ID for the switch. Valid value is a 6-byte value in the format &lt;xxxx.xxxx.xxxx&gt;.</p> <p><b>Important:</b><br/>After you have configured the SPBM nickname and enabled IS-IS, if you require a change of the system ID, you must also change the nickname. However, for naming convention purposes or configuration purposes, you may not want to change the nickname. To maintain the same nickname with a different system ID, see <a href="#">Job aid</a> on page 1008.</p> |

Use the data in the following table to use the **IS-IS Interfaces** tab.

| Name              | Description                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>      | The identifier of this circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value. |
| <b>AdminState</b> | Specifies the administrative state of the circuit: on or off.                                                                                                              |

Use the data in the following table to use the **IS-IS Interfaces SPBM** tab.

| Name         | Description                                                  |
|--------------|--------------------------------------------------------------|
| <b>State</b> | Specifies whether the SPBM interface is enabled or disabled. |

**Job aid****Important**

After you have configured the SPBM nickname and enabled IS-IS. To maintain the same nickname with a different system ID, perform the following steps:

1. Disable IS-IS.
2. Change the system ID.
3. Change the nickname to a temporary one.
4. Enable IS-IS.
5. Wait up to 20 minutes for the LSPs with the original system ID to age out.

**Note**

To check the age out time, use the **show isis lsdb sysid <original-sys-id>** command on any of the other SPB nodes in the network. When there is no output from this command, proceed to the next step. The time left (in seconds) for the LSPs to age out is shown under the column **LIFETIME**.

6. Disable IS-IS.
7. Change the nickname to the original nickname.
8. Enable IS-IS.

*Displaying SPBM and IS-IS summary information*

Use the following procedure to view a summary of SPBM and IS-IS protocol information.

**Procedure**

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **Protocol Summary** tab.

**Protocol Summary field descriptions**

Use the data in the following table to use the **Protocol Summary** tab.

| Name                | Description                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Globals ISIS</b> |                                                                                                                                                                                                                        |
| <b>AdminState</b>   | Indicates the global status of IS-IS on the switch.                                                                                                                                                                    |
| <b>SystemId</b>     | Indicates the IS-IS system ID for the switch. Valid value is a 6-byte value in the format <xxxx.xxxx.xxxx>                                                                                                             |
| <b>HostName</b>     | Indicates a name for the system. This may be used as the host name for dynamic host name exchange in accordance with RFC 2763.<br>By default, the system name comes from the host name configured at the system level. |
| <b>Globals SPBM</b> |                                                                                                                                                                                                                        |
| <b>GlobalEnable</b> | Indicates whether SPBM is enabled or disabled at the global level.                                                                                                                                                     |

| Name                       | Description                                                                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NodeNickName</b>        | Indicates the nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.                                                                                  |
| <b>PrimaryVlan</b>         | Indicates the primary VLAN ID for this SPBM instance.                                                                                                                                     |
| <b>SmltSplitBEB</b>        | Indicates whether the switch is the primary or secondary IST peer.                                                                                                                        |
| <b>ISIS Interfaces</b>     |                                                                                                                                                                                           |
| <b>Circuit Index</b>       | Displays the identifier of this IS-IS circuit, unique within the Intermediate System. This is for SNMP Indexing purposes only and need not have any relation to any protocol value.       |
| <b>IfIndex</b>             | Indicates the interface to which this circuit corresponds.                                                                                                                                |
| <b>AdminState</b>          | Indicates the administrative state of the circuit: on or off.                                                                                                                             |
| <b>OperState</b>           | Indicates the operational state of the circuit: up or down.                                                                                                                               |
| <b>ISIS Adjacency View</b> |                                                                                                                                                                                           |
| <b>Circuit Index</b>       | Displays the identifier of this IS-IS circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value. |
| <b>AdjIndex</b>            | Displays a unique value identifying the IS adjacency from all other such adjacencies on this circuit. This value is automatically assigned by the system when the adjacency is created    |
| <b>AdjIfIndex</b>          | Indicates the interface to which this circuit corresponds.                                                                                                                                |
| <b>AdjState</b>            | Indicates the state of the adjacency: <ul style="list-style-type: none"> <li>• down</li> <li>• initializing</li> <li>• up</li> <li>• failed</li> </ul>                                    |
| <b>AdjNeighSysID</b>       | Indicates the system ID of the neighboring Intermediate System.                                                                                                                           |
| <b>AdjHostName</b>         | Indicates the host name listed in the LSP, or the system name if the host name is not configured.                                                                                         |

#### *View the SPBM I-SID Information*

Use the following procedure to display the SPBM Service Instance Identifier (I-SID) information. The SPBM B-MAC header includes an I-SID with a length of 24 bits. This I-SID can be used to identify and transmit any virtualized traffic in an encapsulated SPBM frame.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **SPBM**.
3. Select the **I-SID** tab.

### I-SID field descriptions

Use the data in the following table to use the **I-SID** tab.

| Name            | Description                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------|
| <b>SysId</b>    | Indicates the system identifier.                                                                  |
| <b>Vlan</b>     | Indicates the B-VLAN where this I-SID was configured or discovered.                               |
| <b>Isid</b>     | Indicates the IS-IS SPBM I-SID identifier.                                                        |
| <b>NickName</b> | Indicates the nickname of the node where this I-SID was configured or discovered.                 |
| <b>HostName</b> | Indicates the host name listed in the LSP, or the system name if the host name is not configured. |
| <b>Type</b>     | Indicates the SPBM I-SID type; either configured or discovered.                                   |

### View Level 1 Area Information

Use the following procedure to display Level 1 area information. IS-IS provides support for hierarchical routing, which enables you to partition large routing domains into smaller areas. IS-IS uses a two-level hierarchy, dividing the domain into multiple Level 1 areas and one Level 2 area. The Level 2 area serves as backbone of the domain, connecting to all the Level 1 areas.

#### Important

The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **L1 Area** tab.

### L1 Area field descriptions

Use the data in the following table to use the **L1 Area** tab.

| Name            | Description                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>AreaAddr</b> | Specifies an area address reported in a Level 1 link-state packets (LSP) generated or received by this Intermediate System. |

### Configuring SMLT parameters for SPBM

Use the following procedure to configure the required Split MultiLink Trunking (SMLT) parameters to allow SPBM to interoperate with SMLT on the switch.

#### Note

- The assignment of primary and secondary roles to the vIST peers is automatic. The switch with the lower system ID (between the two vIST peers) is primary, and the switch with the higher system ID is secondary when default system-id values are being used.
- SMLT peer system ID is part of the required configuration. You must configure the SMLT peer system ID as the nodal MAC of the peer device. In the IS-IS network, the nodal MAC of devices should be eight apart from each other.
- When using the default hardware assigned system-id value, the SMLT Virtual BMAC is automatically derived by comparing the system-id values of the two vIST peers. A value of 0x01 plus the lower of the two system-id values is used as the SMLT Virtual BMAC.

When using a manually configured system-id value, the SMLT Virtual BMAC must also be manually configured.

- An I-SID must be assigned to every VLAN that is a member of an Layer 2 VSN. Also if an Layer 2 VSN is created on one vIST Peer, it must also be created on the other vIST peer.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS > SPBM**.
2. Click the **SPBM** tab.
3. Use the **SmltSplitBEB** field to see whether the switch is the primary or secondary vIST peer. This field cannot be modified.
4. Use the **SmltVirtualBmac** field to specify a virtual MAC address that can be used by both peers.
5. Use the **SmltPeerSysId** field to specify the vIST peer B-MAC address.
6. Click **Apply**.

### Enabling or disabling SPBM at the global level

Use the following procedure to enable or disable SPBM at the global level. SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **SPBM**.
3. Click the **Globals** tab.
4. To enable or disable SPBM, click **enable** or **disable** in the **GlobalEnable** field.
5. To configure the global ethertype value, click the desired option in the **GlobalEtherType** field.
6. Click **Apply**.

#### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                                                                                                                        | Description                                                                                                                                                                                     |
|-----------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GlobalEnable</b>                                                                                                         | Enables or disables SPBM globally. The default is disabled.<br>To ensure proper cleanup of MAC tables after you disable SPBM, save the configuration, and then reboot the switch.               |
| <b>GlobalEtherType</b>                                                                                                      | Specifies the global ethertype value as 0x8100 or 0x88a8. The default value is 0x8100.                                                                                                          |
| <b>NicknameServerEnable</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series.            | Enables or disables the nickname server. The default is disabled.                                                                                                                               |
| <b>NicknameDynamicAllocationStatus</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series. | Displays the Dynamic Nickname Allocation service operational status.                                                                                                                            |
| <b>NicknameServerPrefix</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series.            | Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default is A.00.00. |

### Configuring SPBM parameters

Use the following procedure to configure SPBM global parameters. SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **SPBM**.
3. Click the **SPBM** tab.
4. To create an SPBM instance, click **Insert**.
5. Configure the SPBM parameters.
6. Click **Apply**.

#### SPBM Field Descriptions

Use the data in the following table to use the **SPBM** tab.

| Name                                                                           | Description                                                                                                                                                                                       |
|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                                                                      | Specifies the SPBM instance ID. Only one SPBM instance is supported.                                                                                                                              |
| <b>NodeNickName</b>                                                            | Specifies a nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.                                                                                            |
| <b>PrimaryVlan</b>                                                             | Specifies the primary SPBM B-VLANs to add to the SPBM instance.                                                                                                                                   |
| <b>Vlans</b>                                                                   | Specifies the SPBM B-VLANs to add to the SPBM instance.                                                                                                                                           |
| <b>LsdbTrap</b>                                                                | Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disable.                                                                                                |
| <b>IpShortcut</b>                                                              | Enables or disables SPBM IP shortcut state. The default is disable.                                                                                                                               |
| <b>SmltSplitBEB</b>                                                            | Specifies whether the switch is the primary or secondary vIST peer. The default is primary.                                                                                                       |
| <b>SmltVirtualBmac</b>                                                         | Specifies a virtual MAC address that can be used by both peers.                                                                                                                                   |
| <b>SmltPeerSysId</b>                                                           | Specifies the system ID of the SPBM SMLT for this SPBM instance.                                                                                                                                  |
| <b>Mcast</b>                                                                   | Specifies if IP multicast over SPBM is enabled. The default is disabled.                                                                                                                          |
| <b>McastFwdCacheTimeout</b>                                                    | Specifies the global forward cache timeout in seconds. The default is 210 seconds.                                                                                                                |
| <b>Ipv6Shortcut</b>                                                            | Enables or disables SPBM IPv6 shortcut state. The default is disable.                                                                                                                             |
| <b>McastSpbPimGwControllerEnable</b>                                           | Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default.                                                                                                          |
| <b>McastSpbPimGwGatewayEnable</b>                                              | Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default.                                                                                                                     |
| <b>StpMultiHoming</b>                                                          | Enables or disables MSTP-Fabric Connect Multi Homing. The default is disabled (false).                                                                                                            |
| <b>BVlanOrigin</b>                                                             | Shows how the B-VLAN was created. The values can be config for manual configuration using CLI or SNMP, or dynamic through Zero Touch Fabric Configuration and Auto-sense. The default is dynamic. |
| <b>Note:</b><br>Exception: not supported on XA1400 Series and VSP 8600 Series. |                                                                                                                                                                                                   |

### Displaying SPBM nicknames

Use the following procedure to display SPBM nicknames.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.

2. Click **SPBM**.
3. Click the **Nick Names** tab.

### Nickname field descriptions

Use the data in the following table to use the **NickName** tab.

| Name                  | Description                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------|
| <b>Level</b>          | Indicates the level at which the system displays this LSP.                                       |
| <b>ID</b>             | Indicates the 8 byte LSP ID, consisting of the SystemID, Circuit ID, and Fragment Number.        |
| <b>LifetimeRemain</b> | Indicates the remaining lifetime in seconds for the LSP.                                         |
| <b>NickName</b>       | Indicates the nickname for the SPBM node.                                                        |
| <b>HostName</b>       | Indicates the hostname listed in the LSP, or the system name if the host name is not configured. |

### Configure Interface SPBM Parameters

Use the following procedure to configure the SPBM interface parameters.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **SPBM**.
3. Select the **Interfaces SPBM** tab.
4. Configure the SPBM interface parameters.
5. Select **Apply**.

### Interfaces SPBM Field Descriptions

Use the data in the following table to use the **Interfaces SPBM** tab.

| Name                                                                                            | Description                                                                                                                                                                         |
|-------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                                                                                    | Specifies an Index value for the SPBM interface.                                                                                                                                    |
| <b>SpbmId</b>                                                                                   | Specifies the SPBM ID.                                                                                                                                                              |
| <b>State</b>                                                                                    | Specifies whether the SPBM interface is enabled or disabled.                                                                                                                        |
| <b>Type</b>                                                                                     | Configures the SPBM instance interface-type on the IS-IS interface located on the specified port or MLT: ptpt or bcast. Only the point-to-point (ptpt) interface type is supported. |
| <b>L1Metric</b>                                                                                 | Configures the IS-IS Interface level 1 metric on the specified port or MLT. The default value is 10.                                                                                |
| <b>Origin</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series and XA1400 Series. | Specifies the source of the SPBM instance configuration, either manually configured through CLI or EDM or dynamically configured through Auto-sense.                                |

*Configuring SPBM on an interface*

Use the following procedure to configure SPBM on an interface.

**Procedure**

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **Interfaces** tab.
4. Click the **SPBM** button.
5. In the **Interfaces SPBM** tab, click **Insert**.
6. Click **Insert**.

**SPBM field descriptions**

Use the data in the following table to use the **Interfaces SPBM** tab.

| Name                                                                                            | Description                                                                                                                                                                         |
|-------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                                                                                    | Specifies an Index value for the SPBM interface.                                                                                                                                    |
| <b>SpbmId</b>                                                                                   | Specifies the SPBM ID.                                                                                                                                                              |
| <b>State</b>                                                                                    | Specifies whether the SPBM interface is enabled or disabled.                                                                                                                        |
| <b>Type</b>                                                                                     | Configures the SPBM instance interface-type on the IS-IS interface located on the specified port or MLT: ptpt or bcast. Only the point-to-point (ptpt) interface type is supported. |
| <b>L1Metric</b>                                                                                 | Configures the IS-IS Interface level 1 metric on the specified port or MLT. The default value is 10.                                                                                |
| <b>Origin</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series and XA1400 Series. | Specifies the source of the SPBM instance configuration, either manually configured through CLI or EDM or dynamically configured through Auto-sense.                                |

*View the IP Unicast FIB*

Use the following procedure to display the IP unicast Forwarding Information Base (FIB). The tab shows IP routes from remote Backbone Edge Bridges (BEBs)

In SPBM, each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB). When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are never exchanged in the network as IP Shortcuts allows for Global Routing Table (GRT) IP networks to be transported across IS-IS.

The **IP Unicast FIB** tab displays all of the IS-IS routes in the IS-IS LSDB. The Preference column in the **IP Unicast FIB** tab displays the IP route preference.

Routes within the same VSN are added to the LSDB with a default preference of 7. Inter-VSN routes are added to the LSDB with a route preference of 200. IS-IS accept policies allow you to change the route preference for incoming routes. If the same route is learned from multiple sources with different route preferences, then the routes are not considered equal cost multipath (ECMP) routes. The route with the lowest route preference is the preferred route. In Layer 2, in the event of a tie-break between routes from multiple sources, the tie-breaking is based on cost and hop count.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **SPBM**.
3. Select the **IP Unicast FIB** tab.

### IP Unicast FIB field descriptions

Use the data in the following table to use the **IP Unicast FIB** tab.

| Name                         | Description                                                        |
|------------------------------|--------------------------------------------------------------------|
| <b>VrfId</b>                 | Specifies the VRF ID of the IP unicast FIB entry, 0 indicates NRE. |
| <b>DestinationIpAddrType</b> | Specifies the address type of the destination IP address.          |
| <b>DestinationIpAddr</b>     | Specifies the destination IP Address of the IP unicast FIB entry.  |
| <b>DestinationMask</b>       | Specifies the destination IP mask of the IP unicast FIB entry      |
| <b>NextHopBmac</b>           | Specifies the nexthop B-MAC of the IP unicast FIB entry.           |
| <b>DestId</b>                | Specifies the destination I-SID of the IP unicast FIB entry.       |
| <b>Vlan</b>                  | Specifies the VLAN of the IP unicast FIB entry.                    |
| <b>Isid</b>                  | Specifies the I-SID of the IP unicast FIB entry.                   |
| <b>NextHopName</b>           | Specifies the nexthop hostname of the IP unicast FIB entry.        |
| <b>OutgoingPort</b>          | Specifies the outgoing port of the IP unicast FIB entry.           |
| <b>PrefixCost</b>            | Specifies the prefix cost of the IP unicast FIB entry.             |
| <b>SpbmCost</b>              | Specifies the B-MAC cost of the IP unicast FIB entry.              |
| <b>Preference</b>            | Specifies the IP Route preference of the IP unicast FIB entry      |
| <b>MetricType</b>            | Specifies the IP Metric Type of the IP unicast FIB entry.          |

### View the IPv6 Unicast FIB

Use the following procedure to display the IPv6 unicast Forwarding Information Base (FIB). The tab shows IPv6 routes from remote Backbone Edge Bridges (BEBs)

In SPBM, each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB). When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every

node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are never exchanged in the network as IP Shortcuts allows for Global Routing Table (GRT) IP networks to be transported across IS-IS.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **SPBM**.
3. Select the **IPv6 Unicast FIB** tab.

### IPv6 Unicast FIB Field Descriptions

Use the data in the following table to use the **IPv6 Unicast FIB** tab.

| Name                         | Description                                                           |
|------------------------------|-----------------------------------------------------------------------|
| <b>Vrflid</b>                | Specifies the VRF ID of the IPv6 unicast FIB entry, 0 indicates NRE.  |
| <b>DestinationIpAddrType</b> | Specifies the address type of the destination IPv6 address.           |
| <b>DestinationIpAddr</b>     | Specifies the destination IPv6 Address of the IPv6 unicast FIB entry. |
| <b>DestinationMask</b>       | Specifies the destination IPv6 mask of the IPv6 unicast FIB entry     |
| <b>NextHopBmac</b>           | Specifies the nexthop B-MAC of the IPv6 unicast FIB entry.            |
| <b>DestIsid</b>              | Specifies the destination I-SID of the IPv6 unicast FIB entry.        |
| <b>Vlan</b>                  | Specifies the VLAN of the IPv6 unicast FIB entry.                     |
| <b>Isid</b>                  | Specifies the I-SID of the IPv6 unicast FIB entry.                    |
| <b>NextHopName</b>           | Specifies the nexthop hostname of the IPv6 unicast FIB entry.         |
| <b>OutgoingPort</b>          | Specifies the outgoing port of the IPv6 unicast FIB entry.            |
| <b>PrefixCost</b>            | Specifies the prefix cost of the IPv6 unicast FIB entry.              |
| <b>SpbmCost</b>              | Specifies the B-MAC cost of the IPv6 unicast FIB entry.               |
| <b>MetricType</b>            | Specifies the Metric Type of the IPv6 unicast FIB entry.              |

### *View the Unicast FIB*

Use the following procedure to display the unicast FIB.

In SPBM, B-MAC addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node

to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **SPBM**.
3. Select the **Unicast FIB** tab.

### Unicast FIB field descriptions

Use the data in the following table to use the **Unicast FIB** tab.

| Name                      | Description                                                                 |
|---------------------------|-----------------------------------------------------------------------------|
| <b>SysId</b>              | Specifies the system ID of the node where the unicast FIB entry originated. |
| <b>Vlan</b>               | Specifies the VLAN of the unicast FIB entry.                                |
| <b>DestinationMacAddr</b> | Specifies the destination MAC Address of the unicast FIB entry.             |
| <b>OutgoingPort</b>       | Specifies the outgoing port of the unicast FIB entry.                       |
| <b>HostName</b>           | Specifies the host name of the node where unicast FIB entry originated.     |
| <b>Cost</b>               | Specifies the cost of the unicast FIB entry.                                |

### *View LSP Summary Information*

Use the following procedure to display link-state packet (LSP) summary information. Link State Packets (LSP) contain information about the state of adjacencies or defined and distributed static routes. Intermediate System to Intermediate System (IS-IS) exchanges this information with neighboring IS-IS routers at periodic intervals.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **LSP Summary** tab.

### LSP Summary field descriptions

Use the data in the following table to use the **LSP Summary** tab.

| Name            | Description                                                                               |
|-----------------|-------------------------------------------------------------------------------------------|
| <b>Level</b>    | Specifies the level at which the system displays this LSP.                                |
| <b>ID</b>       | Specifies the 8 byte LSP ID, consisting of the SystemID, Circuit ID, and Fragment Number. |
| <b>Seq</b>      | Specifies the sequence number for this LSP.                                               |
| <b>Checksum</b> | Specifies the 16 bit Fletcher Checksum for this LSP.                                      |

| Name                  | Description                                                                    |
|-----------------------|--------------------------------------------------------------------------------|
| <b>LifetimeRemain</b> | The remaining lifetime in seconds for this LSP.                                |
| <b>HostName</b>       | The hostname listed in LSP, or the system name if host name is not configured. |

### View IS-IS Adjacencies

Use the following procedure to display IS-IS adjacency information. The platform sends IS-IS Hello (IIH) packets to discover IS-IS neighbors and establish and maintain IS-IS adjacencies. The platform continues to send IIH packets to maintain the established adjacencies. For two nodes to form an adjacency the B-VLAN pairs for the primary B-VLAN and secondary B-VLAN must match.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **Adjacency** tab.

#### Adjacency field descriptions

Use the data in the following table to use the **Adjacency** tab.

| Name                 | Description                                                                                                                                                                                                                                       |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>     | Specifies the IS-IS interface on which the adjacency is found.                                                                                                                                                                                    |
| <b>Level</b>         | Indicates the level of the IS-IS interface (Level 1 [default] or Level 2).                                                                                                                                                                        |
| <b>State</b>         | Specifies the state of the adjacency: <ul style="list-style-type: none"> <li>• down</li> <li>• initializing</li> <li>• up</li> <li>• failed</li> </ul>                                                                                            |
| <b>LastUpTime</b>    | Indicates when the adjacency most recently entered the state <b>up</b> , measured in hundredths of a second since the last re-initialization of the network management subsystem. Displays 0 if the adjacency has never been in state <b>up</b> . |
| <b>NeighPriority</b> | Specifies the priority of the neighboring Intermediate System for becoming the Designated Intermediate System.                                                                                                                                    |
| <b>HoldTimer</b>     | Specifies the holding time in seconds for this adjacency. This value is based on received IS-IS Hello (IIH) PDUs and the elapsed time since receipt.                                                                                              |
| <b>NeighSysID</b>    | Specifies the system ID of the neighboring Intermediate System.                                                                                                                                                                                   |

| Name                  | Description                                                                                                                                                                  |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdjHostName</b>    | Specifies the host name listed in the LSP, or the system name if host name is not configured.                                                                                |
| <b>ParallelActive</b> | Specifies if the current adjacency among all the parallel adjacencies between two nodes is active. <ul style="list-style-type: none"> <li>• true</li> <li>• false</li> </ul> |

### Configure IS-IS Global Parameters

Use the following procedure to configure IS-IS global parameters. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **Globals** tab.
4. Configure the global IS-IS parameters.
5. Click **Apply**.

#### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminState</b> | Specifies the global status of IS-IS on the switch: on or off. The default is off.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>LevelType</b>  | Sets the router type globally: <ul style="list-style-type: none"> <li>• level1: Level-1 router type</li> <li>• level1and2: Level-1/2 router type is not supported.</li> </ul> The default value is level1.                                                                                                                                                                                                                                                                                           |
| <b>SystemId</b>   | Specifies the IS-IS system ID for the switch. Valid value is a 6-byte value in the format <xxxx.xxxx.xxxx>. <p><b>Important:</b><br/>After you have configured the SPBM nickname and enabled IS-IS, if you require a change of the system ID, you must also change the nickname. However, for naming convention purposes or configuration purposes, you may not want to change the nickname. To maintain the same nickname with a different system ID, see <a href="#">Job aid</a> on page 1008.</p> |

| Name                                                                                             | Description                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MaxLspGenInt</b>                                                                              | Specifies the maximum interval, in seconds, between generated LSPs by this Intermediate system. The value must be greater than any value configured for RxmtLsplnt. The default value is 900 seconds.                            |
| <b>Csnplnt</b>                                                                                   | Specifies the Complete Sequence Number Packet (CSNP) interval in seconds. This is a system level parameter that applies for L1 CSNP generation on all interfaces. The default value is 10.                                       |
| <b>RxmtLsplnt</b>                                                                                | Specifies the minimum time between retransmission of an LSP. This defines how fast the switch resends the same LSP. This is a system level parameter that applies for L1 retransmission of LSPs. The default value is 5 seconds. |
| <b>PSNPInterval</b>                                                                              | Specifies the Partial Sequence Number Packet (PSNP) interval in seconds. This is a system level parameter that applies for L1 PSNP generation on all interfaces. The default value is 2.                                         |
| <b>SpfDelay</b>                                                                                  | Specifies the SPF delay in milliseconds. This value is used to pace successive SPF runs. The timer prevents two SPF runs from being scheduled very closely. The default value is 100 milliseconds.                               |
| <b>HostName</b>                                                                                  | Specifies a name for the system. This can be used as the host name for dynamic host name exchange in accordance with RFC 2763. By default, the system name comes from the host name configured at the system level.              |
| <b>IpSourceAddress</b>                                                                           | Specifies IP source address for SPBM IP shortcuts.                                                                                                                                                                               |
| <b>Ipv6SourceAddress</b>                                                                         | Specifies IPv6 source address for SPBM IP shortcuts.                                                                                                                                                                             |
| <b>IpTunnelSourceAddress</b><br><br><b>Note:</b><br>Exception: Not supported on VSP 8600 Series. | Specifies the IS-IS IP tunnel source address.                                                                                                                                                                                    |
| <b>IpTunnelVrf</b><br><br><b>Note:</b><br>Exception: Not supported on VSP 8600 Series.           | Specifies the VRF name associated with the IP tunnel.                                                                                                                                                                            |
| <b>MgmtIpAddr</b><br><br><b>Note:</b><br>Exception: Not supported on VSP 8600 Series.            | Specifies the DvR management IP address for this node, in the DvR domain.                                                                                                                                                        |

| Name                                                                                          | Description                                                                                                                                                     |
|-----------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>BackboneEnable</b>                                                                         | Select to enable this node to join the DvR backbone so that it can receive redistributed DvR host routes from all DvR Controllers in the network.               |
| <b>FanMember</b><br><b>Note:</b><br>Exception: Not supported on VSP 8600 Series.              | Specifies whether the node is a member of the Fabric Area Network (FAN) .                                                                                       |
| <b>DynamicallyLearnedArea</b><br><b>Note:</b><br>Exception: Not supported on VSP 8600 Series. | For FAN members, specifies the IS-IS area that is dynamically learned from the neighbor's Hello PDU if the node does not have the IS-IS manual area configured. |
| <b>MAOperState</b><br><b>Note:</b><br>Exception: Only supported on VSP 7400 Series.           | Specifies the Multi-area SPB operational state. The default is disabled.                                                                                        |
| <b>HelloPadding</b><br><b>Note:</b><br>Exception: Not supported on VSP 8600 Series.           | Configures IS-IS hello padding on all IS-IS NNI links. IS-IS hello padding is enabled by default.                                                               |

### Configuring system-level IS-IS parameters

Use the following procedure to configure system-level IS-IS parameters.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS > IS-IS**.
2. Click the **System Level** tab.
3. Configure the IS-IS system level parameters.
4. Click **Apply**.

#### System Level field descriptions

Use the data in the following table to use the **System Level** tab.

| Name         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b> | Specifies the level: I1 or I2.<br>Only I1 is supported.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>State</b> | Specifies the state of the database at this level. The value 'off' indicates that IS-IS is not active at this level. The value 'on' indicates that IS-IS is active at this level, and not overloaded. The value 'waiting' indicates a database that is low on an essential resources, such as memory. The administrator may force the state to 'overloaded' by setting the object <b>SetOverload</b> . If the state is 'waiting' or 'overloaded', you originate LSPs with the Overload bit set. |

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SetOverload</b>      | Sets or clears the overload condition. The possible values are true or false.<br>The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SetOverloadUntil</b> | Sets the IS-IS overload-on-startup value in seconds. The overload-on-startup value is used as a timer to control when to send out LSPs with the overload bit cleared after IS-IS startup.<br><br><b>Note:</b><br>If you configure <b>SetOverloadUntil</b> to a number other than zero, then the overload bit is set at this level when the <b>AdminState</b> variable goes to the state 'on' for this Intermediate System.<br>After the <b>SetOverloadUntil</b> seconds elapse, the overload flag remains set if the implementation runs out of memory or if you configured it manually using <b>SetOverload</b> to true.<br>If <b>SetOverload</b> is false, the system clears the overload bit after <b>SetOverloadUntil</b> seconds elapse, if the system has not run out of memory.<br><br>The default value is 20. |
| <b>MetricStyle</b>      | Specifies the IS-IS metric type. Available values are narrow, wide or both. Only wide is supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### View IS-IS System Statistics

Use the following procedure to view the Intermediate-System-to-Intermediate-System (IS-IS) system statistics.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **Stats**.
3. Select the **System Stats** tab.

#### System Stats field descriptions

Use the data in the following table to use the **System Stats** tab.

| Name                        | Description                                                                                                                                                           |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CorrLSPs</b>             | Indicates the number of corrupted in-memory link-state packets (LSPs) detected. LSPs received from the wire with a bad checksum are silently dropped and not counted. |
| <b>AuthFails</b>            | Indicates the number of authentication key failures recognized by this Intermediate System.                                                                           |
| <b>LSPDbaseOloads</b>       | Indicates the number of times the LSP database has become overloaded.                                                                                                 |
| <b>ManAddrDropFromAreas</b> | Indicates the number of times a manual address has been dropped from the area.                                                                                        |

| Name                        | Description                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>AttmpToExMaxSeqNums</b>  | Indicates the number of times the IS has attempted to exceed the maximum sequence number.                                   |
| <b>SeqNumSkips</b>          | Indicates the number of times a sequence number skip has occurred.                                                          |
| <b>OwnLSPPurges</b>         | Indicates the number of times a zero-aged copy of the system's own LSP is received from some other node.                    |
| <b>IDFieldLenMismatches</b> | Indicates the number of times a PDU is received with a different value for ID field length to that of the receiving system. |
| <b>PartChanges</b>          | Indicates partition changes.                                                                                                |
| <b>AbsoluteValue</b>        | Displays the counter value.                                                                                                 |
| <b>Cumulative</b>           | Displays the total value since you opened the Stats tab.                                                                    |
| <b>Average/sec</b>          | Displays the average value for each second.                                                                                 |
| <b>Minimum/sec</b>          | Displays the minimum value for each second.                                                                                 |
| <b>Maximum/sec</b>          | Displays the maximum value for each second.                                                                                 |
| <b>LastVal/sec</b>          | Displays the last value for each second.                                                                                    |

### Configure IS-IS Interfaces

Use the following procedure to configure the IS-IS interfaces. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **Interfaces** tab.
4. Configure the IS-IS interface parameters.
5. Select **Apply**.

#### Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name           | Description                                                                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>   | The identifier of this circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value. |
| <b>IfIndex</b> | Specifies the interface on which the circuit is configured (port or MLT).                                                                                                  |
| <b>Type</b>    | Specifies the IS-IS circuit type. Only the point-to-point (PtToPt) interface type is supported.                                                                            |

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminState</b> | Specifies the administrative state of the circuit: on or off.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OperState</b>  | Specifies the operational state of the circuit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>AuthType</b>   | <p>Specifies the authentication type:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• simple: If selected, you must also specify a key value but the key id is optional. Simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet.</li> <li>• hmac-md5: If selected, you must also specify a key value, but the key-id is optional. MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. There is an optional key ID.</li> <li>• hmac-sha-256: If selected, you must also specify a key value, but the key-id is optional. With SHA-256 authentication, the switch adds an hmac-sha-256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet. There is an optional key ID.</li> </ul> <p><b>Note:</b><br/>Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate IS-IS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key.<br/>This feature is in full compliance with RFC 5310.</p> <p>The default is none.</p> |
| <b>AuthKey</b>    | Specifies the authentication key.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>KeyId</b>      | Specifies the authentication key ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>LevelType</b>  | <p>Specifies the router type globally:</p> <ul style="list-style-type: none"> <li>• level1: Level-1 router type</li> <li>• level 1and2: Level-1/2 router type. | <b>AutoNniEnable</b>                                                                            | Enable to have the node create an IS-IS interface, attach the interface to an SPBM instance, and then enable IS-IS on the port interface.<br>This field displays on the Insert Interfaces dialog box and applies to port interfaces only. |
| <b>Origin</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series and XA1400 Series. | Specifies the origin of the IS-IS circuit configuration on the port, either manually configured through CLI or EDM or dynamically configured through Auto-sense.                                                                          |

### Configure IS-IS Interface Level Parameters

Use the following procedure to configure IS-IS interface level parameters. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **Interfaces Level** tab.
4. Configure the IS-IS interface level parameters.
5. (Optional) Select the **Remote** button to configure the remote IS-IS interface level parameters.

#### Note

This step only applies to the VSP 7400 Series.

6. Select **Apply**.

#### Interfaces Level Field Descriptions

Use the data in the following table to use the **Interfaces Level** tab.

| Name              | Description                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>      | The identifier of this circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value.                                     |
| <b>Level</b>      | Specifies the router type globally: <ul style="list-style-type: none"> <li>• l1: Level1 router type</li> <li>• l12: Level1/Level2 router type. This type is not supported.</li> </ul> The default value is l1. |
| <b>ISPriority</b> | Specifies an integer sub-range for IS-IS priority. The default is 64.                                                                                                                                          |

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HelloTimer</b>      | Configures the level 1 hello interval. Specifies the maximum period, in milliseconds, between IS-IS Hello Packets (IIH) PDUs on multiaccess networks at this level for LANs. The value at Level1 is used as the period between Hellos on Level1/Level2 point to point circuits. Setting this value at Level 2 on an Level1/Level2 point-to-point circuit results in an error of InconsistentValue. The default value is 9000 milliseconds or 9 seconds. |
| <b>HelloMultiplier</b> | Configures the level 1 hello multiplier. The default value is 3 seconds.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DRHelloTimer</b>    | Indicates the period, in milliseconds, between Hello PDUs on multiaccess networks when this Intermediate System is the Designated Intermediate System. The default is 3.                                                                                                                                                                                                                                                                                |

### View IS-IS Interface Counters

Use the following procedure to view the Intermediate-System-Intermediate-System (IS-IS) interface counters.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **Stats**.
3. Select the **Interface Counters** tab.

#### Interface Counters Field Descriptions

Use the data in the following table to use the **Interface Counters** tab.

| Name                         | Description                                                                                                                                                                                                                                                  |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                 | Shows a unique value identifying the IS-IS interface.                                                                                                                                                                                                        |
| <b>Level</b>                 | Shows the type of circuit that discovered the interface counters. The point to point Hello PDU includes both Layer 1 and Layer 2, and IS from a single adjacency on point to point links, therefore combining counts on point to point links into one group. |
| <b>AdjChanges</b>            | Shows the number of times an adjacency state change has occurred on this circuit.                                                                                                                                                                            |
| <b>InitFails</b>             | Shows the number of times initialization of this circuit has failed. This counts events such as PPP NCP failures. Failures to form an adjacency are counted by isisCircRejAdjs.                                                                              |
| <b>RejAdjs</b>               | Shows the number of times an adjacency has been rejected on this circuit.                                                                                                                                                                                    |
| <b>IDFieldLenMismatches</b>  | Shows the number of times an IS-IS control PDU with an ID field length different to that for this system has been received.                                                                                                                                  |
| <b>MaxAreaAddrMismatches</b> | Shows the number of times an IS-IS control PDU with a max area address field different to that for this system has been received.                                                                                                                            |

| Name                   | Description                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AuthFails</b>       | Shows the number of times an IS-IS control PDU with the correct auth type has failed to pass authentication validation.                      |
| <b>LANDesISChanges</b> | Shows the number of times the Designated IS has changed on this circuit at this level. If the circuit is point to point, this count is zero. |

### *View IS-IS interface control packets*

Use the following procedure to view the Intermediate-System-to-Intermediate-System (IS-IS) interface control packets.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **Stats**.
3. Select the **Interface Control Packets** tab.

#### **Interface Control Packets Field Descriptions**

Use the data in the following table to use the **Interface Control Packets** tab.

| Name             | Description                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>     | Shows a unique value identifying the Intermediate-System-to-Intermediate-System (IS-IS) interface.                 |
| <b>Direction</b> | Indicates whether the switch is sending or receiving the PDUs.                                                     |
| <b>Hello</b>     | Indicates the number of IS-IS Hello frames seen in this direction at this level.                                   |
| <b>LSP</b>       | Indicates the number of IS-IS LSP frames seen in this direction at this level.                                     |
| <b>CSNP</b>      | Indicates the number of IS-IS Complete Sequence Number Packets (CSNP) frames seen in this direction at this level. |
| <b>PSNP</b>      | Indicates the number of IS-IS Partial Sequence Number Packets (PSNP) frames seen in this direction at this level.  |

### *View Statistical Graph of IS-IS Interface Counters*

Use the following procedure to view statistical graph of the IS-IS interface counters.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **Interfaces** tab.
4. Select an interface.
5. Select the **Graph** button.

### Interface Counters field descriptions

The following table describes the fields in the **Interface Counters** tab.

| Name                         | Description                                                                                                                                                                    |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InitFails</b>             | Indicates the number of times initialization of this circuit has failed. This counts events such as PPP NCP failures.                                                          |
| <b>RejAdjs</b>               | Indicates the number of times an adjacency has been rejected on this circuit.                                                                                                  |
| <b>IDFieldLenMismatches</b>  | Indicates the number of times an Intermediate-System-to-Intermediate-System (IS-IS) control PDU with an ID field length different from that for this system has been received. |
| <b>MaxAreaAddrMismatches</b> | Indicates the number of times an IS-IS control PDU with a max area address field different from that for this system has been received.                                        |
| <b>AuthFails</b>             | Indicates the number of times an IS-IS control PDU with the correct auth type has failed to pass authentication validation.                                                    |
| <b>LANDesISChanges</b>       | Indicates the number of times the Designated IS has changed on this circuit at this level. If the circuit is point to point, this count is zero.                               |
| <b>AbsoluteValue</b>         | Displays the counter value.                                                                                                                                                    |
| <b>Cumulative</b>            | Displays the total value since you opened the Stats tab.                                                                                                                       |
| <b>Average/Sec</b>           | Displays the average value for each second.                                                                                                                                    |
| <b>Minimum/Sec</b>           | Displays the minimum value for each second.                                                                                                                                    |
| <b>Maximum/Sec</b>           | Displays the maximum value for each second.                                                                                                                                    |
| <b>Last Val/Sec</b>          | Displays the last value for each second.                                                                                                                                       |

#### *View Statistical Graph of IS-IS Interface Sending Control Packet*

Use the following procedure to view the statistical graph of the IS-IS interface sending control packet.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **Interfaces** tab.
4. Select an interface.
5. Select the **Graph** button.
6. Select the **Interface Sending Control Packets** tab.

### Interface Sending Control Packets field descriptions

The following table describes the fields in the **Interface Sending Control Packets** tab.

| Name                 | Description                                                                                                                                                                                                        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Hello</b>         | Indicates the number of IS-IS Hello (IIH) PDUs seen in this direction at this level. Point-to-Point IIH PDUs are counted at the lowest enabled level: at L1 on Layer 1 or L1L2 circuits, and at Layer 2 otherwise. |
| <b>LSP</b>           | Indicates the number of IS-IS LSP frames seen in this direction at this level.                                                                                                                                     |
| <b>CSNP</b>          | Indicates the number of IS-IS Complete Sequence Number Packet (CSNP) frames seen in this direction at this level.                                                                                                  |
| <b>PSNP</b>          | Indicates the number of IS-IS Partial Sequence Number Packets (PSNPs) seen in this direction at this level.                                                                                                        |
| <b>AbsoluteValue</b> | Displays the counter value.                                                                                                                                                                                        |
| <b>Cumulative</b>    | Displays the total value since you opened the Stats tab.                                                                                                                                                           |
| <b>Average/Sec</b>   | Displays the average value for each second.                                                                                                                                                                        |
| <b>Minimum/Sec</b>   | Displays the minimum value for each second.                                                                                                                                                                        |
| <b>Maximum/Sec</b>   | Displays the maximum value for each second.                                                                                                                                                                        |
| <b>Last Val/Sec</b>  | Displays the last value for each second.                                                                                                                                                                           |

#### *View Statistical Graph of IS-IS Interface Receiving Control Packets*

Use the following procedure to view statistical graph of the IS-IS interface receiving control packets.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **Interfaces** tab.
4. Select an interface.
5. Select the **Graph** button.
6. Select the **Interface Receiving Control Packets** tab.

#### **Interface Receiving Control Packets field descriptions**

The following table describes the fields in the **Interface Receiving Control Packets** tab.

| Name         | Description                                                                                                                                                                                                  |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Hello</b> | Indicates the number of IS-IS Hello PDUs seen in this direction at this level. Point-to-Point IIH PDUs are counted at the lowest enabled level: at L1 on Layer 1 or L1L2 circuits, and at Layer 2 otherwise. |
| <b>LSP</b>   | Indicates the number of IS-IS link-state packet (LSP) frames seen in this direction at this level.                                                                                                           |
| <b>CSNP</b>  | Indicates the number of IS-IS Complete Sequence Number Packet (CSNP) frames seen in this direction at this level.                                                                                            |
| <b>PSNP</b>  | Indicates the number of IS-IS Partial Sequence Number Packets (PSNPs) seen in this direction at this level.                                                                                                  |

| Name                 | Description                                              |
|----------------------|----------------------------------------------------------|
| <b>AbsoluteValue</b> | Displays the counter value.                              |
| <b>Cumulative</b>    | Displays the total value since you opened the Stats tab. |
| <b>Average/Sec</b>   | Displays the average value for each second.              |
| <b>Minimum/Sec</b>   | Displays the minimum value for each second.              |
| <b>Maximum/Sec</b>   | Displays the maximum value for each second.              |
| <b>Last Val/Sec</b>  | Displays the last value for each second.                 |

### Configure an IS-IS Manual Area

Use the following procedure to configure an IS-IS manual area.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **Manual Area** tab.
4. Select **Insert**.
5. In the **AreaAddr** field, type the Area Address.
6. Select **Insert**.

### Manual Area or Manual Area Remote Field Descriptions

Use the data in the following table to use the **Manual Area** or **Manual Area Remote** tab.

| Name            | Description                                                                                                                                                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AreaAddr</b> | Specifies the IS-IS manual area. Valid value is 1-13 bytes in the format <xx.xxxx.xxx...xxxx>. Only one manual area is supported. Use the same manual area across the entire SPBM cloud. For IS-IS to operate, you must configure at least one manual area. |

### Configure Dynamic Nickname Assignment

#### About This Task

Use this procedure to enable Dynamic Nickname Assignment and specify a nickname allocation range.

#### Note

You must disable Dynamic Nickname Assignment before you can change the nickname allocation range.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **SPBM**.
3. Select the **Globals** tab.
4. To enable the Nick-name server, select **enable** for **NicknameServerEnable**.

5. In **NicknameServerPrefix**, type a prefix.
6. Select **Apply**.

### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                                                                                                                        | Description                                                                                                                                                                                     |
|-----------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GlobalEnable</b>                                                                                                         | Enables or disables SPBM globally. The default is disabled.<br>To ensure proper cleanup of MAC tables after you disable SPBM, save the configuration, and then reboot the switch.               |
| <b>GlobalEtherType</b>                                                                                                      | Specifies the global ethertype value as 0x8100 or 0x88a8. The default value is 0x8100.                                                                                                          |
| <b>NicknameServerEnable</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series.            | Enables or disables the nickname server. The default is disabled.                                                                                                                               |
| <b>NicknameDynamicAllocationStatus</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series. | Displays the Dynamic Nickname Allocation service operational status.                                                                                                                            |
| <b>NicknameServerPrefix</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series.            | Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default is A.00.00. |

## Fabric Extend Configuration using EDM

The following sections provide procedural information you can use to configure Fabric Extend (FE) using Enterprise Device Manager (EDM).

For information about how to configure an IPsec NAT-T Responder, see [IPsec configuration using EDM](#) on page 1776.

### Configure Fabric Extend Tunnels

Use the following procedure to configure Fabric Extend (FE) between a Main office to a Branch office. This is a typical deployment. However, if your deployment creates tunnels between two switches that support Fabric Extend natively, then repeat those steps and ignore the steps for switches that require an ONA.

#### Note

VRF is an optional parameter. If a VRF is not configured, then FE uses the GRT.

## Before You Begin

The tunnel source IP address can be either a brouter port IP, a CLIP IP, or a VLAN IP.

### Note

Product Notice: Except VSP 8600 Series, all product series support a VLAN IP as the Fabric Extend tunnel source IP address.

If using the tunnel originating address on the GRT, Fabric Extend has the following requirements:

- The tunnel source IP address must be on the GRT, not on a VRF.

### Note

A best practice is to use separate IP addresses for the SPBM IP Shortcuts **ip-source-address** command and the Fabric Extend **ip-tunnel-source-address** command. However, if you want these IP addresses to be the same, you MUST exclude the **ip-source-address** address with an IS-IS accept policy. You cannot use the redistribute command with a route map exclusion.

Specify a CLIP interface to use as the source address for SPBM IP shortcuts.

- If IP Shortcuts is enabled, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.

If you are using the tunnel originating address on a VRF, Fabric Extend has the following requirements:

- Configure a CLIP and tunnel source IP address on the VRF.
- Remote management of the VSP 4450 Series is possible after establishing IP Shortcut over IS-IS. (Alternatively, you can enable GRT-VRF redistribution locally.)

## About This Task

Configuring Fabric Extend consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

Note that the VSP 4450 Series source address command is different than other platforms. Also note that the logical interface commands are different between Layer 2 and Layer 3 networks.

## Procedure

The following steps are for platforms that support FE natively:

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **Globals** tab.
4. In the **IpTunnelSourceAddress** field, enter the IP tunnel source address.
5. If you are using a VRF, select **IpTunnelVrf** field.
6. Select **Apply**.

The following steps are for platforms that require an ONA to support FE:

### Note

The interface VLAN connecting to the ONA network port is always in the GRT and the member port that the VLAN is part of is always an access port.

7. In the navigation pane, expand **Configuration > IS-IS**.
8. Select **IS-IS**.
9. Select the **Globals** tab.
10. In the **IpTunnelSourceAddress** field, enter the IP tunnel source address.
11. In the **IpTunnelPort** field, select the physical port that the logical interface is connected to in an Layer 2 network.
12. If you are using a VRF, select its name from the list for **IpTunnelVrf**.
13. In the **IpTunnelMtu** field, enter a value between 750 and 1950 to specify the size of the maximum transmission unit (MTU).
14. Select **Apply**.

### Fabric Extend Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                         | Description                                                                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpTunnelSourceAddress</b> | Specifies the IS-IS IPv4 tunnel source address.                                                                                                 |
| <b>IpTunnelPort</b>          | Specifies the physical port that the logical interface is connected to in an Layer 2 network.<br>The parameter is for the VSP 4450 Series only. |
| <b>IpTunnelVrf</b>           | Specifies the VRF name associated with the IP tunnel.                                                                                           |
| <b>IpTunnelMtu</b>           | Specifies the size of the maximum transmission unit (MTU). The default is 1950.<br>This parameter applies to an ONA configuration only.         |

### Configure Fabric Extend Logical Interfaces

Use the following procedures to configure Fabric Extend (FE) between a Main office to a Branch office, which is a typical deployment.

VSP 4450 Series supports FE, but the switch must connect to an Open Networking Adapter (ONA) because the VSP 4450 Series does not support FE natively:

- [Configure Fabric Extend Logical Interfaces for Native Support](#) on page 1163
- [Configure Fabric Extend Logical Interfaces for ONA Support](#) on page 1165

### Configure Fabric Extend Logical Interfaces for Native Support

#### About This Task

Configuring Fabric Extend consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

VRF is an optional parameter. If a VRF is not configured, then FE uses the GRT.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **Logical Interfaces** tab.
4. Select **Insert**.

5. In **Id**, type the index number that uniquely identifies this logical interface.
6. For **Type**, select the type of core network that the tunnel will traverse:

**Note**

Different fields will be available depending on the type of core network you select.

- If it is a Layer 2 Core, select **layer2**.
  - If it is a Layer 3 Core, select **ip**.
7. For **Name**, type the name of this logical interface.
  8. To enable BFD, select **enable** for **BFDEnable**.
  9. For a Layer 2 Core, configure the following fields:

**Note**

This step does not apply to XA1400 Series.

- a. For **DestIfIndex**, select the physical port that the logical interface connects to or enter the name of the MLT.
- b. In **Vids**, type the list of VLANs for this logical interface.
- c. In **PrimaryVid**, type the primary tunnel VLAN ID.

**Note**

The primary VLAN ID must be one of the VIDs listed in the **Vids** field.

10. For a Layer 3 Core, complete the following field:
  - a. In **DestIPAddr**, type the destination IP address for the logical interface.
11. For XA1400 Series only, make the following selections:
  - a. For **Compression**, select whether to enable compression for a Fabric Extend over IPsec connection.
  - b. For **IpsecEnable**, select whether to enable a Fabric Extend over IPsec connection for the logical interface.
  - c. Select the IPsec authentication method.
  - d. For a pre-shared key, in **AuthenticationKey**, type the authentication key to secure your Fabric Extend over IPsec connection for the logical interface.
  - e. In **ShapingRate**, type the value in Mbps of the shaper used for Egress Tunnel Shaping.
  - f. In **Mtu**, type a value to specify the size of the maximum transmission unit (MTU).
  - g. For **Esp**, select the Encapsulating Security Payload (ESP) cipher suite for IPsec.

**Note**

You cannot change the ESP cipher suite when IPsec is enabled on the FE tunnel.

- h. In **IpsecTunnelDestAddress**, type the destination IP address for the IPsec tunnel.
  - i. For **TunnelSourceType**, select the source type for the IPsec tunnel.
  - j. In **TunnelSourceAddress**, type the source IP address for the IPsec tunnel.
  - k. If you are using a VRF, in **TunnelVrf**, type the VRF name for the source IPsec tunnel.
12. Select **Insert**.

## Configure Fabric Extend Logical Interfaces for ONA Support

### About This Task

Configuring Fabric Extend consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

The VSP 4450 Series source address command is different than other platforms. The logical interface commands are different between Layer 2 and Layer 3 networks.

#### Note

The interface VLAN that connects to the ONA network port is always in the GRT, and the member port that the VLAN is part of is always an access port.

VRF is an optional parameter. If a VRF is not configured, then FE uses the GRT.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **Logical Interfaces** tab.
4. Select **Insert**.
5. In **Id**, type the index number that uniquely identifies this logical interface.
6. For **Name**, type the name of this logical interface.
7. For **Type**, select the type of core network that the tunnel will traverse:

#### Note

Different fields will be available depending on the type of core network you select.

- If it is a Layer 2 Core, select **layer2**.
  - If it is a Layer 3 Core, select **ip**.
8. For a Layer 2 Core, complete the following fields:
    - a. For **DestIfIndex**, select the physical port that the logical interface connects to or enter the name of the MLT.
    - b. In **Vids**, type the list of VLANs for this logical interface.
    - c. In **PrimaryVid**, type the primary tunnel VLAN ID.

#### Note

The primary VLAN ID must be one of the VIDs listed in the **Vids** field.

9. For a Layer 3 Core, configure the following field:
  - a. In **DestIPAddr**, type the destination IP address for the logical interface.
10. For **IpssecEnable**, select whether to enable a Fabric Extend over IPsec connection for the logical interface.
11. For **AuthenticationKey** field, type the authentication key to secure your Fabric Extend over IPsec connection for the logical interface.
12. For **ShapingRate** field, type the value in Mbps of the shaper used for Egress Tunnel Shaping.
13. Select **Insert**.

### Logical Interfaces Field Descriptions

Use the data in the following table to use the **Logical Interfaces** tab and the **Insert Logical Interfaces** dialog. The available fields in the dialog differ depending on the type of core you select: **layer 2** or **ip**.

| Name                                                                                      | Description                                                                                                                                                                                                                                                                |
|-------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                                                                                 | Specifies the index number that uniquely identifies this logical interface.<br>This field displays on the <b>Insert Logical Interfaces</b> dialog only.                                                                                                                    |
| <b>IfIndex</b>                                                                            | Specifies the index number that uniquely identifies this logical interface. This field is read-only.<br>This field displays on the <b>Logical Interfaces</b> tab only.                                                                                                     |
| <b>Name</b>                                                                               | Specifies the administratively assigned name of this logical interface, which can be up to 64 characters.                                                                                                                                                                  |
| <b>Type</b><br><b>Note:</b><br>Exception: Type Layer 2 is not supported on XA1400 Series. | Specifies the type of logical interface to create: <ul style="list-style-type: none"> <li>Specify <b>layer 2</b> for a Layer 2 core network that the tunnel will traverse.</li> <li>Specify <b>ip</b> for a Layer 3 core network that the tunnel will traverse.</li> </ul> |
| <b>DestIPAddr</b>                                                                         | Specifies the destination IP address for the IP-type logical interface.                                                                                                                                                                                                    |
| <b>DestIfIndex</b><br><b>Note:</b><br>Exception: Not supported on XA1400 Series.          | Specifies the physical port or MultiLink Trunking (MLT) that the Layer 2 logical interface is connected to.                                                                                                                                                                |

### Adjust the TCP Maximum Segment Size

#### Note

This procedure only applies to VSP 4900 Series, VSP 7400 Series, and XA1400 Series.

Adjust the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency.

### About This Task

#### Note

If you downgrade to an earlier release that does not support this feature, you must disable the feature and save the configuration. Downgrading to an earlier release requires a compatible configuration file.

The default varies depending on hardware platform:

- For XA1400 Series, this functionality is enabled when at least one Fabric Extend (FE) tunnel with a MTU less than or equal to 1500 is configured, and the value is auto-derived.
- For VSP 4900 Series and VSP 7400 Series, this functionality is disabled. The default value, when enabled, is 1300.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IP**.
3. Select the **Globals** tab.
4. Select **TcpAdjustMssEnable** to enable this functionality.
5. (Optional) Enter a value in **TcpAdjustMssValue**.
6. Select **Apply**.

## Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Forwarding</b>                     | Configures the system for forwarding (routing) or nonforwarding. The default value is forwarding.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DefaultTTL</b>                     | Configures the default time-to-live (TTL) value for a routed packet. TTL indicates the maximum number of seconds elapsed before a packet is discarded. Enter an integer from 1 to 255. The default value of 255 is used if a value is not supplied in the datagram header.                                                                                                                                                                                                                                                                |
| <b>ReasmTimeout</b>                   | Specifies the maximum number of seconds that received fragments are held while they wait for reassembly. The default value is 30 seconds.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ICMPUnreachableMsgEnable</b>       | <p>Enables the generation of Internet Control Message Protocol (ICMP) network unreachable messages if the destination network is not reachable from this system. These messages help determine if the system is reachable over the network. The default is disabled.</p> <p><b>Important:</b><br/>As a best practice, enable icmp-unreach-msg only if it is absolutely required. If icmp-unreach-msg is enabled and a packet is received for which there is no route in the routing table, CPU utilization can dramatically increase.</p> |
| <b>ICMPRedirectMsgEnable</b>          | Enables or disables the system sending ICMP destination redirect messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>IcmpEchoBroadcastRequestEnable</b> | Enables or disables IP ICMP echo broadcast request feature. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>AlternativeEnable</b>              | <p>Globally enables or disables the Alternative Route feature.</p> <p>If the alternative-route parameter is disabled, all existing alternative routes are removed. After the parameter is enabled, all alternative routes are re-added. The default is enabled.</p>                                                                                                                                                                                                                                                                       |
| <b>RouteDiscoveryEnable</b>           | Enables the ICMP Router Discovery feature. The default is disabled (not selected). Use ICMP Router Discovery to enable hosts attached to multicast or broadcast networks to discover the IP addresses of neighboring routers.                                                                                                                                                                                                                                                                                                             |

| Name                                        | Description                                                                                                                                                                                                                                                                      |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AllowMoreSpecificNonLocalRouteEnable</b> | Enables or disables a more-specific nonlocal route. If enabled, the system can enter a more-specific nonlocal route into the routing table. The default is disabled.                                                                                                             |
| <b>SuperNetEnable</b>                       | Enables or disables supernetting. If supernetting is globally enabled, the system can learn routes with a route mask less than 8 bits. Routes with a mask length less than 8 bits cannot have ECMP paths, even if you globally enable the ECMP feature. The default is disabled. |
| <b>UdpChecksumEnable</b>                    | Enables or disables the UDP checksum calculation. The default is enable.                                                                                                                                                                                                         |
| <b>SourceRouteEnable</b>                    | Enables or disables IP Source Routing globally. It is disabled by default.                                                                                                                                                                                                       |
| <b>ARPLifeTime</b>                          | Specifies the lifetime of an ARP entry within the system, global to the switch. The default value is 360 minutes.                                                                                                                                                                |
| <b>EcmpEnable</b>                           | Globally enables or disables the Equal Cost Multipath (ECMP) feature. The default is disabled. After ECMP is disabled, the <code>EcmpMaxPath</code> is reset to the default value of 1.                                                                                          |
| <b>EcmpMaxPath</b>                          | Globally configures the maximum number of ECMP paths. You cannot configure this feature unless ECMP is enabled globally. Different hardware platforms can support a different number of ECMP paths. For more information, see <a href="#">VOSS Release Notes</a> .               |
| <b>Ecmp1PathList</b>                        | Selects a preconfigured ECMP path.                                                                                                                                                                                                                                               |
| <b>Ecmp2PathList</b>                        | Selects a preconfigured ECMP path.                                                                                                                                                                                                                                               |
| <b>Ecmp3PathList</b>                        | Selects a preconfigured ECMP path.                                                                                                                                                                                                                                               |
| <b>Ecmp4PathList</b>                        | Selects a preconfigured ECMP path.                                                                                                                                                                                                                                               |
| <b>Ecmp5PathList</b>                        | Selects a preconfigured ECMP path.                                                                                                                                                                                                                                               |
| <b>Ecmp6PathList</b>                        | Selects a preconfigured ECMP path.                                                                                                                                                                                                                                               |
| <b>Ecmp7PathList</b>                        | Selects a preconfigured ECMP path.                                                                                                                                                                                                                                               |
| <b>Ecmp8PathList</b>                        | Selects a preconfigured ECMP path.                                                                                                                                                                                                                                               |
| <b>EcmpPathListApply</b>                    | Applies changes in the ECMP pathlist configuration, or in the prefix lists configured as the pathlists.                                                                                                                                                                          |

| Name                                                                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TcpAdjustMssEnable</b><br><b>Note:</b><br>Exception: Only supported on VSP 4900 Series, VSP 7400 Series, and XA1400 Series. | Adjusts the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency. The default varies depending on hardware platform: <ul style="list-style-type: none"> <li>For XA1400 Series, the default value is enabled when at least one Fabric Extend (FE) tunnel with a MTU less than or equal to 1500 is configured.</li> <li>For VSP 4900 Series and VSP 7400 Series, the default is disabled.</li> </ul> |
| <b>TcpAdjustMssStatus</b><br><b>Note:</b><br>Exception: Only supported on VSP 4900 Series, VSP 7400 Series, and XA1400 Series. | Displays the activation status of the MSS adjustment functionality.<br>On XA1400 Series, the MSS adjustment functionality only activates when at least one FE tunnel with a maximum transmission unit (MTU) less than or equal to 1500 is configured.                                                                                                                                                                                                          |
| <b>TcpAdjustMssType</b><br><b>Note:</b><br>Exception: Only supported on VSP 4900 Series, VSP 7400 Series, and XA1400 Series.   | Displays if the MSS adjustment value is manually configured or auto-derived.                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>TcpAdjustMssValue</b><br><b>Note:</b><br>Exception: Only supported on VSP 4900 Series, VSP 7400 Series, and XA1400 Series.  | Configures the MSS adjustment value. The default varies depending on hardware platform: <ul style="list-style-type: none"> <li>For XA1400 Series, the default value is auto-derived.</li> <li>For VSP 4900 Series and VSP 7400 Series, the default value is 1300.</li> </ul>                                                                                                                                                                                   |

### Display the Logical Interface Next Hop

Use the following procedure to display the next hop for the logical interface.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS > IS-IS**.
2. Select the **Logical Interfaces NextHop** tab.

#### Logical Interfaces NextHop field descriptions

Use the data in the following table to use the **Logical Interfaces NextHop** tab.

| Name      | Description                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------|
| <b>Id</b> | Shows a unique value that identifies the logical interface tunnel.                            |
| <b>Ip</b> | Shows a unique value that identifies the next hop IP address of the logical interface tunnel. |

| Name               | Description                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------|
| <b>DestIfIndex</b> | Shows the next hop destination interface index to reach the next hop IP of the logical interface tunnel. |
| <b>DestVid</b>     | Shows the next hop destination VLAN ID to reach the next hop IP of the logical interface tunnel.         |

## Fabric Attach configuration using the EDM

The following sections provide procedural information you can use to configure Fabric Attach (FA) and Logical Link Discovery Protocol (LLDP) using Enterprise Device Manager (EDM). For information about LLDP related to FA, see [Link Layer Discovery Protocol configuration using EDM](#) on page 2209.

### Configure Fabric Attach Globally

Use this procedure to configure FA globally or view existing FA global configuration.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Fabric Attach**.
3. Click the **Globals** tab.
4. To enable or disable the Fabric Attach service, click **enabled** or **disabled** in the **Service** field.

#### Caution

Disabling FA flushes all FA element discovery and mappings.

5. View the element type in the **ElementType** field.

#### Note

The only supported element type is **faServer** (FA Server).

6. To specify the assignment time-out, enter a time-out value in seconds in the **AsgnTimeout** field.
7. View the provision mode in the **ProvisionMode** field.

#### Note

The supported provision mode is **spbm**.

8. To specify the discovery time-out, enter a time-out value in seconds in the **DiscTimeout** field.
9. To clear the FA statistics, select the **Clear FA Statistics** checkbox.
10. To clear the error counters, select the check boxes **ClearErrorCounters** and/or **ClearGlobalErrorCounters**.
11. Click **Apply**.

### Fabric Attach Globals Field Descriptions

Use the data in the following table to use the **Fabric Attach Globals** tab.

| Name                            | Description                                                                                                             |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Service</b>                  | Enables or disables Fabric Attach service globally. The default is enable.                                              |
| <b>ElementType</b>              | Specifies the Fabric Attach element type. The supported element type is Fabric Attach Server.                           |
| <b>AsgnTimeout</b>              | Specifies the Fabric Attach assignment time-out in seconds. The range is 45 to 480 seconds. The default is 240 seconds. |
| <b>ProvisionMode</b>            | Specifies the Fabric Attach provision mode. The supported provision mode is SPB.                                        |
| <b>DiscTimeout</b>              | Specifies the Fabric Attach discovery time-out in seconds. The range is 45 to 480 seconds. The default is 240 seconds.  |
| <b>Clear FA Statistics</b>      | Clears Fabric Attach statistics.                                                                                        |
| <b>ClearGlobalErrorCounters</b> | Clears Fabric Attach global error counters. Disabled by default.                                                        |

### Configure Fabric Attach I-SID-to-VLAN Assignments

Use this procedure to view or configure FA I-SID-to-VLAN assignment information.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Fabric Attach**.
3. Click the **Assignment** tab.
4. If you make configuration changes, click **Apply** to save changes.

### Assignments Field Descriptions

Use the data in the following table to use the **Assignments** tab.

| Name             | Description                                                                                                                                                                                                            |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>   | Specifies the interface identifier of the I-SID-to-VLAN assignment.                                                                                                                                                    |
| <b>Isid</b>      | Specifies the I-SID value of the I-SID-to-VLAN assignment.                                                                                                                                                             |
| <b>Vlan</b>      | Specifies the VLAN ID component of the I-SID-to-VLAN assignment.                                                                                                                                                       |
| <b>State</b>     | Specifies the current state of the I-SID-to-VLAN assignment. It can be one of the following values: <ul style="list-style-type: none"> <li>• Other</li> <li>• Pending</li> <li>• Active</li> <li>• Rejected</li> </ul> |
| <b>Origin</b>    | Specifies the origin information of the I-SID-to-VLAN assignment.                                                                                                                                                      |
| <b>Isid name</b> | Specifies the I-SID name.                                                                                                                                                                                              |

## Configure Fabric Attach Interface-level Settings

Use this procedure to configure FA interface-level settings or view existing interface-level settings.

You can enable Fabric Attach on a port, static MLT or an LACP MLT. Enabling FA on a port not only enables tagging but also disables spanning tree on that port. Enabling FA on an MLT enables FA on all ports of the MLT. When FA is enabled on ports in an MLT or LACP MLT, tagging is enabled and spanning tree is disabled on all those ports.

### Before You Begin

Ensure that FA is enabled globally on the switch.

### About This Task

Enabling FA on a port or MLT is necessary for element discovery. On the FA Server, FA is enabled globally by default. However, you must explicitly enable FA on a desired port or MLT interface, following which the FA Server can begin transmitting LLDP PDUs that contain the element discovery TLVs. This information is received by FA Client and FA Proxy devices which in turn also transmit their FA capabilities and settings. After the element handshake completes, the FA Server receives I-SID-to-VLAN assignment mappings from the connected client or proxy devices, on that port or MLT.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Fabric Attach**.
3. Click the **Ports** tab.

The FA interface-level settings are displayed.

4. To modify existing settings, double-click on the fields on this window. After making the required changes, click **Apply** to save your changes.
5. To configure FA on a new port or MLT interface:
  - a. Click **Insert**.

The **Insert Ports** dialog box opens.
  - b. To configure FA on a port, enter a port number in the format slot/port[/sub-port], or click **Port** to select from a list of available ports.
  - c. To configure FA on an MLT, enter an MLT ID or click **MLT** to select from a list of configured MLTs.

#### Note

FA is successfully enabled on the MLT, only if all ports of the MLT have FA successfully enabled. Enabling FA enables LLDP on all ports. Tagging is enabled and spanning tree is disabled.

- d. Click **Insert** to save your changes.
6. To remove (delete) FA on a port or MLT:
    - a. In the content pane, select a port or MLT from the list.

- b. Click **Delete**.

**Caution**

Removing FA on an interface flushes all FA element discovery and I-SID-to-VLAN mappings associated with that interface.

### Ports Field Descriptions

Use the data in the following table to use the **Ports** tab.

| Name                                                                                            | Description                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>                                                                                  | Specifies the interface (port or MLT) on which Fabric Attach is configured.                                                                                                                                                                                                                   |
| <b>State</b>                                                                                    | Specifies the current state of the Fabric Attach port. It is either enabled or disabled.<br>This field indicates whether LLDP PDUs (that include FA TLVs) are generated on the port (enabled) or not (disabled).                                                                              |
| <b>MsgAuthStatus</b>                                                                            | Specifies the Fabric Attach message authentication status on the port. It is either enabled or disabled.                                                                                                                                                                                      |
| <b>MsgAuthKey</b>                                                                               | Specifies the Fabric Attach message authentication key for the associated port.<br>The maximum length of this key is 32 characters.                                                                                                                                                           |
| <b>MgmtIsid</b>                                                                                 | Specifies the Fabric Attach management I-SID for the associated port. The range is 0 to 16777215.<br>A zero value indicates that the management I-SID is not specified for the interface.                                                                                                     |
| <b>MgmtCvid</b>                                                                                 | Specifies the Fabric Attach management customer VLAN ID (C-VID) for the interface.<br>A zero value indicates that no C-VID is specified for the interface. Using the maximum configuration value for your switch indicates the port is untagged. Platform support determines the C-VID range. |
| <b>Origin</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series and XA1400 Series. | Specifies the origin of Fabric Attach port, either manually configured through CLI or EDM or dynamically configured through Auto-sense.                                                                                                                                                       |

#### *Viewing Fabric Attach discovered elements*

Use this procedure to view discovered Fabric Attach elements.

#### **About This Task**

When FA is enabled on an FA Server switch, LLDP PDUs are exchanged between the FA Server and FA Clients or Proxies. Standard LLDPs allow neighbors to be learned. In addition, organizational specific element discovery TLVs allow the Client or Proxy to recognize that it has attached to an FA Server. Only after the discovery handshake is complete, an FA Client or Proxy can transmit I-SID-to-VLAN assignments to join the SPB Fabric through the FA Server.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Fabric Attach**.
3. In the content pane, click the **Elements** tab.

### Elements field descriptions

Use the data in the following table to use the **Elements** tab.

| Name                              | Description                                                                                                                                              |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>                    | Specifies the interface (port or MLT) at which the Fabric Attach element was discovered.                                                                 |
| <b>ElementType</b>                | Specifies the element type of the discovered Fabric Attach element, as advertised using LLDP.<br>The supported element type is the Fabric Attach Server. |
| <b>ElementVlan</b>                | Specifies the VLAN ID of the discovered Fabric Attach element, as advertised using LLDP.                                                                 |
| <b>ElementId</b>                  | Specifies the system ID of the discovered Fabric Attach element, as advertised using LLDP.                                                               |
| <b>ElementState</b>               | Specifies the state flag data associated with the discovered Fabric Attach element, as advertised using LLDP.                                            |
| <b>ElementOperAuthStatus</b>      | Specifies the authentication status of the discovered Fabric Attach element.                                                                             |
| <b>ElementAsgnsOperAuthStatus</b> | Specifies the authentication status of remote assignments.                                                                                               |
| <b>ElementAuth</b>                | Specifies the discovered element authentication status.                                                                                                  |
| <b>AsgnsAuth</b>                  | Specifies the assignment authentication status.                                                                                                          |

### Viewing FA statistics

Use this procedure to view FA statistics.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Fabric Attach**.
3. In the content pane, click the **Stats** tab.

### Stats field descriptions

Use the data in the following table to use the **Stats** tab.

| Name                    | Description                                                       |
|-------------------------|-------------------------------------------------------------------|
| <b>PortIndex</b>        | Specifies the port for which the FA statistics are displayed.     |
| <b>DiscElemReceived</b> | Specifies the number of element discoveries received on the port. |
| <b>AsgnReceived</b>     | Specifies the number of remote assignments received on the port.  |
| <b>AsgnAccepted</b>     | Specifies the number of remote assignments accepted on the port.  |

| Name                   | Description                                                                        |
|------------------------|------------------------------------------------------------------------------------|
| <b>AsgnRejected</b>    | Specifies the number of remote assignments rejected on the port.                   |
| <b>AsgnExpired</b>     | Specifies the number of remote assignments that have expired, on the port.         |
| <b>AuthFailed</b>      | Specifies the number of authentications that have failed on the port.              |
| <b>DiscElemExpired</b> | Specifies the number of discovery elements that have expired on the port.          |
| <b>DiscElemDeleted</b> | Specifies the number of discovery elements that are deleted on the port.           |
| <b>AsgnDeleted</b>     | Specifies the number of remote assignments deleted on the port.                    |
| <b>AsgnAuthFailed</b>  | Specifies the number of remote assignment authentications that failed on the port. |

### View Global FA Statistics Graphically

Use this procedure to view the global FA statistics graphically.

#### Procedure

1. In the navigation pane, expand **Configuration > Graph**.
2. Click **Chassis**.
3. Click the **Fabric Attach** tab.
4. To view a graphical representation of the statistics, select a row and click the appropriate icon on the top left-hand-side of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
5. Click **Clear Counters** to clear the existing counters, and fix a reference point in time to restart the counters.
6. Click **Export**, to export the statistical data to a file.
7. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

### Fabric Attach field descriptions

Use the data in the following table to use the **Fabric Attach** tab.

| Name                    | Description                                                                     |
|-------------------------|---------------------------------------------------------------------------------|
| <b>DiscElemReceived</b> | Specifies the number of discovery elements received globally.                   |
| <b>AsgnReceived</b>     | Specifies the number of remote I-SID-to-VLAN assignments received globally.     |
| <b>AsgnAccepted</b>     | Specifies the number of remote I-SID-to-VLAN assignments accepted globally.     |
| <b>AsgnRejected</b>     | Specifies the number of remote I-SID-to-VLAN assignments rejected globally.     |
| <b>AsgnExpired</b>      | Specifies the number of remote I-SID-to-VLAN assignments that expired globally. |
| <b>AuthFailed</b>       | Specifies the number of authentications that failed globally.                   |

| Name                   | Description                                                             |
|------------------------|-------------------------------------------------------------------------|
| <b>DiscAuthFailed</b>  | Specifies the number of discovery authentications that failed globally. |
| <b>DiscElemExpired</b> | Specifies the number of discovery elements that expired globally.       |
| <b>DiscElemDeleted</b> | Specifies the number of discovery elements that were deleted globally.  |
| <b>AsgnDeleted</b>     | Specifies the number of remote assignments that were deleted globally.  |

### View FA Port Statistics Graphically

Use this procedure to view the FA port statistics graphically.

#### Before You Begin

Ensure that a switch port is selected in the **Device Physical View** tab.

#### Procedure

1. In the navigation pane, expand **Graph > Port**.
2. Click the **Fabric Attach** tab.  
The FA port statistics are displayed.
3. To view a graphical representation of the port statistics, select a row and click the appropriate icon on the top left-hand-side of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
4. Click **Clear Counters** to clear the existing counters, and fix a reference point in time to restart the counters.
5. Click **Export**, to export the statistical data to a file.
6. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

#### Fabric Attach Field Descriptions

Use the data in the following table to use the **Fabric Attach** tab.

| Name                    | Description                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>DiscElemReceived</b> | Specifies the number of discovery elements received on a given port.                                            |
| <b>AsgnReceived</b>     | Specifies the number of remote I-SID-to-VLAN assignments received on a given port.                              |
| <b>AsgnAccepted</b>     | Specifies the number of remote I-SID-to-VLAN assignments accepted on a given port.                              |
| <b>AsgnRejected</b>     | Specifies the number of remote I-SID-to-VLAN assignments rejected on a given port.                              |
| <b>AsgnExpired</b>      | Specifies the number of remote I-SID-to-VLAN assignments that expired on a given port.                          |
| <b>AuthFailed</b>       | Indicates the number of received TLVs for which authentication was attempted and failed on the identified port. |

| Name                   | Description                                                                            |
|------------------------|----------------------------------------------------------------------------------------|
| <b>DiscElemExpired</b> | Specifies the number of discovery elements that expired on a given port.               |
| <b>DiscElemDeleted</b> | Specifies the number of discovery elements that were deleted on a given port.          |
| <b>AsgnDeleted</b>     | Specifies the number of remote assignments that were deleted on a given port.          |
| <b>AsgnAuthFailed</b>  | Specifies the number of remote assignment authentications that failed on a given port. |

### *Inserting a Zero Touch Client*

Use this procedure to insert a FA Zero Touch Client.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Fabric Attach**.
3. Click the **Zero Touch Client Auto Attach** tab.
4. Click **Insert**.  
The **Insert Zero Touch Client** dialog box opens.
5. In the **Type** field click the ellipsis and select a client. Click **Ok** to select the client or **Refresh** to update the list.
6. In the **Isid** field enter the I-SID value.  
The I-SID value is between 0 and 16777214.
7. Click **Insert**.

### *Configure FA Zero Touch Client Auto Attach*

Use this procedure to configure FA Zero Touch Client auto attach.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Fabric Attach**
3. Select the **Zero Touch Client Auto Attach** tab.  
From the Zero Touch Client Auto Attach tab you can configure a number of auto attach settings.
4. Select **Insert**.
5. In the **Type** field, select the ellipsis and select a client.
6. Select **Ok** to select the client or **Refresh** to update the list.
7. In the **Isid** field enter the I-SID value.
8. Select **Insert**.
9. (Optional) To **Delete** a FA Zero Touch client select it from the auto attach table and select **Delete**.

## Zero Touch Client Auto Attach Field Descriptions

Use the data in the following table to use the **Zero Touch Client Auto Attach** tab

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Type</b> | This column describes the type of client assigned to auto attach. Available FA client types are: <ul style="list-style-type: none"> <li>• Wireless AP (Type 1)</li> <li>• Wireless AP (Type 2)</li> <li>• Switch</li> <li>• Router</li> <li>• IP Phone</li> <li>• IP Camera</li> <li>• IP Video</li> <li>• Security Device</li> <li>• Virtual Switch</li> <li>• Server Endpoint</li> <li>• ONA (SDN)</li> <li>• ONA (spbOIP)</li> </ul> |
| <b>Vlan</b> | Specifies the VLAN ID component of the I-SID-to-VLAN assignment.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Isid</b> | Specifies the I-SID value of the I-SID-to-VLAN assignment.                                                                                                                                                                                                                                                                                                                                                                              |

## Configure Endpoint Tracking Using EDM

The following sections provide procedural information to configure Endpoint Tracking using Enterprise Device Manager (EDM).

### *Configure Endpoint Tracking Interfaces*

Configure ports and MLT/SMLT interfaces for Endpoint Tracking.

#### **Before You Begin**

- In Extreme Management Center or ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center or ExtremeCloud IQ - Site Engine.

#### **About This Task**

Enable Endpoint Tracking on ports or MLT/SMLT interfaces.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Endpoint Tracking**.
3. Select the **Interface** tab.
4. Select **Insert**.

5. Select **Port** or **Mlt**, select the slot and port number or MLT ID, and select **OK**.
6. Select **InterfaceEnable**.
7. Select **Insert**.
8. Select **Apply**.

### What to Do Next

Configure Endpoint Tracking globally on the switch.

### Interface Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name                   | Description                                                |
|------------------------|------------------------------------------------------------|
| <b>InterfaceIndex</b>  | Specifies the interface index of the selected port or MLT. |
| <b>InterfaceEnable</b> | Enables Endpoint Tracking on the selected port or MLT.     |

### Configure Endpoint Tracking Globally

Configure Endpoint Tracking globally on the switch.

#### Before You Begin

- In Extreme Management Center or ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center or ExtremeCloud IQ - Site Engine.
- Create and enable Endpoint Tracking on interfaces.

#### About This Task

Optionally, if the RADIUS outbound attributes do not include an I-SID value, configure an I-SID offset value, and globally enable I-SID offset for Endpoint Tracking. The I-SID offset value is used to calculate an I-SID value for a switched UNI if no I-SID value is provided by the RADIUS server. In that case, the I-SID value is calculated as follows: I-SID = VLAN ID + configured I-SID offset value.

After optionally configuring an I-SID offset value, enable Endpoint Tracking globally on the switch.

#### Note

If you have previously enabled Endpoint Tracking globally and want to change the currently configured I-SID offset value, you must disable Endpoint Tracking globally, change the I-SID value, and then re-enable Endpoint Tracking globally.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Endpoint Tracking**.
3. Select the **Globals** tab.

4. (Optional) Configure an I-SID offset value, and enable I-SID offset globally on the switch:  
Enter a value into the **AutosidOffset** field and select **AutosidOffsetEnable**.
5. Select **GlobalEnable**.
6. Select **Apply**.

### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                       | Description                                                                             |
|----------------------------|-----------------------------------------------------------------------------------------|
| <b>AutosidOffset</b>       | The I-SID offset value. The default is 15990000.                                        |
| <b>AutosidOffsetEnable</b> | Enables or disables I-SID offset value globally on the switch. The default is disabled. |
| <b>GlobalEnable</b>        | Enables or disables Endpoint Tracking globally on the switch. The default is disabled.  |
| <b>VisibilityEnable</b>    | Enables or disables visibility mode for Endpoint Tracking. The default is disabled.     |

### Display Binding Information

Display Endpoint Tracking binding information.

### About This Task

Display all VLAN:ISID binding information on the switch for Endpoint Tracking.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Endpoint Tracking**.
3. Select the **Binding** tab.

### Binding Field Descriptions

Use the data in the following table to use the **Binding** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>    | Specifies the interface index of the selected port or MLT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>MacAddress</b> | Specifies the MAC address that corresponds to the VLAN:ISID binding.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Status</b>     | Specifies the Endpoint Tracking data binding status as follows: <ul style="list-style-type: none"> <li>• pending: indicates that a request has been sent to the RADIUS server</li> <li>• accept: indicates that the RADIUS server has successfully returned the request</li> <li>• reject: indicates that the RADIUS server has rejected the request</li> <li>• timeout: indicates that the RADIUS server request has timed out. The entry is deleted if it remains in this state for 15 minutes.</li> <li>• serverNotConfigured: indicates that the RADIUS server is not configured for Endpoint Tracking. The entry is deleted if it remains in this state for 15 minutes.</li> </ul> |
| <b>VlanId</b>     | Specifies the VLAN ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Isid</b>          | Specifies the I-SID value, either provided by the RADIUS server, or calculated using the VLAN ID plus the configured I-SID offset value.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>IsidSource</b>    | Specifies whether the I-SID value is provided by the RADIUS server (radius), or calculated using the VLAN ID plus the configured endpoint-tracking offset value (autoconfig).                                                                                                                                                                                                                                                                                                                                                      |
| <b>Timeout</b>       | Specifies the timeout period that is applied to the MAC in the bindings table when the MAC is aged out. If the MAC is in timeout state (there is no response from the RADIUS server), the timeout triggers immediately with a 15 minute period. Otherwise, the default timeout is one day, and triggers the moment the MAC ages out from the VLAN/I-SID bridge forwarding database (FDB) table. The default timeout of one day can be overridden by the RADIUS server if the Session-Timeout attribute is configured and returned. |
| <b>TimeRemaining</b> | Specifies the time remaining until the Endpoint Tracking data binding entry expires.                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Multi-area SPB Configuration using EDM

Perform the procedures in this section to configure Multi-area SPB parameters like area virtual node, remote Intermediate-System-to-Intermediate-System (IS-IS), remote Shortest Path Bridging MAC (SPBM), layer 2 unicast and multicast redistribution, and IPv4 and IPv6 route redistribution on the switch using the Enterprise Device Manager (EDM).

### Configure Multi-area SPB Layer 2 I-SID List

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to configure layer 2 I-SID list.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **MultiArea**.
3. Select the **L2 ISID List** tab.
4. Select **Insert**.
5. Configure the layer 2 I-SID list parameters.
6. Select **Insert**.

### L2 I-SID List Field Descriptions

Use data in the following table to use the **L2 I-SID List** tab.

| Name              | Description                                                                 |
|-------------------|-----------------------------------------------------------------------------|
| <b>Name</b>       | Specifies the name of the layer 2 I-SID list.                               |
| <b>RangeStart</b> | Specifies the I-SID value as the starting range for the layer 2 I-SID list. |
| <b>RangeEnd</b>   | Specifies the I-SID value as the ending range for the layer 2 I-SID list.   |

*Configure Layer 2 Multi-area SPB I-SID Redistribution***Note**

This procedure only applies to the VSP 7400 Series.

**About This Task**

Perform this procedure to configure Multi-area SPB layer 2 redistribution.

**Procedure**

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **MultiArea**.
3. Select the **L2 ISID Redist** tab.
4. Select **Insert**.
5. Configure the layer 2 I-SID redistribution parameters.
6. Select **Insert**.

**L2 Redistribute Field Descriptions**

Use the data in the following table to use the **L2 Redistribute** tab.

| Name                  | Description                                                                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Type</b>           | Specifies the layer 2 Redistribution type.                                                                                                                                                          |
| <b>Permit</b>         | Configures the Multi-area SPB layer 2 I-SID redistribution policy as permit or deny.                                                                                                                |
| <b>ExceptListName</b> | Configures the name of layer 2 I-SID list. The system does not apply the Multi-area SPB layer 2 I-SID redistribution policy to I-SID values or the range of I-SID values in the layer 2 I-SID list. |

*Configure Multi-area SPB Layer 2 Multicast I-SID Redistribution for Home Area***Note**

This procedure only applies to the VSP 7400 Series.

**About This Task**

Perform this procedure to configure the Multi-area SPB layer 2 multicast redistribution for specific I-SID value(s) in the home area.

**Procedure**

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **MultiArea**.
3. Select the **L2 MC Redist Home ISID** tab.
4. Select **Insert**.
5. In the **I-sid** field, type the I-SID value.
6. Select **Enable**.
7. (Optional) In the **PolicyName** field, type the name of the redistribution policy.
8. Select **Insert**.

## L2 MC Redist Home ISID Field Descriptions

Use the data in the following table to use the **L2 MC Redist Home ISID** tab.

| Name              | Description                                                                         |
|-------------------|-------------------------------------------------------------------------------------|
| <b>I-sid</b>      | Specifies the I-SID value.                                                          |
| <b>Enable</b>     | Enables layer 2 multicast redistribution for specific I-SID value in the home area. |
| <b>PolicyName</b> | Specifies the name of the redistribution policy.                                    |

*Configure Multi-area SPB L2 Multicast I-SID List Redistribution for Home Area*

### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to configure the Multi-area SPB layer 2 multicast I-SID list redistribution for the home area.

## Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **MultiArea**.
3. Select the **L2 MC Redist Home ISID List** tab.
4. Select **Insert**.
5. In the **ISID List Name** field, type the name of the I-SID list.
6. Select **Enable**.
7. (Optional) In the **PolicyName** field, type the policy name.
8. Select **Insert**.

## L2 MC Redist Home ISID List Field Descriptions

Use the data in the following table to use the **L2 MC Redist Home ISID List** tab.

| Name                  | Description                                                                                           |
|-----------------------|-------------------------------------------------------------------------------------------------------|
| <b>ISID List Name</b> | Specifies the name of the I-SID list.                                                                 |
| <b>Enable</b>         | Enables Multi-area SPB layer 2 multicast redistribution for the specific I-SID list in the home area. |
| <b>PolicyName</b>     | Specifies the name of the redistribution policy.                                                      |

*Apply Multi-area SPB Layer 2 Multicast Redistribution in Home Area*

### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to apply the Multi-area SPB layer 2 multicast redistribution that you configure in the home area.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **MultiArea**
3. Select the **L2 MC Apply Home** tab.
4. In the **McastApply** field, select **apply**.

### L2 MC Apply Home Field Descriptions

Use data in the following table to use the **L2 MC Apply Home** tab.

| Name              | Description                                                                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>McastApply</b> | Applies or disables the Multi-area SPB layer 2 multicast redistribution in the home area. <ul style="list-style-type: none"> <li>• noAction</li> <li>• apply</li> </ul> |

### Configure Multi-area SPB Layer 2 Multicast I-SID Redistribution for Remote Area

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to configure the Multi-area SPB layer 2 multicast redistribution for specific I-SID value(s) in the remote area.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **MultiArea**.
3. Select the **L2 MC Redist Remote ISID** tab.
4. Select **Insert**.
5. In the **I-sid** field, type the I-SID value.
6. Select **Enable**.
7. (Optional) In the **PolicyName** field, type the name of the redistribution policy.
8. Select **Insert**.

### L2 MC Redist Remote ISID Field Descriptions

Use the data in the following table to use the **L2 MC Redist Remote ISID** tab.

| Name              | Description                                                                           |
|-------------------|---------------------------------------------------------------------------------------|
| <b>I-sid</b>      | Specifies the I-SID value.                                                            |
| <b>Enable</b>     | Enables layer 2 multicast redistribution for specific I-SID value in the remote area. |
| <b>PolicyName</b> | Specifies the name of the redistribution policy.                                      |

### Configure Multi-area SPB L2 Multicast I-SID List Redistribution for Remote Area

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to configure the Multi-area SPB layer 2 multicast I-SID list redistribution for the remote area.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **MultiArea**.
3. Select the **L2 MC Redist Remote ISID List** tab.
4. Select **Insert**.
5. In the **ISID List Name** field, type the name of the I-SID list.
6. Select **Enable**.
7. (Optional) In the **PolicyName** field, type the policy name.
8. Select **Insert**.

### L2 MC Redist Remote ISID List Field Descriptions

Use the data in the following table to use the **L2 MC Redist Remote ISID List** tab.

6

| Name                  | Description                                                                                             |
|-----------------------|---------------------------------------------------------------------------------------------------------|
| <b>ISID List Name</b> | Specifies the name of the I-SID list.                                                                   |
| <b>Enable</b>         | Enables Multi-area SPB layer 2 multicast redistribution for the specific I-SID list in the remote area. |
| <b>PolicyName</b>     | Specifies the name of the redistribution policy.                                                        |

### Apply Multi-area SPB Layer 2 Multicast Redistribution in Remote Area

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to apply the Multi-area SPB layer 2 multicast redistribution that you configure in the remote area.

## Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **MultiArea**
3. Select the **L2 MC Apply Remote** tab.
4. In the **McastApply** field, select **apply**.

### L2 MC Apply Remote Field Descriptions

Use data in the following table to use the **L2 MC Apply Remote** tab.

| Name              | Description                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>McastApply</b> | Applies or disables the Multi-area SPB layer 2 multicast redistribution in the remote area. <ul style="list-style-type: none"> <li>• noAction</li> <li>• apply</li> </ul> |

### Configure Multi-area SPB Layer 3 Redistribution in Home Area

#### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to configure Multi-area SPB layer 3 redistribution in the home area.

## Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **MultiArea**.
3. Select the **L3 Redist Home** tab.
4. Select **Insert**.
5. In the **Vrflid** field, type the Virtual Router Forwarding ID.
6. In the **Type** field, select the layer 3 redistribution type.
7. (Optional) In the **RoutePolicy** field, type the name of the redistribution policy.
8. Select **Enable**.
9. In the **Apply** field, select **apply**.
10. Select **Insert**.

### L3 Redist Home Field Descriptions

Use the data in the following table to use the **L3 Redist Home** tab.

| Name          | Description                                                                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Vrflid</b> | Specifies the Virtual Router Forwarding ID.                                                                                                                                                                                            |
| <b>Type</b>   | Specifies the layer 3 redistribution type. The options are: <ul style="list-style-type: none"> <li>• <b>ip-ucast</b> - IPv4 unicast</li> <li>• <b>ip-mcast</b> - IPv4 multicast</li> <li>• <b>ipv6-ucast</b> - IPv6 unicast</li> </ul> |

| Name               | Description                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------|
| <b>RoutePolicy</b> | Associates a route policy to a specific layer 3 redistribution entry in the home area.                     |
| <b>Enable</b>      | Enables layer 3 redistribution in the home area. The default value is disabled.                            |
| <b>Apply</b>       | Applies the Multi-area SPB layer 3 redistribution filters in the home area. The default value is noAction. |

### Configure Multi-area SPB Layer 3 Redistribution in Remote Area

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to configure Multi-area SPB layer 3 redistribution in the remote area.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **MultiArea**.
3. Select the **L3 Redist Remote** tab.
4. Select **Insert**.
5. In the **Vrflid** field, type the Virtual Router Forwarding ID.
6. In the **Type** field, select the layer 3 redistribution type.
7. (Optional) In the **RoutePolicy** field, type the name of the redistribution policy.
8. Select **Enable**.
9. In the **Apply** field, select **apply**.
10. Select **Insert**.

### L3 Redist Remote Field Descriptions

Use the data in the following table to use the **L3 Redist Remote** tab.

| Name               | Description                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Vrflid</b>      | Specifies the Virtual Router Forwarding ID.                                                                                                                                                                                            |
| <b>Type</b>        | Specifies the layer 3 redistribution type. The options are: <ul style="list-style-type: none"> <li>• <b>ip-ucast</b> - IPv4 unicast</li> <li>• <b>ip-mcast</b> - IPv4 multicast</li> <li>• <b>ipv6-ucast</b> - IPv6 unicast</li> </ul> |
| <b>RoutePolicy</b> | Associates a route policy to a specific layer 3 redistribution entry in the remote area.                                                                                                                                               |
| <b>Enable</b>      | Enables layer 3 redistribution in the remote area. The default value is disabled.                                                                                                                                                      |
| <b>Apply</b>       | Applies the Multi-area SPB layer 3 redistribution filters in the remote area. The default value is noAction.                                                                                                                           |

*Configure Multi-area SPB DvR Redistribution***Note**

This procedure only applies to the VSP 7400 Series.

**About This Task**

Perform this procedure to configure the Multi-area SPB Distributed Virtual Routing (DvR) backbone redistribution on the switch.

**Procedure**

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **MultiArea**
3. Select the **DVR Redistribute** tab.
4. Select **DvrBbRedistribute**.
5. Select **Apply**.

**DVR Redistribute Field Descriptions**

Use data in the following table to use the **DVR Redistribute** tab.

| Name                     | Description                                                                              |
|--------------------------|------------------------------------------------------------------------------------------|
| <b>DvrBbRedistribute</b> | Configures the Multi-area SPB DvR redistribution on the switch. The default is disabled. |

*Display Remote IS-IS and SPBM Summary***Note**

This procedure only applies to the VSP 7400 Series.

**About This Task**

Perform this procedure to view the remote Intermediate-System-to-Intermediate-System (IS-IS) and SPBM summary.

**Procedure**

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS Remote**.
3. Select the **Protocol Summary** tab.

**Protocol Summary Field Descriptions**

Use data in the following table to use the **Protocol Summary** tab.

| Name              | Description                                                |
|-------------------|------------------------------------------------------------|
| <b>AdminState</b> | Indicates the global status of remote IS-IS on the switch. |
| <b>SystemId</b>   | Indicates the remote IS-IS system ID of the switch.        |

| Name                 | Description                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NodeNickName</b>  | Indicates the nickname for the remote SPBM instance globally.                                                                                                         |
| <b>Circuit Index</b> | Indicates the identifier of the IS-IS circuit. This value is for SNMP indexing purposes only and does not have any relation to any protocol value.                    |
| <b>IfIndex</b>       | Indicates the interface to which the circuit corresponds.                                                                                                             |
| <b>AdminState</b>    | Indicates the administrative state of the circuit. <ul style="list-style-type: none"> <li>• on</li> <li>• off</li> </ul>                                              |
| <b>OperState</b>     | Indicates the operational state of the circuit. <ul style="list-style-type: none"> <li>• up</li> <li>• down</li> </ul>                                                |
| <b>Circuit Index</b> | Indicates the unique identifier of the remote IS-IS circuit. This value is for SNMP Indexing purposes only and does not have any relation to any protocol value.      |
| <b>AdjIndex</b>      | Indicates value identifying the IS-IS adjacency from all other such adjacencies on the circuit. The system dynamically assigns this value when it forms an adjacency. |
| <b>Interface</b>     | Indicates the remote IS-IS interface.                                                                                                                                 |
| <b>AdjState</b>      | Indicates the state of the adjacency: <ul style="list-style-type: none"> <li>• down</li> <li>• initializing</li> <li>• up</li> <li>• failed</li> </ul>                |
| <b>AdjNeighSysID</b> | Indicates the system ID of the neighboring IS-IS.                                                                                                                     |
| <b>AdjHostName</b>   | Indicates the host name listed in the LSP, or the system name if the host name is not configured.                                                                     |

### Configure Remote IS-IS Global Parameters

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to configure remote IS-IS global parameters. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.

2. Select **IS-IS Remote**.
3. Select the **Globals** tab.
4. Configure the remote IS-IS global parameters.
5. Click **Apply**.

### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminState</b>             | Specifies the global status of remote IS-IS on the switch. The default is off.                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SystemId</b>               | Specifies the IS-IS system ID for the switch. Valid value is a 6-byte value in the format <xxxx.xxxx.xxxx>. <p><b>Important:</b><br/>After you configure the SPBM nickname and enable remote IS-IS, if you change the system ID, you must also change the nickname. However, changing the nickname could impact the naming convention or configuration. To maintain the same nickname with a different system ID, see <a href="#">Job aid</a> on page 1008.</p> |
| <b>DynamicallyLearnedArea</b> | For FAN members, specifies the remote IS-IS area that is dynamically learned from the neighbor's Hello PDU if the node does not have the IS-IS manual area configured.                                                                                                                                                                                                                                                                                          |
| <b>MAOperState</b>            | Specifies the Multi-area SPB operational state: <ul style="list-style-type: none"> <li>• Disabled – Multi-area SPB is disabled on the switch.</li> <li>• Init – the switch is initializing to function as a boundary node.</li> <li>• Designated – the switch is up and running as a designated boundary node.</li> <li>• Non-designated – the switch is up and running as a non-designated boundary node.</li> </ul> The default is disabled.                  |

### Configure Remote IS-IS Interfaces

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to configure the remote IS-IS interfaces. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS Remote**.
3. Select the **Interfaces** tab.
4. Select **Insert** to create a remote IS-IS instance.
5. Configure the IS-IS interface parameters.
6. Select **Insert**.

### Interfaces Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name              | Description                                                                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>      | Specifies the identifier of the circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value. |
| <b>IfIndex</b>    | Specifies the interface on which the circuit is configured (port or MLT).                                                                                                           |
| <b>Type</b>       | Specifies the IS-IS circuit type. Only the point-to-point (PtToPt) interface type is supported.                                                                                     |
| <b>AdminState</b> | Specifies the administrative state of the circuit: on or off.                                                                                                                       |
| <b>OperState</b>  | Specifies the operational state of the circuit.                                                                                                                                     |

| Name             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AuthType</b>  | <p>Specifies the authentication type:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• simple: If selected, you must also specify a key value but the key id is optional. Simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet.</li> <li>• hmac-md5: If selected, you must also specify a key value, but the key-id is optional. MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. There is an optional key ID.</li> <li>• hmac-sha-256: If selected, you must also specify a key value, but the key-id is optional. With SHA-256 authentication, the switch adds an hmac-sha-256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet. There is an optional key ID.</li> </ul> <p><b>Note:</b><br/>Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate IS-IS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key.<br/>This feature is in full compliance with RFC 5310.</p> <p>The default is none.</p> |
| <b>AuthKey</b>   | Specifies the authentication key.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>KeyId</b>     | Specifies the authentication key ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AutoNniEnable</b> | Enable to have the node create an IS-IS interface, attach the interface to an SPBM instance, and then enable IS-IS on the port interface. This field displays on the Insert Interfaces dialog box and applies to port interfaces only. |
| <b>Origin</b>        | Specifies the origin of the IS-IS circuit configuration on the port, either manually configured through CLI or EDM or dynamically configured through Auto-sense.                                                                       |

### Configure Remote IS-IS Interface Level Parameters

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to configure remote IS-IS interface level parameters. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS Remote**.
3. Select the **Interfaces Level** tab.
4. Configure the remote IS-IS interface level parameters.
5. Select **Apply**.

### Interfaces Level Field Descriptions

Use the data in the following table to use the **Interfaces Level** tab.

| Name              | Description                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>      | Specifies the identifier of the circuit, the value is unique within the remote IS-IS. The value is for SNMP Indexing purposes only and does not relate to any protocol value.                                  |
| <b>Level</b>      | Specifies the router type globally: <ul style="list-style-type: none"> <li>• l1: Level1 router type</li> <li>• l12: Level1/Level2 router type. This type is not supported.</li> </ul> The default value is l1. |
| <b>ISPriority</b> | Specifies an integer sub-range for remote IS-IS priority. The default is 64.                                                                                                                                   |

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HelloTimer</b>      | Configures the level 1 hello interval. Specifies the maximum period, in milliseconds, between IS-IS Hello Packets (IIH) PDUs on multiaccess networks at this level for LANs. The value at Level1 is used as the period between Hellos on Level1/Level2 point to point circuits. Setting this value at Level 2 on an Level1/Level2 point-to-point circuit results in an error of InconsistentValue. The default value is 9000 milliseconds or 9 seconds. |
| <b>HelloMultiplier</b> | Configures the level 1 hello multiplier. The default value is 3 seconds.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DRHelloTimer</b>    | Indicates the period, in milliseconds, between Hello PDUs on multiaccess networks when this Intermediate System is the Designated Intermediate System. The default is 3.                                                                                                                                                                                                                                                                                |

### Configure Remote SPBM on an Interface

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to configure remote Shortest Path Bridging MAC (SPBM) on an interface.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS Remote**.
3. Select the **Interfaces** tab.
4. Select the **SPBM** button.
5. Select **Insert**
6. Configure the interfaces SPBM parameters.
7. Select **Insert**.

### SPBM Field Descriptions

Use data in the following table to use the **Interfaces SPBM** tab.

| Name          | Description                                                                                                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>  | Specifies an Index value for the remote SPBM interface.                                                                                                                                                             |
| <b>SpbmId</b> | Specifies the remote SPBM ID.                                                                                                                                                                                       |
| <b>State</b>  | Specifies whether the remote SPBM interface is enabled or disabled.                                                                                                                                                 |
| <b>Type</b>   | Configures the remote SPBM instance interface-type on the IS-IS interface on the specific port or MLT, the values are point-to-point (ptpt) or broadcast (bcast). The system supports the ptpt interface type only. |

| Name            | Description                                                                                                                                                                                                                    |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>L1Metric</b> | Configures the remote SPBM instance l1-metric on the IS-IS interface on the specific port or MLT. The default value is 10.                                                                                                     |
| <b>Origin</b>   | Specifies the source of the remote SPBM instance configuration. <ul style="list-style-type: none"> <li>config - configure manually through CLI or EDM.</li> <li>dynamic - configure dynamically through Auto-sense.</li> </ul> |

### View Statistical Graph of Remote IS-IS Interface Counters

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to view statistical graph of the remote IS-IS interface counters.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS Remote**.
3. Select the **Interfaces** tab.
4. Select an interface.
5. Select the **Graph** button.

### Interface Counters Field Descriptions

The following table describes the fields in the **Interface Counters** tab.

| Name                         | Description                                                                                                                                                                    |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InitFails</b>             | Indicates the number of times initialization of this circuit has failed. This counts events such as PPP NCP failures.                                                          |
| <b>RejAdjs</b>               | Indicates the number of times an adjacency has been rejected on this circuit.                                                                                                  |
| <b>IDFieldLenMismatches</b>  | Indicates the number of times an Intermediate-System-to-Intermediate-System (IS-IS) control PDU with an ID field length different from that for this system has been received. |
| <b>MaxAreaAddrMismatches</b> | Indicates the number of times an IS-IS control PDU with a max area address field different from that for this system has been received.                                        |
| <b>AuthFails</b>             | Indicates the number of times an IS-IS control PDU with the correct auth type has failed to pass authentication validation.                                                    |
| <b>LANDesISChanges</b>       | Indicates the number of times the Designated IS has changed on this circuit at this level. If the circuit is point to point, this count is zero.                               |

| Name                 | Description                                              |
|----------------------|----------------------------------------------------------|
| <b>AbsoluteValue</b> | Displays the counter value.                              |
| <b>Cumulative</b>    | Displays the total value since you opened the Stats tab. |
| <b>Average/Sec</b>   | Displays the average value for each second.              |
| <b>Minimum/Sec</b>   | Displays the minimum value for each second.              |
| <b>Maximum/Sec</b>   | Displays the maximum value for each second.              |
| <b>Last Val/Sec</b>  | Displays the last value for each second.                 |

### View Statistical Graph of Remote IS-IS Interface Sending Control Packets

#### Note

This procedure applies only to the VSP 7400 Series.

### About This Task

Perform this procedure to view statistical graph of the remote IS-IS interface sending control packets.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS Remote**.
3. Select the **Interfaces** tab.
4. Select an interface.
5. Select the **Graph** button.
6. Select the **Interface Sending Control Packets** tab.

### Interface Sending Control Packets Field Descriptions

Use data in the following table to use the **Interface Sending Control Packets** tab.

| Name                 | Description                                                                                                                                                                                                        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Hello</b>         | Indicates the number of IS-IS Hello (IIH) PDUs seen in this direction at this level. Point-to-Point IIH PDUs are counted at the lowest enabled level: at L1 on Layer 1 or L1L2 circuits, and at Layer 2 otherwise. |
| <b>LSP</b>           | Indicates the number of IS-IS LSP frames seen in this direction at this level.                                                                                                                                     |
| <b>CSNP</b>          | Indicates the number of IS-IS Complete Sequence Number Packet (CSNP) frames seen in this direction at this level.                                                                                                  |
| <b>PSNP</b>          | Indicates the number of IS-IS Partial Sequence Number Packets (PSNPs) seen in this direction at this level.                                                                                                        |
| <b>AbsoluteValue</b> | Displays the counter value.                                                                                                                                                                                        |
| <b>Cumulative</b>    | Displays the total value since you opened the Stats tab.                                                                                                                                                           |
| <b>Average/Sec</b>   | Displays the average value for each second.                                                                                                                                                                        |
| <b>Minimum/Sec</b>   | Displays the minimum value for each second.                                                                                                                                                                        |

| Name                | Description                                 |
|---------------------|---------------------------------------------|
| <b>Maximum/Sec</b>  | Displays the maximum value for each second. |
| <b>Last Val/Sec</b> | Displays the last value for each second.    |

### *View Statistical Graph of Remote IS-IS Interface Receiving Control Packet*

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to view statistical graph of the remote IS-IS interface receiving control packets.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS Remote**.
3. Select the **Interfaces** tab.
4. Select an interface.
5. Select the **Graph** button.
6. Select the **Interface Receiving Control Packets** tab.

### Interface Receiving Control Packets Field Descriptions

Use data in the following table to use the **Interface Receiving Control Packets** tab.

| Name                 | Description                                                                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Hello</b>         | Indicates the number of IS-IS Hello PDUs seen in this direction at this level. Point-to-Point IIH PDUs are counted at the lowest enabled level: at L1 on L1 or L1L2 circuits, and at L2 otherwise. |
| <b>LSP</b>           | Indicates the number of IS-IS link-state packet (LSP) frames seen in this direction at this level.                                                                                                 |
| <b>CSNP</b>          | Indicates the number of IS-IS Complete Sequence Number Packet (CSNP) frames seen in this direction at this level.                                                                                  |
| <b>PSNP</b>          | Indicates the number of IS-IS Partial Sequence Number Packets (PSNPs) seen in this direction at this level.                                                                                        |
| <b>AbsoluteValue</b> | Displays the counter value.                                                                                                                                                                        |
| <b>Cumulative</b>    | Displays the total value since you opened the Stats tab.                                                                                                                                           |
| <b>Average/Sec</b>   | Displays the average value for each second.                                                                                                                                                        |
| <b>Minimum/Sec</b>   | Displays the minimum value for each second.                                                                                                                                                        |
| <b>Maximum/Sec</b>   | Displays the maximum value for each second.                                                                                                                                                        |
| <b>Last Val/Sec</b>  | Displays the last value for each second.                                                                                                                                                           |

*Configure Remote IS-IS Manual Area***Note**

This procedure only applies to the VSP 7400 Series.

**About This Task**

Perform this procedure to configure a remote IS-IS manual area.

**Procedure**

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS Remote**.
3. Select the **Manual Area** tab.
4. Select **Insert**.
5. In the **AreaAddr** field, type the Area Address.
6. Select **Insert**.

**Manual Area Field Descriptions**

Use the data in the following table to use the **Manual Area** tab.

| Name            | Description                                                           |
|-----------------|-----------------------------------------------------------------------|
| <b>AreaAddr</b> | Specifies the remote IS-IS manual-area in the range of 1 to 13 bytes. |

*View Level 1 Remote Area Information***Note**

This procedure applies only to the VSP 7400 Series.

**About This Task**

Perform this procedure to display Level 1 remote area information. Remote Intermediate-System-to-Intermediate-System (IS-IS) provides support for hierarchical routing, which enables the system to partition large routing domains into smaller areas. Remote IS-IS uses a two-level hierarchy, dividing the domain into multiple Level 1 areas and one Level 2 area. The Level 2 area serves as backbone of the domain, connecting to all the Level 1 areas.

**Important**

The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled.

**Procedure**

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS Remote**.
3. Select the **L1 Area** tab.

## L1 Area Remote Field Descriptions

Use the data in the following table to use the **L1 Area Remote** tab.

| Name            | Description                                                                                                                                     |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AreaAddr</b> | Specifies an area address reported in a Level 1 link-state packets (LSP) that the system generates or receives through the Intermediate System. |

*View Remote LSP Summary Information*

### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to view the remote link-state packet (LSP) summary information. Link State Packets (LSP) contain information about the state of adjacencies or defined and distributed static routes. Intermediate-System-to-Intermediate-System (IS-IS) exchanges this information with neighboring IS-IS routers at periodic intervals.

## Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS Remote**.
3. Select the **LSP Summary** tab.

## LSP Summary Field Descriptions

Use the data in the following table to use the **LSP Summary** tab.

| Name                  | Description                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------|
| <b>Level</b>          | Specifies the level at which the system displays the remote LSP.                           |
| <b>ID</b>             | Specifies the 8-byte LSP ID, consisting of the system ID, circuit ID, and Fragment Number. |
| <b>Seq</b>            | Specifies the sequence number for the LSP.                                                 |
| <b>Checksum</b>       | Specifies the 16-bit Fletcher Checksum for the LSP.                                        |
| <b>LifetimeRemain</b> | Specifies the remaining lifetime in seconds for the LSP.                                   |
| <b>HostName</b>       | Specifies the host name.                                                                   |

*View Remote IS-IS Adjacencies*

### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to view remote IS-IS adjacency information. The platform sends IS-IS Hello (IIH) packets to discover IS-IS neighbors and establish and maintain the IS-IS adjacency. The platform continues to send IIH packets to maintain the adjacencies that the system establishes. For two nodes to form an adjacency the B-VLAN pairs for the primary B-VLAN and secondary B-VLAN must match.

## Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS Remote**.
3. Select the **Adjacency** tab.

## Adjacency Field Descriptions

Use the data in the following table to use the **Adjacency** tab.

| Name                  | Description                                                                                                                                                                                                                                       |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>      | Specifies the remote IS-IS interface on which the adjacency is found.                                                                                                                                                                             |
| <b>Level</b>          | Indicates the level of the remote IS-IS interface (Level 1 [default] or Level 2).                                                                                                                                                                 |
| <b>State</b>          | Specifies the state of the adjacency: <ul style="list-style-type: none"> <li>• down</li> <li>• initializing</li> <li>• up</li> <li>• failed</li> </ul>                                                                                            |
| <b>LastUpTime</b>     | Indicates when the adjacency most recently entered the state <b>up</b> , measured in hundredths of a second since the last re-initialization of the network management subsystem. Displays 0 if the adjacency has never been in state <b>up</b> . |
| <b>NeighPriority</b>  | Specifies the priority of the neighboring Intermediate System to transition to the Designated Intermediate System.                                                                                                                                |
| <b>HoldTimer</b>      | Specifies the holding time in seconds for this adjacency. This value is based on received IS-IS Hello (IIH) PDUs and the elapsed time since receipt.                                                                                              |
| <b>NeighSysID</b>     | Specifies the system ID of the neighboring Intermediate System.                                                                                                                                                                                   |
| <b>AdjHostName</b>    | Specifies the host name listed in the LSP.                                                                                                                                                                                                        |
| <b>ParallelActive</b> | Specifies if the current adjacency among all the parallel adjacencies between two nodes is active. The values are: <ul style="list-style-type: none"> <li>• true</li> <li>• false</li> </ul>                                                      |

### Configure IS-IS Area Virtual Node

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to configure the area virtual node parameters like system name, system ID, and nickname on the Intermediate-System-to-Intermediate-System (IS-IS) instance.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS**.
3. Select the **Area VNode** tab.
4. Configure the parameters.
5. Select **Apply**.

### Area VNode Field Descriptions

Use the data in the following table to use the **Area VNode** tab.

| Name                 | Description                                                          |
|----------------------|----------------------------------------------------------------------|
| <b>VNodeNickName</b> | Specifies the nickname of the virtual node on the IS-IS instance.    |
| <b>VNodeSysId</b>    | Specifies the system ID of the virtual node on the IS-IS instance.   |
| <b>VNodeSysName</b>  | Specifies the system name of the virtual node on the IS-IS instance. |

### Configure Remote IS-IS Area Virtual Node

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to configure the area virtual node parameters like system name, system ID, and nickname on the remote Intermediate-to-Intermediate-System (IS-IS) instance.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **IS-IS Remote**.
3. Select the **Area VNode** tab.
4. Configure the parameters.
5. Select **Apply**.

### Area VNode Field Descriptions

Use the data in the following table to use the **Area VNode** tab.

| Name                 | Description                                                             |
|----------------------|-------------------------------------------------------------------------|
| <b>VNodeNickName</b> | Specifies the nickname of the virtual node on remote IS-IS instance.    |
| <b>VNodeSysId</b>    | Specifies the system ID of the virtual node on remote IS-IS instance.   |
| <b>VNodeSysName</b>  | Specifies the system name of the virtual node on remote IS-IS instance. |

*Configure Remote SPBM Parameters***Note**

This procedure only applies to the VSP 7400 Series.

**About This Task**

Perform this procedure to configure remote SPBM global parameters. SPBM uses the remote Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

**Procedure**

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **SPBM Remote**.
3. Select the **SPBM** tab.
4. Select **Insert** to create a remote SPBM instance.
5. Configure the remote SPBM parameters.
6. Select **Insert**.

**SPBM Field Descriptions**

Use data in the following table to use the **SPBM** tab.

| Name                        | Description                                                                                                 |
|-----------------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                   | Specifies the remote SPBM instance ID.                                                                      |
| <b>NodeNickName</b>         | Specifies a nickname for the remote SPBM instance globally. The value is 2.5 bytes in the format <x.xx.xx>. |
| <b>PrimaryVlan</b>          | Specifies the primary SPBM B-VLANs to add to the remote SPBM instance.                                      |
| <b>Vlans</b>                | Specifies the SPBM B-VLANs to add to the remote SPBM instance.                                              |
| <b>LsdbTrap</b>             | Enables or disables a trap when the SPBM LSDB changes. The default is disable.                              |
| <b>IpShortcut</b>           | Enables or disables SPBM IP shortcut state. The default is disable.                                         |
| <b>SmltSplitBEB</b>         | Specifies whether the switch is the primary or secondary vIST peer. The default is primary.                 |
| <b>SmltVirtualBmac</b>      | Specifies a virtual MAC address that can be used by both peers.                                             |
| <b>SmltPeerSysId</b>        | Specifies the system ID of the SPBM SMLT for this remote SPBM instance.                                     |
| <b>Mcast</b>                | Specifies if IP multicast over remote SPBM is enabled. The default is disabled.                             |
| <b>McastFwdCacheTimeout</b> | Specifies the global forward cache timeout in seconds. The default is 210 seconds.                          |

| Name                                 | Description                                                                                                                                                                                                                                               |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Ipv6Shortcut</b>                  | Enables or disables SPBM IPv6 shortcut state. The default is disable.                                                                                                                                                                                     |
| <b>McastSpbPimGwControllerEnable</b> | Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default.                                                                                                                                                                  |
| <b>McastSpbPimGwGatewayEnable</b>    | Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default.                                                                                                                                                                             |
| <b>StpMultiHoming</b>                | Enables or disables MSTP-Fabric Connect Multi Homing.<br>The default is disabled (false).                                                                                                                                                                 |
| <b>BVlanOrigin</b>                   | Specifies the origin of the B-VLAN. The values are: <ul style="list-style-type: none"> <li>config - manual configuration using CLI or SNMP.</li> <li>dynamic - through Zero Touch Fabric Configuration and Auto-sense.</li> </ul> The default is dynamic. |

### Configure Remote SPBM Parameters on the Interface

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to configure the remote SPBM interface parameters.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **SPBM Remote**.
3. Select the **Interfaces SPBM** tab.
4. Select **Insert** to create a remote SPBM instance on the interface.
5. Configure the remote SPBM interface parameters.
6. Select **Insert**.

### Interfaces SPBM Field Descriptions

Use the data in the following table to use the **Interfaces SPBM** tab.

| Name          | Description                                                         |
|---------------|---------------------------------------------------------------------|
| <b>Index</b>  | Specifies an Index value for the remote SPBM interface.             |
| <b>SpbmId</b> | Specifies the remote SPBM ID.                                       |
| <b>State</b>  | Specifies whether the remote SPBM interface is enabled or disabled. |

| Name            | Description                                                                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Type</b>     | Configures the remote SPBM instance interface-type on the IS-IS interface on the specific port or MLT, the values are point-to-point (ptpt) or broadcast (bcast). The system supports the ptpt interface type only.                |
| <b>L1Metric</b> | Configures the remote SPBM instance l1-metric on the IS-IS interface on the specific port or MLT. The default value is 10.                                                                                                         |
| <b>Origin</b>   | Specifies the source of the remote SPBM instance configuration. <ul style="list-style-type: none"> <li>• config - configure manually through CLI or EDM.</li> <li>• dynamic - configure dynamically through Auto-sense.</li> </ul> |

### View Remote SPBM I-SID Information

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to view the SPBM Service Instance Identifier (I-SID) information. The SPBM B-MAC header includes an I-SID with a length of 24 bits. This I-SID can be used to identify and transmit any virtualized traffic in an encapsulated SPBM frame.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **SPBM Remote**.
3. Select the **I-SID** tab.
4. (Optional) Select the **Filter** button to filter the rows on basis of specific criteria.

### I-SID Field Descriptions

Use data in the following table to use the **I-SID** tab.

| Name            | Description                                                                            |
|-----------------|----------------------------------------------------------------------------------------|
| <b>SysId</b>    | Indicates the system identifier.                                                       |
| <b>Vlan</b>     | Indicates the B-VLAN where the remote I-SID is configured or discovered.               |
| <b>Isid</b>     | Indicates the remote IS-IS SPBM I-SID identifier.                                      |
| <b>NickName</b> | Indicates the nickname of the node where the remote I-SID is configured or discovered. |

| Name            | Description                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------|
| <b>HostName</b> | Indicates the host name listed in the LSP, or the system name, if you do not configure the host name. |
| <b>Type</b>     | Indicates the remote SPBM I-SID type. The values are discover or configure.                           |

### View Remote SPBM Nicknames

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to view remote SPBM nicknames on the switch.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **SPBM Remote**.
3. Select the **Nick Names** tab.

### Nick Names Field Descriptions

Use the data in the following table to use the **Nick Names** tab.

| Name                  | Description                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Level</b>          | Indicates the level at which the system displays this LSP.                                                         |
| <b>ID</b>             | Indicates the 8 byte LSP ID, consisting of the System ID, Circuit ID, and Fragment Number.                         |
| <b>LifetimeRemain</b> | Indicates the remaining lifetime in seconds for the LSP.                                                           |
| <b>NickName</b>       | Indicates the nickname for the remote SPBM node.                                                                   |
| <b>HostName</b>       | Indicates the hostname that the system displays in the LSP, or the system name if the host name is not configured. |

### View Remote IP Unicast FIB

#### Note

This procedure only applies to the VSP 7400 Series.

In SPBM, each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. The system populates these Backbone MAC addresses into the SPBM VLAN Forwarding Information Base (FIB). When the system discovers a network topology and stores it in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information that it receives from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are never exchanged in the network as IP Shortcuts allows for Global Routing Table (GRT) IP networks to be transported across IS-IS.

The system adds the routes within the same VSN to the LSDB with a default preference of 7 and the inter-VSN routes with a route preference of 200. With IS-IS accept policies you can change the route preference for incoming routes. If the system learns the same route from multiple sources with different route preferences, then the routes are not equal cost multipath (ECMP) routes. The system prefers the route with the lowest route preference. In Layer 2, if there is a tie-break between routes from multiple sources, the tie-breaking is based on cost and hop count.

### About This Task

Perform this procedure to display the remote IP unicast FIB. You can view the IP routes from remote Backbone Edge Bridges (BEBs)

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **SPBM Remote**.
3. Select the **IP Unicast FIB** tab.
4. (Optional) Select the **Filter** button to filter the rows on basis of specific criteria.

### IP Unicast FIB Field Descriptions

Use the data in the following table to use the **IP Unicast FIB** tab.

| Name                         | Description                                                               |
|------------------------------|---------------------------------------------------------------------------|
| <b>Vrfid</b>                 | Specifies the VRF ID of the remote IP unicast FIB entry, 0 indicates NRE. |
| <b>DestinationIpAddrType</b> | Specifies the address type of the destination IP address.                 |
| <b>DestinationIpAddr</b>     | Specifies the destination IP Address of the remote IP unicast FIB entry.  |
| <b>DestinationMask</b>       | Specifies the destination IP mask of the remote IP unicast FIB entry      |
| <b>NextHopBmac</b>           | Specifies the nexthop B-MAC of the remote IP unicast FIB entry.           |
| <b>DestIsid</b>              | Specifies the destination I-SID of the remote IP unicast FIB entry.       |
| <b>Vlan</b>                  | Specifies the VLAN of the remote IP unicast FIB entry.                    |
| <b>Isid</b>                  | Specifies the I-SID of the remote IP unicast FIB entry.                   |
| <b>NextHopName</b>           | Specifies the nexthop hostname of the remote IP unicast FIB entry.        |
| <b>OutgoingPort</b>          | Specifies the outgoing port of the remote IP unicast FIB entry.           |
| <b>PrefixCost</b>            | Specifies the prefix cost of the remote IP unicast FIB entry.             |
| <b>SpbmCost</b>              | Specifies the B-MAC cost of the remote IP unicast FIB entry.              |

| Name              | Description                                                          |
|-------------------|----------------------------------------------------------------------|
| <b>Preference</b> | Specifies the IP Route preference of the remote IP unicast FIB entry |
| <b>MetricType</b> | Specifies the IP Metric Type of the remote IP unicast FIB entry.     |

### View Remote IPv6 Unicast FIB

#### Note

This procedure only applies to the VSP 7400 Series.

In SPBM, each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. The system populates these Backbone MAC addresses into the SPBM VLAN Forwarding Information Base (FIB). When the system discovers a network topology and stores it in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information that it receives from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are not exchanged in the network as IP Shortcuts allows for Global Routing Table (GRT) IP networks to be transported across IS-IS.

### About This Task

Perform this procedure to display the remote IPv6 unicast FIB. You can view the IPv6 routes from remote Backbone Edge Bridges (BEBs).

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **SPBM Remote**.
3. Select the **IPv6 Unicast FIB** tab.
4. (Optional) Select the **Filter** button to filter the rows on basis of specific criteria.

### IPv6 Unicast FIB Field Descriptions

Use the data in the following table to use the **IPv6 Unicast FIB** tab.

| Name                         | Description                                                                  |
|------------------------------|------------------------------------------------------------------------------|
| <b>VrfId</b>                 | Specifies the VRF ID of the remote IPv6 unicast FIB entry, 0 indicates NRE.  |
| <b>DestinationIpAddrType</b> | Specifies the address type of the destination IPv6 address.                  |
| <b>DestinationIpAddr</b>     | Specifies the destination IPv6 Address of the remote IPv6 unicast FIB entry. |
| <b>DestinationMask</b>       | Specifies the destination IPv6 mask of the remote IPv6 unicast FIB entry     |
| <b>NextHopBmac</b>           | Specifies the nexthop B-MAC of the remote IPv6 unicast FIB entry.            |

| Name                | Description                                                           |
|---------------------|-----------------------------------------------------------------------|
| <b>DestIsid</b>     | Specifies the destination I-SID of the remote IPv6 unicast FIB entry. |
| <b>Vlan</b>         | Specifies the VLAN of the remote IPv6 unicast FIB entry.              |
| <b>Isid</b>         | Specifies the I-SID of the IPv6 unicast FIB entry.                    |
| <b>NextHopName</b>  | Specifies the nexthop hostname of the remote IPv6 unicast FIB entry.  |
| <b>OutgoingPort</b> | Specifies the outgoing port of the remote IPv6 unicast FIB entry.     |
| <b>PrefixCost</b>   | Specifies the prefix cost of the remote IPv6 unicast FIB entry.       |
| <b>SpbmCost</b>     | Specifies the B-MAC cost of the remote IPv6 unicast FIB entry.        |
| <b>MetricType</b>   | Specifies the Metric Type of the remote IPv6 unicast FIB entry.       |

### View Remote Unicast FIB

#### Note

This procedure only applies to the VSP 7400 Series.

In SPBM, the IS-IS link-state database carries the B-MAC addresses. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the system discovers a network topology and stores it in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information that it receives from SPBM into the FIB for forwarding purposes.

### About This Task

Perform this procedure to view the remote unicast FIB.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **SPBM Remote**.
3. Select the **Unicast FIB** tab.

### Unicast FIB Remote Field Descriptions

Use the data in the following table to use the **Unicast FIB Remote** tab.

| Name                      | Description                                                                        |
|---------------------------|------------------------------------------------------------------------------------|
| <b>SysId</b>              | Specifies the system ID of the node where the remote unicast FIB entry originates. |
| <b>Vlan</b>               | Specifies the VLAN of the remote unicast FIB entry.                                |
| <b>DestinationMacAddr</b> | Specifies the destination MAC Address of the remote unicast FIB entry.             |
| <b>OutgoingPort</b>       | Specifies the outgoing port of the remote unicast FIB entry.                       |
| <b>HostName</b>           | Specifies the host name of the node where the remote unicast FIB entry originates. |
| <b>Cost</b>               | Specifies the cost of the remote unicast FIB entry.                                |

### View Remote Multicast FIB

#### Note

This procedure only applies to the VSP 7400 Series.

In SPBM, the IS-IS link-state database carries the B-MAC addresses. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. The system populates these Backbone MAC addresses into the SPBM VLAN Forwarding Information Base (FIB).

When the system discovers a network topology and stores it in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information that it receives from SPBM into the FIB for forwarding purposes.

The system produces the remote multicast FIB only after you configure the virtual services and the system learns them.

### About This Task

Perform this procedure to view the remote multicast FIB.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **SPBM Remote**.
3. Select the **Multicast FIB** tab.

### Multicast FIB Field Descriptions

Use the data in the following table to use the **Multicast FIB** tab.

| Name         | Description                                                                          |
|--------------|--------------------------------------------------------------------------------------|
| <b>SysId</b> | Specifies the system ID of the node where the remote multicast FIB entry originates. |
| <b>Vlan</b>  | Specifies the VLAN ID of the remote multicast FIB entry.                             |

| Name                      | Description                                                                           |
|---------------------------|---------------------------------------------------------------------------------------|
| <b>McastDestMacAddr</b>   | Specifies the multicast destination MAC Address of the remote multicast FIB entry.    |
| <b>Isid</b>               | Specifies the I-SID value in the remote multicast FIB entry.                          |
| <b>Isid Name</b>          | Specifies the name that the system assigns to the I-SID.                              |
| <b>HostName</b>           | Specifies the host name of the node where the multicast FIB entry originates.         |
| <b>OutgoingInterfaces</b> | Specifies the switched UNI port outgoing interface of the remote multicast FIB entry. |
| <b>IncomingInterface</b>  | Specifies the incoming interface (port or MLT) of the remote multicast FIB entry.     |

### View Remote IP Multicast over Fabric Connect Routes

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to view the remote IP Multicast over Fabric Connect routes.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **SPBM Remote**.
3. Select the **IpMcastRoutes** tab.

### IpMcastRoutes Field Descriptions

Use the data in the following table to use the **IpMcastRoutes** tab.

| Name             | Description                                                                           |
|------------------|---------------------------------------------------------------------------------------|
| <b>VsnIsid</b>   | Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.        |
| <b>Group</b>     | Specifies the group IP address for the IP Multicast over Fabric Connect route.        |
| <b>Source</b>    | Specifies the IP address where the IP Multicast over Fabric Connect route originated. |
| <b>SourceBeb</b> | Specifies the source BEB for the IP multicast route.                                  |
| <b>VlanId</b>    | Specifies the ID for the C-VLAN.                                                      |
| <b>VrfName</b>   | Specifies the VRF name.                                                               |

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Datalsid</b>      | Specifies the data I-SID for the IP Multicast over Fabric Connect route. A a BEB receives IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| <b>Type</b>          | Specifies the type for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                                       |
| <b>Bvlan</b>         | Specifies the B-VLAN for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                                     |
| <b>NniInterfaces</b> | Specifies the NNI ports for the IP multicast route. SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports that face a customer VLAN are user-to-network interface (UNI) ports.                                                                                                                                                                   |

*View UNI Ports for remote IP Multicast Routes*

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to view the UNI ports associated with particular remote IP multicast routes.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **SPBM Remote**.
3. Select the **IpMcastRoutes** tab.
4. Select an entry.
5. Select the **UNI Ports** button.

### IpMcastRoutes-Uni Ports Field Descriptions

Use data in the following table to use the **IpMcastRoutes-Uni Ports** tab.

| Name            | Description                                                                           |
|-----------------|---------------------------------------------------------------------------------------|
| <b>Vsnlsid</b>  | Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.        |
| <b>Group</b>    | Specifies the group IP address for the IP Multicast over Fabric Connect route.        |
| <b>Source</b>   | Specifies the IP address where the IP Multicast over Fabric Connect route originates. |
| <b>NickName</b> | Specifies the nickname.                                                               |

| Name                     | Description                                          |
|--------------------------|------------------------------------------------------|
| <b>EgressVlan</b>        | Specifies the egress VLAN of the IP multicast route. |
| <b>EgressActivePorts</b> | Specifies the egress active ports.                   |

### View Remote IS-IS System Statistics

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to view the remote Intermediate-System-to-Intermediate-System (IS-IS) system statistics.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **Stats Remote**.
3. Select the **System Stats** tab.

### System Stats Field Descriptions

Use the data in the following table to use the **System Stats** tab.

| Name                        | Description                                                                                                                                                           |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CorrLSPs</b>             | Indicates the number of corrupted in-memory link-state packets (LSPs) detected. LSPs received from the wire with a bad checksum are silently dropped and not counted. |
| <b>AuthFails</b>            | Indicates the number of authentication key failures recognized by this Intermediate System.                                                                           |
| <b>LSPDbaseOloads</b>       | Indicates the number of times the LSP database has become overloaded.                                                                                                 |
| <b>ManAddrDropFromAreas</b> | Indicates the number of times a manual address has been dropped from the area.                                                                                        |
| <b>AttmptToExMaxSeqNums</b> | Indicates the number of times the IS has attempted to exceed the maximum sequence number.                                                                             |
| <b>SeqNumSkips</b>          | Indicates the number of times a sequence number skip has occurred.                                                                                                    |
| <b>OwnLSPPurges</b>         | Indicates the number of times a zero-aged copy of the system's own LSP is received from some other node.                                                              |
| <b>IDFieldLenMismatches</b> | Indicates the number of times a PDU is received with a different value for ID field length to that of the receiving system.                                           |
| <b>PartChanges</b>          | Indicates partition changes.                                                                                                                                          |
| <b>AbsoluteValue</b>        | Displays the counter value.                                                                                                                                           |
| <b>Cumulative</b>           | Displays the total value since you opened the Stats tab.                                                                                                              |

| Name               | Description                                 |
|--------------------|---------------------------------------------|
| <b>Average/sec</b> | Displays the average value for each second. |
| <b>Minimum/sec</b> | Displays the minimum value for each second. |
| <b>Maximum/sec</b> | Displays the maximum value for each second. |
| <b>LastVal/sec</b> | Displays the last value for each second.    |

### View Remote IS-IS Interface Counters

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to view the remote Intermediate-System-Intermediate-System (IS-IS) interface counters.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **Stats Remote**.
3. Select the **Interface Counters** tab.

### Interface Counters Field Descriptions

Use the data in the following table to use the **Interface Counters** tab.

| Name                         | Description                                                                                                                                                                                                                                                  |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                 | Shows a unique value identifying the IS-IS interface.                                                                                                                                                                                                        |
| <b>Level</b>                 | Shows the type of circuit that discovered the interface counters. The point to point Hello PDU includes both Layer 1 and Layer 2, and IS from a single adjacency on point to point links, therefore combining counts on point to point links into one group. |
| <b>AdjChanges</b>            | Shows the number of times an adjacency state change has occurred on this circuit.                                                                                                                                                                            |
| <b>InitFails</b>             | Shows the number of times initialization of this circuit has failed. This counts events such as PPP NCP failures. Failures to form an adjacency are counted by isisCircRejAdjs.                                                                              |
| <b>RejAdjs</b>               | Shows the number of times an adjacency has been rejected on this circuit.                                                                                                                                                                                    |
| <b>IDFieldLenMismatches</b>  | Shows the number of times an IS-IS control PDU with an ID field length different to that for this system has been received.                                                                                                                                  |
| <b>MaxAreaAddrMismatches</b> | Shows the number of times an IS-IS control PDU with a max area address field different to that for this system has been received.                                                                                                                            |

| Name                   | Description                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AuthFails</b>       | Shows the number of times an IS-IS control PDU with the correct auth type has failed to pass authentication validation.                      |
| <b>LANDesISChanges</b> | Shows the number of times the Designated IS has changed on this circuit at this level. If the circuit is point to point, this count is zero. |

### View Remote IS-IS Interface Control Packets

#### Note

This procedure only applies to the VSP 7400 Series.

### About This Task

Perform this procedure to view the remote Intermediate-System-to-Intermediate-System (IS-IS) interface control packets.

### Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **Stats Remote**.
3. Select the **Interface Control Packets** tab.

### Interface Control Packets Field Descriptions

Use the data in the following table to use the **Interface Control Packets** tab.

| Name             | Description                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>     | Shows a unique value identifying the Intermediate-System-to-Intermediate-System (IS-IS) interface.                 |
| <b>Level</b>     | Specifies the level.                                                                                               |
| <b>Direction</b> | Indicates whether the switch is sending or receiving the PDUs.                                                     |
| <b>Hello</b>     | Indicates the number of IS-IS Hello frames seen in this direction at this level.                                   |
| <b>LSP</b>       | Indicates the number of IS-IS LSP frames seen in this direction at this level.                                     |
| <b>CSNP</b>      | Indicates the number of IS-IS Complete Sequence Number Packets (CSNP) frames seen in this direction at this level. |
| <b>PSNP</b>      | Indicates the number of IS-IS Partial Sequence Number Packets (PSNP) frames seen in this direction at this level.  |

### View the Remote I-SID Forwarding Database

#### Note

This procedure only applies to the VSP 7400 Series.

## About This Task

Perform this procedure to view the remote I-SID forwarding database (FDB) on the switch.

### Note

To view the T-UNI I-SID FDB entries filtered on a port that is part of an MLT, you must mention the MLT ID in the option for the port.

## Procedure

1. In the navigation pane, expand the **Configuration > IS-IS** folders.
2. Select **ISID Remote**.
3. (Optional) Select the **Filter** button to filter the rows on basis of specific criteria.

## FDB Field Descriptions

Use data in the following table to use the **FDB** tab.

| Name                        | Description                                                                                                    |
|-----------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>IsidId</b>               | Specifies the service interface identifier (I-SID).                                                            |
| <b>Address</b>              | Specifies the MAC address of the port assigned to the specific I-SID or C-MAC learned on the particular I-SID. |
| <b>Status</b>               | Specifies the learning status of the associated MAC.                                                           |
| <b>Port</b>                 | Specifies the port on which the MAC is learned for the specific I-SID.                                         |
| <b>PortType</b>             | Specifies if the MAC address is learned locally or on an NNI port from a remote destination.                   |
| <b>RemoteMacDestAddr</b>    | Specifies the virtual B-MAC address or system-ID of the remote destination.                                    |
| <b>RemoteMacBVlanId</b>     | Specifies the B-VLAN ID on which the remote destination was discovered.                                        |
| <b>RemoteMacDestSysName</b> | Specifies the remote destination system name.                                                                  |
| <b>Cvid</b>                 | Specifies the customer VLAN ID of the associated Switched UNI port.                                            |

## SPBM configuration examples

This section provides configuration examples to configure basic SPBM and IS-IS infrastructure.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

### Basic SPBM configuration example

The following figure shows a sample greenfield deployment for SPBM.

### Figure 83: Greenfield SPBM deployment

**Note**

For migration purposes, SPBM can coexist with existing SMLT configurations.

*Ethernet and MLT configuration*

The following sections show the steps required to configure the Ethernet and MLT interfaces in this example.

**SwitchC**

```
PORT CONFIGURATION - PHASE 1

interface GigabitEthernet 1/30
encapsulation dot1q
exit
```

**SwitchG**

```
PORT CONFIGURATION - PHASE 1

interface GigabitEthernet 1/5
encapsulation dot1q
exit

MLT CONFIGURATION

mlt 1 enable
mlt 1 member 1/21-1/22
mlt 1 encapsulation dot1q
```

**SwitchD**

```
MLT CONFIGURATION

mlt 1 enable
mlt 1 member 1/20,1/30
mlt 1 encapsulation dot1q
```

*IS-IS SPBM global configuration*

The following figure shows the IS-IS area information added to the network.

**Figure 84: IS-IS SPBM global**

The following sections show the steps required to configure the global IS-IS SPBM parameters in this example.

### SwitchC

```
enable
configure terminal
prompt SwitchC

BOOT CONFIGURATION

spbm
spbm ethertype 0x8100

ISIS SPBM CONFIGURATION

router isis
spbm 1
spbm 1 nick-name f.30.13
spbm 1 b-vid 20

ISIS CONFIGURATION

is-type l1
manual-area 30.0000
sys-name SwitchC
exit
router isis enable

VLAN CONFIGURATION

vlan create 20 name "B-VLAN" type spbm-bvlan
```

### SwitchG

```
enable
configure terminal
prompt SwitchG

BOOT CONFIGURATION

spbm
spbm ethertype 0x8100

ISIS SPBM CONFIGURATION

router isis
```

```
spbm 1
spbm 1 nick-name f.30.10
spbm 1 b-vid 20

ISIS CONFIGURATION

is-type l1
manual-area 30.0000
sys-name SwitchG
exit
router isis enable

VLAN CONFIGURATION

vlan create 20 name "B-VLAN" type spbm-bvlan
```

### SwitchD

```
enable
configure terminal
prompt SwitchD

BOOT CONFIGURATION

spbm
spbm ethertype 0x8100

ISIS SPBM CONFIGURATION

router isis
spbm 1
spbm 1 nick-name f.30.14
spbm 1 b-vid 20

ISIS CONFIGURATION

is-type l1
manual-area 30.0000
sys-name SwitchD
exit
router isis enable

VLAN CONFIGURATION

vlan create 20 name "B-VLAN" type spbm-bvlan
```

### *IS-IS SPBM Interface Configuration*

The following figure shows the IS-IS area information and interfaces in the network.

### **Figure 85: IS-IS SPBM interface**

The following sections show the steps required to configure the IS-IS SPBM interfaces in this example.

### SwitchC

```
PORT CONFIGURATION - PHASE II

interface GigabitEthernet 1/30
isis
isis spbm 1
isis enable
exit
```

### SwitchG

```
PORT CONFIGURATION - PHASE II

interface GigabitEthernet 1/5
isis
isis spbm 1
isis enable
exit

MLT INTERFACE CONFIGURATION

interface mlt 1
isis
isis spbm 1
isis enable
exit
```

### SwitchD

```
MLT INTERFACE CONFIGURATION

interface mlt 1
isis
isis spbm 1
isis enable
exit
```

### Verify SPBM Operations

The following sections show the output from verifying the sample IS-IS SPBM configuration.

#### Checking Operation — SwitchC

```

## Fabric Extend Configuration Examples

This section provides configuration examples to configure Fabric Extend in the following deployment scenarios.

- [Fabric Extend over IP using the GRT](#) on page 1225
- [Fabric Extend over IP using a VRF](#) on page 1228
- [Fabric Extend over VPLS](#) on page 1230
- [Fabric Extend over Layer 2 Pseudowire](#) on page 1233
- [Fabric Extend with ONAs in the Core and Branches](#) on page 1235
- [Fabric Extend Over IPsec](#) on page 1238

For more configuration examples, see *Shortest Path Bridging (802.1aq) Technical Configuration Guide*.

*Fabric Extend over IP using the GRT*

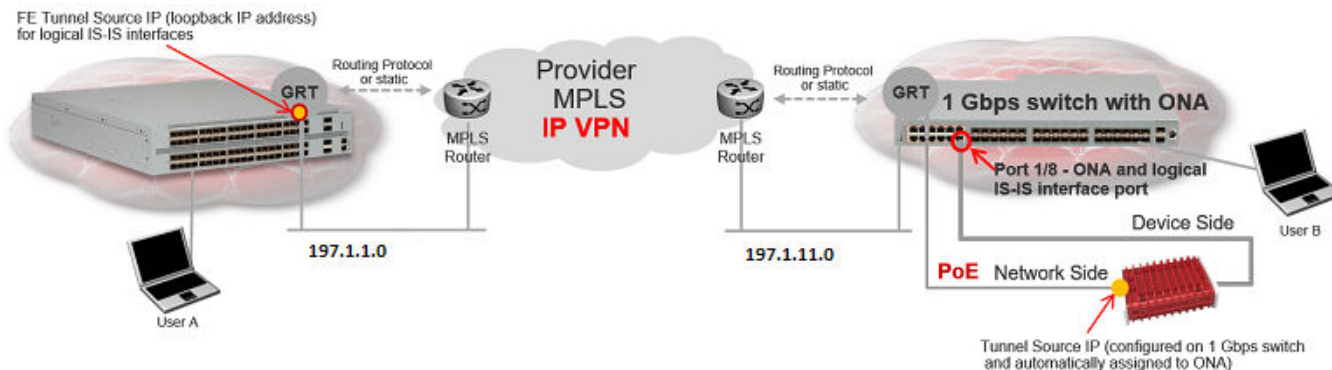

This example shows a typical Fabric Extend deployment with a 10/40/100 Gbps switch in the core and a 1 Gbps switch in one of the branch offices. The 10/40/100 Gbps switch supports Fabric Extend natively and is connected over an IP network to a 1 Gbps switch, which requires an ONA to encapsulate SPB traffic with a VXLAN header. The ONA sets up a bridge between the ONA device-side port and the ONA network-side port. Fabric Extend uses a VXLAN tunnel to send traffic to and from the 10/40/100 Gbps switch through the 1 Gbps switch to the ONA.

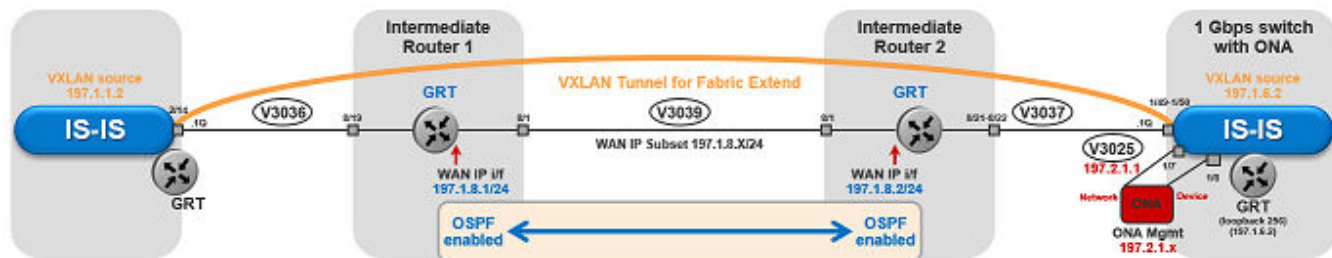

**Note**

- This deployment uses the **GRT** so the tunnel source IP address must be on the GRT, not on a VRF.
- If IP Shortcuts is enabled, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.
- Add any IP address used for setting up the logical tunnel (such as local network and loopback IP addresses) to the IS-IS accept policy or exclude route-map to prevent these addresses from being advertised into IS-IS.

The following figure shows a sample Fabric Extend deployment over IP using the GRT.

**Figure 86: IP using GRT traffic flow**

**Figure 87: IP (GRT) traffic flow component view**

**For 10/40/100 Gbps Switches**

(The tunnel source IP address is configured in the GRT.)

```
Switch(config)# interface GigabitEthernet 2/14
Switch(config-if)# no shutdown
```

```

Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-SP-core"
Switch(config-if)# brouter port 2/14 vlan 3036 subnet 197.1.1.2/255.255.255.0
Switch(config-if)# no spanning-tree mstp force-port-state enable
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.1.2
Switch(config-isis)# exit

Switch(config)# logical-intf isis 255 dest-ip 197.1.6.2 name "Tunnel-to-Branch1"
Switch(config-isis-255-197.1.6.2)# isis
Switch(config-isis-255-197.1.6.2)# isis spbm 1
Switch(config-isis-255-197.1.6.2)# isis enable
Switch(config-isis-255-197.1.6.2)# exit

Switch(config)# ip prefix-list "isis-tunnel-addr" 197.1.0.0/16 ge 16 le 32
Switch(config)# route-map "deny-isis-tunnel-network" 1
Switch(route-map)# no permit
Switch(route-map)# enable
Switch(route-map)# match network "isis-tunnel-addr"
Switch(route-map)# match protocol isis
Switch(route-map)# exit

Switch(config)# router isis
Switch(config-isis)# accept route-map "deny-isis-tunnel-network"
Switch(config-isis)# exit
Switch(config)# isis apply accept

```

### For 1 Gbps Switches

(The tunnel source address is a CLIP address on the GRT. This address is configured on the 1 Gbps switch and then automatically assigned to the ONA.)

```

Switch(config)# interface loopback 256
Switch(config-if)# ip address 256 197.1.6.2/255.255.255.0
Switch(config-if)# ip ospf 256
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3037 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3037 1/49-1/50 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface vlan 3037
Switch(config-if)# ip address 197.1.11.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3025 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3025 1/7 portmember
Switch(config)# interface vlan 3025
Switch(config-if)# ip address 197.2.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 mode bootp_dhcp

```

```

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.6.2 port 1/8 mtu 1950
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.1.2 name "Tunnel-to-HQ"
Switch(config-isis-255-197.1.1.2)# isis
Switch(config-isis-255-197.1.1.2)# isis spbm 1
Switch(config-isis-255-197.1.1.2)# isis enable
Switch(config-isis-255-197.1.1.2)# exit

Switch(config)# ip prefix-list "isis-tunnel-addr" 197.1.0.0/16 ge 16 le 32
Switch(config)# route-map "deny-isis-tunnel-network" 1
Switch(route-map)# no permit
Switch(route-map)# enable
Switch(route-map)# match network "isis-tunnel-addr"
Switch(route-map)# match protocol isis
Switch(route-map)# exit

Switch(config)# router isis
Switch(config-isis)# accept route-map "deny-isis-tunnel-network"
Switch(config-isis)# exit
Switch(config)# isis apply accept

```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

#### For Intermediate Router 1

```

Switch(config)# interface GigabitEthernet 8/19
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-from-Headoffice"
Switch(config-if)# no shutdown
Switch(config-if)# brouter port 8/19 vlan 3036 subnet 197.1.1.3/255.255.255.0 mac-offset 2
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.1 255.255.255.0 2
Switch(config)# ip ospf enable
Switch(config)# exit

```

#### For Intermediate Router 2

```

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.2 255.255.255.0 0
Switch(config)# ip ospf enable
Switch(config)# exit

Switch(config)# vlan create 3037 name "ospf-intf-from-branch1" type port-mstprstp 0
Switch(config)# vlan members 3037 8/21-8/22 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface Vlan 3037
Switch(config)# ip address 197.1.11.1 255.255.255.0 5
Switch(config)# ip ospf enable
Switch(config)# exit

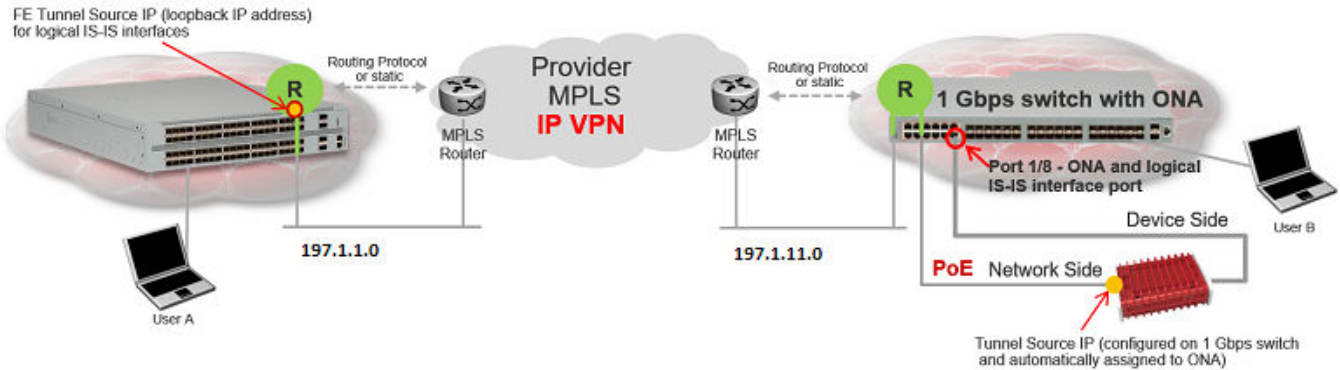

```

### Fabric Extend over IP using a VRF

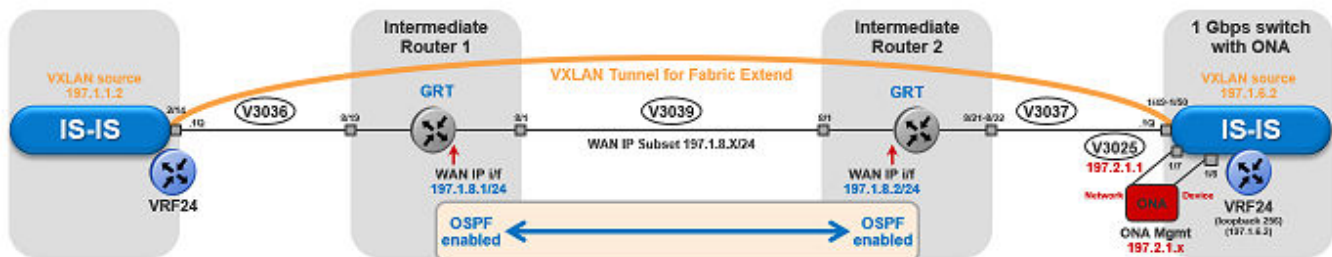

This example is the same as the previous IP example except this Fabric Extend deployment uses a VRF instead of the GRT. Because this deployment is using a VRF, Fabric Extend has the following requirements:

- Configure a CLIP and tunnel source IP address on the same VRF.
- Remote management of the 1 Gbps switch is only possible after establishing IP Shortcut over IS-IS. (Alternatively, you can enable GRT-VRF redistribution locally.)

The following figure shows a sample Fabric Extend deployment over IP using a VRF.

**Figure 88: IP using VRF traffic flow**

**Figure 89: IP (VRF) traffic flow component view**

### For 10/40/100 Gbps Switches

(The tunnel source IP address is configured as a brouter address in the VRF.)

```
Switch(config)# ip vrf vrf24
Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface GigabitEthernet 2/14
Switch(config-if)# no shutdown
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-SP-core"
Switch(config-if)# vrf vrf24
Switch(config-if)# brouter port 2/14 vlan 3036 subnet 197.1.1.2/255.255.255.0 mac-offset 1
Switch(config-if)# no spanning-tree mstp force-port-state enable
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# router isis
```

```
Switch(config-isis)# ip-tunnel-source-address 197.1.1.2 vrf vrf24
Switch(config-isis)# exit

Switch(config)# logical-intf isis 255 dest-ip 197.1.6.2 name "Tunnel-to-Branch1"
Switch(config-isis-255-197.1.6.2)# isis
Switch(config-isis-255-197.1.6.2)# isis spbm 1
Switch(config-isis-255-197.1.6.2)# isis enable
Switch(config-isis-255-197.1.6.2)# exit
```

### For 1 Gbps Switches

(The tunnel source address is a CLIP address on the VRF. This address is configured on the 1 Gbps switch and then automatically assigned to the ONA.)

```
Switch(config)# ip vrf vrf24

Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface loopback 256
Switch(config-if)# ip address 197.1.6.2 255.255.255.255 vrf vrf24
Switch(config-if)# ip ospf vrf vrf24
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3037 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3037 1/49-1/50 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface vlan 3037
Switch(config-if)# vrf vrf24
Switch(config-if)# ip address 197.1.11.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3025 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3025 1/7 portmember
Switch(config)# interface vlan 3025
Switch(config-if)# ip address 197.2.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.6.2 port 1/8 vrf vrf24 mtu 1950
Switch(config-isis)# exit

Switch(config)# logical-intf isis 255 dest-ip 197.1.1.2 name "Tunnel-to-HQ"
Switch(config-isis-255-197.1.1.2)# isis
Switch(config-isis-255-197.1.1.2)# isis spbm 1
Switch(config-isis-255-197.1.1.2)# isis enable
Switch(config-isis-255-197.1.1.2)# exit
```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

### For Intermediate Router 1

```
Switch(config)# interface GigabitEthernet 8/19
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-from-Headoffice"
Switch(config-if)# no shutdown
Switch(config-if)# brouter port 8/19 vlan 3036 subnet 197.1.1.3/255.255.255.0 mac-offset 2
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.1 255.255.255.0 2
Switch(config)# ip ospf enable
Switch(config)# exit
```

### For Intermediate Router 2

```
Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.2 255.255.255.0 0
Switch(config)# ip ospf enable
Switch(config)# exit

Switch(config)# vlan create 3037 name "ospf-intf-from-branch1" type port-mstprstp 0
Switch(config)# vlan members 3037 8/21-8/22 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface Vlan 3037
Switch(config)# ip address 197.1.11.1 255.255.255.0 5
Switch(config)# ip ospf enable
Switch(config)# exit
```

### Fabric Extend over VPLS

This example shows a Fabric Extend deployment over MPLS Virtual Private LAN Service (VPLS). In this scenario, VPLS emulates a LAN with full mesh connectivity. The SPB nodes connect with point-to-point Ethernet links and also use MPLS for normal forwarding.

#### Note

On the Core side, the 10/40/100 Gbps switches require a single next hop IP address as a default gateway for all tunnels. To ensure the single next hop, VPLS uses a loopback IP address and an additional VRF.

The following figure shows a sample Fabric Extend deployment over VPLS.

**Figure 90: FE over VPLS traffic flow**

#### For 10/40/100 Gbps Switches

(The tunnel source IP address is configured as a brouter address in the VRF.)

```
Switch(config)# interface GigabitEthernet 2/14
Switch(config-if)# no shutdown
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-SP-core"
Switch(config-if)# vrf vrf24
Switch(config-if)# brouter port 2/14 vlan 3036 subnet 197.1.1.2/255.255.255.0 mac-offset 1
Switch(config-if)# no spanning-tree mstp force-port-state enable
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.1.2 vrf vrf24
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.6.2 name "Tunnel-to-Branch1"
Switch(config-isis-255-197.1.6.2)# isis
Switch(config-isis-255-197.1.6.2)# isis spbm 1
Switch(config-isis-255-197.1.6.2)# isis enable
Switch(config-isis-255-197.1.6.2)# exit
```

#### For 1 Gbps Switches

(The tunnel source address is a CLIP address on the VRF. This address is configured on the 1 Gbps switch and then automatically assigned to the ONA.)

```
Switch(config)# ip vrf vrf24

Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface loopback 256
Switch(config-if)# ip address 197.1.6.2 255.255.255.255 vrf vrf24
```

```

Switch(config-if)# ip ospf vrf vrf24
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3037 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3037 1/49-1/50 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface vlan 3037
Switch(config-if)# vrf tunnel
Switch(config-if)# ip address 197.1.11.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3025 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3025 1/7 portmember
Switch(config)# interface vlan 3025
Switch(config-if)# ip address 197.2.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.6.2 port 1/8 vrf vrf24 mtu 1950
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.1.2 name "Tunnel-to-HQ"
Switch(config-isis-255-197.1.1.2)# isis
Switch(config-isis-255-197.1.1.2)# isis spbm 1
Switch(config-isis-255-197.1.1.2)# isis enable
Switch(config-isis-255-197.1.1.2)# exit

```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

#### For Intermediate Router 1

```

Switch(config)# interface GigabitEthernet 8/19
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-from-Headoffice"
Switch(config-if)# no shutdown
Switch(config-if)# brouter port 8/19 vlan 3036 subnet 197.1.1.3/255.255.255.0 mac-offset 2
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.1 255.255.255.0 2
Switch(config)# ip ospf enable
Switch(config)# exit

```

#### For Intermediate Router 2

```

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039

```

```

Switch(config)# ip address 197.1.8.2 255.255.255.0 0
Switch(config)# ip ospf enable
Switch(config)# exit

Switch(config)# vlan create 3037 name "ospf-intf-from-branch1" type port-mstprstp 0
Switch(config)# vlan members 3037 8/21-8/22 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface Vlan 3037
Switch(config)# ip address 197.1.11.1 255.255.255.0 5
Switch(config)# ip ospf enable
Switch(config)# exit

```

### Fabric Extend over Layer 2 Pseudowire

This example shows a Fabric Extend deployment using service provider VLAN tunnels over MPLS Pseudowire. In this scenario, you map two dedicated VLAN IDs (VIDs) from the Hub to the Spoke sites. Then the logical IS-IS interfaces translate the BVIDs to map them to the per branch provider VIDs. Because the tunnels are point-to-point VLAN connections, not VXLAN, there is no need to encapsulate a VXLAN header to SPB packets. Therefore, the 1 Gbps switches in this type of deployment do not require ONAs.

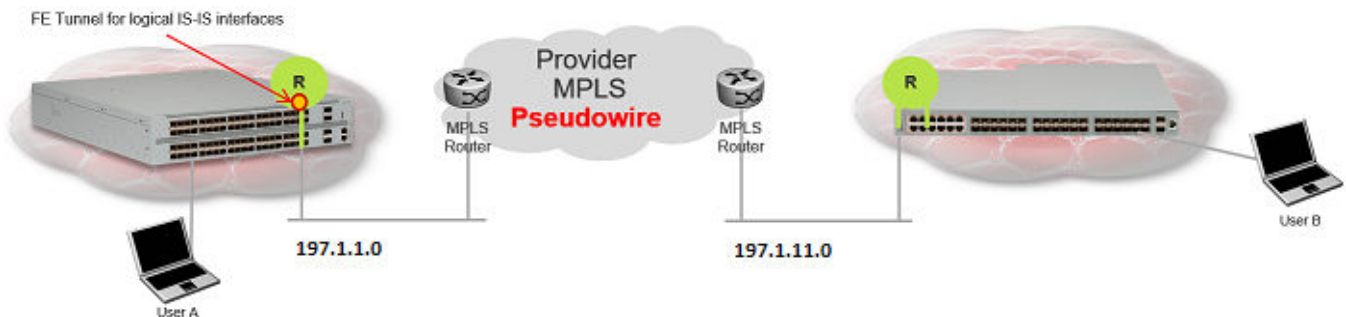

#### Important

10/40/100 Gbps switch — — — — — Core — — — — — 1 Gbps switch

- You cannot have IS-IS in the Core.
- Do not create the two VLANs represented in the logical interface connection on the BEBs. If you do, you will not be able add any Fabric Extend ports to be members of those VLANs. One links the port that is facing the core and those VLANs in the logical interface connection.

The following figure shows a sample Fabric Extend deployment over Pseudowire.

**Figure 91: FE over Pseudowire traffic flow**

**Figure 92: FE over Pseudowire traffic flow component view**

### For 10/40/100 Gbps Switches

#### Note

Logical interface VLANs cannot be the same as the SPBM B-VLANs and you cannot create these VLANs locally. Use these VLANs for configuring the logical interface only. Once a port is being used for a logical interface it cannot be added to any platform VLAN and spanning tree is automatically disabled on the port.

```
Switch(config)# logical-intf isis 255 vid 200,300 primary-vid 200 port 2/14 name
fe_to_Switch
Switch(config-isis-255)# isis
Switch(config-isis-255)# isis spbm 1
Switch(config-isis-255)# isis enable
Switch(config-isis-255)# exit
```

### For 1 Gbps Switches

#### Note

Logical interface VLANs cannot be the same as the SPBM B-VLANs and you cannot create these VLANs locally. Use these VLANs for configuring the logical interface only. Once a port is being used for a logical interface it cannot be added to any platform VLAN and spanning tree is automatically disabled on the port.

```
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# router isis enable

Switch(config)# logical-intf isis 255 vid 200,300 primary-vid 200 mlt 11 name fe_to_Switch
Switch(config-isis-255)# isis
Switch(config-isis-255)# isis spbm 1
Switch(config-isis-255)# isis enable
Switch(config-isis-255)# exit
```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

### For Intermediate Router 1

```
Switch(config)# vlan create 200 type port-mstprstp 1
Switch(config)# vlan create 300 type port-mstprstp 1
Switch(config)# vlan member add 200 8/1,8/19
Switch(config)# vlan member add 300 8/1,8/19
```

**For Intermediate Router 2**

```
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# vlan create 200 type port-mstprstp 1
Switch(config)# vlan create 300 type port-mstprstp 1
Switch(config)# vlan member add 200 8/1
Switch(config)# vlan mlt 200 11
Switch(config)# vlan member add 300 8/1
Switch(config)# vlan mlt 300 11
```

*Fabric Extend with ONAs in the Core and Branches*

This example shows a Fabric Extend deployment with 1 Gbps switches in the core of the network and in the branch sites. This type of deployment is not only a lower cost Fabric Extend solution, it also addresses situations where large MTU sizes (over 1594 bytes) are a problem for the Service Provider.

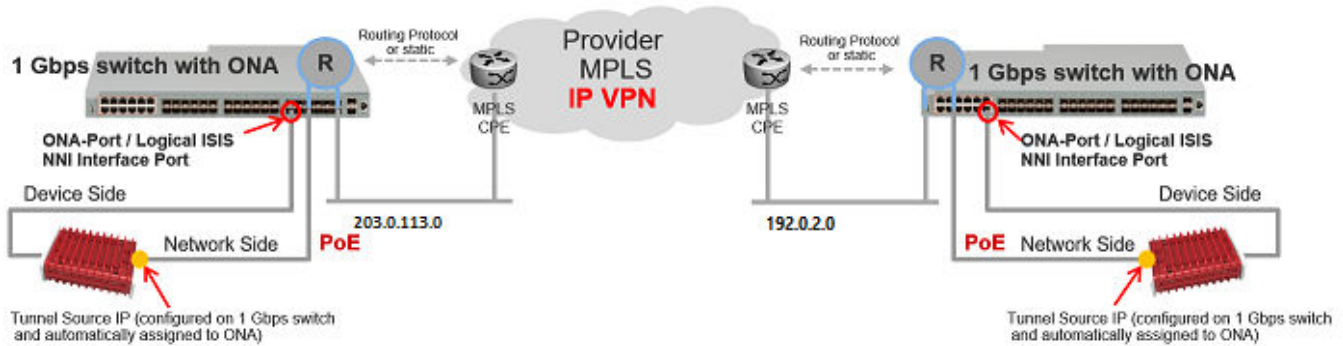

MTU sizes less than 1594 bytes require fragmentation and reassembly of packets and the 1 Gbps switch with ONA supports fragmentation and reassembly. However, you must have 1 Gbps switches with ONAs at BOTH ends of the IP WAN connection.

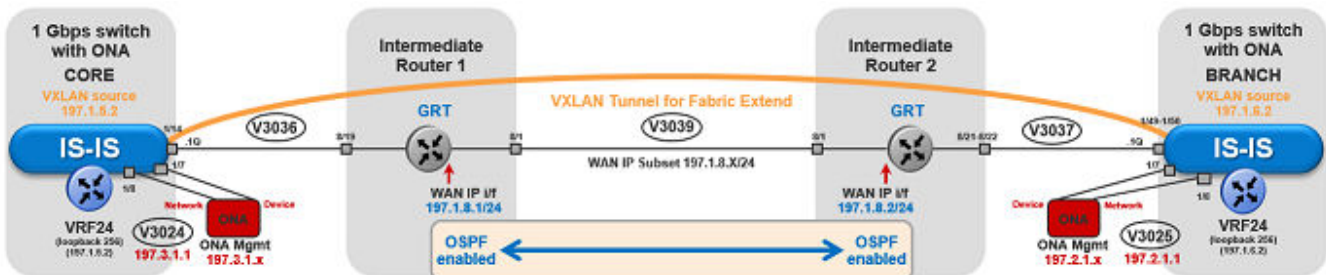

**Important**

There is no fragmentation/reassembly support in Layer 2 core solutions.

The following figure shows a sample Fabric Extend deployment using VRFs with both switches.

**Figure 93: Fabric Extend traffic flow**

**Figure 94: Fabric Extend traffic flow component view**

### Core switch configuration

(The tunnel source address is a CLIP address on the VRF. This address is configured on the switch and then automatically assigned to the ONA.)

```
Switch(config)# ip vrf vrf24
Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface loopback 256
Switch(config-if)# ip address 197.1.5.2 255.255.255.255 vrf vrf24
Switch(config-if)# ip ospf vrf vrf24
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3036 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3036 1/14 portmember
Switch(config)# interface vlan 3036
Switch(config)# vrf vrf24
Switch(config-if)# ip address 197.1.1.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3024 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3024 1/8 portmember
Switch(config)# interface vlan 3024
Switch(config-if)# ip address 197.3.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.3.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.3.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.3.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.5.2 port 1/7 vrf vrf24 mtu 1950
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.6.2 name "Tunnel-to-Branch1"
Switch(config-isis-255-197.1.6.2)# isis
Switch(config-isis-255-197.1.6.2)# isis spbm 1
Switch(config-isis-255-197.1.6.2)# isis enable
Switch(config-isis-255-197.2.1.1)# exit
```

### Branch switch configuration

(The tunnel source address is a CLIP address on the VRF. This address is configured on the switch and then automatically assigned to the ONA.)

```
Switch(config)# ip vrf vrf24

Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface loopback 256
Switch(config-if)# ip address 197.1.6.2 255.255.255.255 vrf vrf24
Switch(config-if)# ip ospf vrf vrf24
Switch(config-if)# exit
```

```

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3037 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3037 1/49-1/50 portmember
Switch(config)# interface vlan 3037
Switch(config-if)# vrf vrf24
Switch(config-if)# ip address 197.1.11.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3025 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3025 1/8 portmember
Switch(config)# interface vlan 3025
Switch(config-if)# ip address 197.2.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.6.2 port 1/7 vrf vrf24 mtu 1950
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.5.2 name "Tunnel-to-HQ"
Switch(config-isis-255-197.1.1.2)# isis
Switch(config-isis-255-197.1.1.2)# isis spbm 1
Switch(config-isis-255-197.1.1.2)# isis enable
Switch(config-isis-255-197.1.1.2)# exit

```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

### Intermediate Router 1 Configuration

```

Switch(config)# interface GigabitEthernet 8/19
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-from-Headoffice"
Switch(config-if)# no shutdown
Switch(config-if)# brouter port 8/19 vlan 3036 subnet 197.1.1.3/255.255.255.0 mac-offset 2
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.1 255.255.255.0 2
Switch(config)# ip ospf enable
Switch(config)# exit

```

### Intermediate Router 2 Configuration

```

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.2 255.255.255.0 0
Switch(config)# ip ospf enable
Switch(config)# exit

Switch(config)# vlan create 3037 name "ospf-intf-from-branch1" type port-mstprstp 0
Switch(config)# vlan members 3037 8/21-8/22 portmember
Switch(config)# mlt 11

```

```
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface Vlan 3037
Switch(config)# ip address 197.1.11.1 255.255.255.0 5
Switch(config)# ip ospf enable
Switch(config)# exit
```

### Fabric Extend Over IPsec

The following example shows a Fabric Extend deployment using service provider VLAN tunnels and IPsec.

#### Note

Fabric Extend over IPsec limitations:

- Only pre-shared authentication key IPsec parameters are user configurable. Other, third-party solutions are not configurable.
- The key exchange only uses the Internet Key Exchange (IKE) v2 protocol.
- IPsec support is only added for Fabric Extend tunnels.
- IPsec is not supported for regular layer 3 routed packets.

### Global SPBM for Fabric Extend over IPsec Configuration

The global SPBM parameters must be configured before you can configure the Fabric Extend over IPsec tunnel.

#### Note

The **ipsec** command is only available after the **auth-key** command is configured.

```
Switch> enable
Switch# configure terminal

Switch(config)# spbm
Switch(config-isis)# router isis
Switch(config-isis)# spbm 1
Switch(config-isis)# spbm 1 nick-name 1.11.40
Switch(config-isis)# spbm 1 b-vid 2,3 primary 2
Switch(config-isis)# is-type 11
Switch(config-isis)# manual-area c0.2000.0000.00
Switch(config-isis)# sys-name SwitchB
Switch(config-isis)# exit

Switch(config)# vlan create 2 type spbm-bvlan
Switch(config)# vlan create 3 type spbm-bvlan
Switch(config)# router isis enable
```

### Fabric Extend tunnel and IPsec configuration

Configuring Fabric Extend over IPsec consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

```
Switch> enable
Switch# configure terminal

Switch(config)# interface GigabitEthernet 1/1
Switch(config-if)# brouter port 1/1 vlan 2500 subnet 192.0.2.0/255.255.255.0 mac-offset 0
Switch(config-if)# exit

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 192.0.2.0
Switch(config-isis)# exit

Switch(config)# logical-intf isis 1 dest-ip 198.51.100.0
Switch(config-isis-1-198.51.100.0)# isis
Switch(config-isis-1-198.51.100.0)# isis spbm 1
Switch(config-isis-1-198.51.100.0)# isis enable
Switch(config-isis-1-198.51.100.0)# auth-key 12345678
Switch(config-isis-1-198.51.100.0)# ipsec encryption-key-length 256
Switch(config-isis-1-198.51.100.0)# ipsec
Switch(config-isis-1-198.51.100.0)# exit
```

#### Note

Product Notice: 256-bit IPsec Encryption for Fabric Extend Tunnels is only supported on XA1400 Series devices.

## Fabric Attach configuration examples

This section provides configuration examples to configure Fabric Attach.

### *Configure a Fabric Attach Solution*

The following section describes a simple configuration example to configure Fabric Attach (FA) at the edge of a Fabric Connect network. This is a typical deployment at its simplest level and is powerful because of its use in conjunction with a Fabric Connect core.

#### About This Task

Configuring FA primarily consists of configuring the FA Server. The FA Server in turn discovers neighboring FA component devices (like the FA Proxies and FA Clients) using FA TLVs within the LLDP PDUs.

In the following deployment, the switch at the edge of the Fabric Connect cloud is configured as the FA Server. On this switch, FA is enabled globally and at the interface (port) level. Another switch, functioning as the FA Proxy connects to the FA enabled port (1/3) on the FA Server. User A is an end user device that needs to send and receive data traffic from User B (another end user device) across the network.

### Before You Begin

Configure SPBM and IS-IS on the edge and core switches. For more information, see [Configure Minimum SPBM and IS-IS Parameters](#) on page 1005.

### Procedure

#### Configure the edge switch (BEB) as the FA Server:

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable FA globally:  

```
fa enable
```
3. Enter port interface configuration mode:  

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
4. Enable FA on the port:  

```
fa enable
```

#### Note

Enabling FA automatically enables message authentication. Also, the authentication key is set to the default value and the system displays the encrypted authentication key on the output.

#### Note

Enabling FA on a port not only enables tagging but also disables spanning tree on that port.

#### Verify global and interface level FA configuration:

5. Verify global configuration of FA using one of the following commands:

- show fa
- show fa agent

6. Verify interface level configuration of FA:

```
show fa interface
```

7. Verify the discovery of clients attaching to the FA Server:

```
show fa elements
```

8. Display the FA I-SID-to-VLAN assignments:

```
show fa assignment
```

To verify I-SID-to-VLAN assignments on a specific port, enter:

```
show fa assignment {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

9. Verify creation of Switched UNI (ELAN) I-SIDs:

```
show i-sid elan
```

### Example

#### SPBM and IS-IS configuration on the core and edge switches:

SPBM configuration:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spbm
Switch:1(config)#spbm ethertype 0x8100
```

IS-IS SPBM configuration:

```
Switch:1(config)#router isis
Switch:1(config)#spbm 1
Switch:1(config-isis)#spbm 1 nick-name 1.00.01
Switch:1(config-isis)#spbm 1 b-vid 41-42 primary 41
Switch:1(config-isis)#spbm 1 ip enable
```

IS-IS router configuration:

```
Switch:1(config-isis)#router isis
Switch:1(config-isis)#sys-name BEB-Switch
Switch:1(config-isis)#ip-source-address 3.3.3.3
Switch:1(config-isis)#is-type 11
Switch:1(config-isis)#system-id 0001.0001.0001
Switch:1(config-isis)#manual-area c0.2000.000.00
Switch:1(config-isis)#exit
```

Interface (port-level) configuration

```
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)#no shutdown
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-isis)#exit
Switch(config)#vlan create 41 type spbm-vlan
Switch(config)#vlan create 42 type spbm-vlan
```

```
Switch(config)#router isis enable
Switch(config)#show isis spbm
```

### Configuration of the edge switch as the FA Server.

Enable FA globally.

```
Switch:1(config)#fa enable
Switch:1(config)#show fa

=====
                        Fabric Attach Configuration
=====
                        FA Service : enabled
                        FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
FA Provision Mode : spbm
```

Enable FA on the port.

Enabling FA automatically enables message authentication. The authentication key is configured with the default value, which the system displays in encrypted format in the output.

```
Switch:1(config)#int gigabitEthernet 1/3
Switch:1(config-if)#fa enable
Switch:1(config-if)#show fa interface port 1/3

=====
                        Fabric Attach Interfaces
=====
INTERFACE      SERVER  MGMT   MGMT   MSG AUTH  MSG AUTH  ORIGIN
STATUS         ISID   CVID   STATUS  KEY
-----
Port1/3        enabled  0      0      enabled  ****

-----
1 out of 1 Total Num of fabric attach interfaces displayed
-----

Switch:1(config-if)#exit
Switch:1(config)#exit
```

Verify that the FA Proxy is discovered by the FA Server.

```
Switch:1(config)#show fa elements

=====
                        Fabric Attach Discovery Elements
=====
PORT   TYPE           MGMT          ELEM ASGN
      VLAN STATE  SYSTEM ID    AUTH AUTH
-----
1/3   proxy         2    T / S  10:cd:ae:09:40:00:20:00:00:01  AP  AP

-----
                        Fabric Attach Authentication Detail
=====
      ELEM OPER          ASGN OPER
PORT  AUTH STATUS          AUTH STATUS
-----
1/3   successAuth        successAuth
```

```

State Legend: (Tagging/AutoConfig)
T= Tagged,    U= Untagged,    D= Disabled,    S= Spbm,    V= Vlan,    I= Invalid

NA= Not Authenticated,  N= None

-----

2 out of 2 Total Num of fabric attach discovery elements displayed

```

Verify the FA I-SID-to-VLAN assignment. An `active` state indicates that the FA (ELAN) I-SID is successfully created with endpoint of type Switched UNI. By default, this I-SID is created for Layer 2.

```

Switch:1#show fa assignment

=====
                          Fabric Attach Assignment Map
=====
Interface  I-SID      Vlan      State      Origin
-----
1/3        44         2         active     proxy

-----

1 out of 1 Total Num of fabric attach assignment mappings displayed
-----

```

For Layer 3 support, you must configure a platform VLAN. The platform VLAN can have the same value as that of the C-VID or it can have a different value.

In this example, the platform VLAN has the same value as the C-VID.

```

Switch:1(config)#vlan create 2 type port-mstprstp 0
Switch:1(config)#vlan i-sid 2 44
Switch:1#show i-sid elan

=====
                          Isid Info
=====

Port    Type         Subtype      VLAN   Auth   System ID
-----
1/3     Server      Server (Auth)  0      AP     aa:bb:cc:dd:ee:11:30:01:00:01

Switch:2(config)#show fa i-sid

I-SID   VLAN   Source      Status
-----
44      2      Proxy      Active

```

### Configure Fabric Attach in an SMLT

The following example describes FA configuration and behavior in a dual-homed SMLT deployment.

The following figure shows a simple FA solution in a dual-homed SMLT deployment. In this deployment, a pair of BEB switches (BEB A and BEB B) operating as IST peers are configured as the FA Server. An access switch or a wiring closet switch configured as an FA Proxy connects to the FA Server. The FA Proxy advertises I-SID-to-VLAN assignment mappings to the FA Server. Both BEB switches receive the mapping information using LLDP PDUs containing assignment TLVs. The switch that learns the mapping first considers the I-SID to be discovered locally and creates the I-SID on its device. The mapping information is then shared with its IST peer switch. When the peer switch receives the mapping across IST in a new SMLT message, it too creates the I-SID on its device. This I-SID however, is considered to be discovered remotely because it is learnt from synchronization with the peer switch. The mappings can also be learned on the FA Server from both LLDP PDUs and from IST synchronization.

**Figure 95: FA configuration in dual-homed SMLT**

### Before You Begin

Ensure that the proxy device (for example, an access switch) is properly configured for FA. See the corresponding product documentation for information on how to configure FA on the switch.

### Procedure

1. Configure SMLT and vIST on switches BEB A and BEB B.

#### Caution

For the IST peer switches acting as the FA Server to transmit the same FA System ID (based on the virtual MAC), SMLT configuration on both the switches must be the same.

For detailed information on configuring SMLT and vIST, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2334.

### Configure BEB A and BEB B as the FA Server

Perform the following configuration on each switch.

2. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

3. Enable FA globally:

```
fa enable
```

4. Enter MLT interface configuration mode:

```
interface mlt <1-512>
```

5. Enable FA on the MLT:

```
fa enable
```

#### Note

Enabling FA automatically enables message authentication. Also, the authentication key is set to the default value and the system displays the encrypted authentication key on the output.

6. (Optional) Configure an FA authentication key with a value different from that of the default value:

```
fa authentication-key [WORD<0-32>]
```

#### Caution

When you configure the FA authentication key, you must configure the same value on both BEB switches in the SMLT.

#### Verify global and MLT-level FA configuration on BEB A and BEB B:

7. Verify global configuration of FA using one of the following commands:

- `show fa`
- `show fa agent`

8. Verify MLT-level (interface-level) configuration of FA:

```
show fa interface
```

#### Verify FA discovery on BEB A and BEB B:

9. Verify discovery of the FA Proxy.

```
show fa elements
```

#### View FA I-SID-to-VLAN assignments on BEB A and BEB B:

10. View the FA I-SID-to-VLAN assignments:

```
show fa assignment
```

To view FA I-SID-to-VLAN assignments on specific ports, enter:

```
show fa assignment {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Verify creation of Switched UNI I-SIDs on BEB A and BEB B:

## 11. Verify creation of Switched UNI (ELAN) I-SIDs:

- View ELAN I-SID information using `show i-sid elan`.
- View ELAN I-SID information on a specific MLT using `show mlt i-sid [<1-512>]`.

**Note**

Viewing ELAN I-SID information on an MLT is very useful to understand the origin of the I-SID, when multiple client or proxy devices connecting to the FA Server using SMLT MLT advertise the same I-SID-to-VLAN mappings. In the event of a link failure on an MLT, the origin of the I-SID helps determine on which MLT, and thereby from which proxy or client device, the mappings were successfully learnt.

**Examples****SMLT configuration on BEB A and BEB B:**

On BEB A:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface mlt 1
Switch:1(config)#smlt
```

On BEB B:

```
Switch:2>en
Switch:2#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:2(config)#interface mlt 1
Switch:2(config)#smlt
```

**vIST configuration on BEB A and BEB B:**

On BEB A:

```
Switch:1(config)#vlan create 2261 type port-mstprstp 0
Switch:1(config)#vlan i-sid 2261 1502261
Switch:1(config)#interface vlan 2261
Switch:1(config)#ip address 192.0.2.0 255.255.255.0 2
```

Configure BEB B (IP address 192.0.2.1) as the IST peer.

```
Switch:1(config)#virtual-ist peer-ip 192.0.2.1 vlan 2261
Switch:1(config)#show virtual-ist
Switch:1(config)#exit
```

On BEB B:

```
Switch:2(config)#vlan create 2261 type port-mstprstp 0
Switch:2(config)#vlan i-sid 2261 1502261
Switch:2(config)#interface vlan 2261
Switch:2(config)#ip address 192.0.2.1 255.255.255.0 2
```

Configure BEB A (IP address 192.0.2.1) as the IST peer.

```
Switch:2(config)#virtual-ist peer-ip 192.0.2.1 vlan 2261
Switch:2(config)#show virtual-ist
Switch:2(config)#exit
```

**FA configuration on BEB A:**

Enable FA globally and on the MLT:

```
Switch:1(config)#fa enable
Switch:1>show fa

=====
                          Fabric Attach Configuration
=====
                          FA Service : enabled

### Multi-area SPB Configuration Example

The following figure is an example of the devices connecting to each other in the Multi-area SPB network.

**Figure 97: Multi-area SPB network example**

The following sections display an example to configure the two boundary nodes in the Multi-area SPB network (BG1 and BG2), to enable remote Intermediate-System-to-Intermediate-System (IS-IS), and to configure the layer 2 and layer 3 unicast redistribution.

**Note**

You must first configure basic SPBM and IS-IS infrastructure. For more information, see [SPBM configuration examples](#) on page 1218.

#### Boundary Node BG1 Configuration

```
enable
configure terminal
router isis remote
manual-area 49.0050
spbm 1 nick-name 1.21.15
exit
router isis remote enable
show isis area-vnode
```

|                                       | VSP 8600 Series | VSP 8600 6.3       |
|                                       | XA1400 Series   | Not Supported      |

## Layer 2 VSN configuration fundamentals

This section provides fundamentals concepts for Layer 2 VSN.

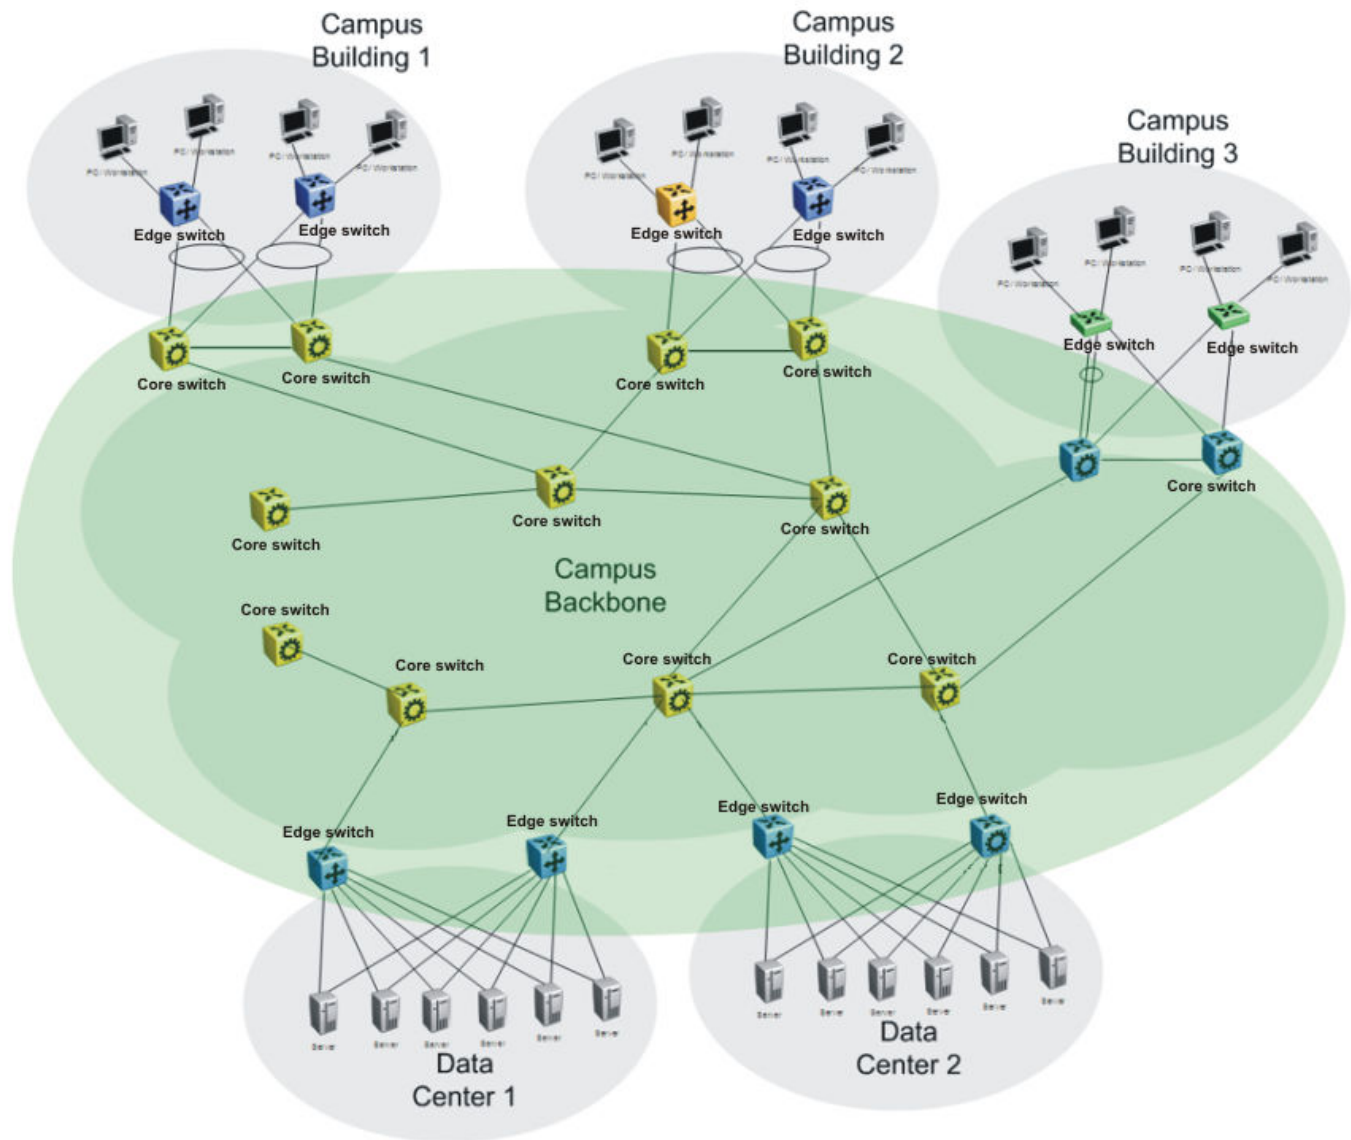

### SPBM L2 VSN

SPBM supports Layer 2 VSN functionality where customer VLANs (C-VLANs) are bridged over the SPBM core infrastructure.

At the Backbone Edge Bridges (BEBs), customer VLANs (C-VLAN) are mapped to I-SIDs based on the local service provisioning. Outgoing frames are encapsulated in a MAC-in-MAC header, and then forwarded across the core to the far-end BEB, which strips off the encapsulation and forwards the frame to the destination network based on the I-SID-to-C-VLAN provisioning.

In the backbone VLAN (B-VLAN), Backbone Core Bridges (BCBs) forward the encapsulated traffic based on the B-MAC-DA, using the shortest path topology learned using IS-IS.

The following figure shows a sample campus SPBM Layer 2 VSN network.

**Figure 98: SPBM L2 VSN in a campus**

One of the key advantages of the SPBM Layer 2 VSN is that network virtualization provisioning is achieved by configuring only the edge of the network (BEBs). As a result, the intrusive core provisioning

that other Layer 2 virtualization technologies require is not needed when new connectivity services are added to the SPBM network. For example, when new virtual server instances are created and need their own VLAN instances, they are provisioned at the network edge only and do not need to be configured throughout the rest of the network infrastructure.

Based on its I-SID scalability, this solution can scale much higher than any 802.1Q tagging based solution. Also, due to the fact that there is no need for Spanning Tree in the core, this solution does not need any core link provisioning for normal operation.

Redundant connectivity between the C-VLAN domain and the SPBM infrastructure can be achieved by operating two SPBM switches in switch clustering (SMLT) mode. This allows the dual homing of any traditional link aggregation capable device into an SPBM network.

### **Configuration difference from ERS 8800**

One major difference between these VSP switches and the ERS 8800 is how they connect to two SMLT devices.

The ERS 8800 uses an interswitch trunk (IST). The IST connects directly to two SMLT devices with a dedicated MLT and runs IS-IS over it. The dedicated MLT carries the IST control traffic and data traffic during an SMLT failover. This feature dramatically improves resiliency over other methods. However, if the dedicated MLT breaks, then there is no way to communicate between the IST peers, which causes traffic loss.

These VSP switches use a virtual IST (vIST) that eliminates this single point of failure. The vIST feature creates a virtualized IST channel in the SPBM cloud. With vIST, the IST tunnel is always up as long as there is SPBM connectivity between the vIST peers. vIST also interoperates between any two devices that support vIST, and the devices do not have to be the same type of device.

Before you can create a vIST, you must do the following:

- Enable SPBM and IS-IS globally.
- Configure SPBM and IS-IS.
- Create a VLAN (that is not used anywhere else) for each peer.
- Create an I-SID that is not used anywhere else.
- Configure an IP address for the vIST VLAN.
- Configure an Layer 2 VSN by assigning an I-SID to the C-VLAN, which is used by the vIST.

#### **Important**

- An I-SID must be assigned to every VLAN that is a member of an Layer 2 VSN.
- For proper traffic flow, if an Layer 2 VSN is created on one vIST peer, it must also be created on the other vIST peer.
- For Simplified vIST deployment, if a VLAN is part of an SMLT it must be configured on both the IST peers.

For information about vIST, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2334.

### **Fabric Connect Service Types**

The Fabric Connect technology delivers Layer 2 and Layer 3 virtualization. These virtualized Layer 2 and Layer 3 instances are referred to as Virtual Service Networks (VSNs). A Service Identifier (I-SID) is used

to uniquely distinguish these service instances network-wide, and a User Network Interface (UNI) is the boundary or demarcation point between the “service layer” of traditional networks, that is VLANs and VRFs, and the Fabric Connect “service layer”, that is Layer 2 & Layer 3 VSNs.

- Layer 2 VSNs are virtual broadcast domains interconnecting UNI members that share the same Layer 2 VSN I-SID. MAC learning/aging is applied to all Layer 2 VSNs.
- Layer 3 VSNs are virtual routed Layer 3 networks (Layer 3 VPN) leveraging IS-IS as the routing protocol between VRFs that share the same Layer 3 VSN I-SID.

Fabric Connect uses the User-Network-Interface (UNI) to denote the capabilities and attributes of the service interfaces. Fabric connect devices support the following UNI types:

- VLAN UNI (C-VLAN) — a device-specific VLAN-ID maps to a Layer 2 VSN I-SID – all device physical ports that are associated with the VLAN are therefore associated with the UNI.
- Flex UNI — it has the following sub-types:
  - Switched UNI — a VLAN-ID and a given port (VID, port) maps to a Layer 2 VSN I-SID. With this UNI type, VLAN-IDs can be reused on other ports and therefore mapped to different I-SIDs.
  - Transparent Port UNI — a physical port maps to a Layer 2 VSN I-SID (all traffic through that port, 802.1Q tagged or untagged, ingress and egress is mapped to the I-SID). Note: All VLANs on a Transparent Port UNI interface now share the same single MAC learning table of the Transparent Port UNI I-SID.
- E-Tree UNI — it extends Private VLANs beyond one Switch to form a network-wide E-Tree service infrastructure. An E-Tree UNI is a Layer 2 VSN where broadcast traffic flows from Hub sites to Spokes sites, and from Spokes to Hubs, but not between Spoke sites. E-Tree Hubs can be formed with any VLAN UNI, while E-Tree Spokes must be configured as Private VLAN UNIs.
- Layer 3 VSN UNI — a device-specific VRF maps to an I-SID, and the control plane exchanges the Layer 3 routes belonging to the same I-SID. All VRFs in a network sharing the same Layer 3 I-SID effectively form an Layer 3 VPN. Layer 3 VSNs can be configured to simultaneously support both IP Unicast and IP Multicast.

### Transparent Port UNI

Use a Transparent Port User-Network-Interface (Transparent Port UNI or T-UNI) to map an entire port or an MLT to an I-SID. C-MAC learning is done against the I-SID. T-UNI configures a transparent port where all traffic is MAC switched on an internal virtual port using the assigned I-SID. No VLAN is involved in this process. Devices switch tagged and untagged traffic in the assigned I-SID regardless of the VLAN ID. The T-UNI port or MLT can be either static or LACP and is not a member of any VLAN or Spanning Tree Group (STG). The T-UNI port or MLT is always in the forwarding state.

You can map multiple ports to a T-UNI I-SID. Multiple ports on the same switch and on other BEBs can use the common I-SID to switch traffic.

T-UNI is a point to point service and all traffic that ingress the UNI egress from the remote UNI end-point

For information about QoS re-marking, see [QoS re-marking on a Transparent Port UNI](#) on page 2651.

Transparent

T-UNI is transparent because the MAC learning occurs within the I-SID, and packets that ingress from any CVLAN are processed in an identical manner. Devices switch tagged and untagged traffic in the

assigned I-SID. Devices switch control protocols, such as BPDU, LACP, LLDP, and others, in the assigned I-SID, rather than forwarding to the CP.

The service classification of packets that are received on a T-UNI port, is independent of the VLAN ID values present in those packets. All data packets received on a T-UNI port are classified into the same service. When data packets enter and exit the T-UNI service, no VLAN tag modifications are performed on the data packets.

#### T-UNI based MAC learning

When a packet ingresses a port or MLT associated with a T-UNI I-SID, the system performs MAC lookup based on the I-SID. A packet that ingresses a T-UNI port on a BEB can transfer through the SPB network, or can egress out another T-UNI port configured to the same I-SID.

When a packet ingresses an NNI port, before egressing a T-UNI port, the system performs a MAC Destination Address (DA) lookup based on the I-SID. If the DA lookup fails, the packet floods to all T-UNI ports.

#### Considerations

Consider the following design requirements when you configure a T-UNI:

- Only E-LAN based T-UNI is supported. All T-UNI I-SID end points for a given I-SID become members of the same shared E-LAN service. If an E-LINE type of service is required, provision T-UNI at the two end points comprising the point-to-point service.
- You cannot configure a T-UNI on the same I-SID as a C-VLAN.
- A port or MLT associated with a T-UNI I-SID cannot be part of any VLAN and does not belong to any STG.
- Ensure that you always associate a T-UNI LACP MLT with a VLAN (even if it is the default VLAN) before adding it to a T-UNI I-SID. Otherwise, traffic is not forwarded on the T-UNI LACP MLT.
- No Layer 3 processing takes place on packets ingressing on a T-UNI port.
- Pause frames do not switch through the T-UNI I-SID.
- Multiple ports or MLTs can be associated with same T-UNI I-SID.
- One port or MLT cannot be part of multiple T-UNI I-SIDs.
- An I-SID mapped to a T-UNI service must not be mapped to any other service, such as Layer 2 VSN and Layer 3 VSN, on any of the remote BEBs in the SPBM network.
- Any Spanning Tree Protocol implementation is disabled on the port or MLT associated with the T-UNI I-SID. The port will always be in a Forwarding state.
- No additional IS-IS TLVs are added to advertise or withdraw T-UNI I-SID services. Extreme Networks makes use of the existing IS-IS TLV-144 and sub TLV-3 to carry I-SID information.
- MACs are learned against the combination of the I-SID and port or MLT.
- The MAC address limit is supported on a per-I-SID basis. For example, the MAC addresses learned on the T-UNI I-SID can be limited.

#### Note

MAC learning limit for T-UNI service is not supported on all hardware platforms.

- Static MAC is not supported for a T-UNI port.
- IP traffic and control packets are transparently bridged over T-UNI endpoints.

- Untagged traffic ingressing on the T-UNI port will use COS 0. B-TAG and I-TAG priorities are derived from the best effort queue that is assigned. If the T-UNI port is set as a Layer 2 untrusted port, a best-effort queue is assigned.
- The 802.1p bits of the incoming traffic are used to derive the B-TAG and I-TAG priorities for tagged traffic.
- LACP, VLACP and LLDP PDUs are extracted to the CP and all other control packets are transparently bridged over the T-UNI port or MLT.

This feature handles control PDUs in the following manner:

All the Layer 2 and Layer 3 control packets are transparently bridged over the T-UNI port or MLT with the exception of LACP, VLACP and LLDP PDUs. LACP PDUs, VLACP PDUs and LLDP PDUs are not transparently bridged over the T-UNI port or MLT if LACP, VLACP or LLDP is enabled on the port or MLT.

- If an LACP MLT is associated with a T-UNI I-SID, LACP PDUs are extracted to CP and processed locally.
- If LACP is not enabled globally and LACP MLT is not associated with the T-UNI I-SID, LACP PDUs are transparently bridged across the T-UNI port or MLT.
- If a VLACP enabled port is added to a T-UNI I-SID, VLACP PDUs are extracted to the CP for local processing. If a port that is not VLACP enabled is added to the T-UNI I-SID, VLACP PDUs are transparently bridged across T-UNI port.
- If a LLDP enabled port is added to a T-UNI I-SID, LLDP PDUs are extracted to the CP for local processing.
- If LLDP is not enabled on the port or MLT interface associated to TUNI I-SID , LLDP PDUs are transparently bridged across the T-UNI port or MLT.

The following list of control packet types are transparently bridged across the T-UNI I-SID:

- SLPP
- VRRP
- OSPF
- RIP
- BGP
- ISIS
- CFM
- STP
- SONMP

Use T-UNI when either of the following apply:

- All tagged and untagged traffic on a port must be classified into the same broadcast domain.
- You want to offer a transparent provider solution.

An example of an application for T-UNI is a typical Ethernet provider deployment with port-based classification and transparent forwarding.

### **Transparent Port UNI over vIST**

Virtual IST (vIST) provides the ability to dual-home hosts, servers and other network devices to a pair of Multi-Chassis Link Aggregation (MC-LAG) enabled devices. The system displays the MC-LAG nodes to

the connected devices as one link-aggregated group. So, although the physical connection is spread between two individual network nodes, logically the system displays them as a single connection.

Transparent Port UNI (T-UNI) over vIST peers extends the capability of dual-home hosts on the SPB cloud to achieve higher network resiliency. The MACs learnt on the T-UNI interface of any one vIST peer is synchronized with the other peer through MAC synchronization.

In the following figure, the T-UNI access switch ACCESS-1 is dual-homed into vIST peer hosts VIST-PEER 1 and VIST-PEER 2. At ACCESS-1, a link aggregation is created to connect to the SPBM cluster. On the VIST peers, an SMLT is created towards ACCESS-1. Depending on the link aggregation hashing logic, traffic is hashed on to VIST-PEER 1 and VIST-PEER 2. The MACs learnt on the T-UNI interfaces of either host is synchronized with the other host.

**Figure 99: Example of Transparent Port UNI over vIST**

If one of the links between ACCESS-1 and the vIST cluster goes down, all traffic is serviced through the other link. The same applies when any of the vIST peers go down. Since MAC learning on both peers are synchronized, both peers can switch traffic with the same efficiency.

Single-homed T-UNI service on a vIST-enabled node

If you configure a T-UNI service as a single-homed service on a vIST-enabled node, you must configure the same I-SID service without port/MLT being mapped to I-SID, on the other vIST peer node. Failure to perform this configuration on the vIST peer node can result in the loss of traffic to the single-homed T-UNI service in various scenarios.

## Switched UNI

Switched User Network Interface (S-UNI) allows the association of local endpoints to I-SIDs based on local port and VLAN together. With Switched UNI, the same VLAN can be used on one port to create an endpoint to one I-SID, and on another port to create an endpoint to another I-SID.

Switched UNI summary:

- Switched UNI is a VLAN and ports associated with I-SIDs.
- Local significance on the ports.
- You can re-use the same VLAN to associate different ports with different I-SIDs.
- You can use a different VLAN to the same ports, or you can assign different ports to the same I-SID.
- Supports VLAN mapping on the local switch.
- To accept untagged traffic, the port needs to be configured as untagged-traffic in the I-SID.

Use Switched UNI when either of the following apply:

- Vlan ID (VID) reuse is required. The same VID is used on different broadcast domains (multi-tenant applications).
- Multiple VLANs must be part of the same broadcast domain.
- VID translation is required.

An example of an application for Switched UNI is a typical host and provider deployment, with a port and VID-based classification.

#### Switched UNI based MAC learning

MAC learning is done on I-SID MAC. When a packet ingresses on a port or MLT which is associated with Switched UNI I-SID, the system performs MAC look up based on the I-SID. Switched UNI operates on Any-To-Any (ELAN) mode, there can be one or more ports associated to a Switched UNI I-SID. A packet that ingresses to a Switched UNI port on a BEB can transfer through the SPBM cloud, or can egress out another Switched UNI port configured to the same I-SID.

When a packet ingresses an NNI port, before egressing a Switched UNI port, the system performs a MAC Destination Address (DA) lookup based on the I-SID. If the DA lookup fails, the packet floods to all Switched UNI ports in the I-SID.

#### Considerations

Consider the following when you configure a Switched UNI:

- The VLAN tag is removed before the traffic egresses out on the untagged-traffic port or MLT.
- VLAN priority received on the packet is maintained across VLAN IDs.
- Spanning tree is disabled on all Switched UNI ports, and the ports remain in forwarding state.
- The Switched UNI I-SID is advertised to the SPBM cloud.
- The Broadcast and unknown Unicast packets are flooded to all ports in the I-SID.

#### Limitations

- You cannot change from one UNI type to another dynamically. The I-SID has to be deleted and created with new UNI type (Customer VLAN (C-VLAN), Transparent port user-network-interface (T-UNI), ELAN).
- I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or Transparent Port UNI.
- If the port is a member of MLT, the entire MLT has to be added to the VID.
- The port is always in the forwarding state.
- The same VID, port, or MLT cannot be member of more than one I-SID.
- Static MAC, Static ARP and static IGMP group are not supported on Switched UNI enabled ports.
- For a Switched UNI endpoint without a platform VLAN on the VSP 7400 Series, when MAC-in-MAC terminated traffic is sent out to the UNI endpoint the packet is re-marked based on existing QoS rules.
- On VSP 8600 Series, dynamically learned Fabric Attach announced VLAN:ISID bindings and manually configured Switched-UNI end-points are not supported on the same interface.

#### BPDU handling on S-UNI port/MLT

The switch handles Bridge Protocol Data Units (BPDUs) according to whether or not you configure a platform VLAN.

- When you configure a platform VLAN:
  - BPDUs are forwarded to the CPU by default.
  - For both the ingress and egress ports, BPDUs are not flooded in the S-UNI I-SID associated with the platform VLAN.

**Note**

If the platform VLAN is configured for the S-UNI port, you cannot enable BPDU forwarding.

- When you DO NOT configure a platform VLAN:
  - BPDUs received on untagged-traffic ports are dropped by default.
  - To flood BPDUs in its I-SID, enable BPDU forwarding under S-UNI I-SID using the command **untagged-traffic port <port no> bpdu enable**.

*SPBM sample operation—L2 VSN*

The following section shows how a SPBM network is established, in this case, a Layer 2 VSN.

1. Discover network topology

**Figure 100: SPBM topology discover**

IS-IS runs on all nodes of the SPBM domain. Since IS-IS is the basis of SPBM, the IS-IS adjacency must be formed first. After the neighboring nodes see hellos from each other they look for the same Level (Level 1) and the same area (for example, Area 2f.8700.0000.00). After the hellos are confirmed both nodes send Link State Protocol Data Units, which contain connectivity information for the SPBM node. These nodes also send copies of all other LSPs they have in their databases. This establishes a network of connectivity providing the necessary information for each node to find the best and proper path to all destinations in the network.

Each node has a system ID, which is used in the topology announcement. This same System ID also serves as the switch Backbone MAC address (B-MAC), which is used as the source and destination MAC address in the SPBM network.

2. Each IS-IS node automatically builds trees from itself to all other nodes

When the network topology is discovered and stored in the IS-IS link state database (LSDB), each node calculates shortest path trees for each source node. A unicast path now exists from every node to every other node

With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes. Multicast FIB is not produced until Layer 2 VSN services are configured and learned.

- IS-IS advertises new service communities of interest

When a new service is provisioned, its membership is flooded throughout the topology with an IS-IS advertisement.

**Figure 101: SPBM BMAC and I-SID population**

BMAC and I-SID information is flooded throughout the network to announce new I-SID memberships. In this case, VLAN 20 is mapped to I-SID 100.

**Note**

I-SIDs are only used for virtual services (Layer 2 and Layer 3 VSNs). If IP Shortcuts only is enabled on the BEBs, I-SIDs are never exchanged in the network as IP Shortcuts allow for IP networks to be transported across IS-IS.

Each node populates its FDB with the BMAC information derived from the IS-IS shortest path tree calculations. Thus there is no traditional flooding and learning mechanism in place for the B-VLAN, but FDBs are programmed by the IS-IS protocol.

- 4. When a node receives notice of a new service AND is on the shortest path, it updates the FDB

In this scenario, where there are three source nodes having a membership on I-SID 100, there are three shortest path trees calculated (not counting the Equal Cost Trees (ECTs)).

Figure 102: Shortest path tree for source node A

Figure 103: Shortest path tree for source node B

**Figure 104: Shortest path tree for source node C**

The paths between any two nodes are always the shortest paths. Also, the paths in either direction are congruent, thus a bidirectional communication stream can be monitored easily by mirroring ingress and egress on a link to a network analyzer.

VLAN traffic arriving on switch A and VLAN 20 is forwarded following the blue path, traffic arriving on switch B and VLAN 20 the orange path and on switch C VLAN 20 traffic is following the green path.

If the destination CMAC is unknown at the SPBM ingress node or the traffic is of type broadcast or multicast, then it is flooded to all members of the topology which spans VLAN 20. If the destination CMAC is already known, then the traffic is only forwarded as a unicast to the appropriate destination. In the SPBM domain, the traffic is switched on the BMAC header only. The bridge filtering database (FDB) at the VLAN to I-SID boundary (backbone edge bridge BEB), maintains a mapping between CMACs and corresponding BMACs.

For example, Switch B learns all CMACs which are on VLAN 20 connected to switch A with the BMAC of A in its FDB and the CMACs which are behind C are learned with the BMAC of C.

## Layer 2 VSN configuration using the CLI

This section provides procedures to configure Layer 2 VSNs using the CLI.

### Configure SPBM Layer 2 VSN

SPBM supports Layer 2 Virtual Service Network (VSN) functionality where customer VLANs (C-VLANs) are bridged over the SPBM core infrastructure.

At the BEBs, customer VLANs (C-VLAN) are mapped to I-SIDs based on the local service provisioning. Outgoing frames are encapsulated in a MAC-in-MAC header, and then forwarded across the core to the far-end BEB, which strips off the encapsulation and forwards the frame to the destination network based on the I-SID-to-C-VLAN provisioning.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Map a customer VLAN (C-VLAN) to a Service Instance Identifier (I-SID):

```
vlan i-sid <1-4059> <0-16777215> [force]
```

### Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in an SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

3. Display C-VLAN information:

```
show vlan i-sid
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#vlan i-sid 10 100
Switch:1(config)#show vlan i-sid

Switch:1>show vlan i-sid
=====
                Vlan I-SID
=====
VLAN_ID      I-SID      I-SID NAME
-----
```

```

1
10          100      Hospital-Server-10
90          1000     ISID-1000

3 out of 3 Total Num of Vlans displayed

```

## Variable Definitions

The following table defines parameters for the `vlan i-sid` command.

| Variable     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>     | Specifies the primary VLAN ID.<br>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <0-16777215> | Specifies the service instance identifier (I-SID).<br><br><b>Note:</b><br>The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in an SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.<br><br>This value is the same for the primary and secondary VLANs.                                            |
| <i>force</i> | Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.                                                                                                                                                                                                                                                                                                                                                                       |

### Configure a Global I-SID Name

You can configure a service name for I-SIDs, loopback interfaces, and static routes. The service name can be configured before or after the I-SID is created for the following services:

- Layer 2 VSN
- Layer 3 VSN
- ELAN I-SID or Switched UNI I-SID
- ELAN transparent I-SID or Transparent UNI I-SID
- IPv4 and IPv6 static routes
- IPv4 and IPv6 loopback CLIP interface

#### Note

The service name for I-SIDs does not support the following special characters: " " # \$ % ' / [ \ ] ^ { | } ~ @.

By default, the service is named ISID-x, where x correlates to the I-SID number of the service.

#### Note

Product Notice: For XA1400 Series, you can configure a service name for IPv4 static routes and IPv4 loopback CLIP interfaces only.

#### Note

Product Notice: This procedure does not apply to VSP 8600 Series.

### About This Task

Use this procedure to provide a descriptive name for the Service Identifier (I-SID).

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enter a name for the global I-SID.  

```
i-sid name <1-6777215> WORD<1-64>
```
3. Display I-SID names for all configured I-SIDs.  

```
show i-sid name
```
4. Display I-SID name by I-SID.  

```
show i-sid name <1-6777215>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#i-sid name 1 ExtremeServer1
Switch:1(config)#i-sid name 20 ExtremeServer7
```

View the configured I-SID names:

```
Switch:1(config)#show i-sid name
=====
I-SID Name
=====
I-SID          I-SID NAME          TYPE
-----
1              ExtremeServer1      adminName
2              ExtremeServer2      adminName
3              ExtremeServer3      config adminName
4              ISID-4              config
23             ISID-23             config
25             ExtremeServer4      config adminName

Total number of I-SID Name entries: 6.
```

View the configured I-SID by number:

```
Switch:1#show i-sid name 1
=====
I-SID Name
```

```

=====
I-SID          I-SID NAME          TYPE
-----
1              ExtremeServer1      adminName

Switch:1#show i-sid name 20
=====
                          I-SID Name
=====
I-SID          I-SID NAME          TYPE
-----
20            ExtremeServer7      adminName

```

### Variable Definitions

Use the data in the following table to use the **i-sid name** command.

| Variable                                                                               | Value                                                                                                                                                                                                                 |
|----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-6777215>                                                                            | Specifies the I-SID number.                                                                                                                                                                                           |
| WORD<1-64><br><b>Note:</b><br>This parameter does not apply to all hardware platforms. | Specifies the name of the I-SID. The I-SID can be named before or after the I-SID is created.<br>By default, for an I-SID in use, the service is named ISID-x, where x correlates to the I-SID number of the service. |

### Displaying C-VLAN I-SID information

Use the following procedure to display C-VLAN I-SID information.

#### Procedure

1. Display the C-VLAN to I-SID associations:  

```
show vlan i-sid <1-4059>
```
2. Display the IS-IS SPBM multicast-FIB calculation results by I-SID:  

```
show isis spbm i-sid {all|config|discover} [vlan <1-4059>] [id <1-16777215>] [nick-name <x.xx.xx>]
```
3. Discover where entries are learned:  

```
show vlan mac-address-entry [spbm-tunnel-as-mac]
```
4. Display the VLAN remote MAC table for a C-VLAN:  

```
show vlan remote-mac-table <1-4059>
```

#### Example

```

Switch:1>show vlan i-sid
=====
                          Vlan I-SID
=====
VLAN_ID  I-SID  I-SID NAME

### Configuring an SPBM Layer 2 Transparent Port UNI

Use this procedure to configure a Transparent Port UNI or E-LAN Transparent service.

#### Note

If you are configuring a T-UNI to terminate on a port or MLT on a switch in a vIST switch cluster, you must also configure the T-UNI I-SID on the other switch of the vIST switch cluster. You must configure the T-UNI I-SID on both switches of a vIST pair. It is not necessary to assign an actual port or MLT to the T-UNI on the second switch.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes creating the SPBM B-VLANs.
- You must associate a T-UNI LACP MLT with a VLAN before mapping the LACP MLT to a T-UNI I-SID.

#### Caution

In the case of T-UNI LACP SMLT, before you configure SMLT on switch peers, ensure that the T-UNI LACP MLT on each peer is always associated with a VLAN, even if it is the default VLAN, and that it is added to a T-UNI I-SID. Otherwise, traffic is not forwarded on the T-UNI LACP MLT.

### About This Task

You can configure Transparent Port UNI when either of the following apply:

- You want all tagged and untagged traffic on a port to be classified into the same broadcast domain.
- You want to offer a transparent provider solution.

### Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure a Transparent Port UNI (Elan-Transparent based service). Enter:

```
i-sid <1-16777215> elan-transparent
```

This command automatically takes you to the Elan-Transparent I-SID Configuration mode.

3. Add ports to the Elan-Transparent based service. Enter:

```
port {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

A warning message displays indicating that adding a port to a T-UNI I-SID removes the port from all VLANs. Click **y** when prompted, to continue.

4. Add an MLT to the Elan-Transparent based service. Enter:

```
mlt <1-512>
```

A warning message displays indicating that adding an MLT to a Transparent Port UNI I-SID removes the MLT from all VLANs. Click **y** when prompted, to continue.

5. To verify the Transparent Port UNI configuration, enter:

```
show i-sid <1-16777215>
```

6. To remove ports or MLT from the Elan-Transparent based service, enter one of the following commands:

```
no port {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

OR

```
no mlt <1-512>
```

7. To delete the Elan-Transparent based service, enter:

```
no i-sid <1-16777215>
```

### Example

Configure a Transparent Port UNI I-SID (elan-transparent based service).

```
Switch:1(config)#i-sid 3 elan-transparent

Switch:1(elan-tp:3)#port 1/25
Adding Ports to Transparent UNI i-sid removes it from all VLANs.
Do you wish to continue (y/n) ? y
Switch:1(elan-tp:3)#

Switch:1(elan-tp:3)#mlt 1
Adding MLTs to Transparent UNI i-sid removes it from all VLANs.
Do you wish to continue (y/n) ? y
Switch:1(elan-tp:3)#
```

Verify Transparent Port UNI or Elan-Transparent based service configuration.

```
Switch:1(config)#show i-sid 3

## Variable definitions

The following table defines parameters for the **i-sid** command.

### Note

When SPB is enabled, I-SID IDs 16000000 (0xF42400) and greater, up to 16,777,215 (0xFFFFF), are reserved for dynamic i-sid allocation and used to support IP Multicast traffic over SPB and other advanced Fabric services.

| Variable                                                                | Value                                                                                                       |
|-------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>i-sid &lt;1-16777215&gt; elan-transparent</code>                  | Creates an Elan-Transparent based service. The service interface identifier (I-SID) range is 1 to 16777215. |
| <code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Add ports to the Elan-Transparent based service.                                                            |
| <code>mlt &lt;1-512&gt;</code>                                          | Add MLTs to the Elan-Transparent based service. The MLT range is 1 to 512.                                  |

### View all Configured I-SIDs

Perform this procedure to view all the configured I-SIDs including their types, ports, and MLTs.

### About This Task

View all configured I-SIDs (both CVLAN and T-UNI). View also the I-SID types and the ports or MLTs that are assigned to each I-SID.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. View all configured I-SIDs. This command displays both CVLAN and T-UNI based I-SIDs.  
`show i-sid`
3. View all T-UNI (Elan-Transparent) I-SIDs.  
`show i-sid [elan-transparent]`
4. View information for a particular T-UNI I-SID.  
`show i-sid [<1-16777215>]`
5. View all IS-IS SPBM I-SID information by I-SID ID:  
`show isis spbm i-sid {all|config|discover} [vlan <2-4059>] [id <1-16777215>] [nick-name <x.xx.xx>]`

### Example

View all configured I-SIDs.

```
Switch:1(config)#show i-sid

| <code>id &lt;1-16777215&gt;</code>     | Displays I-SID information for the specified I-SID.                                                                                                                                       |
| <code>nick-name &lt;x.xx.xx&gt;</code> | Displays I-SID information for the specified nickname.                                                                                                                                    |

## View C-MACs Learned on T-UNI Ports for an I-SID

Perform this procedure to view the I-SID bridge forwarding database.

### About This Task

The **show i-sid mac-address-entry** command displays the C-MACs learned on T-UNI I-SIDs. It also displays the C-MACs learned on T-UNI I-SIDs for a specific I-SID, MAC address, port or port list or remote MAC address.

### Procedure

1. To enter User EXEC mode, log on to the switch.

- View C-MACs learned on the T-UNI I-SIDs:  

```
show i-sid mac-address-entry [<1-16777215>] [home] [mac
<0x00:0x00:0x00:0x00:0x00:0x00>] [non-local] [port {slot/port[/sub-
port]} [-slot/port[/sub-port]] [,...]] [remote]
```

**Example**

View C-MACs learned on all T-UNI I-SIDs.

```
Switch:1#show i-sid mac-address-entry

## Variable Definitions

The following table defines parameters for the **show i-sid mac-address-entry** command.

| Variable                                                                | Value                                                                                            |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| <code>&lt;1-16777215&gt;</code>                                         | Displays the MAC address learned on the service interface identifier (I-SID).                    |
| <code>home</code>                                                       | Filters the command output to show only MAC addresses learned in the home area.                  |
| <code>mac &lt;0x00:0x00:0x00:0x00:0x00:0x00&gt;</code>                  | Displays the I-SID FDB details for the specified MAC address.                                    |
| <code>non-local</code>                                                  | Filters the command output to show only MAC addresses learned from other nodes; not local nodes. |
| <code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Displays the MAC address learned on the specified port or port list.                             |
| <code>remote</code>                                                     | Filters the command output to show only MAC addresses learned in the remote area.                |

### Viewing I-SID maximum MAC-limit

Perform this procedure to view the maximum MAC learning limit information for an I-SID.

#### Important

The command **show i-sid limit-fdb-learning** is supported only on the VSP 4450 Series.

### About This Task

The total MAC learning limit per switch is 32000. MAC learning on I-SID stops when the maximum limit is reached.

### Procedure

View the maximum MAC learning limit configured for an I-SID:

```
show i-sid limit-fdb-learning <1-16777215>
```

### Example

View maximum MAC learning limit for all I-SIDs.

```
Switch:1#show i-sid limit-fdb-learning

### Variable definitions

The following table defines parameters for the **show i-sid limit-fdb-learning** command.

#### Important

The command **show i-sid limit-fdb-learning** is supported only on the VSP 4450 Series.

| Variable                  | Value                                                                                |
|---------------------------|--------------------------------------------------------------------------------------|
| <i>limit-fdb-learning</i> | Displays the I-SID-based maximum MAC limit information.                              |
| <1-6777215>               | Displays the service interface identifier (I-SID). The I-SID range is 1 to 16777215. |

### Configure an SPBM Layer 2 Switched UNI on an MLT

Shortest Path Bridging MAC (SPBM) supports Layer 2 Virtual Service Network (VSN) functionality where Switched UNIs are bridged over the SPBM core infrastructure.

Switched User Network Interface (S-UNI) allows the association of local endpoints to I-SIDs based on local port and VLAN together. With Switched UNI, the same VLAN can be used on one port to create an endpoint to one I-SID, and on another port to create an endpoint to another I-SID.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

#### About This Task

To configure a Switched UNI on an MLT, you must create a Switched UNI I-SID, and map an MLT to the Switched UNI I-SID.

#### Note

When you configure Switched UNI, Spanning tree is disabled on all the Switched UNI ports.

#### Procedure

1. Enter MLT Interface Configuration mode:

```
enable

configure terminal

interface mlt <1-512>
```

2. Enable S-UNI on MLT:

```
flex-uni enable
```

#### Note

You cannot enable Switched UNI on EAPoL enabled interface.

3. Configure a Switched UNI Service Instance Identifier (I-SID):

```
i-sid <1-16777215> [elan]
```

This command automatically takes you to the Elan I-SID Configuration mode.

4. Add an MLT to a Switched UNI I-SID:

```
c-vid <c-vid> mlt <1-512>
```

#### Note

You can run this command again to map a Switched UNI MLT to multiple I-SIDs.

5. Add untagged traffic to a Switched UNI I-SID:

```
untagged-traffic mlt <1-512> [bpdu enable]
```

6. Display the Switched UNI information:

```
show mlt i-sid
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#mlt 10
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#flex-uni enable
Switch:1(config-mlt)#i-sid 100
Switch:1(elan:100)#c-vid 20 mlt 10
Switch:1(elan:100)#untagged-traffic mlt 10 bpdu enable
Switch:1(elan:100)#show mlt i-sid
```

```

**Variable definitions**

The following table defines parameters for the **i-sid** command to configure a Switched UNI.

| Variable                                    | Value                                                                                                                                                               |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| i-sid <l-16777215> elan                     | Creates an Elan based service. The service interface identifier (I-SID) range is 1 to 16777215.                                                                     |
| c-vid <c-vid> mlt <mlt-id>                  | Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch. |
| untagged-traffic mlt <mlt-id> [bpdu enable] | Add untagged traffic to the Elan-based service.                                                                                                                     |

*Configuring an SPBM Layer 2 Switched UNI on a Port*

Shortest Path Bridging MAC (SPBM) supports Layer 2 Virtual Service Network (VSN) functionality where Switched UNIs are bridged over the SPBM core infrastructure.

**Note**

EAP and FA can co-exist on the same port. EAP and FA can be enabled in any order; however, EAP must have Flex UNI enabled in order to function on an FA-enabled port. If EAP is currently enabled, FA can only be enabled if the port is a Flex UNI-enabled port. VSP 4450 Series, VSP 8600 Series, or XA1400 Series do not support EAP and FA on the same port.

## Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

## About This Task

To configure a Switched UNI on a port, you must create a Switched UNI I-SID, and map the port to the Switched UNI I-SID.

### Note

When you configure Switched UNI, Spanning tree is disabled on all the Switched UNI ports.

## Procedure

- Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Enable Switched UNI on a port:

```
flex-uni enable
```

### Note

You cannot enable EAP on a Switched UNI (S-UNI) on the VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

- Configure a Switched UNI Service Instance Identifier (I-SID):

```
i-sid <1-16777215> [elan]
```

This command automatically takes you to the Elan I-SID Configuration mode.

- Add ports to a Switched UNI I-SID:

```
c-vid <c-vid> port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

- Add untagged traffic to a Switched UNI I-SID:

```
untagged-traffic port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} [bpdu enable]
```

- Display the Switched UNI information:

```
show interface gigabitethernet i-sid {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

## Examples

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Switch:1(config)#interface gigabitEthernet 1/1,1/2
Switch:1(config-if)#flex-uni enable
Switch:1(config-if)#i-sid 100
Switch:1(elan:100)#c-vid 10 port 1/1,1/2
Switch:1(elan:100)#untagged-traffic port 1/1,1/2 bpdu enable
```

**Note**

Not all fields are supported on all hardware platforms.

```
Switch:1#show interface gigabitEthernet i-sid
```

```

### Variable Definitions

The following table defines parameters for the **i-sid** command.

| Variable                                             | Value                                                       |
|------------------------------------------------------|-------------------------------------------------------------|
| elan                                                 | Displays only all the Elan (S-UNI based) I-SIDs.            |
| MLT ID <1-512>                                       | Specifies the MLT associated with the Switched UNI I-SID.   |
| {slot/port[/sub-port] [-slot/port[/sub-port]][,...]} | Specifies the ports associated with the Switched UNI I-SID. |

### Display C-VLAN and Switched UNI I-SID Information

Use the following procedure to display C-VLAN and Switched UNI (S-UNI) I-SID information.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the C-VLAN to I-SID associations:  

```
show vlan i-sid <1-4059>
```
3. Display I-SID information and Switched UNI to I-SID associations:  

```
show i-sid <1-16777215>
```
4. Display the IS-IS SPBM multicast-FIB calculation results by I-SID:  

```
show isis spbm i-sid {all|config|discover} [vlan <1-4059>] [id <1-16777215>] [nick-name <x.xx.xx>]
```

5. Display all elan I-SID:
  - show i-sid elan
6. Display I-SID configured on MLT:
  - show mlt i-sid
7. Display I-SID configured on port:
  - show interfaces gigabitethernet i-sid

**Examples**

```
Switch# show isis spbm i-sid all

## Layer 2 VSN configuration using EDM

This section provides procedures to configure Layer 2 Virtual Services Networks (VSNs) using Enterprise Device Manager (EDM).

### Configuring SPBM Layer 2 VSN

After you have configured the SPBM infrastructure, you can enable the SPBM Layer 2 Virtual Service Network (VSN) using the following procedure.

SPBM supports Layer 2 VSN functionality where customer VLANs (C-VLANs) are bridged over the SPBM core infrastructure.

At the BEBs, customer VLANs (C-VLAN) are mapped to I-SIDs based on the local service provisioning. Outgoing frames are encapsulated in a MAC-in-MAC header, and then forwarded across the core to the far-end BEB, which strips off the encapsulation and forwards the frame to the destination network based on the I-SID-to-C-VLAN provisioning.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.

### Procedure

- In the navigation pane, expand **Configuration > VLAN**.
- Click **VLANs**.
- Click the **Advanced** tab.
- To map a C-VLAN to a Service instance identifier (I-SID), in the **I-sid** field, specify the I-SID to associate with the specified VLAN.

- Click **Apply**.

#### Important

- When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.
- The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in an SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

#### *Displaying the remote MAC table for a C-VLAN*

Use the following procedure to view a the remote MAC table for a C-VLAN.

#### Procedure

- In the navigation pane, expand **Configuration > VLAN**.
- Click **VLANs**.
- Click the **Remote MAC** tab.

#### Remote MAC field descriptions

Use the data in the following table to use the **Remote MAC** tab.

| Name                        | Description                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>               | Indicates the VLAN ID for this MAC address.                                                          |
| <b>Addr</b>                 | Indicates the customer MAC address for which the bridge has forwarding and/or filtering information  |
| <b>DestAddr</b>             | Indicates the provider MAC address for which the bridge has forwarding and/or filtering information. |
| <b>PrimaryBVlanId</b>       | Indicates the primary B-VLAN ID for this MAC address.                                                |
| <b>PrimaryDestSysName</b>   | Indicates the primary system name of the node where the MAC address entry comes from.                |
| <b>PrimaryPort</b>          | Either displays the value 0, or indicates the primary port on which a frame came from.               |
| <b>SecondaryBVlanId</b>     | Indicates the secondary B-VLAN ID for this MAC address                                               |
| <b>SecondaryDestSysName</b> | Indicates the secondary system name of the node where the MAC address entry comes from.              |
| <b>SecondaryPort</b>        | Either displays the value 0, or indicates the secondary port on which a frame came from.             |

| Name              | Description                                                                                                                                                         |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SmItRemote</b> | Indicates the MAC address entry for the remote vIST peer.                                                                                                           |
| <b>Status</b>     | Indicates the status of this entry: <ul style="list-style-type: none"> <li>• other</li> <li>• invalid</li> <li>• learned</li> <li>• self</li> <li>• mgmt</li> </ul> |

### Configure UNI

Use the following procedure to configure a Transparent Port UNI or Switched UNI by mapping an I-SID to a port or MLT and VLAN together.

#### Note

If you are configuring a T-UNI to terminate on a port or MLT on a switch in a vIST switch cluster, you must also configure the T-UNI I-SID on the other switch of the vIST switch cluster. You must configure the T-UNI I-SID on both switches of a vIST pair. It is not necessary to assign an actual port or MLT to the T-UNI on the second switch.

### About This Task

You must first create a type of service instance identifier (I-SID) to create the different types of services available. After you create an I-SID you can add members (ports or MLTs) to the I-SID to create end-points for the service.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **ISID**.
3. Click the **Service** tab.
4. To create a Transparent Port UNI service:
  - a. Click **Insert**.
  - b. Select **elan Transparent** in the **Type** field.
  - c. Enter the I-SID in the **Id** field.
5. To create a Switched UNI service:

#### Note

Flex UNI must be enabled to create a Switched UNI service.

- a. Click **Insert**.
  - b. Select **elan** in the **Type** field.
  - c. Enter the I-SID in the **Id** field.
6. Click **Insert**.

### Service Field Descriptions

Use the data in the following table to use the **Service** tab.

| Name                                                                                    | Description                                                                    |
|-----------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| <b>ID</b>                                                                               | Specifies a unique value to identify the service associated with this entry.   |
| <b>Type</b>                                                                             | Specifies the type of service associated with this entry.                      |
| <b>MacLimitEnable</b>                                                                   | Indicates whether the MAC limit is enabled (true) or disabled (false).         |
| <b>MaxMacLimit</b>                                                                      | Indicates the maximum learned value of the MAC address for each service I-SID. |
| <b>Action</b>                                                                           | Specifies I-SID related actions.                                               |
| <b>OriginBitMap</b>                                                                     | Specifies the origin of the I-SID.                                             |
| <b>VnId</b>                                                                             | Identifies the VXLAN service associated with this I-SID.                       |
| <b>Name</b><br><br><b>Note:</b><br>This field does not apply to all hardware platforms. | Specifies the name of the I-SID.                                               |

#### *Associate a Port and MLT with an I-SID for Elan Transparent*

Transparent Port UNI (T-UNI) maps a port or MLT to an I-SID. Transparent Port UNI configures a transparent port where all traffic is MAC switched on an internal virtual port using the assigned I-SID. Multiple ports on the same unit and on other Backbone Edge Bridges (BEBs) are switched on a common I-SID. No VLAN is involved in this process. The T-UNI port is not a member of any VLAN or STG.

Use the following procedure to associate a port and MLT with an I-SID.

#### **Before You Begin**

- You must configure Transparent Port UNI. For more information, see [Configuring Transparent UNI](#).
- You must associate a T-UNI LACP MLT with a VLAN before mapping the LACP MLT to a T-UNI I-SID.

#### **Caution**

Ensure that a T-UNI LACP MLT is always associated with a VLAN (even if it is the default VLAN) before adding it to a T-UNI I-SID. Otherwise, traffic is not forwarded on the T-UNI LACP MLT.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **ISID**.
3. On the **Service** tab, select a row with the type configured as elanTransparent.
4. Select **ELAN**.
5. Select port members.
6. Select MLT Ids.
7. Select **Apply**.

## Elan Transparent field descriptions

Use the data in the following table to use the Elan Transparent tab.

| Name        | Description                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| PortMembers | The set of ports that are members of the elanTransparent service type. From the ports available, you can select single or multiple ports.            |
| MltIds      | The set of bits that represent the MLT Ids. From the MLTs available, you can select any, or all of the MLTs to be a part of elan transparent i-sid . |

### Viewing the I-SID forwarding database

View the I-SID forwarding database (FDB).

#### Note

To view the T-UNI I-SID FDB entries filtered on a port that is part of an MLT, you must mention the MLT ID in the option for the port.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **ISID**.
3. Select the **FDB** tab.
4. (Optional) Select the **Filter** button to filter rows based on specific filter criteria.

## FDB Field Descriptions

Use data in the following table to use the **FDB** tab.

| Name                        | Description                                                                                                    |
|-----------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>IsidId</b>               | Specifies the service interface identifier (I-SID).                                                            |
| <b>Address</b>              | Specifies the MAC address of the port assigned to the specific I-SID or C-MAC learned on the particular I-SID. |
| <b>Status</b>               | Specifies the learning status of the associated MAC.                                                           |
| <b>Port</b>                 | Specifies the port on which the MAC is learned for the specific I-SID.                                         |
| <b>PortType</b>             | Specifies if the MAC address is learned locally or on an NNI port from a remote destination.                   |
| <b>RemoteMacDestAddr</b>    | Specifies the virtual B-MAC address or system-ID of the remote destination.                                    |
| <b>RemoteMacBVlanId</b>     | Specifies the B-VLAN ID on which the remote destination was discovered.                                        |
| <b>RemoteMacDestSysName</b> | Specifies the remote destination system name.                                                                  |
| <b>Cvid</b>                 | Specifies the customer VLAN ID of the associated Switched UNI port.                                            |

### Associate a Port and MLT with an I-SID for Elan

Shortest Path Bridging MAC (SPBM) supports Layer 2 Virtual Service Network (VSN) functionality where Switched UNIs are bridged over the SPBM core infrastructure.

Switched User Network Interface (S-UNI) allows the association of local endpoints to I-SIDs based on local port and VLAN together. With switched UNI, the same VLAN can be used on one port to create an endpoint to one I-SID, and on another port to create an endpoint to another I-SID.

Use the following procedure to associate a port and MLT with an I-SID.

### About This Task

You must configure Switched UNI.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **ISID**.
3. On the **Service** tab, select a row with the type configured as elan.
4. Select **Switched Uni**.
5. Select **Insert**.
6. Enter the VLAN ID in the **Cvid** field.
7. Select **Port** or **Mlt** to update the interface index in the **IfIndex** field.
8. Select **Insert**.

### Switched Uni field descriptions

Use the data in the following table to use the **Switched Uni** tab.

| Name                | Description                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------|
| <b>Isid</b>         | Displays the I-SID.                                                                              |
| <b>Cvid</b>         | Specifies the customer VLAN identifier.                                                          |
| <b>IfIndex</b>      | Specifies the interface index of the Elan end point.                                             |
| <b>Bpdu</b>         | Enables or disables for an untagged end point. The default is disabled.                          |
| <b>OriginBitmap</b> | Specifies the origin information of the service associated with the I-SID Elan end point.        |
| <b>MacBased</b>     | Shows if the current entry is associated to a MAC-based Switched User Network Interface (S-UNI). |

### Viewing the I-SID interface

View the I-SID interface.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **ISID**.
3. Click the **Interface** tab.  
Click **Filter** to filter rows on specific filter criteria.

### Interface field descriptions

Use the data in the following table to use the **Interface** tab.

| Name                | Description                                                              |
|---------------------|--------------------------------------------------------------------------|
| <b>IfIndex</b>      | Specifies the interface index.                                           |
| <b>Isid</b>         | Specifies the service interface identifier (I-SID).                      |
| <b>Isid Name</b>    | Specifies the service interface identifier name.                         |
| <b>Vlan</b>         | Specifies the platform VLAN.                                             |
| <b>Cvid</b>         | Specifies the customer VID.                                              |
| <b>Type</b>         | Specifies the type of service associated with the I-SID interface.       |
| <b>OriginBitMap</b> | Specifies the origin of the service associated with the I-SID interface. |
| <b>Bpdu</b>         | Specifies the BPDU forward option for the untagged traffic port.         |
| <b>MacBased</b>     | Specifies the Switched UNI MAC address.                                  |

### Modify Global I-SID Name

#### About This Task

Use this procedure to modify the assigned name for the Service Identifier (I-SID).

#### Note

Product Notice: For XA1400 Series, you can modify a service name for IPv4 static routes and IPv4 loopback CLIP interfaces only. For information about feature support, see [VOSS Feature Support Matrix](#).

#### Note

This procedure is not supported on VSP 8600 Series.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **ISID**.
3. Select **Global Name**.
4. View the name of the I-SID in the **ISID Name** field. To modify, double-click the name of the I-SID and type a new name.
5. Select **Apply**.

## Global Name Field Descriptions

Use the data in the following table to use the **Global Name** tab.

| Name              | Description                                                                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISID Id</b>    | Specifies the index number that uniquely identifies the I-SID.                                                                                                                      |
| <b>ISID Name</b>  | Specifies the name of the I-SID, which can be up to 64 characters. This field is not supported on all hardware platforms.                                                           |
| <b>UsedByType</b> | Specifies the I-SIDs that are in use as services. An I-SID can have one base type or a combination of base types so that multiple services can use the same I-SID at the same time. |

## Layer 2 VSN configuration examples

This section provides configuration examples to configure Layer 2 VSNs.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

### Layer 2 VSN Configuration Example

The following figure shows a sample Layer 2 VSN deployment.

**Figure 105: Layer 2 VSN**

The following sections show the steps required to configure the Layer 2 VSN parameters in this example. You must first configure basic SPBM and IS-IS infrastructure. For more information, see: [SPBM configuration examples](#) on page 1218.

### SwitchC

```
VLAN CONFIGURATION

vlan create 10 type port-mstprstp 1
vlan members 10 1/1 portmember
vlan i-sid 10 12990010
```

### SwitchD

```
VLAN CONFIGURATION

vlan create 10 type port-mstprstp 1
```

```
vlan members 10 1/1 portmember
vlan i-sid 10 12990010
```

### Verifying Layer 2 VSN operation

The following sections show how to verify the Layer 2 VSN operation in this example.

#### SwitchC

```
Switch# show isis spbm i-sid all

### Layer 2 VSN Example with VLAN ID Translation

The following figure shows a sample Layer 2 VSN deployment where the C- VLAN IDs are different at each end. You must first configure basic SPBM and IS-IS infrastructure. For more information, see [SPBM configuration examples](#) on page 1218.

**Figure 106: Layer 2 VSN with different VLAN IDs**

The following sections show the steps required to configure the Layer 2 VSN parameters in this example.

#### SwitchC

##### VLAN CONFIGURATION

```
vlan create 9 type port 1
vlan members 9 1/1 portmember
vlan i-sid 9 9
```

#### SwitchD

##### VLAN CONFIGURATION

```
vlan create 19 type port 1
vlan members 19 1/1 portmember
vlan i-sid 19 9
```

## Inter-VSN Routing Configuration

**Table 109: Inter-VSN Routing product support**

| Feature                  | Product         | Release introduced |
|--------------------------|-----------------|--------------------|
| Inter-VSN routing (IPv4) | 5420 Series     | VOSS 8.4           |
|                          | 5520 Series     | VOSS 8.2.5         |
|                          | VSP 4450 Series | VSP 4000 4.0       |
|                          | VSP 4900 Series | VOSS 8.1           |
|                          | VSP 7200 Series | VOSS 4.2.1         |
|                          | VSP 7400 Series | VOSS 8.0           |
|                          | VSP 8200 Series | VSP 8200 4.0       |
|                          | VSP 8400 Series | VOSS 4.2           |
|                          | VSP 8600 Series | VSP 8600 6.1       |
|                          | XA1400 Series   | VOSS 8.0.50        |

**Table 109: Inter-VSN Routing product support (continued)**

| Feature                  | Product         | Release introduced |
|--------------------------|-----------------|--------------------|
| Inter-VSN routing (IPv6) | 5420 Series     | VOSS 8.4           |
|                          | 5520 Series     | VOSS 8.2.5         |

## Inter-VSN routing configuration fundamentals

This section provides fundamental concepts on Inter-VSN Routing.

### Inter-VSN routing

Inter-VSN routing with SPBM allows routing between Layer 2 VLANs with different I-SIDs.

**Figure 107: Inter-VSN routing**

Inter-VSN routing provides a routing hub for Layer 2 Virtual Services Network edge devices, Layer 3 devices, routers, or hosts connected to the SPBM cloud using the SPBM Layer 2 VSN service. To go between a routed network, a Layer 2 VSN termination point provides the routing services to hop onto another Layer 2 VSN, using I-SID.

#### Note

The Layer 2 VLANs must be in the same VRF. You cannot route traffic between two different VRFs with Inter-VSN routing.

In this example, the C-VLANs are associated with I-SIDs on the BEBs using SPBM Layer 2 VSN. With Inter-VSN routing enabled, BCB C can route traffic between VLAN 11 (I-SID 2011) and VLAN 12 (I-SID 2012).

IP interfaces are where the routing instance exists. In this case, on Switch-20.

#### Note

The switch does not support IP multicast over Fabric Connect routing on inter-VSN routing interfaces.

## Inter-VSN routing configuration using the CLI

This section provides a procedure to configure Inter-VSN routing using the CLI.

### Configure SPBM Inter-VSN Routing

Inter-VSN allows you to route between IP networks on Layer 2 VLANs with different I-SIDs. Inter-VSN routing is typically used only when you have to extend a VLAN as a Layer 2 Virtual Services Network (VSN) for applications such as vMotion. As a best practice, use IP Shortcuts or Layer 3 VSNs to route traffic. You must configure both the Backbone Edge Bridges (BEBs) and the Backbone Core Bridge (BCB).

#### Note

To enable inter-VSN routing, you must configure IP interface where the routing instance exists.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Follow the procedures below on the Backbone Edge Bridges (BEBs) containing the VSNs you want to route traffic between.
  - Create a customer VLAN (C-VLAN) by port:
 

```
vlan create <2-4059> type port-mstprstp <0-63>
```
  - Add ports in the C-VLAN:
 

```
vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

- c. Map a customer VLAN (C-VLAN) to a Service Instance Identifier (I-SID):

```
vlan i-sid <1-4059> <0-16777215> [force]
```

#### Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

3. On the Backbone Core Bridge (BCB), create a VRF and add a VLAN for each VSN:

- a. Create a VRF:

```
ip vrf WORD<1-16> vrfid <1-511>
```

- b. Create a VLAN to associate with each VSN:

```
vlan create <2-4059> type port-mstprstp <0-63>
```

- c. Enter VLAN Interface Configuration mode:

```
interface vlan <1-4059>
```

- d. Add a VLAN to the VRF you created in step a:

```
vrf WORD<1-16>
```

- e. Associate an I-SID with the VLAN:

```
vlan i-sid <1-4059> <0-16777215> [force]
```

#### Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in an SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

- f. Configure an IP address for the VLAN:

```
ip address {A.B.C.D/X}
```

- g. Repeat steps b to f for every VLAN you want to route traffic between.

### Variable Definitions

The following table defines parameters for the **vlan create** command.

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <2-4059>                                                   | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <i>type port-mstprstp</i> <0-63><br><i>[color</i> <0-32> ] | Creates a VLAN by port: <ul style="list-style-type: none"> <li>• &lt;0-63&gt; is the STP instance ID.</li> <li>• <i>color</i> &lt;0-32&gt; is the color of the VLAN.</li> </ul>                                                                                                                                                                                                    |

The following table defines parameters for the **vlan members add** command.

| Variable                                                                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                                                                              | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| { <i>slot/port</i> [/<br><i>sub-port</i> ] [-<br><i>slot/port</i> [/<br><i>sub-port</i> ]]<br>[,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

The following table defines parameters for the **vlan i-sid** command.

| Variable     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>     | Specifies the primary VLAN ID.<br>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <0-16777215> | Specifies the service instance identifier (I-SID). You cannot use I-SID 0x00ffffff. The system reserves this I-SID to advertise the virtual BMAC in an SMLT dual-homing environment.<br>This value is the same for the primary and secondary VLANs.                                                                                                                                                                                                          |
| <i>force</i> | Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.                                                                                                                                                                                                                                                                                                                                                                       |

The following table defines parameters for the **ip vrf** command.

| Variable             | Value                                                    |
|----------------------|----------------------------------------------------------|
| <i>WORD</i> <1-16>   | Create the VRF and specify the name of the VRF instance. |
| <i>vrfid</i> <1-511> | Specifies the VRF instance by number.                    |

The following table defines parameters for the **vrf** command.

| Variable           | Value                                               |
|--------------------|-----------------------------------------------------|
| <i>WORD</i> <1-16> | Specifies the VRF name. Associates a port to a VRF. |

The following table defines parameters for the **ip address** command.

| Variable             | Value                                  |
|----------------------|----------------------------------------|
| { <i>A.B.C.D/X</i> } | Configures an IP address for the VLAN. |

## Inter-VSN routing configuration using EDM

This section provides procedures to configure Inter-VSN routing using Enterprise Device Manager (EDM).

### Configure BEBs for Inter-VSN Routing

Inter-VSN allows you to route between IP networks on Layer 2 VLANs with different I-SIDs. Inter-VSN routing is typically used only when you have to extend a VLAN as a Layer 2 Virtual Services Network (VSN) for applications such as vMotion. Use IP Shortcuts or Layer 3 VSNs to route traffic. You must configure both the Backbone Edge Bridges (BEBs) and the Backbone Core Bridge (BCB).

#### Note

To enable inter-VSN routing, you must configure the IP interface where the routing instance exists.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

### About This Task

Follow the procedures below on the Backbone Edge Bridges (BEBs) that contain the VSNs you want to route traffic between.

### Procedure

- Create a customer VLAN (C-VLAN) by port and add ports in the C-VLAN. In the navigation pane, expand **Configuration > VLAN**.
- Click **VLANs**.
- In the **Basic** tab, click **Insert**.
- In the **Id** box, enter an unused VLAN ID, or use the ID provided.

5. In the **Name** box, type the VLAN name, or use the name provided.
6. In the **Color Identifier** box, click the down arrow and choose a color from the list, or use the color provided.
7. In the **Type** box, select **byPort**.
8. In the **PortMembers** box, click the **(...)** button.
9. Click on the ports to add as member ports.  
The ports that are selected are recessed, while the nonselected ports are not recessed. Port numbers that are dimmed cannot be selected as VLAN port members.
10. Click **OK**.
11. Click **Insert**.
12. Collapse the **VLANS** tab.  
The VLAN is added to the Basic tab.
13. Map a C-VLAN to an I-SID. In the navigation pane, expand **Configuration > VLAN**.
14. Click **VLANS**.
15. Click the **Advanced** tab.
16. To map a C-VLAN to an I-SID, in the **Isid** field, specify the I-SID to associate with the specified VLAN.  
The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in a SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.
17. Click **Apply**.

#### Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

18. Configure the Backbone Core Bridge (BCB) for Inter-VSN Routing. For more information, see [Configuring BCBs for Inter-VSN Routing](#) on page 1314.

### Advanced Field Descriptions

Use the data in the following table to use the **Advanced** tab.

| Name        | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>   | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>Name</b> | Specifies the name of the VLAN.                                                                                                                                                                                                                                                                                                                                                                                            |

| Name                                                                                         | Description                                                                                                                                                                                                                                             |
|----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>                                                                               | Specifies the logical interface index assigned to the VLAN.                                                                                                                                                                                             |
| <b>Type</b>                                                                                  | Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul>                                                                                                 |
| <b>Isid</b>                                                                                  | Specifies the I-SID number assigned to a customer VLAN (C-VLAN). The range is 0 - 16777215. The default value is 0, which indicates that no I-SID is assigned.                                                                                          |
| <b>Isid Name</b><br><br><b>Note:</b><br>This field does not apply to all hardware platforms. | Specifies the name of the I-SID.                                                                                                                                                                                                                        |
| <b>ProtocolId</b>                                                                            | Specifies the network protocol for protocol-based VLANs.<br>If the VLAN type is not protocol-based, None is displayed in the Basic tab ProtocolId field.                                                                                                |
| <b>AgingTime</b>                                                                             | Specifies the timeout period for dynamic VLAN membership. A potential VLAN port is made ACTIVE after it receives a packet that matches the VLAN; if no such packet is received for AgingTime seconds, the port is no longer active. The default is 600. |
| <b>MacAddress</b>                                                                            | Specifies the MAC address assigned to the virtual router interface for this VLAN. This field is relevant only after the VLAN is configured for routing. This MAC address is used as the Source MAC in routed frames and ARP replies.                    |

| Name                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Vlan Operation Action</b>     | <p>Performs an operation on the VLAN. The values are:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• flushMacFdb: Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN.</li> <li>• flushArp: Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN.</li> <li>• flushIp: Configures action to flushIp. This action removes the learned IP addresses from the forwarding table for the selected VLAN.</li> <li>• flushDynMemb: Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN and removes MAC addresses learned on those ports.</li> <li>• all: Configures action to all. This action performs all the supported actions; it does not perform the Snoop-related actions.</li> </ul> <p>The default is none.</p> |
| <b>Result</b>                    | Specifies the result code after you perform an action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>NlbMode</b>                   | Enables or disables Microsoft Network Load Balancing (NLB) operations on the VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SpbMulticast</b>              | Enables or disables Multicast over Fabric Connect. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SpbPimGatewayMulticast</b>    | Enables or disables SPB-PIM Gateway Multicast on a VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>RmonEnable</b>                | Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Ipv6FhsSnoopDhcpEnable</b>    | Enables or disables IPv6 dhcp snooping on a VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Ipv6FhsNDInspectionEnable</b> | Enables or disables neighbor discovery (ND) inspection on a VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DvrEnable</b>                 | <p>Enables or disables DvR on a VLAN that is configured on the DvR Controller. The default is disabled.</p> <p><b>Note:</b><br/>You must enable DvR on every VLAN that is configured on a DvR Controller.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Name                  | Description                                                                                                                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DvrGwIpv4Addr</b>  | Specifies the DvR gateway IPv4 address for a VLAN.<br><br><b>Important:</b><br>Ensure that you configure the same gateway IPv4 address on all Controllers in the DvR domain that belong to a VLAN. |
| <b>DvrGwIpv4Onelp</b> | Enables or disables the DvR One IP for a VLAN. The default is disabled (false).                                                                                                                    |

### Basic Field Descriptions

Use the data in the following table to use the **Basic** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>               | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <b>Name</b>             | Specifies the name of the VLAN.                                                                                                                                                                                                                                                                                                                                                    |
| <b>IfIndex</b>          | Specifies the logical interface index assigned to the VLAN.                                                                                                                                                                                                                                                                                                                        |
| <b>Color Identifier</b> | Specifies a proprietary color scheme to associate a color with the VLAN. Color does not affect how frames are forwarded.                                                                                                                                                                                                                                                           |
| <b>Type</b>             | Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul>                                                                                                                                                                                                                            |
| <b>MstpInstance</b>     | Identifies the MSTP instance.                                                                                                                                                                                                                                                                                                                                                      |
| <b>VrfId</b>            | Indicates the Virtual Router to which the VLAN belongs.                                                                                                                                                                                                                                                                                                                            |
| <b>VrfName</b>          | Indicates the name of the Virtual Router to which the VLAN belongs.                                                                                                                                                                                                                                                                                                                |
| <b>PortMembers</b>      | Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.                                                                                                                                                                                                                                                                          |
| <b>ActiveMembers</b>    | Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.                                                                                                                                                                                                                                                                          |

| Name                  | Description                                                                                                                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>StaticMembers</b>  | Specifies the slot/port of each static member of a policy-based VLAN. The system displays the sub-port only for channelized ports.                                                                                            |
| <b>NotAllowToJoin</b> | Specifies the slot/ports that are never allowed to become a member of the policy-based VLAN. The system displays the sub-port only for channelized ports.                                                                     |
| <b>ProtocolId</b>     | Specifies the network protocol for protocol-based VLANs. This value is taken from the Assigned Numbers of remote function call (RFC).<br>If the VLAN type is port-based, none is displayed in the Basic tab ProtocolId field. |
| <b>AgingTime</b>      | Specifies the timeout period, in seconds, to age out dynamic members of this VLAN. This field only applies to policy-based VLANs.<br>The default is 600.                                                                      |

#### Note

If you or another user changes the name of an existing VLAN using the VLAN **Basic** tab (or using CLI), the system does not display the new name initially in EDM. To display the updated name, perform one of the following actions:

- Refresh your browser to reload EDM.
- Log out of EDM and log in again to restart EDM.
- Click **Refresh** in the VLAN **Basic** tab toolbar. If the system displays the old VLAN name in other tabs, click **Refresh** on those tabs as well.

### Configuring BCBs for Inter-VSN Routing

Inter-VSN allows you to route between IP networks on Layer 2 VLANs with different I-SIDs. Inter-VSN routing is typically used only when you have to extend a VLAN as a Layer 2 Virtual Services Network (VSN) for applications such as vMotion. Use IP Shortcuts to route traffic. You must configure both the Backbone Edge Bridges (BEBs) and the Backbone Core Bridge (BCB).

#### Note

To enable inter-VSN routing, you must configure the IP interface where the routing instance exists.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must configure the Backbone Edge Bridges (BEBs) containing the VSNs you want to route traffic between. For more information, see [Configure BEBs for Inter-VSN Routing](#) on page 1309.

### About This Task

Follow the procedures below to configure the Backbone Core Bridge (BCB) for inter-VSN routing.

## Procedure

1. On the Backbone Core Bridge (BCB), create a VRF. In the navigation pane, expand **Configuration > IP**.
2. Click **VRF**.
3. Click **Insert**.
4. Specify the VRF ID.
5. Name the VRF instance.
6. Configure the other parameters as required.
7. Click **Insert**.
8. Create a VLAN to associate with each VSN. In the navigation pane, expand **Configuration > VLAN**.
9. Click **VLANs**.
10. In the **Basic** tab, click **Insert**.
11. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
12. In the **Name** box, type the VLAN name, or use the name provided.
13. In the **Color Identifier** box, click the down arrow and choose a color from the list, or use the color provided.
14. In the **Type** box, select **byPort**.
15. In the **PortMembers** box, click the **(...)** button.
16. Click on the ports to add as member ports.

The ports that are selected are recessed, while the nonselected ports are not recessed. Port numbers that are dimmed cannot be selected as VLAN port members.
17. Click **OK**.
18. Click **Insert**.
19. Collapse the **VLANs** tab.

The VLAN is added to the **Basic** tab.
20. Associate the VLAN with an I-SID. In the navigation pane, expand **Configuration > VLAN**.
21. Click **VLANs**.
22. In the VLANs tab, click the **Advanced** tab.
23. In the **I-sid** box, specify the I-SID to associate with the VLAN.
24. Click **Apply**.
25. Configure a circuitless IP interface (CLIP). In the navigation pane, expand **Configuration > IP**.
26. Click **IP**.
27. Click the **Circuitless IP** tab.
28. Click **Insert**.
29. In the **Interface** field, assign a CLIP interface number.
30. Enter the IP address.
31. Enter the network mask.
32. Click **Insert**.

## VRF field descriptions

Use the data in the following table to help you use the **VRF** tab.

| Name                       | Description                                                                                                                                                                                                       |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                  | Specifies the ID number of the VRF instance. VRF ID 0 is reserved for the GlobalRouter.                                                                                                                           |
| <b>Name</b>                | Names the VRF instance.                                                                                                                                                                                           |
| <b>ContextName</b>         | Identifies the VRF. The SNMPv2 Community String or SNMPv3 contextName denotes the VRF context and is used to logically separate the MIB module management.                                                        |
| <b>TrapEnable</b>          | Enables the VRF to send VRF Lite-related traps (VrfUp and VrfDown). The default is true.                                                                                                                          |
| <b>MaxRoutes</b>           | Configures the maximum number of routes allowed for the VRF. The maximum value varies per platform. See <a href="#">VOSS Release Notes</a> for platform-specific scaling information. The default value is 10000. |
| <b>MaxRoutesTrapEnable</b> | Enables the generation of the VRF Max Routes Exceeded traps. The default is true.                                                                                                                                 |

Advanced field descriptions

Use the data in the following table to use the **Advanced** tab.

| Name                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                                                            | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>Name</b>                                                          | Specifies the name of the VLAN.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>IfIndex</b>                                                       | Specifies the logical interface index assigned to the VLAN.                                                                                                                                                                                                                                                                                                                                                                |
| <b>Type</b>                                                          | Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul>                                                                                                                                                                                                                                                                    |
| <b>Isid</b>                                                          | Specifies the I-SID number assigned to a customer VLAN (C-VLAN). The range is 0 - 16777215. The default value is 0, which indicates that no I-SID is assigned.                                                                                                                                                                                                                                                             |
| <b>Isid Name</b>                                                     | Specifies the name of the I-SID.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Note:</b><br>This field does not apply to all hardware platforms. |                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ProtocolId</b>             | Specifies the network protocol for protocol-based VLANs.<br>If the VLAN type is not protocol-based, None is displayed in the Basic tab ProtocolId field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>AgingTime</b>              | Specifies the timeout period for dynamic VLAN membership. A potential VLAN port is made ACTIVE after it receives a packet that matches the VLAN; if no such packet is received for AgingTime seconds, the port is no longer active. The default is 600.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>MacAddress</b>             | Specifies the MAC address assigned to the virtual router interface for this VLAN. This field is relevant only after the VLAN is configured for routing. This MAC address is used as the Source MAC in routed frames and ARP replies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Vlan Operation Action</b>  | <p>Performs an operation on the VLAN. The values are:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• flushMacFdb: Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN.</li> <li>• flushArp: Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN.</li> <li>• flushIp: Configures action to flushIp. This action removes the learned IP addresses from the forwarding table for the selected VLAN.</li> <li>• flushDynMemb: Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN and removes MAC addresses learned on those ports.</li> <li>• all: Configures action to all. This action performs all the supported actions; it does not perform the Snoop-related actions.</li> </ul> <p>The default is none.</p> |
| <b>Result</b>                 | Specifies the result code after you perform an action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>NlbMode</b>                | Enables or disables Microsoft Network Load Balancing (NLB) operations on the VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SpbMulticast</b>           | Enables or disables Multicast over Fabric Connect. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SpbPimGatewayMulticast</b> | Enables or disables SPB-PIM Gateway Multicast on a VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>RmonEnable</b>             | Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Name                             | Description                                                                                                                                                                                           |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Ipv6FhsSnoopDhcpEnable</b>    | Enables or disables IPv6 dhcp snooping on a VLAN. The default is disabled.                                                                                                                            |
| <b>Ipv6FhsNDInspectionEnable</b> | Enables or disables neighbor discovery (ND) inspection on a VLAN. The default is disabled.                                                                                                            |
| <b>DvrEnable</b>                 | Enables or disables DvR on a VLAN that is configured on the DvR Controller. The default is disabled.<br><br><b>Note:</b><br>You must enable DvR on every VLAN that is configured on a DvR Controller. |
| <b>DvrGwIpv4Addr</b>             | Specifies the DvR gateway IPv4 address for a VLAN.<br><br><b>Important:</b><br>Ensure that you configure the same gateway IPv4 address on all Controllers in the DvR domain that belong to a VLAN.    |
| <b>DvrGwIpv4OneIp</b>            | Enables or disables the DvR One IP for a VLAN. The default is disabled (false).                                                                                                                       |

Circuitless IP field descriptions

Use the data in the following table to use the **Circuitless IP** tab.

| Name              | Description                                                    |
|-------------------|----------------------------------------------------------------|
| <b>Interface</b>  | Specifies the number assigned to the interface, from 1 to 256. |
| <b>Ip Address</b> | Specifies the IP address of the CLIP.                          |
| <b>Net Mask</b>   | Specifies the network mask.                                    |

### Basic Field Descriptions

Use the data in the following table to use the **Basic** tab.

| Name           | Description                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>      | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <b>Name</b>    | Specifies the name of the VLAN.                                                                                                                                                                                                                                                                                                                                                    |
| <b>Ifindex</b> | Specifies the logical interface index assigned to the VLAN.                                                                                                                                                                                                                                                                                                                        |

| Name                    | Description                                                                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Color Identifier</b> | Specifies a proprietary color scheme to associate a color with the VLAN. Color does not affect how frames are forwarded.                                                                                                   |
| <b>Type</b>             | Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul>                                                                    |
| <b>MstpInstance</b>     | Identifies the MSTP instance.                                                                                                                                                                                              |
| <b>VrfId</b>            | Indicates the Virtual Router to which the VLAN belongs.                                                                                                                                                                    |
| <b>VrfName</b>          | Indicates the name of the Virtual Router to which the VLAN belongs.                                                                                                                                                        |
| <b>PortMembers</b>      | Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.                                                                                                                  |
| <b>ActiveMembers</b>    | Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.                                                                                                                  |
| <b>StaticMembers</b>    | Specifies the slot/port of each static member of a policy-based VLAN. The system displays the sub-port only for channelized ports.                                                                                         |
| <b>NotAllowToJoin</b>   | Specifies the slot/ports that are never allowed to become a member of the policy-based VLAN. The system displays the sub-port only for channelized ports.                                                                  |
| <b>ProtocolId</b>       | Specifies the network protocol for protocol-based VLANs. This value is taken from the Assigned Numbers of remote function call (RFC). If the VLAN type is port-based, none is displayed in the Basic tab ProtocolId field. |
| <b>AgingTime</b>        | Specifies the timeout period, in seconds, to age out dynamic members of this VLAN. This field only applies to policy-based VLANs. The default is 600.                                                                      |

#### Note

If you or another user changes the name of an existing VLAN using the VLAN **Basic** tab (or using CLI), the system does not display the new name initially in EDM. To display the updated name, perform one of the following actions:

- Refresh your browser to reload EDM.
- Log out of EDM and log in again to restart EDM.
- Click **Refresh** in the VLAN **Basic** tab toolbar. If the system displays the old VLAN name in other tabs, click **Refresh** on those tabs as well.

## Inter-VSN Routing Configuration Example

The following topics provide a configuration example for Inter-VSN routing.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

### Inter-VSN Routing with SPBM Configuration Example

The following figure shows a sample Inter-VSN deployment.

**Figure 108: Inter-VSN routing configuration**

The following sections show the steps required to configure the Inter-VSN parameters in this example. You must first configure basic SPBM and IS-IS infrastructure. For more information, see: [SPBM configuration examples](#) on page 1218.

Note that the IP interfaces are configured where the routing instance exists, namely, on SwitchG.

#### SwitchC

```
VLAN CONFIGURATION

vlan create 11 type port-mstprstp 1
vlan members 11 1/2 portmember
vlan i-sid 11 12990011
```

#### SwitchG

## SPBM Reference Architectures

### Reference Architectures

SPBM has a straightforward architecture that simply forwards encapsulated C-MACs across the backbone. Because the B-MAC header stays the same across the network, there is no need to swap a label or perform a route lookup at each node. This architecture allows the frame to follow the most efficient forwarding path from end to end.

The following reference architectures illustrate SPBM with multiple switches in a network.

For information about solution-specific architectures like Video Surveillance or Data Center implementation using the VSP switch, see [Solution-Specific Reference Architectures](#) on page 1332.

The following figure shows the MAC-in-MAC SPBM domain with BEBs on the boundary and BCBs in the core.

The following figure illustrates an existing edge that connects to an SPBM core.

The boundary between the MAC-in-MAC SPBM domain and the 802.1Q domain is handled by the BEBs. At the BEBs, VLANs or VRFs are mapped into I-SIDs based on the local service provisioning. Services (whether Layer 2 or Layer 3 VSNs) only need to be configured at the edge of the SPBM backbone (on the BEBs). There is no provisioning needed on the core SPBM nodes.

Provisioning an SPBM core is as simple as enabling SPBM and IS-IS globally on all the nodes and on the core facing links. To migrate an existing edge configuration into an SPBM network is just as simple.

**Figure 109: SPBM basic architecture**

**Figure 110: Access to the SPBM Core**

All BEBs that have the same I-SID configured can participate in the same VSN. That completes the configuration part of the migration and all the traffic flows return to normal operation.

For Layer 3 virtualized routing (Layer 3 VSN), map IPv4-enabled VLANs to VRFs, create an IP VPN instance on the VRF, assign an I-SID to the VRF, and then configure the desired IP redistribution of IP routes into IS-IS.

For Layer 2 virtualized bridging (Layer 2 VSN), identify all the VLANs that you want to migrate into SPBM and assign them to an I-SID on the BEB.

### *Campus Architecture*

For migration purposes, you can add SPBM to an existing network that has SMLT configured. In fact, if there are other protocols already running in the network, such as Open Shortest Path First (OSPF), you can leave them in place too. SPBM uses IS-IS, and operates independently from other protocols. However, as a best practice, eliminate SMLT in the core and eliminate other unnecessary protocols. This reduces the complexity of the network and makes it much simpler to maintain and troubleshoot.

Whether you configure SMLT in the core, the main point to remember is that SPBM separates services from the infrastructure. For example, in a large campus, a user may need access to other sites or data centers. With SPBM you can grant that access by associating the user to a specific I-SID. With this mechanism, the user can work without getting access to confidential information of another department.

The following figure depicts a topology where the BEBs in the edge and data center distribution nodes are configured in SMLT clusters. Prior to implementing SPBM, the core nodes would also have been configured as SMLT clusters. When migrating SPBM onto this network design, it is important to note that you can deploy SPBM over the existing SMLT topology without network interruption. After the SPBM infrastructure is in place, you can create VSN services over SPBM or migrate them from the previous end-to-end SMLT-based design.

**Figure 111: SPBM campus without SMLT**

After you migrate all services to SPBM, the customer VLANs (C-VLANs) will exist only on the BEB SMLT clusters at the edge of the SPBM network. The C-VLANs will be assigned to an I-SID instance and then associated with either a VLAN in an Layer 2 VSN or terminated into a VRF in an Layer 3 VSN. You can also terminate the C-VLAN into the default router, which uses IP shortcuts to IP route over the SPBM core.

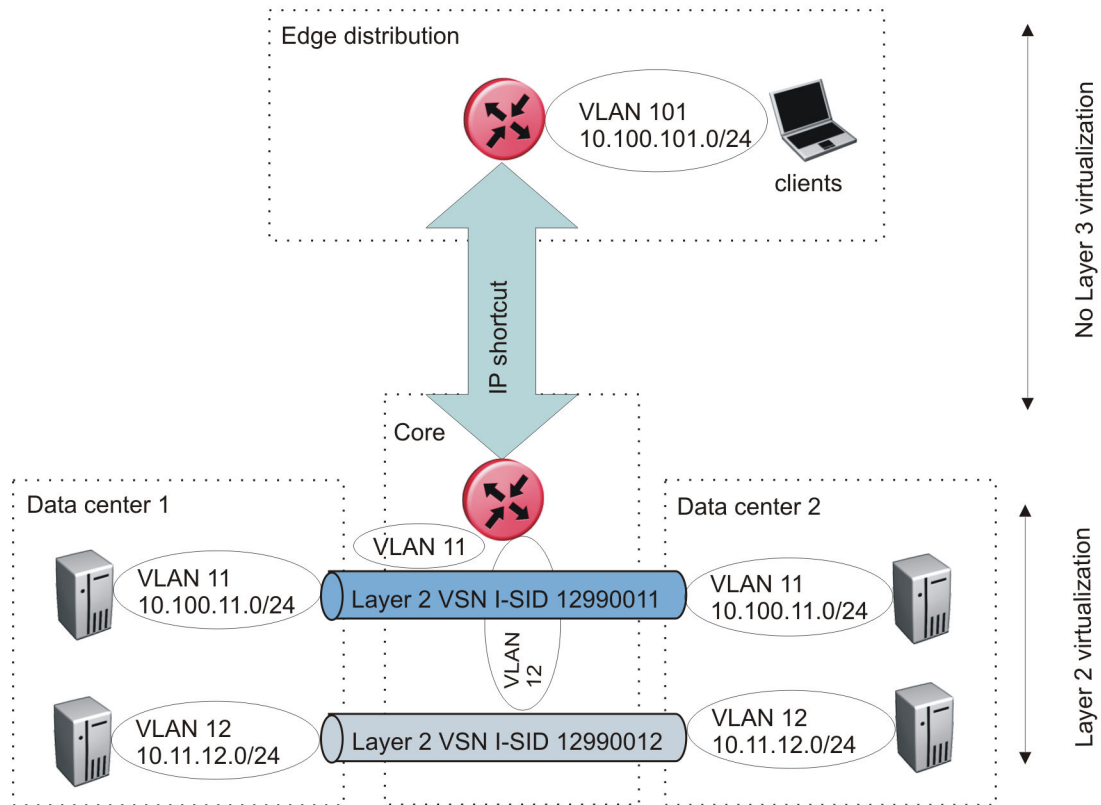

In an SPBM network design, the only nodes where it makes sense to have an SMLT cluster configuration is on the BEB nodes where VSN services terminate. These are the SPBM nodes where C-VLANs exist and these C-VLANs need to be redundantly extended to non-SPBM devices such as Layer 2 edge stackable switches. On the BCB core nodes where no VSNs are terminated and no Layer 2 edge stackables are connected, there is no longer any use for the SMLT clustering functionality. Therefore, in the depicted SPBM design, the SMLT/vIST configuration can be removed from the core nodes because they now act as pure BCBs that simply transport VSN traffic and the only control plane protocol they need to run is IS-IS.

Because SMLT BEB nodes exist in this design (the edge BEBs) and it is desirable to use equal cost paths to load balance VSN traffic across the SPBM core, all SPBM nodes in the network are configured with the same two B-VIDs.

Where the above figure shows the physical topology, the following two figures illustrate a logical rendition of the same topology. In both of the following figures, you can see that the core is almost identical. Because the SPBM core just serves as a transport mechanism that transmits traffic to the destination BEB, all the provisioning is performed at the edge.

In the data center, VLANs are attached to Inter-VSNs that transmit the traffic across the SPBM core between the data center on the left and the data center on the right. A common application of this service is VMotion moving VMs from one data center to another.

The following figure uses IP shortcuts that route VLANs. There is no I-SID configuration and no Layer 3 virtualization between the edge distribution and the core. This is normal IP forwarding to the BEB.

**Figure 112: IP shortcut scenario to move traffic between data centers**

The following figure uses Layer 3 VSNs to route VRFs between the edge distribution and the core. The VRFs are attached to I-SIDs and use Layer 3 virtualization.

**Figure 113: VRF scenario to move traffic between data centers**

*Large data center architecture*

SPBM supports data centers with IP shortcuts, Layer 2 VSNs, or Layer 3 VSNs. If you use vMotion, you must use Layer 2 between data centers (Layer 2 VSN). With Layer 2 VSNs, you can add IP addresses to the VLAN on both data centers and run Virtual Router Redundancy Protocol (VRRP) between them to allow the ESX server to route to the rest of the network.

The following figure shows an SPBM topology of a large data center. This figure represents a full-mesh data center fabric using SPBM for storage over Ethernet. This topology is optimized for storage transport because traffic never travels more than two hops.

**Note**

As a best practice, use a two-tier, full-mesh topology for large data centers.

**Figure 114: SPBM data center—full mesh**

#### Traditional data center routing of VMs

In a traditional data center configuration, the traffic flows into the network to a VM and out of the network in almost a direct path.

The following figure shows an example of a traditional data center with VRRP configured. Because end stations are often configured with a static default gateway IP address, a loss of the default gateway router causes a loss of connectivity to the remote networks. VRRP eliminates the single point of failure that can occur when the single static default gateway router for an end station is lost.

**Figure 115: Traditional routing before moving VMs**

A VM is a virtual server. When you move a VM, the virtual server is moved as is. This action means that the IP addresses of that server remain the same after the server is moved from one data center to the other. This in turn dictates that the same IP subnet (and hence VLAN) exist in both data centers.

In the following figure, the VM moved from the data center on the left to the data center on the right. To ensure a seamless transition that is transparent to the user, the VM retains its network connections through the default gateway. This method works, but it adds more hops to all traffic. As you can see in the figure, one VM move results in a complicated traffic path. Multiply this with many moves and soon the network look like a tangled mess that is very inefficient, difficult to maintain, and almost impossible to troubleshoot.

**Figure 116: Traditional routing after moving VMs**

#### Optimized data center routing of VMs

Two features make a data center optimized:

- VLAN routers in the Layer 2 domain (green icons)
- VRRP BackupMaster

The VLAN routers use lookup tables to determine the best path to route incoming traffic (red dots) to the destination VM.

VRRP BackupMaster solves the problem of traffic congestion on the vIST. Because there can be only one VRRP Master, all other interfaces are in backup mode. In this case, all traffic is forwarded over the vIST link towards the primary VRRP switch. All traffic that arrives at the VRRP backup interface is forwarded, so there is not enough bandwidth on the vIST link to carry all the aggregated riser traffic. VRRP BackupMaster overcomes this issue by ensuring that the vIST trunk is not used in such a case for primary data forwarding. The VRRP BackupMaster acts as an IP router for packets destined for the logical VRRP IP address. All traffic is directly routed to the destined subnetwork and not through Layer 2 switches to the VRRP Master. This avoids potential limitation in the available vIST bandwidth.

The following figure shows a solution that optimizes your network for bidirectional traffic flows. However, this solution turns two SPBM BCB nodes into BEBs where MAC and ARP learning will be enabled on the Inter-VSN routing interfaces. If you do not care about top-down traffic flows, you can omit the Inter-VSN routing interfaces on the SPBM BCB nodes. This makes the IP routed paths top-down less optimal, but the BCBs remain pure BCBs, thus simplifying core switch configurations.

**Figure 117: Optimized routing before moving VMs**

In the traditional data center, chaos resulted after many VMs were moved. In an optimized data center as shown in the following figure, the incoming traffic enters the Layer 2 domain where an edge switch uses Inter-VSN routing to attach an I-SID to a VLAN. The I-SID bridges traffic directly to the destination. With VRRP BackupMaster, the traffic no longer goes through the default gateway; it takes the most direct route in and out of the network.

**Figure 118: Optimized routing after moving VMs**

## Solution-Specific Reference Architectures

The following sections describe solution-specific reference architectures, like for example for Video Surveillance or Data Center implementation, using the VSP 4450 Series.

### *Multi-tenant — fabric connect*

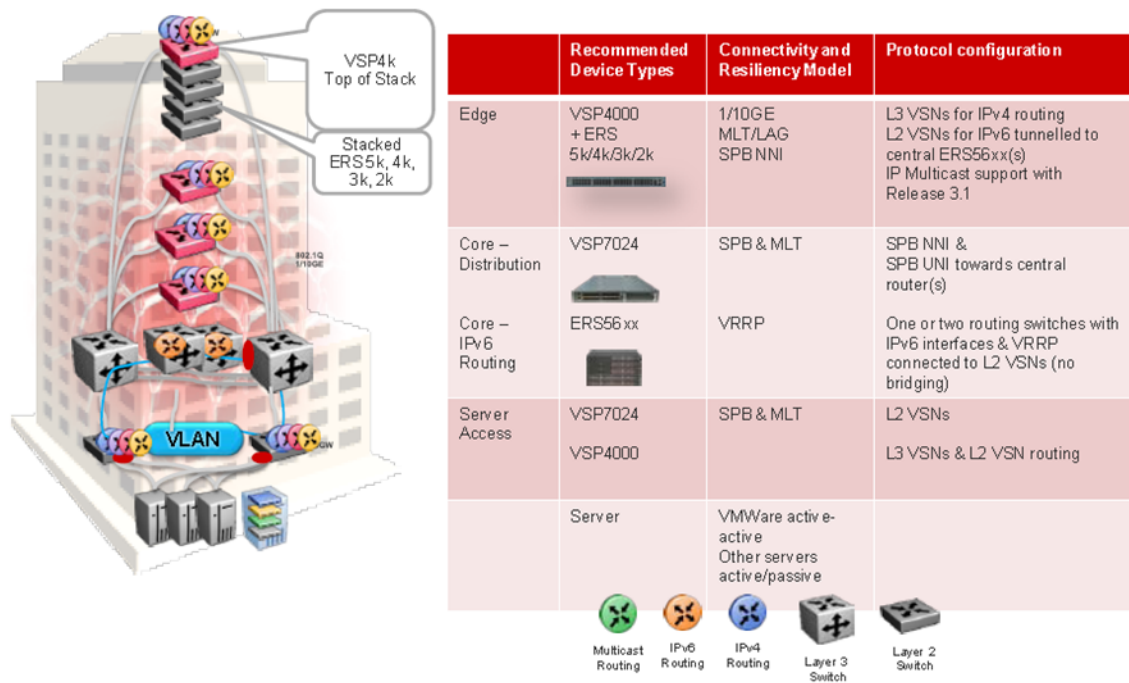

This fabric connect-based solution leverages the fabric capabilities of the VSP platforms: a VSP 7000 core and a VSP 4450 Series edge. This solution provides the ability to run, by default, up to 24 VRFs for each wiring closet and is well suited for multi-tenant applications. The zero-touch core is enabled by the fabric connect endpoint provisioning capabilities.

#### Note

You can increase VRF scaling to run more than 24 VRFs. The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [VOSS Release Notes](#).

If this solution must support IPv6, then a central router-pair routes all IPv6 traffic. The IPv6 traffic is tunneled from each wiring closet to the IPv6 routers by extending Layer 2 VSNs to the q-tagged router interfaces.

**Figure 119: Small core – multi-tenant**

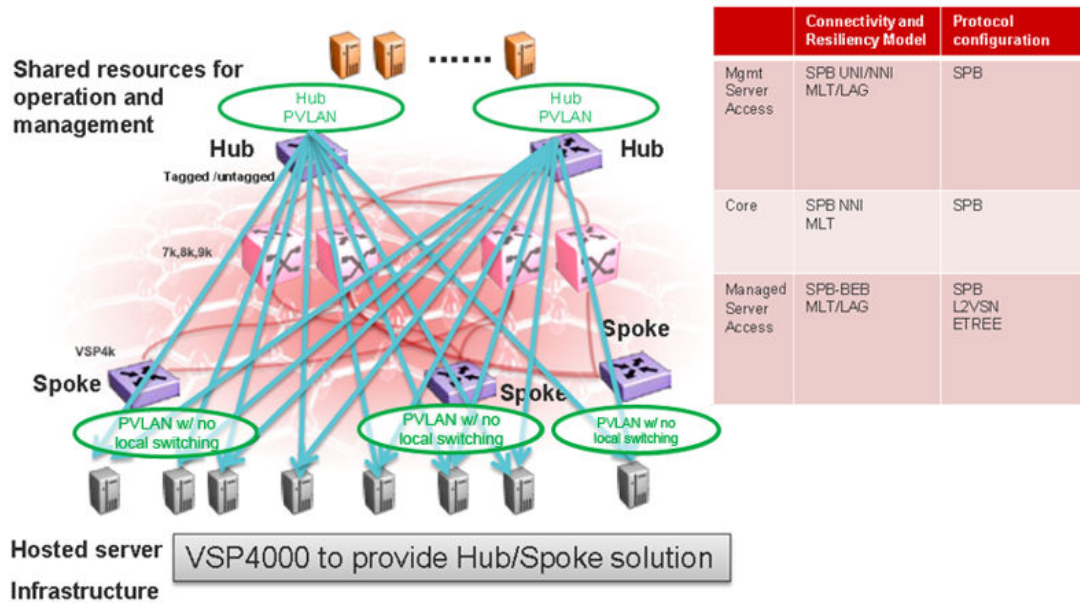

The following list outlines the benefits of the fabric connect-based solution:

- Endpoint provisioning
- Fast failover
- Simple to configure
- Layer 2 and Layer 3 virtualized

#### *Hosted data center management solution – E-Tree*

In some hosted data center solutions, the hosting center operating company takes responsibility for managing customer servers. For this shared management, shown in the following figure, servers that control the operating system level of the production servers, such as the patch level, are deployed. Because customer production servers do not communicate with each other, a distributed private VLAN solution based on fabric connect is deployed to manage all production servers. This solution builds a distributed set of E-Trees for each management domain.

The VSP switches as access, provide an elegant network-wide E-Tree solution. Spokes, or managed servers, cannot communicate to each other over this network, but the shared management servers on the hub ports can access all spokes. Because of the Layer 2 – E-Tree nature of this setup, the managed servers do not require any route entries, and only require one IP interface in this management private VLAN. This solution supports tagged and untagged physical and virtual (VM) servers.

**Figure 120: Data center hosting private VLAN**

The following list outlines the benefits of the hosted data center management solution:

- Easy endpoint provisioning
- Optimal resiliency
- Secure tenant separation

*Video surveillance – bridged*

In a video surveillance solution, optimal traffic forwarding is a key requirement to ensure proper operation of the camera and recorder solutions. However, signaling is also important to ensure quick channel switching. This is achieved by deploying a fabric connect based IP multicast infrastructure that is optimized for multicast transport, so that the cameras can be selected quickly, and so that there is no unnecessary traffic sent across the backbone.

**Figure 121: Deployment scenario — bridged video surveillance and IP camera deployment for transportation, airports, and government**

The following list outlines the benefits of the bridged video surveillance solution:

- Easy end-point provisioning
- sub second resiliency and mc forwarding
- secure tenant separation
- quick camera switching

#### *Video surveillance — routed*

In a video surveillance solution, optimal traffic forwarding is a key requirement to ensure proper operation of the camera and recorder solutions. However, signaling is also important to ensure quick channel switching. This is achieved by deploying an IP multicast infrastructure that is optimized for multicast transport, so that the cameras can be selected quickly, and so that there is no unnecessary traffic sent across the backbone. In the topology shown in the following figure, each camera is attached to its own IP subnet. In a larger topology, this can reduce network overhead. To increase network scalability, you can attach a set of cameras to a Layer 2 switch that has IGMP, and then connect the cameras to the fabric edge (BEB) which has a routing instance.

In many customer scenarios, surveillance must be separated from the rest of the infrastructure. This can be achieved by deploying a Layer 3 VSN for the surveillance traffic to keep the surveillance traffic isolated from any other tenant.

**Figure 122: Deployment scenario — Routed video surveillance and IP camera deployment for transportation, airports, and government**

The following list outlines the benefits of the routed video surveillance solution:

- Easy endpoint provisioning
- Optimal resiliency and mc forwarding
- Secure tenant separation
- Rapid channel/camera switching

#### *Metro-Ethernet Provider solution*

VOSS switches provide an end-to-end Metro-Ethernet Provider solution. Leveraging fabric connect throughout the infrastructure enables a scalable and flexible wholesale provider infrastructure.

This use case extends the Transparent Port UNI functionality to transparently forward any customer VLAN across the services.

**Figure 123: Metro ring access solution**

The following list outlines the benefits of the Metro-Ethernet Provider solution:

- Easy endpoint provisioning
- Optimal resiliency
- Secure tenant separation

## IP Shortcuts configuration fundamentals

This section provides fundamental concepts for IP Shortcuts.

Fabric Connect supports both IPv4 Shortcuts and IPv6 Shortcuts. Because IPv6 Shortcuts depend on IPv4 Shortcuts, you should understand how IPv4 Shortcuts work (see [SPBM IP shortcuts](#)) before jumping to the IPv6 section.

### *SPBM IP Shortcuts*

In addition to Layer 2 virtualization, the SPBM model is extended to also support Routed SPBM, otherwise called SPBM IP Shortcuts.

Unlike Layer 2 VSN, with SPBM IP shortcuts, no I-SID configuration is required. Instead, SPBM nodes propagate Layer 3 reachability as “leaf” information in the IS-IS LSPs using Extended IP reachability TLVs (TLV 135), which contain routing information such as neighbors and locally configured subnets. SPBM nodes receiving the reachability information can use this information to populate the routes to the announcing nodes. All TLVs announced in the IS-IS LSPs are grafted onto the shortest path tree (SPT) as leaf nodes.

The following figure shows a network running SPBM IP shortcuts.

**Figure 124: SPBM IP Shortcuts**

In this example, BEB A receives a packet with a destination IP address in the subnet of VLAN 14 and knows to forward the packet to BEB D based on the IP route propagation within IS-IS. After a route lookup, BEB A knows that BEB D is the destination for the subnet and constructs a new B-MAC header with destination B-MAC: D. BCBs B and C need only perform normal Ethernet switching to forward the packet to BEB D. A route lookup is only required once, at the source BEB, to identify BEB D as the node that is closest to the destination subnet.

In contrast to IP routing or Multiprotocol Label Switching (MPLS), SPBM IP shortcuts provide a simpler method of forwarding IP packets in an Ethernet network using the preestablished Ethernet FIBs on the BEBs. SPBM allows a network to make the best use of routing and forwarding techniques, where only the BEBs perform an IP route lookup and all other nodes perform standard Ethernet switching based on the existing SPT. This allows for end to end IP-over-Ethernet forwarding without the need for ARP, flooding, or reverse learning.

In the above example, the SPBM nodes in the core that are not enabled with IP shortcuts can be involved in the forwarding of IP traffic. Since SPBM nodes only forward on the MAC addresses that comprise the B-MAC header, and since unknown TLVs in IS-IS are relayed to the next hop but ignored locally, SPBM nodes need not be aware of IP subnets to forward IP traffic.

With IP shortcuts, there is only one IP routing hop, as the SPBM backbone acts as a virtualized switching backplane.

The following figure shows a sample campus network implementing SPBM IP shortcuts.

**Figure 125: SPBM IP shortcuts in a campus**

To enable IP shortcuts on the BEBs, you can configure a circuitless IP address (loopback address) and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 135.

In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct, static, OSPF, RIP, or BGP routes into IS-IS. To advertise IPv6 routes from the BEBs into the SPBM network, you must enable route redistribution of IPv6 direct, IPv6 static, and OSPFv3 routes into IS-IS.

### *SPBM IPv6 Shortcuts*

Both IPv4 and IPv6 Shortcuts use IS-IS as the Interior Gateway Protocol (IGP) and the link state packet (LSP) for reachability information. However, IPv4 Shortcuts use TLV 135 and IPv6 Shortcuts use TLV 236. All TLVs announced in the IS-IS LSPs are grafted onto the shortest path tree (SPT) as leaf nodes. IS-IS

transports the IPv6 reachability information to remote BEBs and uses the shortest path, calculated by SPBM, for data forwarding.

**Note**

You only configure the IPv6 address information on the edges. There is no IPv6 in the SPBM cloud.

IS-IS transports the IPv6 routes through TLV 236 in the LSP advertisements. These routes are installed in the Global Routing Table (GRT) with the node from which the LSPs carrying the IPv6 routes are received as the next hop.

**IPv6 Shortcuts Dependency on IPv4 Shortcuts**

IPv6 Shortcuts function in a very similar manner to IPv4 Shortcuts and depends on IPv4 Shortcuts for some functions. For example, IPv6 Shortcuts use the BMAC (local and remote) information created by IPv4 Shortcuts.

**Important**

**IPv4 Shortcuts must be enabled before you enable IPv6 Shortcuts.**

An error is displayed if you try to enable IPv6 Shortcuts but do not have IPv4 Shortcuts already enabled.

IPv6 Shortcuts alone can be disabled while leaving IPv4 Shortcuts enabled. When IPv4 Shortcuts is disabled without disabling IPv6 Shortcuts disabled first, a warning or error message is displayed indicating that IPv6 should be disabled first.

**Circuitless IPv6 (CLIPv6)**

To enable IPv6 Shortcuts on the BEBs and to advertise the local BEB to other IS-IS nodes, you must configure a circuitless IPv6 address (loopback address) and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 236.

IPv6 Shortcuts support Circuitless IPv6 (CLIPv6), which ensures uninterrupted connectivity to the switch as long as there is an actual path to reach it. This route always exists and the circuit is always up because there is no physical attachment.

**Migrating the GRT to IPv6 Shortcuts**

Use the following steps to migrate the Global Router Table (GRT) to use IPv6 Shortcuts over the SPBM core:

- Identify the nodes that should be enabled with IPv6 Shortcuts. Apply these steps to all of these nodes.
- Activate and validate basic IPv6 Shortcuts. For information, see [SPBM IPv6 Shortcuts](#) on page 1341.
- Configure IS-IS route preference to ensure that the IPv6 IGP protocol currently being used in the SPBM core is preferred over the IS-IS routes.
- Enable redistribution of direct and static IPv6 routes into IS-IS.
- Create route policies to permit only IPv6 IGP routes from the access side of the SPBM network.
- Configure redistribution of routes from the IPv6 route table from each of the IPv6 IGP protocols into IS-IS along with the appropriate route policy.

- Use the **show isis spbm ipv6-unicast-fib** command to check the IS-IS LSDB, IS-IS routes, and to verify that all the desired IPv6 routes are now in IS-IS.
- Configure redistribution of IS-IS routes from the IPv6 route table into each of the IPv6 IGP protocols in use. This redistribution does not require a route policy since IS-IS is only supported in the SPBM core.
- Change IS-IS route-preference to ensure that IS-IS routes are preferred over other IPv6 IGP routes.
- Disable/delete old IPv6 IGP in the SPBM core.

### Important

Use only one IPv6 routing protocol in the SPBM core to prevent the possibility of routing loops.

### IPv6 Shortcut Limitations and Considerations

The following features are not supported:

- Disabling and enabling alternate routes for IPv6 routes
- Redistribution of RIP into IS-IS
- 6-in-4 tunnels are not supported when the tunnel destination IP is reachable via IPv4 Shortcuts route.

Keep the following considerations in mind when configuring IPv6 Shortcuts:

- IPv4 Shortcuts must be enabled before enabling IPv6 Shortcuts.
- IPv6 Shortcuts support Circuitless IPv6 (CLIPv6) with the following limitations:
  - Stateless address autoconfiguration (SLAAC) is not supported on IPv6 CLIP interfaces.
  - IPv6 CLIP does not support link-local address configuration.
  - To configure an IPv6 address with a prefix length from 65 to 127 on a CLIP interface, you must enable the IPv6 mode flag.

#### Note

This limitation does not apply to VSP 4450 Series switches.

- Neighbor discovery (ND) does not run on an IPv6 CLIP interface. Therefore, the system does not detect when you configure a duplicate IPv6 address.
- Multiple IPv6 address configuration on an IPv6 CLIP interface is not supported.
- You can configure a maximum of 64 IPv6 CLIP interfaces.
- IPv6 CLIP interface is enabled by default and it cannot be disabled.
- IPv6 with vIST provides the same support as IPv4 with vIST.
- To help with debugging, CFM provides full support for both IPv4 and IPv6 addresses for the **12ping** and **12traceroute** commands.

### ECMP with IS-IS

The Equal Cost Multipath (ECMP) feature supports and complements the IS-IS protocol.

With ECMP, the switch can determine multiple equal-cost paths to the same destination prefix.

You can use multiple paths for load sharing of traffic. These multiple paths allow faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use your links between routers more efficiently when sending IP and IPv6 traffic. Equal Cost Multipath is formed using routes from the same protocol.

The number of multiple paths a switch can support differs by hardware platform. For more information about feature support, see [VOSS Release Notes](#).

### ECMP within IS-IS routes

Equal Cost Multipath (ECMP) allows the device to determine up to eight equal cost paths to the same destination prefix. The maximum number of equal cost paths you can configure depends on the hardware platform. For more information, see [VOSS Release Notes](#).

If the device learns the same route from multiple sources, the information is ECMP only if the routes:

- are from the same VSN
- have the same SPBM cost
- have the same prefix cost
- have the same IP route preference

Multiple BEBs can announce the same route, either because the Layer 2 LAN connects to multiple BEBs for redundancy, or because segments of the LAN are Layer 2 bridged. In Layer 2, if the device has to tie-break between multiple sources, the tie-breaking is based on cost and hop count.

In Layer 3, hop count is not used for tie-breaking. Instead, the device uses the following precedence rules to tie-break. In the following order, the device prefers:

1. Routes that do not include nodes with the overload bit set.

When a router node runs out of system resources (memory or CPU), it alerts the other routers in the network by setting the overload bit in its link-state packets (LSPs). When this bit is set, the node is not used for transit traffic but only for traffic packets destined to the node's directly connected networks and IP prefixes.

2. Local routes over remote routes.

If a route is learned locally, for example, through inter-VRF route leaking, it is most preferred.

3. Routes with the lowest route preference.

By default, IS-IS routes within the same VSN are added to the LSDB with a default preference of 7. Inter-VSN routes are added to the LSDB with a route preference of 200. You can however, change the route preference using IS-IS accept policies.

4. Metric type internal (type 1) over metric type external (type 2).
5. Routes with the lowest SPBM cost.
6. Routes with the lowest prefix cost.

If the metric type is internal, then the tie-break is on SPB cost first, and then on the prefix cost. Otherwise the tie-break is only on the prefix cost.

You can either change this using a route-map on the remote advertising node with the **redistribute** command, or using a route-map on the local node with the IS-IS accept policy.

7. Routes within a VSN with a lower Layer 3 VSN I-SID.

The device considers the Global Routing Table (GRT) to have an I-SID equal to zero.

When you use multiple B-VLANs in the SPBM core, multiple paths exist to reach a particular SPBM node, one on each B-VLAN; therefore, any IP prefix or IPv6 prefix that the device receives from a BEB results in multiple ECMP paths. These paths may or may not be physically diverse. SPBM supports up to two B-VLANs; a primary B-VLAN and a secondary B-VLAN.

If more ECMP paths are available than the configured number of paths, then the device adds the routes using the following order: The device selects all routes from the primary B-VLAN and orders the routes learned through that B-VLAN from lowest system ID to the highest IS-IS system ID, then the device moves on to select all routes from the secondary B-VLAN, ordering those routes from lowest IS-IS system ID to the highest IS-IS system ID until you reach the number of equal paths configured.

For example, consider an SPB core configured with two B-VLANs (primary B-VLAN 1000 and secondary B-VLAN 2000), and the device learns routes from two BEBs called BEB-A (with a lower IS-IS system ID) and BEB-B (with a higher IS-IS system ID), then the order in which the next-hop is chosen for those routes are as follows.

If a route is learned only from BEB-A with the maximum number of allowed ECMP paths configured as 8 (default), then the order in which the next-hop is chosen for that route is:

1. BEB-A B-VLAN 1000
2. BEB-A B-VLAN 2000

If routes are learned from both BEB-A and BEB-B with maximum number of allowed ECMP paths configured as 8 (default), then the order in which the next-hop is chosen for those routes are:

1. BEB-A B-VLAN 1000
2. BEB-B B-VLAN 1000
3. BEB-A B-VLAN 2000
4. BEB-B B-VLAN 2000

If ECMP is disabled, the maximum number of allowed ECMP paths is 1 and the device adds the route from the lowest system ID with the primary B-VLAN. In this example, the device adds BEB-A B-VLAN 1000.

#### Note

- ECMP is supported for IPv6 Shortcut routes.
- To add IS-IS equal cost paths in the routing table, you must enable IPv6 ECMP feature globally.

### ECMP Impact on IS-IS Route Selection for Inter-VRF Routes with vIST

This section illustrates the impact ECMP can have on a configuration that implements user-defined VRFs in a vIST cluster and how to avoid incorrect route selection.

Understanding the Configuration

Imagine the following configuration:

- A vIST cluster exists with multiple VRF contexts.
- On both nodes, VRF A redistributes routes into IS-IS as external. VRF B uses an IS-IS accept policy to accept these routes.
- Each node learns three paths to the route:
  - The nodes learn one path using local inter-VRF redistribution.
  - The nodes learn the other two paths from the IST peer.
- The routes are treated as ECMP paths because the preference, metric-type, and metric are equal.

IS-IS sorts paths for the same route by source-BEB B-MAC and B-VLAN ID. The primary B-VLAN ID is first installed for each B-MAC, followed by the secondary B-VLAN ID for each B-MAC, as long as the ECMP max-path value is not reached. On the node with the lowest B-MAC, the first path listed is its own local inter-vrf route, while on the other node, the MIM path across the vIST is listed first.

If you disable ECMP, all but the first path is removed. Because IS-IS orders the paths by B-MAC, each node in the vIST cluster selects the same B-MAC as the nexthop. This configuration leads one of the nodes to select itself, the local inter-vrf route, while the other node selects the MIM path across the vIST to get to the inter-vrf route. This situation results in an incorrect route selection.

#### Avoiding Incorrect Route Selection

To avoid this situation, create a policy to prevent IS-IS from determining that the MIM path across the vIST and the local inter-VRF route are ECMP paths. Configure the local inter-VRF path as the preferred path, and the vIST path as the backup. The following list identifies way that you can accomplish this:

- Redistribute the VRF route into IS-IS using the internal metric-type. IS-IS will always select the local inter-VRF route. For more information about the metric type for IS-IS routes, see [Fabric Basics and Layer 2 Services](#) on page 912.
- If an IS-IS internal metric-type is not an option, configure an IS-IS accept policy to change the preference of inter-VRF routes learned from the IST peer. The local inter-VRF route is preferred over the inter-VRF routes learned from the IST peer.

#### *IS-IS IP Redistribution Policies*

When you connect an SPBM core using IP shortcuts to existing networks running a routing protocol such as OSPF or RIP, a redundant configuration requires two switches:

- One router redistributes IP routes from Routing Information Protocol (RIP)/Open Shortest Path First (OSPF) into IS-IS (IP).
- The second router redistributes from IS-IS (IP) into RIP or OSPF.

The following figure illustrates this configuration.

**Figure 126: Redundant OSPF or RIP Network**

In this scenario it is necessary to take extra care when redistributing through both switches. By default the preference value for IP routes generated by SPBM-IP (IS-IS) is 7. This is a higher preference than OSPF (20 for intra-area, 25 for inter-area, 120 for ext type1, 125 for ext type2) or RIP (100).

**Important**

The lower numerical value determines the higher preference.

In the preceding diagram both nodes (SwitchG and SwitchD) have an OSPF or a RIP route to 192.168.10.0/24 with the next-hop to SwitchA.

As soon as the SwitchG node redistributes that IP route into IS-IS, the SwitchD node learns the same route through IS-IS from SwitchG. (The SwitchG node already has the route through OSPF or RIP). Because IS-IS has a higher preference, SwitchD replaces its 192.168.10.0 OSPF route with an IS-IS one that points at SwitchG as the next-hop. The following figure illustrates this scenario.

**Figure 127: Redistributing Routes into IS-IS**

Clearly this is undesirable and care needs to be taken to ensure that the two redistributing nodes (SwitchG and SwitchD) do not accept redistributed routes from each other. With IS-IS accept policies, you can associate an IS-IS accept policy on SwitchD to reject all redistributed IP routes received from SwitchG, and SwitchG to reject all redistribute IP routes from SwitchD.

An alternate way to solve the preceding problem with existing functionality is to reverse the problem by lowering the SPBM-IP (IS-IS) preference by configuring it to a value greater than RIP (100) or OSPF (20,25,120,125). For example, log on to Global Configuration mode and use the following command to configure a preference of 130:

```
ip route preference protocol spbm-level1 130
```

**Note**

For IPv6, the command is `ipv6 route preference protocol spbm-level1 130`

Now that the OSPF or RIP routes have a higher preference than SPBM-IP (IS-IS), the above problem is temporarily solved. However, the same issue resurfaces when the IS-IS IP routes are redistributed into OSPF or RIP in the reverse direction as shown in the following figure for OSPF:

**Figure 128: Redistributing Routes into OSPF**

In the preceding figure, both SwitchG and SwitchD have an IS-IS IP route for 172.16.0.0/16 with the next hop as SwitchC. As soon as SwitchG redistributes the IS-IS route into OSPF, the SwitchD node learns that same route through OSPF from SwitchG. (The SwitchG node already has the route through IS-IS).

Because OSPF has a higher preference, SwitchD replaces its 172.16.0.0/16 IS-IS route with an OSPF one. (Note that the 172.16.0.0/16 route will be redistributed into OSPF as an AS external route, hence with preference 120 or 125 depending on whether type1 or type2 was used). In this case, however, you can leverage OSPF Accept policies, which can be configured to prevent SwitchD from accepting any AS External (LSA5) routes from SwitchG and prevent SwitchG from accepting any AS External (LSA5) routes from SwitchD. The following is a sample configuration:

```
enable
configure terminal
route-map

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "reject" 1
no permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

OSPF CONFIGURATION - GlobalRouter

router ospf enable

OSPF ACCEPT CONFIGURATION - GlobalRouter

router ospf
accept adv-rtr {A.B.C.D}
```

```
accept adv-rtr {A.B.C.D} enable route-map "reject"  
exit
```

**Note**

Disable alternative routes by issuing the command **no ip alternative-route** to avoid routing loops on the SMLT Backbone Edge Bridges (BEBs).

In the preceding figure, if SwitchA advertises 25000 OSPF routes to SwitchG and SwitchD, then both SwitchG and SwitchD install the 25000 routes as OSPF routes. Since SwitchD and SwitchG have OSPF to IS-IS redistribution enabled, they also learn these 25000 routes as IS-IS routes. IS-IS route preference is configured with a higher numerical value (130) than the OSPF route preference (125), so SwitchD and SwitchG keep IS-IS learned routes as alternative routes.

If SwitchA withdraws its 25000 OSPF routes, SwitchG and SwitchD remove the OSPF routes. While the OSPF routes are removed the routing tables of SwitchG and SwitchD activate the alternative IS-IS routes for the same prefix. Since SwitchG and SwitchD have IS-IS to OSPF redistribution enabled, SwitchA learns these routes as OSPF and this causes a routing loop. Use the **no ip alternative-route** command to disable alternative routes on SwitchG and SwitchD to avoid routing loops.

In the preceding figure, you leveraged OSPF Accept policies, which can be configured to prevent SwitchD from accepting any AS External (LSA5) routes from SwitchG and prevent SwitchG from accepting any AS External (LSA5) routes from SwitchD. In the case of a RIP access network, the preceding solution is not possible because RIP has no concept of external routes and no equivalent of accept policies. However, if you assume that a RIP network acts as an access network to an SPBM core, then it is sufficient to ensure that when IS-IS IP routes are redistributed into RIP they are aggregated into a single default route at the same time. The following figure and sample configuration example illustrates this scenario:

**Figure 129: Redistributing Routes into RIP**

#### SwitchG

```

IP PREFIX LIST CONFIGURATION - GlobalRouter

ip prefix-list "default" 0.0.0.0/0 ge 0 le 32

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "inject-default" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "match-network" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "set-injectlist" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

RIP PORT CONFIGURATION

interface gigabitethernet 1/11
ip rip default-supply enable
exit

IP REDISTRIBUTION CONFIGURATION - GlobalRouter

```

```
router rip
redistribute isis
redistribute isis metric 1
redistribute isis route-map "inject-default"
redistribute isis enable
exit

IP REDISTRIBUTE APPLY CONFIGURATIONS

ip rip apply redistribute isis
```

### SwitchA

```
RIP PORT CONFIGURATION

interface gigabitethernet 1/2
ip rip default-listen enable
exit
interface gigabitethernet 1/3
ip rip default-listen enable
exit
```

### SwitchD

```
IP PREFIX LIST CONFIGURATION - GlobalRouter

ip prefix-list "default" 0.0.0.0/0 ge 0 le 32

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "inject-default" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "match-network" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "set-injectlist" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

RIP PORT CONFIGURATION

interface gigabitethernet 2/11
ip rip default-supply enable
exit

IP REDISTRIBUTION CONFIGURATION - GlobalRouter

router rip
redistribute isis
redistribute isis metric 1
redistribute isis route-map "inject-default"
redistribute isis enable
exit

IP REDISTRIBUTE APPLY CONFIGURATIONS
```

```
ip rip apply redistribute isis
```

You can control the propagation of the default route on the RIP network so that both SwitchG and SwitchD supply the default route on their relevant interfaces, and not accept it on the same interfaces. Likewise, SwitchA will accept the default route on its interfaces to both SwitchG and SwitchD but it will not supply the default route back to them. This will prevent the default route advertised by SwitchG from being installed by SwitchD, and vice-versa.

The preceding example where IS-IS IP routes are aggregated into a single default route when redistributed into the RIP network also applies when redistributing IS-IS IP routes into OSPF if that OSPF network is an access network to an SPBM core. In this case use the following redistribution policy configuration as an example for injecting IS-IS IP routes into OSPF:

```
IP PREFIX LIST CONFIGURATION - GlobalRouter

ip prefix-list "default" 0.0.0.0/0 ge 0 le 32

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "inject-default" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "match-network" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "set-injectlist" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

OSPF CONFIGURATION - GlobalRouter

router ospf enable
router ospf

## IS-IS Accept Policies

You can use Intermediate-System-to-Intermediate-System (IS-IS) accept policies (for IPv4 and IPv6) to filter incoming IS-IS routes over the SPBM cloud and apply route policies to the incoming IS-IS routes. IS-IS accept policies enable the device to determine whether to add an incoming route to the routing table.

### IS-IS Accept Policies and DvR

#### Note

IPv6 IS-IS accept policies for DvR are not supported.

When you configure DvR in an SPB network, you can leverage IS-IS accept policies to control the DvR routes learned from the DvR backbone. The DvR backbone contains the master list of all the host routes learned from various DvR domains.

You can configure accept policies on a DvR Controller or a non-DvR BEB as a filter to determine which DvR host routes to accept into the routing table, from the DvR backbone. Accept policies apply to only those backbone (or inter-domain) host routes that are not part of the Controller's own DvR enabled subnets and do not have the same domain ID as that of the Controller.

For non-DvR BEBs, all the routes present in the backbone are learned, but you can still use the accept policies to filter specific routes.

For information on DvR, see [Distributed Virtual Routing](#) on page 680.

### IS-IS Accept Policy Filters

You can filter traffic with IS-IS accept policies by:

- advertising BEB
- I-SID or I-SID list
- route-map
- backbone-route-map for IPv4 only
- a combination of route-map and backbone-route-map for IPv4 only

You can use IS-IS accept policies to apply at a global default level for all advertising Backbone Edge Bridges (BEBs) or for a specific advertising BEB.

IS-IS accept policies also allow you to use either a service instance identifier (I-SID) or an I-SID list to filter routes. The switch uses I-SIDs to define Virtual Services Networks (VSNs). I-SIDs identify and transmit virtualized traffic in an encapsulated SPBM frame. IS-IS accept policies can use I-SIDs or I-SID lists to filter the incoming virtualized traffic.

IS-IS accept policies can also apply route policies to determine what incoming traffic to accept into the routing table. With route policies the device can determine which routes to accept into the routing table based on the criteria you configure. You can match on the network or the route metric.

On DvR Controllers in a DvR domain, you can configure a backbone route policy to determine what host routes to accept from the DvR backbone, into the routing table. Also, just like on the route policy, you can configure match criteria, and set preferences on the backbone route policy.

To accept both IS-IS routes and host routes from the DvR backbone, you can configure both a route policy and a backbone route policy in the accept policy instance.

For more information on configuring route policies:

- For IPv4, see [IP routing operations fundamentals](#) on page 1809.
- For IPv6, see [IPv6 Routing Basics](#) on page 1875.

The following table describes IPv4 IS-IS accept policy filters.

| Filters into               | Filter                                                                                                                                | Description                                                                                                                                                                                                                                                        |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Global Routing Table (GRT) | <code>accept route-map WORD&lt;1-64&gt;</code>                                                                                        | By default, the device accepts all routes into the GRT and VRF routing table. This is the default accept policy.                                                                                                                                                   |
|                            | <code>accept route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</code>                                                    | This is the default accept policy with configuration to accept specific DvR host routes from the DvR backbone.                                                                                                                                                     |
|                            | <code>accept adv-rtr &lt;x.xx.xx&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</code>                            | The device filters based on the specific advertising BEB defined by the SPBM nickname. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                                                   |
|                            | <code>accept i-sid &lt;1-16777215&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</code>                           | The device filters based on the I-SID, which represents a local or remote Layer 3 VSN. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                                                   |
|                            | <code>accept adv-rtr &lt;x.xx.xx&gt; i-sid &lt;1-16777215&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</code>   | The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                  |
|                            | <code>accept isid-list WORD&lt;1-32&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</code>                         | The device filters based on the list of I-SIDs. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                                                                                          |
|                            | <code>accept adv-rtr &lt;x.xx.xx&gt; isid-list WORD&lt;1-32&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</code> | The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT). The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |

| Filters into                                       | Filter                                                                                                                               | Description                                                                                                                                                                                                                                                                                                  |

| Virtual Routing and Forwarding (VRF) routing table | <i>ipv6 isis accept route-map WORD&lt;1-64&gt; route-map WORD&lt;1-64&gt;</i>                         | The device filters based on the route policy.                                                                                                                                   |
|                                                    | <i>ipv6 isis accept adv-rtr &lt;x.xx.xx&gt; route-map WORD&lt;1-64&gt;</i>                            | The device filters based on the specific advertising BEB defined by the SPBM nickname.                                                                                          |
|                                                    | <i>ipv6 isis accept i-sid &lt;0-16777215&gt; route-map WORD&lt;1-64&gt;</i>                           | The device filters based on the I-SID, which represents a local or remote Layer 3 VSN. The number 0 represents the Global Routing Table (GRT).                                  |
|                                                    | <i>ipv6 isis accept adv-rtr &lt;x.xx.xx&gt; i-sid &lt;0-16777215&gt; route-map WORD&lt;1-64&gt;</i>   | The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN. The number 0 represents the Global Routing Table (GRT). |
|                                                    | <i>ipv6 isis accept isid-list WORD&lt;1-32&gt; route-map WORD&lt;1-64&gt;</i>                         | The device filters based on the list of I-SIDs to which the IS-IS accept policy applies. The number 0 represents the Global Routing Table (GRT).                                |
|                                                    | <i>ipv6 isis accept adv-rtr &lt;x.xx.xx&gt; isid-list WORD&lt;1-32&gt; route-map WORD&lt;1-64&gt;</i> | The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT).                                        |

### IS-IS Accept Policies for the GRT and VRFs

You can create an IS-IS accept policy for incoming routes for the Global Routing Table (GRT), which accepts routes into the routing table, or for a Virtual Routing and Forwarding (VRF) instance, which accepts incoming routes to the routing table of the VRF.

If you create an IS-IS accept policy on the switch for either the GRT or a VRF that operates at a global default level, the accept policy applies to all routes for all BEBs in the GRT or VRF.

If you create an IS-IS accept policy on the switch for a specific advertising BEB for either the GRT or a VRF, the IS-IS accept policy instance applies for that specific advertising BEB. If you use a more specific filter, the system gives preference to the specific filter over the global default level.

### IS-IS Accept Policies for Inter-VRF Route Redistribution

You can also use the filter mechanism for IS-IS accept policies to redistribute routes between different VRFs, or between a VRF and the GRT. For inter-VRF route redistribution, you match the filter based on the I-SID, which represents the Layer 3 VSN context.

You can apply the filter at the global default level, where the IS-IS accept policy applies to all routes for that I-SID from all BEBs, or at a specific advertising BEB level, where the filter only applies to a specific advertising BEB. The device gives preference to a specific filter for a specific advertising BEB over the global default filter.

For inter-VRF route redistribution, an I-SID value of 0 represents the GRT. For inter-VRF route redistribution between VRFs, the I-SID is the source VRF (or remote VRF).

#### Note

If the primary B-VLAN is down either because you did not configure at least one NNI or all configured NNIs are down, the switch does not redistribute inter-VRF routes through IS-IS accept policies.

### IS-IS Accept Policy Considerations

Consider the following when you configure IS-IS accept policies:

- If a VRF uses a different protocol to redistribute routes from another VRF, the IS-IS accept policy feature cannot be used. You can only use the IS-IS accept policy for inter-VSN route redistribution between VRFs.
- IPv4 and IPv6 IS-IS accept policies can exist on the same VRF and GRT; The I-SID list configuration is shared across both protocol versions.

Precedence rules in the same VSN

The following precedence rules apply for IS-IS accept policies used in the same VSN:

- You can only apply one configured IS-IS accept policy for each route.
- You can apply either a default filter for all advertising BEBs or a filter for a specific advertising BEB.
- If you disable the accept filter, the system ignores the filter and the filter with the next highest precedence applies.
- The device prefers the **accept adv-rtt** filter, which filters based on a specific advertising BEB, over the default filter for all advertising BEBs.

- The device accepts all routes within the same VSN by default. You can apply a route policy to filter or change the characteristics of the route by metric or preference.
- The **i-sid** or **isid-list** filters are not valid for routes within the same VSN.

Precedence rules for inter-VSN route redistribution

The following precedence rules apply for IS-IS accept policies used for inter-VSN route redistribution:

- You can only apply one configured IS-IS accept policy for each route.
- You can apply filters at a global default level for all BEBs for a specific I-SID or I-SID list, or you can apply filters for a specific advertising BEB for a specific I-SID or I-SID list.
- If you disable the accept filter, the system ignores the filter and the filter with the next highest precedence applies.
- The device requires a specific filter to redistribute routes between VSNs through the use of the **i-sid** or **isid-list** filters.
- The **i-sid** filter takes precedence over the **isid-list** filter.
- The **adv-rtr** filter for a specific advertising BEB takes precedence over a filter with the same **i-sid** filter without the **adv-rtr** filter.
- The **i-sid** or **isid-list** filters only apply to routes for inter-VSN route redistribution.
- If multiple **isid-list** filters have the same I-SID within the list, the first on the list alphabetically has the higher precedence.

## Route Preference

The relative value of the route preference among different protocols determines which protocol the device prefers. If multiple protocols are in the routing table, the device prefers the route with the lower value. You can change the value at the protocol level, and you can also change the preference of incoming IS-IS routes using the route-map with the IS-IS Accept policy filter for IPv4 only.

## Route Metric

Use route-map to change the metric of a route when you accept a remote IS-IS route with IS-IS accept policies.

You can use route-map to change the metric of a route when you redistribute the route from another protocol to IS-IS through the route redistribution mechanism.

You can also configure the route metric with the base **redistribute** command without the use of route-map.

### Note

For both IPv4 and IPv6 IS-IS accept policies, if there is a mismatch in the route-map (inbound filtering) configured, all routes are accepted by default. Unlike the redistribute route-map (outbound filtering), where if there is a mismatch, all routes are denied by default. For more information, see [IP routing operations fundamentals](#) on page 1809.

For more information on the configuration of route-map:

- For IPv4, see [IP routing operations fundamentals](#) on page 1809.
- For IPv6, see [IPv6 Routing Basics](#) on page 1875.

## IP Shortcuts configuration using the CLI

This section provides procedures to configure IP Shortcuts using the CLI.

### Configuring SPBM IPv4 Shortcuts

In addition to Layer 2 virtualization, the SPBM model is extended to also support Routed SPBM, otherwise called SPBM IP Shortcuts.

SPBM allows a network to make the best use of routing and forwarding techniques, where only the BEBs perform an IP route lookup and all other nodes perform standard Ethernet switching based on the existing shortest path tree. This allows for end to end IP-over-Ethernet forwarding without the need for ARP, flooding, or reverse learning.

To enable IP shortcuts on the BEBs, you can configure a circuitless IP (CLIP) address (loopback address), and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 135. In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct and static routes into IS-IS.

#### Note

The loopback address on each switch or BEB must all be in different subnets to ensure connectivity between them. To do this, use a 32-bit mask with the CLIP address.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- Before redistributing routes into IS-IS, you must create the Customer VLANs, add slots/ports, and add the IP addresses and network masks.

### Procedure

1. Enter Loopback Interface Configuration mode

```
enable

configure terminal

interface Loopback <1-256>
```
2. Configure a CLIP interface to use as the source address for SPBM IP shortcuts:

```
ip address [<1-256>] <A.B.C.D/X>
```
3. Exit the Loopback Interface Configuration mode to Global Configuration mode:

```
exit
```
4. Log on to IS-IS Router Configuration mode:

```
router isis
```
5. Specify the CLIP interface as the source address for SPBM IP shortcuts:

```
ip-source-address <A.B.C.D>
```
6. Configure SPBM IP shortcuts:

```
spbm <1-100> ip enable
```
7. Display the status of SPBM IP shortcuts on the switch:

```
show isis spbm
```

8. Identify routes on the local switch to be announced into the SPBM network:
 

```
redistribute {bgp | direct | ospf | rip | static}
```
9. Enable routes to be announced into the SPBM network
 

```
redistribute {bgp | direct | ospf | rip | static} enable
```
10. If you want to delete the configuration, use the no option:
 

```
no redistribute {bgp | direct | ospf | rip | static}
```

```
no redistribute {bgp | direct | ospf | rip | static} enable
```
11. Exit to Global Configuration mode:
 

```
exit
```
12. Apply the configured redistribution:
 

```
isis apply redistribute {bgp | direct | ospf | rip | static | vrf  
WORD<1-16>}
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface loopback 1
Switch:1(config-if)# ip address 192.0.2.2/8
Switch:1(config-if)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# ip-source-address 192.0.2.2
Switch:1(config-isis)# spbm 1 ip enable
Switch:1(config-isis)# show isis spbm
```

```
show isis spbm
```

```

### Variable definitions

The following table defines parameters for the **ip address** command.

| Variable    | Value                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------|
| <1-256>     | Specifies an interface ID value. This value is optional.                                              |
| <A.B.C.D/X> | Specifies an IP address and subnet mask. Use the <b>no</b> option to delete the specified IP address. |
| <A.B.C.D>   | Specifies an IP address. Use the <b>no</b> option to delete the specified IP address.                 |

The following table defines parameters for the **ip-source-address** command.

| Variable  | Value                                                                            |
|-----------|----------------------------------------------------------------------------------|
| <A.B.C.D> | Specifies the CLIP interface to use as the source address for SPBM IP shortcuts. |

The following table defines parameters for the **spbm** command.

| Variable                 | Value                                                                                                                                             |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-100> <i>ip enable</i> | Enables or disables SPBM IP shortcut state.<br>The default is disabled. Use the <b>no</b> or <b>default</b> options to disable SPBM IP shortcuts. |

The following table defines parameters for the **redistribute** command.

| Variable                                    | Value                                                                                                                                                           |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{bgp   direct   ospf   rip   static}</i> | Specifies the protocol.                                                                                                                                         |
| <i>enable</i>                               | Enables the redistribution of the specified protocol into the SPBM network.<br>The default is disabled. Use the <b>no</b> option to disable the redistribution. |
| <i>metric &lt;0-65535&gt;</i>               | Configures the metric (cost) to apply to redistributed routes. The default is 1.                                                                                |
| <i>metric-type {external internal}</i>      | Configures the type of route to import into the protocol. The default is internal.                                                                              |

| Variable                                | Value                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>route-map WORD&lt;0-64&gt;</code> | Configures the route policy to apply to redistributed routes. Type a name between 0 to 64 characters in length.                                                                                                                                                                                         |
| <code>subnets {allow suppress}</code>   | Indicates whether the subnets are advertised individually or aggregated to their classful subnet. Choose suppress to advertise subnets aggregated to their classful subnet. Choose allow to advertise the subnets individually with the learned or configured mask of the subnet. The default is allow. |

The following table defines parameters for the **isis apply redistribute** command.

| Variable                                          | Value                   |
|---------------------------------------------------|-------------------------|
| <code>{bgp   direct   ospf   rip   static}</code> | Specifies the protocol. |

### Configure SPBM IPv6 Shortcuts

#### Important

You must enable IPv4 Shortcuts before you enable IPv6 Shortcuts because IPv6 Shortcuts depend on IPv4 Shortcuts for some functions.

Configuring IPv6 Shortcuts is essentially the same as the IPv4 procedure except you use the following IPv6 commands instead of their IPv4 equivalents:

- Use **ipv6 interface address** to create a CLIPv6 interface with an IPv6 address.
- Use **ipv6 ipv6-source-address** to specify the CLIPv6 interface as the source address for IPv6 Shortcuts.
- Use **spbm ipv6 enable** to enable IPv6 Shortcuts.
- Use **ipv6 redistribute {bgp | direct | isis | rip | ospf | static} enable** to control the redistribution of GRT IPv6 routes into the SPBM IS-IS domain.
- Use **ipv6 route preference protocol spbm-level1** to change route preference values for IPv6 Shortcut routes learned through IS-IS.

To enable IPv6 Shortcuts on the BEBs, you must configure a circuitless IPv6 (CLIPv6) address (loopback address), and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 236. In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct and static routes into IS-IS.

#### Note

The loopback address on each switch or BEB must all be in different subnets to ensure connectivity between them. To do this, use a 32-bit mask with the CLIP address, and the CLIPv6 address prefix must be 128.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.

- Before redistributing routes into IS-IS, you must create the Customer VLANs, add slots/ports, and add the IPv6 addresses and network masks.

### Procedure

1. Enter Loopback Interface Configuration mode  

```
enable

configure terminal

interface Loopback <1-256>
```
2. Configure a CLIPv6 interface to use as the source address for SPBM IPv6 Shortcuts:  

```
ipv6 interface address WORD<0-255>
```
3. Exit the Loopback Interface Configuration mode to Global Configuration mode:  

```
exit
```
4. Log on to IS-IS Router Configuration mode:  

```
router isis
```
5. Specify the CLIPv6 interface as the source address for SPBM IPv6 Shortcuts:  

```
ipv6-source-address WORD<0-46>
```
6. Enable SPBM IPv6 Shortcuts:  

```
spbm <1-100> ipv6 enable
```
7. Display the status of SPBM IPv6 Shortcuts on the switch:  

```
show isis spbm
```
8. Identify IPv6 routes on the local switch to be announced into the SPBM network.  

```
ipv6 redistribute {bgp | direct | ospf | rip | static}
```
9. Enable the IPv6 routes to be announced into the SPBM network:  

```
ipv6 redistribute {bgp | direct | ospf | rip | static} enable
```
10. Exit to Global Configuration mode:  

```
exit
```
11. (Optional) Change route preference values for IPv6 Shortcut routes learned through IS-IS:  

```
ipv6 route preference protocol spbm-level1 <0-255>
```
12. Apply the configured redistribution:  

```
ipv6 isis apply redistribute {bgp | direct | ospf | rip | static |}
[vrf WORD<1-16>]
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface loopback 123
Switch:1(config-if)#ipv6 interface address 123::1/128
Switch:1(config-if)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#ipv6 ipv6-source-address <non-link-local ipv6-address>
Switch:1(config-isis)#spbm 1 ipv6 enable
Switch:1(config-isis)#show isis spbm

### Variable Definitions

The following table defines parameters for the IPv6 Shortcuts commands.

| Variable                                                                   | Value                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ipv6-source-address WORD&lt;0-46&gt;</code>                          | Specifies the source IPv6 address for locally generated IPv6 packets whose egress port is an SPBM NNI port. The <code>WORD&lt;0-46&gt;</code> value must be a locally configured loopback IPv6 address (CLIPv6). Use the <b>no</b> option to delete the specified IPv6 address. |
| <code>spbml-1-100&gt; ipv6 enable</code>                                   | Enables or disables SPBM IPv6 Shortcuts. The default is disabled. Use the <b>no</b> or <b>default</b> options to disable SPBM IPv6 Shortcuts.                                                                                                                                   |
| <code>ipv6 route preference protocol spbml-level1 &lt;0-255&gt;</code>     | Sets the route preference value for IPv6 Shortcut routes learned through IS-IS. The default preference is 7.                                                                                                                                                                    |
| <code>ipv6 redistribute {bgp   direct   static   ospf   rip} enable</code> | Specifies the GRT IPv6 route that you want to redistribute into the SPBM IS-IS domain. The default is disabled. Use the <b>no</b> option to disable the redistribution.                                                                                                         |

### Configuring inter-VRF IPv4 Accept Policies on VRFs

Configure IS-IS accept policies on a VRF to use inter-VRF accept policies in the SPB cloud. You can use IS-IS accept policies to redistribute routes between different VRFs, including the global routing table

(GRT). First you apply the filter, and then you match the filter based on the I-SID, which represents the Layer 3 VSN context.

#### Note

- The **isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **isis apply accept [vrf<1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **isis apply accept [vrf WORD<1-16>]** at the end.
- If you use the **accept** command for inter-VRF routes based on the remote I-SID, the device only accepts routes coming from remote BEBs. For instance, if a local Layer 3 VSN exists with the same I-SID, the device does not add the local routes. The assumption is that the device uses existent methods, either through use of another protocol or static configuration, to obtain those routes.
- If the route policy changes, you must reapply the IS-IS accept policy, unless it was the last sequence in the configuration.

#### Before You Begin

- Enable IS-IS globally.
- Ensure that a route policy exists.
- Ensure that the VRFs exist.
- You must configure a route-map to apply.

#### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IS-IS accept policy for the I-SID list:

```
ip isid-list WORD<1-32> [<0-16777215>][list WORD<1-1024>]
```

#### Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

3. Create an IS-IS accept policy instance to apply to routes from all Backbone Edge Bridges (BEBs):

```
isis accept [i-sid <0-16777215>][isid-list WORD<1-32>]
```

4. Create an IS-IS accept policy instance to apply to routes for a specific BEB:

```
isis accept [adv-rtr <x.xx.xx>][i-sid <0-16777215>][isid-list WORD<1-32>]
```

5. (Optional) Delete an IS-IS accept policy instance:
 

```
no isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list WORD<1-32>]
```
6. Specify an IS-IS route policy to apply to routes from all BEBs:
 

```
isis accept route-map WORD<1-64>
```
7. Specify an IS-IS route policy to apply for a specific BEB:
 

```
isis accept adv-rtr <x.xx.xx> route-map WORD<1-64>
```
8. (Optional) Delete an IS-IS route policy:
 

```
no isis accept [adv-rtr <x.xx.xx>] [route-map]
```
9. Enable a configured IS-IS accept policy instance:
 

```
isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list WORD<1-32>] [enable]
```
10. (Optional) Disable a configured IS-IS accept policy instance:
 

```
no isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list WORD<1-32>] [enable]
```
11. Exit VRF Router Configuration mode:
 

```
exit
```

You are in Global Configuration mode.
12. Apply the IS-IS accept policy changes, which removes and re-adds all routes with updated filters:
 

```
isis apply accept [vrf WORD<1-16>]
```

### Example

Configure Inter-VRF accept policies on a VRF:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
Switch:1(router-vrf)#isis accept i-sid 100
Switch:1(router-vrf)#isis accept i-sid 100 enable
Switch:1(router-vrf)#exit
Switch:1(config)#isis apply accept vrf green
```

### Variable definitions

The following table defines parameters for the **ip isid-list** command.

| Variable                       | Value                                                                    |
|--------------------------------|--------------------------------------------------------------------------|
| <i>WORD&lt;1-32&gt;</i>        | Creates a name for your I-SID list.                                      |
| <i>&lt;0-16777215&gt;</i>      | Specifies an I-SID value.                                                |
| <i>list WORD&lt;1-1024&gt;</i> | Specifies a list of I-SID values. For example, in the format 1,3,5,8-10. |

The following table defines parameters for the **isis accept** command.

| Variable                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>adv-rtr</i> <x.xx.xx>               | Specifies a specific advertising BEB in which to apply the IS-IS accept policy to routes for a specific advertising BEB. x.xx.xx specifies an SPBM nickname.<br>The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.<br>The system requires an explicit filter to redistribute routes from a particular VSN. If the default global filter or the filter for a specific advertising BEB does not exist, the system does not redistribute the routes from the remote VSN. |
| <i>enable</i>                          | Enables the IS-IS accept policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>i-sid</i> <0-16777215>              | Configures the I-SID to which the IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT).                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>isid-list</i><br><i>WORD</i> <1-32> | Configures a list of I-SIDs to which the IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT).                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>route-map</i> <i>WORD</i><br><1-64> | Specifies a route policy.<br>You must configure a route policy earlier in a separate procedure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

The following table defines parameters for the **isis apply accept** command.

| Variable                      | Value                              |
|-------------------------------|------------------------------------|
| <i>vrf</i> <i>WORD</i> <1-16> | Specifies a specific VRF instance. |

### Configuring Inter-VRF IPv6 Accept Policies on VRFs

Configure IPv6 IS-IS accept policies on a VRF to use inter-VRF accept policies in the SPB cloud. You can use IPv6 IS-IS accept policies to redistribute routes between different VRFs, including the global routing table (GRT). First you apply the filter, and then you match the filter based on the I-SID, which represents the Layer 3 VSN context.

#### Note

- The **ipv6 isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **ipv6 isis apply accept [vrf<1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **ipv6 isis apply accept [vrf WORD<1-16>]** at the end.
- If you use the **ipv6 accept** command for inter-VRF routes based on the remote I-SID, the device accepts routes from other local VRFs to the current VRF, therefore if the accepted I-SID is configured on the local BEB, the device accepts its own IPv6 routes advertised under the accepted I-SID.
- If the route policy changes, you must reapply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

## Before You Begin

- Enable IS-IS globally.
- Configure IPv6 Shortcuts. For more information, see [Configure SPBM IPv6 Shortcuts](#) on page 1363.
- You must configure IPv6 IPVPN.
- Ensure that a route policy exists.
- Ensure that the VRFs exist.
- You must configure a route-map.

## Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IPv6 IS-IS accept policy for the I-SID list:

```
ip isid-list WORD<1-32> {<0-16777215> | list WORD<1-1024>}
```

### Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

3. Configure an IPv6 IS-IS accept policy instance with a route policy.

Use one of the following options:

- a. Configure an IPv6 IS-IS accept policy based on a specific advertising BEB:

```
ipv6 isis accept adv-rtr <x.xx.xx> [enable] [i-sid <0-16777215>]
[isid-list WORD<1-32>] [route-map WORD<1-64>]
```

- b. Configure an IPv6 IS-IS accept policy based on a particular I-SID:

```
ipv6 isis accept i-sid <0-16777215> [enable] [route-map WORD<1-64>]
```

- c. Configure an IPv6 IS-IS accept policy based on a particular I-SID list:

```
ipv6 isis accept isid-list WORD<1-32> [enable] [route-map WORD<1-64>]
```

4. Enable the configured IPv6 IS-IS accept policies:

```
ipv6 isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list
WORD<1-32>] enable
```

5. Exit to Global Configuration mode:

```
exit
```

6. Apply the IPv6 IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

```
ipv6 isis apply accept [vrf WORD<1-16>]
```

## Example

Configure Inter-VRF accept policies on a VRF:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf red
Switch:1(router-vrf)#ipv6 isis accept i-sid 100 enable
Switch:1(router-vrf)#exit
Switch:1(config)#ipv6 isis apply accept vrf red
```

## Variable Definitions

The following table defines parameters for the **ip isid-list** command.

### Note

The I-SID lists created can be associated with both IPv4 or IPv6 routes.

| Variable                  | Value                                                                    |
|---------------------------|--------------------------------------------------------------------------|
| <i>WORD</i> <1-32>        | Creates a name for your I-SID list.                                      |
| <0-16777215>              | Specifies an I-SID value.                                                |
| <i>list WORD</i> <1-1024> | Specifies a list of I-SID values. For example, in the format 1,3,5,8-10. |

The following table defines parameters for the **ipv6 isis accept** command.

| Variable                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>adv-rtr</i><br>< <i>x.xx.xx</i> > | Specifies the SPBM nickname for each advertising BEB to allow you to apply the IPv6 IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.<br><br><b>Note:</b><br>An IPv6 IS-IS accept policy that specifies the <i>adv-rtr</i> without an I-SID or I-SID list will filter routes coming from the I-SID on which the policy is configured and from the specified BEB. |
| <i>enable</i>                        | Enables an IPv6 IS-IS accept policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>i-sid</i><br><0-16777215>         | Specifies an I-SID number to represent a local or remote Layer 3 VSN to which the IPv6 IS-IS accept policy applies.<br>Use the parameter to apply a filter for routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system can redistribute the remote VSN to the VSN where you applied the filter.<br>An I-SID value of 0 represents the global routing table (GRT).                                                                                                        |

| Variable                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>isid-list</i><br><i>WORD</i> <1-32> | Specifies the I-SID list name that represents the local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies.<br>Use the parameter to apply a default filter for all routes from specific I-SIDs, that represent the remote VSN. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter.<br>An I-SID value of 0 represents the global routing table (GRT). |
| <i>route-map</i> <i>WORD</i><br><1-64> | Specifies a route policy.<br>You must configure a route policy earlier in a separate procedure.                                                                                                                                                                                                                                                                                                                                                     |

The following table defines parameters for the **ipv6 isis apply accept** command.

| Variable                      | Value                              |
|-------------------------------|------------------------------------|
| <i>vrf</i> <i>WORD</i> <1-16> | Specifies a specific VRF instance. |

### Configuring IS-IS Accept Policies

Use the following procedure to create and enable IS-IS accept policies to apply to routes from all Backbone Edge Bridges (BEBs) or to all routes from a specific BEB.

Use IS-IS accept policies to filter incoming IS-IS routes the device receives over the SPBM cloud. Accept policies apply to incoming traffic and determine whether to add the route to the routing table.

If DvR is enabled on your switch, and the switch is either a DvR Controller or a non-DvR BEB within the domain, you can configure IS-IS accept policies to accept specific host routes from the DvR backbone. For information on DvR, see [Distributed Virtual Routing](#) on page 680.

IS-IS accept policies are disabled by default.

#### Note

- The **isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **isis apply accept [vrf <1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **isis apply accept [vrf WORD<1-16>]** at the end.
- If the route policy changes, you must reapply the IS-IS accept policy, unless the IS-IS accept policy was the last sequence in the configuration.
- The **isis apply accept [vrf WORD<1-16>]** command is not saved in the configuration file. If you use a saved configuration file for IS-IS accept policy configuration, you must apply the **isis apply accept [vrf WORD<1-16>]** command at the end.
- The number of unique Layer 3 VSN I-SIDs used on a BEB is limited to the number of VRFs supported on the switch. This includes the I-SID values used for Layer 3 VSNs and the I-SID values specified for the ISIS accept policy filters, which can be configured using the **ip isid-list [ISID#]**, **accept i-sid <value>**, or **accept adv-rtr <isis nn> i-sid <value>** commands.

The switch supports 24 VRFs by default, so, in a default configuration, you cannot create an ip isid-list or accept policy with more than 24 unique I-SID entries. However, the configured VRFs take up an entry, so the formula to calculate the limit is: [24 VRF Limit – (currently configured VRFs)]. This gives the number of unique I-SIDs that can be used directly in the IS-IS accept policy filters, which you implement with the **ip isid-list** or **accept policy** command. The I-SIDs used for Layer 3 VSNs can be reused in IS-IS accept policy filters without affecting the limit.

If you increase the VRF scaling, you can create more Layer 3 VSNs. For more information about how to increase the number of supported VRFs, see [Configure the Maximum Number of VRFs](#) on page 3822. The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [VOSS Release Notes](#).

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.
- Ensure that DvR is enabled on the switch before you configure an IS-IS accept policy with a backbone route policy, to accept host routes from the DvR backbone.

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IS-IS accept policy for the I-SID list:

```
ip isid-list WORD<1-32> [<1-16777215>][list WORD<1-1024>]
```

#### Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

- (Optional) Delete an I-SID list:

```
no ip isid-list WORD<1-32> [<1-16777215>][list WORD<1-1024>]
```

#### Note

When deleting an I-SID list, ensure that the I-SID list is not associated with an IS-IS accept policy. Otherwise the deletion fails. An I-SID list associated with an accept policy cannot be deleted because it must contain at least one constituent I-SID.

- Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

Configure IS-IS accept policies with a route policy or a backbone route policy or a combination of both, to determine which routes the IS-IS accept policy applies to.

Configure one of the following types of IS-IS accept policies.

- **An IS-IS accept policy with only the route policy:**

The IS-IS routes are selectively accepted based on the route policy. Since the backbone route policy is not configured, all host routes from the DvR backbone are denied.

If you do not configure a route policy, by default, all IS-IS routes are accepted.

- **An IS-IS accept policy with only the backbone route policy:**

The DvR host routes from the DvR backbone are selectively accepted based on the backbone route policy. Since the route policy is not configured, all IS-IS host routes are accepted.

If you do not configure a backbone route policy, all host routes from the DvR backbone are denied.

- **An IS-IS accept policy with both route policy and backbone route policy:**

IS-IS routes are selectively accepted based on the route policy and host routes from the DvR backbone are selectively accepted based on the backbone route policy.

5. Configure an IS-IS accept policy instance with a route policy.

Use one of the following options:

- a. Create an IS-IS accept policy instance to apply to all BEBs for a specific I-SID or I-SID list:
 

```
accept [i-sid <1-16777215>][isid-list WORD <1-32>]
```
  - b. Create an IS-IS accept policy instance to apply to a specific advertising BEB:
 

```
accept adv-rtr <x.xx.xx> [i-sid <1-16777215>][isid-list WORD <1-32>]
```
  - c. (Optional) Delete an IS-IS accept policy instance:
 

```
no accept [adv-rtr <x.xx.xx>][i-sid <1-16777215>][isid-list WORD <1-32>]
```
  - d. Specify an IS-IS route policy to apply to routes from all BEBs:
 

```
accept route-map WORD<1-64>
```
  - e. Specify an IS-IS route policy to apply to a specific advertising BEB:
 

```
accept adv-rtr <x.xx.xx>[route-map WORD<1-64>]
```
  - f. (Optional) Delete an IS-IS route policy:
 

```
no accept [adv-rtr <x.xx.xx>] [route-map]
```
  - g. Enable an IS-IS route accept instance:
 

```
accept [adv-rtr <x.xx.xx>][enable][i-sid <1-16777215>][i-sid-list WORD<1-32>]
```
  - h. (Optional) Disable an IS-IS route accept instance:
 

```
no accept [adv-rtr <x.xx.xx>][enable][i-sid <1-16777215>][i-sid-list WORD<1-32>]
```
6. Configure an IS-IS accept policy instance with a backbone route policy to accept host routes from the DvR backbone:

#### Note

IS-IS accept policies typically apply to all IS-IS routes. However, to accept DvR host routes from the DvR backbone, you must explicitly configure the IS-IS accept policy with a backbone route policy.

Use one of the following options:

- a. Create the default IS-IS accept policy instance to accept host routes from the DvR backbone:
 

```
accept backbone-route-map WORD <1-64>
```
- b. (Optional) Delete the default IS-IS accept policy instance with backbone route policy configuration:
 

```
no accept backbone-route-map
```
- c. Create an IS-IS accept policy instance to accept host routes from the DvR backbone, and apply to all BEBs for a specific I-SID or I-SID list:
 

```
accept [i-sid <1-16777215>][isid-list WORD <1-32>] backbone-route-map WORD<1-64>
```
- d. (Optional) Delete an IS-IS accept policy instance with backbone route policy configuration, which applies to all BEBs for a specific I-SID or I-SID list:
 

```
no accept [i-sid <1-16777215>][isid-list WORD <1-32>] backbone-route-map
```

- e. Create an IS-IS accept policy instance to accept host routes from the DvR backbone and apply to a specific advertising BEB:
 

```
accept adv-rtr <x.xx.xx> backbone-route-map WORD <1-64>
```
- f. (Optional) Delete an IS-IS accept policy instance with backbone route policy configuration, which applies to a specific advertising BEB
 

```
no accept adv-rtr <x.xx.xx> backbone-route-map
```
7. Configure an IS-IS accept policy with both route policy and backbone route policy, to selectively accept IS-IS routes as well as host routes from the DvR backbone.
  - a. Create the default IS-IS accept policy instance with a route policy to accept IS-IS routes and a backbone route policy to accept host routes from the DvR backbone:
 

```
accept route-map WORD<1-32> backbone-route-map WORD <1-64>
```
  - b. (Optional) Delete the default IS-IS accept policy with route policy and backbone route policy configuration:
 

```
no accept route-map backbone-route-map
```
  - c. Create an accept policy instance to selectively accept IS-IS routes and host routes from the DvR backbone, and apply to all BEBs for a specific I-SID or I-SID list:
 

```
accept [i-sid <1-16777215>][isid-list WORD <1-32>] route-map WORD<1-32> backbone-route-map WORD<1-64>
```
  - d. (Optional) Delete an accept policy instance with route policy and backbone route policy configuration, which applies to all BEBs for a specific I-SID or I-SID list:
 

```
no accept [i-sid <1-16777215>][isid-list WORD <1-32>] route-map backbone-route-map
```
  - e. Create an IS-IS accept policy instance to selectively accept IS-IS routes and host routes from the DvR backbone, and apply to a specific advertising BEB:
 

```
accept adv-rtr <x.xx.xx> route-map WORD<1-32> backbone-route-map WORD <1-64>
```
  - f. (Optional) Delete an IS-IS accept policy instance with route policy and backbone route policy configuration, which applies to a specific advertising BEB:
 

```
no accept adv-rtr <x.xx.xx> route-map backbone-route-map
```
8. Apply the IS-IS accept policy changes, which removes and re-adds all routes with updated filters:
 

```
isis apply accept [vrf WORD <1-16>]
```
9. Exit IS-IS Router Configuration mode:
 

```
exit
```

You are in Global Configuration mode.

### Example

Configure an I-SID based IS-IS accept policy with the route policy test:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#route-map test 1
Switch:1(route-map)#enable
Switch:1(route-map)#exit

Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 101
```

```
Switch:1(config-isis)#accept i-sid 101 route-map test
Switch:1(config-isis)#accept i-sid 101 enable
Switch:1#exit
Switch:1(config)#isis apply accept
```

The following examples show the configuration of an IS-IS accept policy to accept host routes from the DvR backbone

Example 1:

To accept host routes from the DvR backbone, you must configure a backbone route policy and apply it to the IS-IS accept policy.

1. Configure a route policy for DvR:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#route-map dvrmap1 1
Switch:1(route-map)#enable
```

2. Configure an IS-IS accept policy for I-SID 10, and apply the route policy as a backbone route policy:

```
Switch:1(route-map)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 10 backbone-route-map dvrmap1
Switch:1(config-isis)#accept i-sid 10 enable
Switch:1(config-isis)#exit
```

**OR**

Configure the default accept policy for IS-IS and DvR, and apply the route policy as a backbone route policy:

```
Switch:1(config)#route-map isismap1 1
Switch:1(route-map)#enable
Switch:1(route-map)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#accept route-map isismap1 backbone-route-map dvrmap1
```

3. Apply the IS-IS accept policy:

```
Switch:1(config-isis)#exit
Switch:1(config)#isis apply accept
Switch:1(config)#exit
```

4. Verify the configuration:

```
Switch:1#show ip isis accept

=====
                        Isis Accept - GlobalRouter
=====

ADV_RTR  I-SID    ISID-LIST                ENABLE POLICY              BACKBONE
-----  -
-         10        -                          TRUE                        dvrmap1
-         -         -                          isismap1                    dvrmap1

2 out of 2 Total Num of Isis Accept Policies displayed
```

Example 2:

Configure an IS-IS accept policy for I-SID 10 that accepts DVR host routes in a subnet, for example, subnet 126.1.1.0/24.

1. Configure an IP prefix list:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip prefix-list listPrefix 126.1.1.0/24
```

2. Create the route policy dvrmap2 to match the IP prefix list:

```
Switch:1(config)#route-map dvrmap2 1
Switch:1(route-map)#match network listPrefix
Switch:1(route-map)#enable
```

3. Create an IS-IS accept policy with I-SID 10 and apply the route policy as a backbone route policy:

```
Switch:1(route-map)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 10 backbone-route-map dvrmap2
Switch:1(config-isis)#accept i-sid 10 enable
```

4. Apply the IS-IS accept policy:

```
Switch:1(config-isis)#exit
Switch:1(config)#isis apply accept
```

The above command causes IS-IS to accept all routes with I-SID 10. To deny IS-IS routes and accept only DVR host routes, you can configure an additional IS-IS route policy as follows:

```
Switch:1(config)#route-map isismap2 1
Switch:1(route-map)#no permit
Switch:1(route-map)#enable

Switch:1(route-map)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 10 route-map isismap2 backbone-route-map dvrmap2
Switch:1(config-isis)#accept i-sid 10 enable
Switch:1(config-isis)#exit
Switch:1(config)#isis apply accept
```

5. Verify the configuration:

```
Switch:1(config)#exit
Switch:1#show ip isis accept

The following examples show the configuration of IS-IS accept policies for a specific VRF instance.

Example 1:

Configure IS-IS accept policies to accept host routes from the DvR backbone, for a specific VRF instance.

1. In the VRF green context, configure the route policy `dvrmap3` for DvR:

```
Switch:1(config)#router vrf green
Switch:1(router-vrf)#route-map dvrmap3 1
Switch:1(router-vrf-routemap)#enable
```

2. Use one of the following options to configure an IS-IS accept policy, and apply the route policy as a backbone route policy:

Configure an IS-IS accept policy for a specific advertising BEB with nickname `1.11.11`:

```
Switch:1(router-vrf-routemap)#isis accept adv-rtr 1.11.11 backbone-route-map dvrmap3
Switch:1(router-vrf-routemap)#exit
Switch:1(router-vrf)#isis accept adv-rtr 1.11.11 enable
Switch:1(router-vrf)#show ip isis accept vrf green
```

```

Example 2:

Configure an accept policy for I-SID 10 that accepts DvR host routes in a subnet, for example, subnet 126.1.1.0/24.

1. Configure an IP prefix list:

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip prefix-list listPrefix 126.1.1.0/24

```

2. For a specific VRF instance, create a route policy to match the IP prefix list:

```

Switch:1(config)#router vrf green
Switch:1(router-vrf)#route-map dvrmap4 1
Switch:1(router-vrf-routemap)#match network listPrefix
Switch:1(router-vrf-routemap)#enable

```

```
Switch:1(router-vrf-routemap)#exit
Switch:1(router-vrf)#
```

3. Create an IS-IS accept policy with I-SID 10, and apply the route policy as the backbone route policy:

```
Switch:1(router-vrf)#accept i-sid 10 backbone-route-map dvrmap4
Switch:1(router-vrf)#accept i-sid 10 enable
```

4. Apply the IS-IS accept policy:

```
Switch:1(router-vrf)#exit
Switch:1(config)#isis apply accept
```

5. Verify the configuration:

```
Switch:1(config)#exit
Switch:1(router-vrf)#show ip isis accept vrf green

## Variable definitions

The following table defines parameters for the **ip isid-list** command.

| Variable                  | Value                                                                    |
|---------------------------|--------------------------------------------------------------------------|
| <i>WORD</i> <1-32>        | Creates a name for your I-SID list.                                      |
| <1-16777215>              | Specifies an I-SID number.                                               |
| <i>list WORD</i> <1-1024> | Specifies a list of I-SID values. For example, in the format 1,3,5,8-10. |

The following table defines parameters for the **accept** command.

| Variable                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>adv-rtr</i> <x.xx.xx>              | Specifies the SPBM nickname for each advertising BEB to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.                                                                                                                     |
| <i>backbone-route-map WORD</i> <1-64> | Specifies the DvR backbone route map.                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>enable</i>                         | Enables an IS-IS accept policy.                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>i-sid</i><br><1-16777215>          | Specifies an I-SID number to represent a local or remote Layer 3 VSN to which the IS-IS accept policy applies.<br>Use the parameter to apply a filter for routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system can redistribute the remote VSN to the VSN where you applied the filter.<br>An I-SID value of 0 represents the global routing table (GRT). |

| Variable                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>isis-list</code><br><code>WORD&lt;1-32&gt;</code> | Specifies the I-SID list name that represents the local or remote Layer 3 VSNs to which the IS-IS accept policy applies.<br>Use the parameter to apply a default filter for all routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter.<br>An I-SID value of 0 represents the global routing table (GRT). |
| <code>route-map</code><br><code>WORD&lt;1-64&gt;</code> | Specifies a route policy by name.<br>You must configure the route policy earlier in a separate procedure.                                                                                                                                                                                                                                                                                                                                     |

The following table defines parameters for the **isis apply accept** command.

| Variable                          | Value                              |
|-----------------------------------|------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code> | Specifies a specific VRF instance. |

### View IS-IS Accept Policy Information

Use the following procedure to view IS-IS accept policy information on the switch.

#### Procedure

1. Display IS-IS accept policy information:  
`show ip isis accept [vrf WORD<1-16>][vrfids WORD<0-512>]`
2. Display I-SID list information:  
`show ip isid-list [vrf WORD<1-16>][vrfids WORD<0-512>][WORD<1-32>]`
3. Display route information:  
`show ip route [vrf WORD<1-16>]`

The NH VRF/ISID column displays the I-SID for inter-Virtual Services Network (VSN) routes redistributed with IS-IS accept policies, only if the I-SID redistributed does not have an IP VSN associated with it. If an IP VSN exists for that I-SID, the VRF name displays. If the I-SID is 0, the column represents and displays as the GlobalRouter.

The existing IS-IS routes for Layer 3 VSNs continue to display as the VRF name of the IP VSN.

4. Display the SPBM IP unicast Forwarding Information Base (FIB):  
`show isis spbm ip-unicast-fib [all] [id <1-16777215>][spbm-nh-as-mac] [home|remote]`

#### Example

View IS-IS accept policy information:

```
Switch:1#show ip route vrf test

## Variable Definitions

The following table defines parameters for the **show ip isis accept** command.

| Variable                        | Value                                                         |
|---------------------------------|---------------------------------------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Displays I-SID list information for a particular VRF by name. |
| <i>vrfids WORD&lt;0-512&gt;</i> | Displays I-SID list information for a particular VRF ID.      |

The following table defines parameters for the **show ip isid-list** command.

| Variable                        | Value                                                             |
|---------------------------------|-------------------------------------------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Displays I-SID list information for a particular VRF by name.     |
| <i>vrfids WORD&lt;0-512&gt;</i> | Displays I-SID list information for a particular VRF ID.          |
| <i>WORD&lt;1-32&gt;</i>         | Displays I-SID list information for a particular I-SID list name. |

The following table defines parameters for the **show ip route** command.

| Variable                    | Value                                                         |
|-----------------------------|---------------------------------------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i> | Displays I-SID list information for a particular VRF by name. |

The following table defines parameters for the **show isis spbm ip-unicast-fib** command.

| Variable                     | Value                                                                                             |
|------------------------------|---------------------------------------------------------------------------------------------------|
| <i>all</i>                   | Displays all IS-IS SPBM IP unicast Forwarding Information Base (FIB) information.                 |
| <i>home</i>                  | Displays the IS-IS SPBM IP unicast FIB information that the system configures in the home area.   |
| <i>id &lt;1-16777215&gt;</i> | Displays IS-IS SPBM IP unicast FIB information by I-SID ID.                                       |
| <i>remote</i>                | Displays the IS-IS SPBM IP unicast FIB information that the system configures in the remote area. |
| <i>spbm-nh-as-mac</i>        | Displays the next hop B-MAC of the IP unicast FIB entry.                                          |

### Configuring IPv6 IS-IS Accept Policies

Perform the following procedure to create and enable IPv6 IS-IS accept policies based on a particular Backbone Edge Bridge (BEB), I-SID, or I-SID list. IPv6 IS-IS accept policies filter incoming IS-IS routes that the device receives over the SPBM cloud. IPv6 IS-IS accept policies apply to incoming traffic and determine whether to add the route to the routing table.

IPv6 IS-IS accept policies are disabled by default.

#### Note

- IPv6 IS-IS accept policies are not supported for DvR.
- The I-SID lists created can be associated with both IPv4 or IPv6 routes.
- The **ipv6 isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **ipv6 isis apply accept [vrf <1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **ipv6 isis apply accept [vrf WORD<1-16>]** at the end.
- If the route policy associated with an accept policy changes, you must reapply the IPv6 IS-IS accept policy, unless the IPv6 IS-IS accept policy was the last sequence in the configuration.
- The **ipv6 isis apply accept [vrf WORD<1-16>]** command is not saved in the configuration file. If you use a saved configuration file for IPv6 IS-IS accept policy configuration, you must apply the **ipv6 isis apply accept [vrf WORD<1-16>]** command at the end.

The number of unique Layer 3 VSN I-SIDs used on a BEB is limited to the number of VRFs supported on the switch. This includes the I-SID values used for Layer 3 VSNs and the I-SID values specified for the IPv6 IS-IS accept policy filters.

The switch supports 24 VRFs by default, so, in a default configuration, you cannot create an I-SID list or accept policy with more than 24 unique I-SID entries. However, the configured VRFs take up an entry, so the formula to calculate the limit is: [24 VRF Limit – (currently configured VRFs)]. This gives the number of unique I-SIDs that can be used directly in the IPv6 IS-IS accept policy filters, which you implement with the **ip isid-list** or **ipv6 accept** command. The I-SIDs used for Layer 3 VSNs can be reused in IPv6 IS-IS accept policy filters without affecting the limit.

If you increase the VRF scaling, you can create more Layer 3 VSNs. For more information about how to increase the number of supported VRFs, see [Configure the Maximum Number of VRFs](#) on page 3822. The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [VOSS Release Notes](#).

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Configure IPv6 Shortcuts. For more information, see [Configure SPBM IPv6 Shortcuts](#) on page 1363.
- You must configure a route-map.

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IPv6 IS-IS accept policy for the I-SID list:

```
ip isid-list WORD<1-32> {<1-16777215> | list WORD<1-1024>}
```

#### Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

- Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

- Configure an IPv6 IS-IS accept policy instance with a route policy.

Use one of the following options:

- Configure an IPv6 IS-IS accept policy based on a specific advertising BEB:

```
ipv6 isis accept adv-rtr <x.xx.xx> [enable] [i-sid <0-16777215>]
[isid-list WORD<1-32>] [ [route-map WORD<1-64>]
```

- Configure an IPv6 IS-IS accept policy based on a particular I-SID:

```
ipv6 isis accept i-sid <0-16777215> [enable] [route-map WORD<1-64>]
```

- Configure an IPv6 IS-IS accept policy based on a particular I-SID list:

```
ipv6 isis accept isid-list WORD<1-32> [enable] [route-map WORD<1-64>]
```

- Specify a particular route-map to use for all IS-IS routes from all BEBs unless a more specific filter exists for the advertising BEB. :

```
ipv6 isis accept route-map WORD<1-64>
```

- Enable the configured IPv6 IS-IS accept policies:

```
ipv6 isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list
WORD<1-32>] enable
```

- Exit to Global Configuration mode:

```
exit
```

- Apply the IPv6 IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

```
ipv6 isis apply accept [vrf WORD <1-16>]
```

### Example

Configure an IPv6 IS-IS accept policy based on a particular I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrfstest
```

```
Switch:1(config-isis)#ipv6 isis accept i-sid 101 route-map test
Switch:1(config-isis)#ipv6 isis accept i-sid 101 enable
Switch:1#exit
Switch:1(config)#ipv6 isis apply accept
```

## Variable Definitions

The following table defines parameters for the **ip isid-list** command.

### Note

The I-SID lists created can be associated with both IPv4 or IPv6 routes.

| Variable                  | Value                                                                    |
|---------------------------|--------------------------------------------------------------------------|
| <i>WORD</i> <1-32>        | Creates a name for your I-SID list.                                      |
| <1-16777215>              | Specifies an I-SID number.                                               |
| <i>list WORD</i> <1-1024> | Specifies a list of I-SID values. For example, in the format 1,3,5,8-10. |

The following table defines parameters for the **ipv6 isis accept** command.

| Variable                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>adv-rtr</i><br>< <i>x.xx.xx</i> >   | Specifies the SPBM nickname for each advertising BEB to allow you to apply the IPv6 IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.<br><br><b>Note:</b><br>An IPv6 IS-IS accept policy that specifies the <i>adv-rtr</i> without an I-SID or I-SID list will filter routes coming from the I-SID on which the policy is configured and from the specified BEB. |
| <i>enable</i>                          | Enables an IPv6 IS-IS accept policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>i-sid</i><br><0-16777215>           | Specifies an I-SID number to represent a local or remote Layer 3 VSN to which the IPv6 IS-IS accept policy applies.<br>Use the parameter to apply a filter for routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system can redistribute the remote VSN to the VSN where you applied the filter.<br>An I-SID value of 0 represents the global routing table (GRT).                                                                                                        |
| <i>isid-list</i><br><i>WORD</i> <1-32> | Specifies the I-SID list name that represents the local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies.<br>Use the parameter to apply a default filter for all routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter.<br>An I-SID value of 0 represents the global routing table (GRT).                                                                                     |
| <i>route-map</i><br><i>WORD</i> <1-64> | Specifies a route policy by name.<br>You must configure the route policy earlier in a separate procedure.                                                                                                                                                                                                                                                                                                                                                                                                                              |

The following table defines parameters for the **ipv6 isis apply accept** command.

| Variable                          | Value                     |
|-----------------------------------|---------------------------|
| <code>vrf WORD&lt;1-16&gt;</code> | Specifies a VRF instance. |

### Displaying IPv6 IS-IS Accept Policy Information

Perform the following procedure to view IPv6 IS-IS accept policy information on the switch.

#### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Display IPv6 IS-IS accept policy information:  

```
show ipv6 isis accept [vrf WORD<1-16>] [vrfs WORD<0-512>]
```

#### Example

Display IPv6 IS-IS accept policy information for vrfRED:

```
Switch:1>enable
Switch:1#show ipv6 isis accept vrf vrfRED
=====
                        Isis Accept - VRF vrfRED
=====
ADV_RTR  I-SID    ISID-LIST                                ENABLE POLICY
-----
1.11.11  1001        -  TRUE
-----
1 out of 1 Total Num of Isis Accept Policies displayed
```

## IP Shortcuts configuration using EDM

This section provides procedures to configure IP Shortcuts using Enterprise Device Manager (EDM).

### Configure SPBM IP Shortcuts

In addition to Layer 2 virtualization, the SPBM model is extended to also support Routed SPBM, otherwise called SPBM IP Shortcuts.

SPBM allows a network to make the best use of routing and forwarding techniques, where only the BEBs perform an IP route lookup and all other nodes perform standard Ethernet switching based on the existing shortest path tree. This allows for end to end IP-over-Ethernet forwarding without the need for ARP, flooding, or reverse learning.

To enable IP shortcuts on the BEBs, you can configure a circuitless IP address (loopback address) and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 135. In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct and static routes into IS-IS.

After you have configured the SPBM infrastructure, you can enable SPBM IP shortcuts to advertise IP routes across the SPBM network using the following procedure.

## Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- Before redistributing routes into IS-IS, you must create the Customer VLANs, add slots/ports, and add the IP addresses and network masks.

## Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. From the **Globals** tab, in **IpSourceAddress**, specify the CLIP interface to use as the source address for SBPM IP Shortcuts.

### Note

For IPv6 Shortcuts, select **ipv6** in **Ipv6SourceAddressType**, and then use **Ipv6SourceAddress** to specify the CLIPv6 interface to use as the source address for SBPM IPv6 Shortcuts.

4. Select **Apply**.
5. In the navigation pane, expand **Configuration > IS-IS > SPBM**.
6. Select the **SPBM** tab.
7. In **IpShortcut**, select **enable**.

### Note

For IPv6 Shortcuts, select **enable** in **Ipv6Shortcut**.

8. Select **Apply**.
9. In the navigation pane, expand **Configuration > IP**.
10. Select **Policy**.
11. Select the **Route Redistribution** tab.
12. Select **Insert** to identify routes on the local switch to be announced into the SPBM network.
13. Using the fields provided, specify the source protocols to redistribute into IS-IS. In **Protocol**, ensure you specify **isis** as the destination protocol.
14. Select **Insert**.

### *Configuring IPv4 IS-IS redistribution*

Use this procedure to configure IS-IS redistribution. In the Virtual Routing and Forwarding (VRF), just like in the Global Router, the routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: direct, static, RIP, OSPF, or BGP, within the context of a VRF. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

The VRF specific routes are transported in TLV 184 with the I-SID assigned to the VPNs. After extracting the IP VPN IP reachability information, the routes are installed in the route tables of the appropriate VRFs based on the I-SID association.

## Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Complete the fields as required.
6. Click **Insert**.

## IS-IS Redistribute field descriptions

Use the data in the following table to configure the **IS-IS Redistribute** tab.

| Name               | Description                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DstVrflid</b>   | Specifies the destination Virtual Routing and Forwarding (VRF) ID used in the redistribution.                                                                                                                                                                                                           |
| <b>Protocol</b>    | Specifies the protocols that receive the redistributed routes.                                                                                                                                                                                                                                          |
| <b>SrcVrflid</b>   | Specifies the source VRF ID used in the redistribution. For IS-IS, the source VRF ID must be the same as the destination VRF ID.                                                                                                                                                                        |
| <b>RouteSource</b> | Specifies the source protocol for the route redistribution entry.                                                                                                                                                                                                                                       |
| <b>Enable</b>      | Enables or disables a redistribution entry. The default is disable.                                                                                                                                                                                                                                     |
| <b>RoutePolicy</b> | Specifies the route policy to be used for the detailed redistribution of external routes from a specified source into the IS-IS domain.                                                                                                                                                                 |
| <b>Metric</b>      | Specifies the metric for the redistributed route. The value can be a range between 0 to 65535. The default value is 0. Use a value that is consistent with the destination protocol.                                                                                                                    |
| <b>MetricType</b>  | Specifies the metric type. Specifies a type1 or a type2 metric. For metric type1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type2, the cost of the external routes is equal to the external cost alone. The default is type2.         |
| <b>Subnets</b>     | Indicates whether the subnets are advertised individually or aggregated to their classful subnet. Choose suppress to advertise subnets aggregated to their classful subnet. Choose allow to advertise the subnets individually with the learned or configured mask of the subnet. The default is allow. |

### Configure IPv6 IS-IS Redistribution

Use this procedure to configure IS-IS redistribution for IPv6. In the Virtual Routing and Forwarding (VRF), just like in the Global Router, the IPv6 routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS:

v6direct, v6static, RIPng, OSPFv3, or BGPv6, within the context of a VRF. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

#### Note

RIPng is supported only on the Global Router.

The VRF specific routes are transported in TLV 184 with the I-SID assigned to the VPNs. After extracting the IPv6 VPN reachability information, the IPv6 routes are installed in the route tables of the appropriate VRFs based on the I-SID association.

### Before You Begin

Change the VRF instance as required to configure IPv6 IS-IS redistribution on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Complete the fields as required.
6. Click **Insert**.
7. Click **Apply**.

### Redistribute Field Descriptions

Use the data in the following table to configure the **Redistribute** tab.

| Name               | Description                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DstVrfId</b>    | Specifies the destination Virtual Routing and Forwarding (VRF) ID used in redistribution.                                               |
| <b>Protocol</b>    | Specifies the protocols that receive the redistributed routes.                                                                          |
| <b>SrcVrfId</b>    | Specifies the source Virtual Routing and Forwarding (VRF) ID used in redistribution.                                                    |
| <b>RouteSource</b> | Specifies the source protocol for the route redistribution entry.                                                                       |
| <b>Enable</b>      | Enables or disables a redistribution entry. The default is disabled.                                                                    |
| <b>RoutePolicy</b> | Specifies the route policy to be used for the detailed redistribution of external routes from a specified source into the IS-IS domain. |

| Name              | Description                                                                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Metric</b>     | Specifies the metric for the redistributed route. The default value is 0. Use a value that is consistent with the destination protocol.                                                                                                                                                         |
| <b>MetricType</b> | Specifies the metric type. Specifies a type1 or a type2 metric. For metric type1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type2, the cost of the external routes is equal to the external cost alone. The default is type2. |

### Applying IPv4 IS-IS accept policies globally

Apply IS-IS accept policies globally. Use IS-IS accept policies to filter incoming IS-IS routes the device receives over the SPBM cloud. Accept policies apply to incoming traffic and determine whether to add the route to the routing table.

After you apply the IS-IS accept filters, the device removes and re-adds all routes with updated filters.

IS-IS accept policies are disabled by default.

#### Note

- After you apply IS-IS accept policies globally the application can disrupt traffic and cause temporary traffic loss. After you configure the IS-IS accept policies value to **Apply**, the device reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply IS-IS accept policies globally at the end.
- If the route policy changes, you must reapply the IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Ensure the IP IS-IS filter exists.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Global** tab.
4. Select a name from the list or enter name in the **DefaultPolicyName** field, to specify the route policy name for the default filter.
5. Select **Apply** to apply the default policy.

### Accept Global field descriptions

Use the data in the following table to configure the **Accept Global** tab.

| Name                             | Description                                                                                                                                                                                                                                                      |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DefaultPolicyName</b>         | Specifies the route policy name for the default filter.                                                                                                                                                                                                          |
| <b>DefaultBackbonePolicyName</b> | Specifies the backbone host route policy name for the default filter.                                                                                                                                                                                            |
| <b>Apply</b>                     | Applies the default policy when you configure the field to apply. The device only activates the default policy if the route map (the default policy name) has a value. If you do not select apply, the device takes no action. The GRT always returns no action. |

### Configure an IPv4 IS-IS Accept Policy for a Specific Advertising BEB

Configure an IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB). Specify the SPBM nickname and the IS-IS accept policy name to allow you to apply the IS-IS accept policy.

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

#### Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IS-IS**.
3. Select the **Accept Nick Name** tab.
4. Select **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. Select enable in the **Enable** check box to enable the filter.
7. In the **PolicyName** field, specify the route-map name.
8. Select **Insert**.

### Accept Nick Name field descriptions

Use the data in the following table to configure the **Accept Nick Name** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                                                      |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertisingRtr</b>     | Specifies the SPBM nickname to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.<br>The value is 2.5 bytes in the format <x.xx.xx>. |
| <b>Enable</b>             | Enables or disables the SPBM nickname advertising router entry. You must enable the value to filter. The default is disabled.                                                                                                                                                                                                    |
| <b>PolicyName</b>         | Specifies a route policy.<br>You must configure a policy earlier in a separate procedure.                                                                                                                                                                                                                                        |
| <b>BackbonePolicyName</b> | Specifies the route policy for the backbone routes.<br>You must configure a policy earlier in a separate procedure.                                                                                                                                                                                                              |

### Configure an IS-IS Accept Policy to Apply for a Specific I-SID

Configure an IS-IS accept policy for a specific I-SID number to represent a local or remote Layer 3 VSN, which allows the system to redistribute the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).

#### Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Isid** tab.
4. Click **Insert**.
5. In the **Isid** field, specify the SPBM nickname.
6. Select enable in the **Enable** check box to enable the filter.
7. In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

### Accept Isid field descriptions

Use the data in the following table to configure the **Accept Isid** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                                                   |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Isid</b>               | Configures a specific I-SID number to represent a local or remote Layer 3 VSN to which the IS-IS accept policy applies.<br>Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter.<br>An I-SID value of 0 represents the global routing table (GRT). |
| <b>Enable</b>             | Enables or disables the I-SID entry. You must enable the value to filter. The default is disabled.                                                                                                                                                                                                                            |
| <b>PolicyName</b>         | Specifies the route map name. You must configure a policy earlier in a separate procedure.                                                                                                                                                                                                                                    |
| <b>BackbonePolicyName</b> | Specifies the backbone route map name. You must configure a policy earlier in a separate procedure.                                                                                                                                                                                                                           |

### Configure an IPv4 IS-IS Accept Policy for a Specific Advertising BEB and I-SID

Configures a specific advertising Backbone Edge Bridge (BEB) with a specific I-SID to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB.

#### Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Isid** field, specify an I-SID number.
7. Select enable in the **Enable** check box to enable the filter.
8. In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

### Accept Nick-Name Isid descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid** tab.

| Name                      | Description                                                                                                                                                            |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertisingRtr</b>     | Specifies the SPBM nickname to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB.<br>The value is 2.5 bytes in the format <x.xx.xx>. |
| <b>Isid</b>               | Specifies an I-SID used to filter. The value 0 is used for the Global Router.                                                                                          |
| <b>Enable</b>             | Enables or disables the I-SID entry. The default is disabled.                                                                                                          |
| <b>PolicyName</b>         | Specifies the route policy name. You must configure a policy earlier in a separate procedure.                                                                          |
| <b>BackBonePolicyName</b> | Specifies the backbone route policy name. You must configure a policy earlier in a separate procedure.                                                                 |

### Configuring an I-SID list for an IPv4 IS-IS accept policy

Configures a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IS-IS accept policy applies. After you create the list of I-SID numbers, you must then create, configure, and enable the IS-IS accept policy.

#### Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Refresh the EDM tab to view the actual list of I-SIDs in the I-SID list.

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify a name for the I-SID list.
6. Select **Isid** or **Isid-List**.
7. Specify an I-SID number or a list of I-SID numbers.
8. Click **Insert**.

#### Isid-List field descriptions

Use the data in the following table to configure the **Isid-List** tab.

| Name                     | Description                                                                                                                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>              | Specifies the name of the I-SID list.                                                                                                                                                                               |
| <b>Isid or Isid-List</b> | Specifies that you either want to add a particular I-SID or a list of I-SID numbers.                                                                                                                                |
| <b>Isid</b>              | Specifies a particular I-SID number or a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT). |

### Configure an IPv4 IS-IS Accept Policy for a Specific I-SID List

Configure an IS-IS accept policy for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

#### Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify the I-SID list name.
6. Select enable in the **Enable** check box to enable the filter.
7. In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

### Accept Isid-List field descriptions

Use the data in the following table to configure **Accept Isid-List** tab.

| Name                      | Description                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------|
| <b>Name</b>               | Specifies the name of I-SID list.                                                                       |
| <b>Enable</b>             | Enables or disables the I-SID list entry. The value must be enabled to filter. The default is disabled. |
| <b>PolicyName</b>         | Specifies the route policy name.                                                                        |
| <b>BackBonePolicyName</b> | Specifies the backbone route policy name.                                                               |

### Configure an IPv4 IS-IS Accept Policy for a Specific Advertising BEB and I-SID-list

Configure an IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB) for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

#### Note

If the route policy changes, you must reapply the IS-IS accept policy, unless it was the last sequence in the configuration.

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

#### About This Task

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid-List** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Name** field, specify an I-SID list name.
7. Select **enable** in the **Enable** check box to enable the filter.
8. In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

#### Accept Nick-Name Isid-List field descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid-List** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                    |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertisingRtr</b>     | Specifies the SPBM nickname to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter is present the device applies the specific filter. The value is 2.5 bytes in the format <x.xx.xx>. |
| <b>Name</b>               | Specifies the name of the I-SID list used to filter.                                                                                                                                                                                                                                           |
| <b>Enable</b>             | Enables or disables the SPBM nickname advertising router entry. You must enable the value to filter. The default is disabled.                                                                                                                                                                  |
| <b>PolicyName</b>         | Specifies a route policy name.                                                                                                                                                                                                                                                                 |
| <b>BackBonePolicyName</b> | Specifies a backbone route policy name.                                                                                                                                                                                                                                                        |

### Applying IPv6 IS-IS Accept Policies Globally

Apply IPv6 IS-IS accept policies globally. Use IPv6 IS-IS accept policies to filter incoming IS-IS routes the device receives over the SPBM cloud.

After you apply the IPv6 IS-IS accept policy filters, the device removes and re-adds all IPv6 routes with updated filters.

IPv6 IS-IS accept policies are disabled by default.

#### Note

- After you apply IPv6 IS-IS accept policies globally the application can disrupt traffic and cause temporary traffic loss. After you configure the IPv6 IS-IS accept policies value to **Apply**, the device reapplies the accept policies, which deletes all of the IPv6 IS-IS routes, and adds the IPv6 IS-IS routes again. You should make all the relevant accept policy changes, and then apply IPv6 IS-IS accept policies globally at the end.
- If the route policy changes, you must reapply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Ensure the IPv6 IS-IS filter exists.
- Change the VRF instance as required to apply IPv6 IS-IS accept policies on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Global** tab.
4. (Optional) Select a name from the list or enter name in the **DefaultPolicyName** field, to specify the route policy name for the default filter.
5. Select **Apply** to apply the default policy.
6. Click **Apply**.

### Accept Global Field Descriptions

Use the data in the following table to configure the **Accept Global** tab.

| Name                     | Description                                                                                                                                                                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DefaultPolicyName</b> | Specifies the route policy name for the default filter.                                                                                                                                                                                          |
| <b>Apply</b>             | Applies the default policy when you select apply. The device only activates the default policy if the route map (the default policy name) has a value. If you do not select apply, the device takes no action. The GRT always returns no action. |
| <b>NickNameTableSize</b> | Shows the IPv6 IS-IS In Filter Nick Name table size.                                                                                                                                                                                             |

| Name                             | Description                                                     |
|----------------------------------|-----------------------------------------------------------------|
| <b>IsidTableSize</b>             | Shows the IPv6 IS-IS In Filter I-SID table size.                |
| <b>NickNameIsidTableSize</b>     | Shows the IPv6 IS-IS In Filter Nick Name I-SID table size.      |
| <b>IsidListTableSize</b>         | Shows the IPv6 IS-IS In Filter I-SID List table size.           |
| <b>NickNameIsidListTableSize</b> | Shows the IPv6 IS-IS In Filter Nick Name I-SID List table size. |

### Configuring an IPv6 IS-IS Accept Policy for a specific Advertising BEB

Configure an IPv6 IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB). Specify the SPBM nickname and the IS-IS accept policy name to allow you to apply the IPv6 IS-IS accept policy.

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

#### Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular advertising BEB on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Nick Name** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. Select **Enable** to apply the filter.
7. (Optional) In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

## Accept Nick Name Field Descriptions

Use the data in the following table to configure the **Accept Nick Name** tab.

| Name                  | Description                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertisingRtr</b> | Specifies the SPBM nickname to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter. |
| <b>Enable</b>         | Enables the SPBM nickname advertising router entry. The default is disabled.                                                                                                                                                                                     |
| <b>PolicyName</b>     | Specifies a route policy.                                                                                                                                                                                                                                        |

### Configuring an IPv6 IS-IS Accept Policy for a specific I-SID

Configure an IPv6 IS-IS accept policy for a specific I-SID to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

#### Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular I-SID on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Isid** tab.
4. Click **Insert**.
5. In the **Isid** field, specify the I-SID value.
6. Select **Enable** to apply the filter.
7. (Optional) In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

## Accept Isid Field Descriptions

Use the data in the following table to configure the **Accept Isid** tab.

| Name              | Description                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Isid</b>       | Specifies a particular I-SID number that represents local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT). |
| <b>Enable</b>     | Enables or disables the I-SID entry. The default is disabled.                                                                                                                                  |
| <b>PolicyName</b> | Specifies the route policy name.                                                                                                                                                               |

### Configuring an IPv6 IS-IS accept policy for a specific advertising BEB and I-SID

Configures a specific advertising Backbone Edge Bridge (BEB) with a specific I-SID to allow you to apply the IPv6 IS-IS accept policy to routes for a specific advertising BEB.

#### Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular advertising BEB and I-SID on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Isid** field, specify an I-SID number.
7. Select **Enable** to apply the filter.
8. (Optional) In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

## Accept Nick-Name Isid Field Descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid** tab.

| Name                  | Description                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------------------|
| <b>AdvertisingRtr</b> | Specifies the SPBM nickname to apply the IS-IS accept policy to routes for a specific advertising BEB. |
| <b>Isid</b>           | Specifies the I-SID value. The value 0 is used for the Global Router.                                  |
| <b>Enable</b>         | Enables or disables the I-SID entry. The default is disabled.                                          |
| <b>PolicyName</b>     | Specifies the route policy name. You must configure a policy earlier in a separate procedure.          |

### Configuring an I-SID List for an IPv6 IS-IS Accept Policy

Configures a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. After you create the list of I-SID numbers, you must then create, configure, and enable the IPv6 IS-IS accept policy.

#### Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Refresh the EDM tab to view the actual list of I-SIDs in the I-SID list.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Change the VRF instance as required to configure an I-SID list for an IPv6 IS-IS accept policy on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify a name for the I-SID list.
6. Select **Isid** or **Isid-List**.
7. Specify an I-SID number or a list of I-SID numbers.
8. Click **Insert**.
9. Click **Apply**.

## Isid-List Field Descriptions

Use the data in the following table to configure the **Isid-List** tab.

| Name        | Description                                                                                                                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b> | Specifies the name of the I-SID list.                                                                                                                                                                                    |
| <b>Isid</b> | Specifies a particular I-SID number or a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT). |

### Configuring an IPv6 IS-IS Accept Policy for a specific I-SID List

Configure an IPv6 IS-IS accept policy for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

#### Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular I-SID list on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify the I-SID list name.
6. Select **Enable** to apply the filter.
7. (Optional) In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

## Accept Isid-List Field Descriptions

Use the data in the following table to configure **Accept Isid-List** tab.

| Name              | Description                                                        |
|-------------------|--------------------------------------------------------------------|
| <b>Name</b>       | Specifies the name of I-SID list.                                  |
| <b>Enable</b>     | Enables or disables the I-SID list entry. The default is disabled. |
| <b>PolicyName</b> | Specifies the route policy name.                                   |

### Configuring an IPv6 IS-IS Accept Policy for a specific Advertising BEB and I-SID List

Configure an IPv6 IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB) for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

#### Note

If the route policy changes, you must reapply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular advertising BEB and I-SID list on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

#### About This Task

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

#### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid-List** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Name** field, specify an I-SID list name.
7. Select **Enable** to apply the filter.
8. (Optional) In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

#### Accept Nick-Name Isid-List Field Descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid-List** tab.

| Name                  | Description                                                                                                                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertisingRtr</b> | Specifies the SPBM nickname to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter is present the device applies the specific filter. |
| <b>Name</b>           | Specifies the I-SID list name.                                                                                                                                                                                                    |
| <b>Enable</b>         | Enables or disables the SPBM nickname advertising router entry. The default is disabled.                                                                                                                                          |
| <b>PolicyName</b>     | Specifies a route policy name.                                                                                                                                                                                                    |

## IP Shortcuts SPBM Configuration Example

The following figure shows a sample IP Shortcuts over SPBM deployment.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

**Figure 130: SPBM IP Shortcuts**

The following sections show the steps required to configure the SPBM IP Shortcuts parameters in this example. You must first configure basic SPBM and IS-IS infrastructure. For more information, see [SPBM and IS-IS Infrastructure Configuration](#) on page 912.

Note the following:

- IP IS-IS redistribution needs to be configured to inject IP shortcuts routes into IS-IS. The one exception is the circuitless IP address configured as the IS-IS ip-source-address. This address is automatically advertised without the need for a redistribution rule.
- In the displayed configuration, only direct routes are injected (the same configuration is possible for static routes). To inject IPv6 routes, you must enable route redistribution of IPv6 direct, IPv6 static, and OSPFv3 routes into IS-IS.
- No IP address needs to be configured on SwitchG.

The following sections show the steps required to configure the SPBM IP Shortcuts parameters in this example.

### SwitchC

```

CIRCUITLESS INTERFACE CONFIGURATION - GlobalRouter

interface loopback 1
ip address 1 10.0.0.1/255.255.255.255

### Layer 3 VSN Configuration Fundamentals

This section provides fundamental concepts on Layer 3 VSN.

For information about supported service types, see [Fabric Connect Service Types](#) on page 1260.

#### SPBM Layer 3 VSN

The SPBM Layer 3 VSN feature is a mechanism to provide IP connectivity over SPBM for VRFs. SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF.

**Figure 131: SPBM Layer 3 VSN**

In the preceding figure, the BEBs are connected over the SPBM cloud running IS-IS. VRF red and green are configured on the BEBs. VRF red on BEB A has to send and receive routes from VRF red on BEB D. Similar operations are required for VRF green on BEB A and BEB D.

IS-IS TLV 184 is used to advertise SPBM Layer 3 VSN route information across the SPBM cloud. To associate advertised routes with the appropriate VRF, each VRF is associated with an I-SID. All VRFs in the network that share the same I-SID participate in the same VSN.

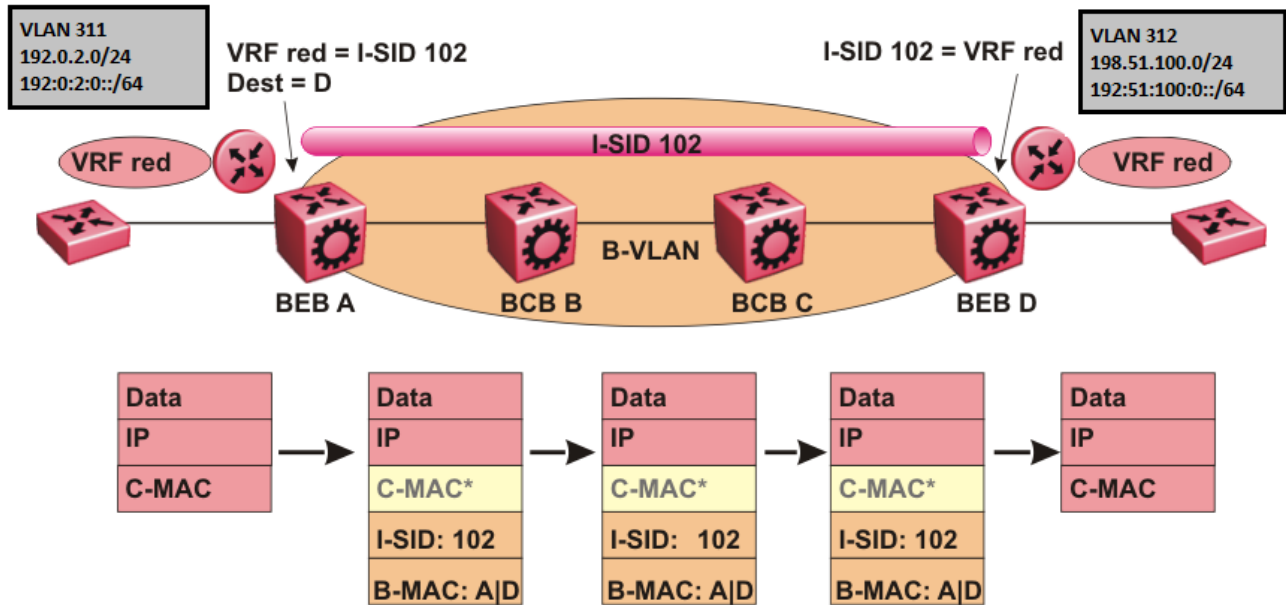

**Note**

IPv4 Layer 3 VSN and IPv6 Layer 3 VSN co-exist and share the same I-SID. You need to configure I-SID only once. The advantage of having two separate VPNs, one for IPv4 and one for IPv6 is because it gives user an option to enable them separately.

In this example, I-SID 101 is associated with VRF green and I-SID 102 is associated with VRF red. The I-SID is used to tie the advertised routes to a particular VRF. This identifier has to be the same on all edge nodes for a particular VRF, and has to be unique across all the VRFs on the same node

When IS-IS receives an update from an edge node, it looks for the Layer 3 VSN TLV, and if one exists, it looks at the I-SID identifier. If that identifier is mapped to a local VRF, extracts the IPv4 or IPv6 routes and add them to the RTM of that VRF.

With SPBM Layer 3 VSN, the packet forwarding works in a similar fashion as the IP Shortcuts on the Global Router, with the difference that the encapsulation includes the I-SID to identify the VRF that the packet belongs to. The following figure shows the packet forwarding for VRF red.

**Figure 132: Packet forwarding in SPBM Layer 3 VSN**

When BEB A receives traffic from VRF red that must be forwarded to the far-end location, it performs a lookup and determines that VRF red is associated with I-SID 102 and that BEB D is the destination for I-SID 102. BEB A then encapsulates the IP data into a new B-MAC header, using destination B-MAC: D.

**Note**

With SPBM Layer 3 VSN, the C-MAC header is all null. This header does not have any significance in the backbone. It is included to maintain the same 802.1ah format for ease of implementation.

At BEB D, the node strips off the B-MAC encapsulation, and performs a lookup to determine the destination for traffic with I-SID 102. After identifying the destination as VRF red, the node forwards the packet to the destination VRF.

**Note**

IPv4 Layer 3 VSN and IPv6 Layer 3 VSN co-exist and share the same I-SID. The advantage of having two separate VPNs, one for IPv4 and one for IPv6 is because it gives user an option to enable them separately.

**IPv6 Layer 3 VSN limitations and considerations**

Consider the following when you configure the IPv6 Layer 3 VSN :

- You can enable IPv6 Layer3 VSN only when **spbm boot** config flag is true.
- IPv4 Shortcuts and IPv6 Shortcuts must be enabled.

*Enable/disable ICMP Response on VRFs/Layer 3 VSNs*

This feature supports VRFs/Layer 3 VSNs to operate in stealth mode by disabling ICMP responses on specific VRFs/Layer 3 VSNs.

If the ICMP response is disabled, the switch does not respond to any ICMP requests received on the VRFs/Layer 3 VSNs.

If the ICMP response is enabled, the switch responds to ICMP requests received on the VRF/Layer 3 VSNs.

## Layer 3 VSN configuration using the CLI

This section provides a procedure to configure Layer 3 VSNs using the command line interface (CLI).

*Configure SPBM IPv4 Layer 3 VSN*

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 VSN to advertise IPv4 routes across the SPBM network from one VRF to another using the following procedure.

SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF. In the VRF, just like in the Global Router (VRF 0), the routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: direct, static, RIP, OSPF, or BGP. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

**Before You Begin**

- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF on the switch. For more information, see [VRF Lite configuration using the CLI](#) on page 3814.
- You must create the Customer VLANs and add slots/ports.

**Procedure**

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Create an IPv4 VPN instance on the VRF:

```
ipvpn
```

3. Configure SPBM Layer 3 VSN:

```
i-sid <0-16777215>
```

4. Enable IPv4 VPN on the VRF:

```
ipvpn enable
```

By default, a new IPv4 VPN instance is disabled.

5. Display all IPv4 VPNs:

```
show ip ipvpn [vrf WORD<1-16>] [vrffids WORD<0-512>]
```

6. Identify routes on the local switch to be announced into the SPBM network:

```
isis redistribute {direct | bgp | ospf | rip | static}
```

7. Enable routes on the local switch to be announced into the SPBM network:

```
isis redistribute {direct | bgp | ospf | rip | static} enable
```

8. If you want to delete or disable the configuration, use the no option:

```
no isis redistribute {direct | bgp | ospf | rip | static}
```

```
no isis redistribute {direct | bgp | ospf | rip | static} enable
```

9. Identify other routing protocols to which to redistribute IS-IS routes:

```
ip {bgp | ospf | rip} redistribute isis
```

10. Enable IS-IS redistribution to other routing protocols:

```
ip {bgp | ospf | rip} redistribute isis enable
```

11. Exit Privileged EXEC mode:

```
exit
```

12. Apply the configured redistribution:

```
isis apply redistribute {direct | bgp | ospf | rip | static} vrf
WORD<1-16>
```

```
ip bgp apply redistribute isis vrf WORD<1-16>
```

```
ip ospf apply redistribute isis vrf WORD<1-16>
```

```
ip rip apply redistribute isis vrf WORD<1-16>
```

13. Display the redistribution configuration:

```
show ip isis redistribute [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

Create the IPv4 VPN instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green

### Variable Definitions

The following table defines parameters for the **show ip ipvpn** command.

| Variable                  | Value                   |
|---------------------------|-------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies the VRF name. |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF ID.   |

The following table defines parameters for the **i-sid** command.

| Variable     | Value                                                                                                                                           |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <0-16777215> | Assigns an I-SID to the VRF being configured.<br>Use the <b>no</b> or <b>default</b> option to remove the I-SID to VRF allocation for this VRF. |

The following table defines parameters for the **isis redistribute** command.

| Variable                                          | Value                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{direct   bgp   ospf   rip   static}</code> | Specifies the protocol.                                                                                                                                                                                                                                                                                                       |
| <code>enable</code>                               | Enables the redistribution of the specified protocol into the SPBM network. The default is disabled. Use the <b>no</b> or <b>default</b> options to disable the redistribution.                                                                                                                                               |
| <code>metric &lt;0-65535&gt;</code>               | Configures the metric (cost) to apply to redistributed routes. The default is 1.                                                                                                                                                                                                                                              |
| <code>metric-type {external internal}</code>      | Configures the type of route to import into the protocol. The default is internal.                                                                                                                                                                                                                                            |
| <code>route-map WORD&lt;0-64&gt;</code>           | Configures the route policy to apply to redistributed routes. Specifies a name.                                                                                                                                                                                                                                               |
| <code>subnets {allow suppress}</code>             | Indicates whether the subnets are advertised individually or aggregated to their classful subnet. Choose <b>suppress</b> to advertise subnets aggregated to their classful subnet. Choose <b>allow</b> to advertise the subnets individually with the learned or configured mask of the subnet. The default is <b>allow</b> . |

The following table defines parameters for the **isis apply redistribute** command.

| Variable                                          | Value                                                                    |
|---------------------------------------------------|--------------------------------------------------------------------------|
| <code>{direct   bgp   ospf   rip   static}</code> | Specifies the protocol.                                                  |
| <code>vrf WORD&lt;1-16&gt;</code>                 | Applies IS-IS redistribute for a particular VRF. Specifies the VRF name. |

### Configure SPBM IPv6 Layer 3 VSN using CLI

#### Before You Begin

- You must enable IPv6 Shortcuts.
- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF instance on the switch. For more information, see [VRF Lite configuration using the CLI](#) on page 3814.

#### About This Task

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 VSN to advertise IPv6 routes across the SPBM network using the following procedure.

## Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:
 

```
enable

configure terminal

router vrf WORD<1-16>
```
2. Create an IPv6 VPN instance on the VRF:
 

```
ipv6 ipvpn
```
3. Configure SPBM Layer 3 VSN:
 

```
i-sid <0-16777215>
```
4. Enable IPv6 VPN on the VRF:
 

```
ipv6 ipvpn enable
```
5. Display all IPv6 VPNs:
 

```
show ipv6 ipvpn [vrf WORD<1-16> | vrfids WORD<0-512>]
```
6. Identify routes on the local switch to be announced into the SPBM network:
 

```
ipv6 isis redistribute {bgp | direct | ospf | static}
```
7. Enable routes on the local switch to be announced into the SPBM network:
 

```
ipv6 isis redistribute {direct | bgp | ospf | rip | static} enable
```
8. Identify the routing protocol to which to redistribute IS-IS routes:
 

```
ipv6 ospf redistribute isis
```
9. Enable IS-IS redistribution to OSPF:
 

```
ipv6 ospf redistribute isis enable
```
10. Return to Privileged EXEC mode:
 

```
end
```
11. Apply the configured redistribution to a specific VRF:
 

```
ipv6 isis apply redistribute {direct | bgp | ospf | rip | static} vrf
WORD<1-16>
```
12. Apply the OSPF configuration to a specific VRF:
 

```
ipv6 ospf apply redistribute isis vrf WORD<1-16>
```
13. Display the redistribution configuration:
 

```
show ipv6 isis redistribute [vrf WORD<1-16> | vrfids WORD<0-512>]
```
14. Verify IPv6 IS-IS routes:
 

```
show ipv6 route vrf WORD<1-16>
```

## Examples

Create the IPv6 VPN instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrfred
Switch:1(router-vrf)#ipv6 ipvpn
Switch:1(router-vrf)#i-sid 100
Switch:1(router-vrf)#ipv6 ipvpn enable
Switch:1(router-vrf)#show ipv6 ipvpn
=====
```

```

## Variable Definitions

The following table defines parameters for the **ipv6 ipvpn** command.

| Variable      | Value                                        |
|---------------|----------------------------------------------|
| <i>enable</i> | Enables IPv6 IPVPN. The default is disabled. |

The following table defines parameters for the **show ipv6 ipvpn** command.

| Variable                        | Value                   |
|---------------------------------|-------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies the VRF name. |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies the VRF ID.   |

The following table defines parameters for the **i-sid** command.

| Variable                  | Value                                         |
|---------------------------|-----------------------------------------------|
| <i>&lt;0-16777215&gt;</i> | Assigns an I-SID to the VRF being configured. |

The following table defines parameters for the **isis redistribute** command.

| Variable                              | Value                                                                                                   |
|---------------------------------------|---------------------------------------------------------------------------------------------------------|
| <i>{bgp   direct   ospf   static}</i> | Specifies the protocol.                                                                                 |
| <i>enable</i>                         | Enables the redistribution of the specified protocol into the SPBM network.<br>The default is disabled. |

Display SPBM IPv6 Unicast Forwarding Information Base

**About This Task**

Perform this procedure to display SPBM IPv6 unicast Forwarding Information Base (FIB).

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display SPBM IPv6 unicast FIB:

```
show isis spbm ipv6-unicast-fib [all] [id <1-16777215>] [spbm-nh-as-
mac] [home|remote]
```

**Example**

```
Switch:1>show isis spbm ipv6-unicast-fib
-----
                SPBM IPv6-UNICAST FIB ENTRY INFO
-----
VRF      VRF  Dest      OUTGOING  SPBM  PREFIX  METRIC  IP ROUTE

```

**Variable Definitions**

The following table defines parameters for the **show isis spbm ipv6-unicast-fib** command.

| Variable                     | Value                                                                                               |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <i>all</i>                   | Displays all IS-IS SPBM IPv6 unicast Forwarding Information Base (FIB) information for all VRFs.    |
| <i>home</i>                  | Displays the IS-IS SPBM IPv6 unicast FIB information that the system configures in the home area.   |
| <i>id &lt;1-16777215&gt;</i> | Displays IS-IS SPBM IPv6 unicast FIB information by I-SID ID.                                       |
| <i>remote</i>                | Displays the IS-IS SPBM IPv6 unicast FIB information that the system configures in the remote area. |
| <i>spbm-nh-as-mac</i>        | Displays the next hop B-MAC of the IPv6 unicast FIB entry.                                          |

Display IS-IS Link State Database Information

Perform the following procedure to display the IS-IS link state database related information on the switch.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS link state database information:

```
show isis lsdb ipv6-unicast [i-sid <0-16777215>] [lspid
xxxx.xxxx.xxxx.xx-xx] [sysid xxxx.xxxx.xxxx] [home|remote]
```

**Example**

```
Switch:1>show isis lsdb ipv6-unicast
=====
                    ISIS IPv6-UNICAST-ROUTE SUMMARY
=====

## Layer 3 VSN configuration using EDM

### Configure SPBM IPv4 Layer 3 VSN

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 Virtual Services Network (VSN) to advertise IPv4 routes across the SPBM network from one VRF to another using the following procedure.

SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF. In the VRF, just like in the Global Router (VRF 0), the routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: direct, static, RIP, OSPF, or BGP. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

### Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF and IP VPN instance on the switch. For more information about how to configure a VRF, see [VRF Lite configuration using Enterprise Device Manager](#) on page 3825.
- You must create the Customer VLANs and add slots/ports.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IP-VPN**.
3. Select the **VPN** tab.
4. To create an IP VPN instance, select **Insert**.
5. Select the ellipsis button (...), select a VRF to associate with the IP VPN, and click **Ok**.
6. Select **Insert**.
7. In the **Enable** column, select **enable** to enable the IP VPN on the VRF.
8. In the **IsidNumber** column, specify an I-SID to associate with the VPN.
9. Select **Apply**.
10. In the navigation pane, expand **Configuration > IP**.
11. Select **Policy**.
12. To identify routes on the local switch to be announced into the SPBM network, select the **Route Redistribution** tab.

13. Select **Insert**.
14. In the **DstVrflid** box, select the ellipsis (...), and then select the destination VRF ID and select **Ok**.
15. In the **Protocol** box, select **isis** as the route destination.
16. In the **SrcVrflid** box, select (...) button, select the source VRF ID and click **Ok**.
17. In the **RouteSource** box, select the source protocol.
18. In the **Enable** box, select **enable**.
19. In the **RoutePolicy** box, select the ellipsis (...), choose the route policy to apply to the redistributed routes and select **Ok**.
20. Configure the other parameters as required.
21. Select **Insert**.
22. To apply the redistribution configuration, select the **Applying Policy** tab.
23. Select **RedistributeApply**, and then select **Apply**.

### *Configuring SPBM IPv6 Layer 3 VSN using EDM*

#### **About This Task**

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 Virtual Services Network (VSN) to advertise IPv6 routes across the SPBM network from one VRF to another using the following procedure.

SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF.

#### **Before You Begin**

- You must enable IPv6 Shortcuts.
- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF and IPv6 VPN instance on the switch. For more information, see [VRF Lite configuration using Enterprise Device Manager](#) on page 3825.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IPv6-VPN**.
3. Click the **VPN** tab.
4. Click **Insert**.
5. Click the ellipsis [...], and select a VRF.
6. Click **Ok**.
7. Click **Insert**.
8. In the **IsidNumber** column, double-click the **0** value, and then enter the service instance identifier (I-SID) to assign to the IPv6-VPN.
9. Click **Apply**.
10. In the **Enable** column, select **true** or **false**.
11. Click **Apply**.
12. In the navigation pane, expand **Configuration > VRF Context View**.
13. Click **Set VRF Context View**.
14. Click the **VRF** tab.

15. Select a context to view.
16. Click **Launch VRF Context view**.  
A new browser tab opens containing the selected VRF view
17. In the navigation pane, expand **Configuration > IPv6**.
18. Click **IS-IS**.
19. Click the **Redistribute** tab.
20. Click **Insert**.
21. Configure the parameters as required.
22. Click **Insert**.
23. Click **Apply**.

## Layer 3 VSN configuration example

The following figure shows a sample Layer 3 VSN deployment.

**Figure 133: Layer 3 VSN**

The following sections show the steps required to configure the Layer 3 VSN parameters in this example.

Note that IP IS-IS redistribution needs to be configured to inject the VRF routes into IS-IS.

You must first configure basic SPBM and IS-IS infrastructure.

### *VRF green configuration*

The following figure shows the green VRF in this Layer 3 VSN example.

**Figure 134: Layer 3 VSN – VRF green**

The following sections show the steps required to configure the green VRF parameters in this example.

### VRF green - Switch-C

```
VRF CONFIGURATION

ip vrf green vrfid 1

|                                                                                         | VSP 4900 Series | VOSS 8.1<br>To support this feature, VIM installation is mandatory in VSP4900-48P. |
|                                                                                         | VSP 7200 Series | Not Supported                                                                      |
|                                                                                         | VSP 7400 Series | Not Supported                                                                      |
|                                                                                         | VSP 8200 Series | Not Supported                                                                      |
|                                                                                         | VSP 8400 Series | Not Supported                                                                      |
|                                                                                         | VSP 8600 Series | Not Supported                                                                      |
|                                                                                         | XA1400 Series   | Not Supported                                                                      |

### Layer 3 Video Surveillance install script

#### Note

The Layer 3 Video Surveillance install script performs the same function as the **run vms endura** script. However, the switch continues to support the **run vms endura** script for backward compatibility.

The **run vms layer-3 switch** command runs the Layer 3 Video Surveillance install script that pre-configures basic and common configuration parameters to deploy a video surveillance network. Use this script to quickly and easily deploy a video surveillance network in accordance with best practices, using networking equipment.

Use this script to use a single command on a switch to configure the core switch where the video surveillance management and operation systems reside. Similarly, using the same command, you can configure each edge switch where the IP cameras connect.

The switch must be in a factory-default state, to ensure correct operation of the configuration.

The Layer 3 Video Surveillance install script performs the following tasks:

- Creates a Shortest Path Bridging (SPB) network core solution with IP Shortcuts to connect IP subnet zones between the core and edge IP subnets.
- Configures all network edge IP subnet areas containing IP cameras with an IP gateway address, that is redistributed over the SPB fabric. This enables the fabric core to act as a single IP routing entity for the solution.

- Relays DHCP services between each IP subnet area and the central server, for IP camera address allocation.
- Enables IP multicast over Fabric Connect virtualization, to support and enable efficient IP multicast communication over the fabric core from IP cameras to central Video Management System (VMS) servers, for viewing and recording video streams.

#### *CLI Command Switch Value*

You must specify a value for the switch in the install script command, and the value must be between 5 and 99. Use the value 5 for a core switch where the VMS core systems are connected.

Use the range 6–99 for switch values when you run the script on edge or access layer switches. Ensure that the switch value is unique for each additional switch that is part of the solution.

For example, the first edge or access switch with the IP Cameras connected would use a value of switch 6. For additional edge or access switches, use switch 7, switch 8, and so on, for each IP subnet and IP camera zone. You can connect up to 48 IP cameras to a switch within an IP subnet zone.

#### *Switch Parameters Configured by the Script*

The following list identifies the major parameters configured by the **run vms layer-3** command:

- SNMP-Server switch hostname
- SPB parameters such as System ID, Nickname, SPB Area ID, Backbone VLAN IDs (4051 and 4052), Multicast virtualization, and Connectivity Fault Management (CFM)
- IP loopback interface addresses
- IP redistribution over IS-IS (IP Shortcuts)
- All SFP ports as SPB NNI ports
- All copper RJ-45 ports as end device ports with Spanning Tree enabled
- Spanning Tree mstprstp mode
- VLAN port memberships
- VLAN IP address (Gateway IP for VLAN)
- DHCP Relay

#### **Note**

DHCP Relay parameters are configured only when you run the script on VSP4900-48P switches.

#### *Configuration File*

After successful completion of the Layer 3 Video Surveillance install script, the switch saves the configuration with a filename based on the switch value provided when you ran the script. The switch updates the primary boot configuration file flags with the new filename.

For example, running the command **run vms layer-3 switch 5** results in a switch configuration filename of `spb-switch-5.cfg`.

### Hardware Considerations

The following list identifies which switches to configure as either a core or edge switch in a VMS solution:

- Core switch:
  - VSP 4450GSX-PWR+  
  
Ports 13 to 50 are network-to-network interface (NNI) ports. All other ports are untagged access ports.
  - VSP4900-12MXU-12XE  
  
Ports 1 to 12 and the Extreme Integrated Application Hosting (IAH) ports are untagged access ports. Ports 13 to 24, and optional Versatile Interface Module (VIM) ports, are NNI ports.
  - VSP4900-24S  
  
Ports 1 to 12 are untagged access ports. Ports 13 to 24, and optional VIM ports, are NNI ports.
  - VSP4900-24XE  
  
Ports 1 to 12 and the IAH ports are untagged access ports. Ports 13 to 24, and optional VIM ports, are NNI ports.
- Edge switch:
  - VSP4900-48P

#### Note

To support this feature, VIM installation is mandatory in VSP4900-48P. The VIM ports are configured as NNI ports while all fixed ports are untagged access ports.

### Modes

The **run vms layer-3** command can run in one of two modes:

- Non-verbose mode: This mode is a fully-automated configuration. The command runs the script with all of the variable defined values without user intervention. This mode is the default mode.
- Verbose mode: This mode prompts you to accept or change the default parameters.

#### Note

Product Notice: Verbose mode only applies to VSP 4900 Series.

## Run the Layer 3 Video Surveillance install script

Use the following procedure to run the Layer 3 Video Surveillance install script.

#### Note

The **run vms layer-3 switch** command performs the same function as the **run vms endura switch** command. The switch supports the **run vms endura switch** command only for backward compatibility.

## Before You Begin

The switch must be in a factory default state; the switch prompts you to confirm this.

## About This Task

Use a switch value of 5 for a switch in the network core where the Video Management System (VMS) servers connect. Use a switch value of 6 onwards (until and including 99) for all switches that connect IP Cameras at the network edge/access layer.

For each additional area and switch, increment the switch number by one. For example, use `switch 7` for the second edge switch. The configuration uses the number you specify to customize the IP subnet, loopback addresses, and SPB information.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Run the Layer 3 Video Surveillance install script:
 

```
run vms Layer-3 switch <5-99> [syntax | verbose]
```

## Examples

The following example shows the configuration of a switch in the VMS core and shows the configuration file created by the script.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#run vms layer-3 switch 5
Do you want to execute the run vms script? Device needs to be in factory default state.
(y/n) ? y
CP1 [05/05/17 07:48:33.760:IST] 0x000045e3 00000000 GlobalRouter SNMP INFO Save config
successful.
CP1 [05/05/17 07:48:37.951:IST] 0x000045e3 00000000 GlobalRouter SNMP INFO Save config
successful.

**Previous configurations stored in pre_vms_install.cfg**
**New VMS configurations stored in new primary config file spb-switch-5.cfg**

*** VMS script execution complete ***
Switch:1(config)#exit
Switch:1#
```

The following example shows the configuration of a switch at the edge, and shows the configuration file created by the script.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

switch:1(config)#run vms layer-3 switch 6
Do you want to execute the run vms script? Device needs to be in factory default state.
(y/n) ? y
CP1 [05/05/17 07:54:04.046:IST] 0x000045e3 00000000 GlobalRouter SNMP INFO Save config
successful.
```

```

CP1 [05/05/17 07:54:05.760:IST] 0x000045e3 00000000 GlobalRouter SNMP INFO Save config
successful.

**Previous configurations stored in pre_vms_install.cfg**
**New VMS configurations stored in new primary config file spb-switch-6.cfg**

*** VMS script execution complete ***
Switch:1(config)#exit
Switch:1#

```

### Variable Definitions

The following table defines parameters for the **run vms Layer-3 switch** command.

| Variable       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <5-99>         | <p>Specifies the numeric switch value used as a common element to configure switch parameters such as name, VLAN ID, SPB, and IP parameters.</p> <p><b>Note:</b><br/>Use a switch value of 5 for a switch in the network core where the Video Management System (VMS) servers are connected. Use a value of 6 onwards (until and including 99) for all switches used for connecting IP Cameras at the network edge/access layer.</p> |
| <i>syntax</i>  | <p>Species that the switch displays all the commands run by the script on the console. Use this parameter to see errors that the script encounters.</p> <p><b>Note:</b><br/>The script does not stop if it encounters errors. To verify that the script runs without errors, use the <i>syntax</i> parameter to display errors or conflicting configurations on the switch.</p>                                                      |
| <i>verbose</i> | <p>Specifies that the switch prompts you to accept or change the default configuration values. If you do not use this optional parameter, the script runs without user intervention.</p>                                                                                                                                                                                                                                             |

## IP multicast fundamentals

---

IP multicast extends the benefits of Layer 2 multicasting on LANs to WANs. Use multicasting techniques on LANs to help clients and servers find each other. With IP multicast, a source can send information to multiple destinations in a WAN with a single transmission. IP multicast results in efficiency at the source and saves a significant amount of bandwidth.

### Enabling multicast on the switch

Shortest Path Bridging (SPB) and Protocol Independent Multicast (PIM) cannot interoperate with each other on the switch at the same time. To ensure that SPB and PIM stay mutually exclusive, use the boot flag called **spbm-config-mode**:

- The **spbm-config-mode** boot flag is enabled by default. This configuration enables you to configure SPB and IS-IS, but you cannot configure PIM either globally or on an interface.

- If you disable the boot flag, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

#### Important

- Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.
- If you plan to disable the boot flag, remove all SPB configurations first.
- If you plan to use the default (enabled) setting, remove all PIM configurations first.

#### *Simplified Virtual-IST*

Simplified Virtual-IST (vIST) is for conventional network deployments that use SMLT and not SPB. The Simplified vIST feature provides a single CLI command to enable the virtual IST for SMLT deployments.

- Simplified vIST is available ONLY for conventional multicast deployments with PIM and IGMP when the boot flag (**spbm-config-mode**) is disabled.
- When the boot flag is enabled (default setting), Simplified vIST is not available. This means that you continue to configure SPB/IS-IS for vIST.
- Simplified vIST requires that the two vIST devices be directly connected.

#### Note

- PIM is supported with Simplified vIST only, not SPB vIST. However, you do not have to configure Simplified vIST to run PIM or IGMP Snooping in a **non-SMLT** topology.
- Do not configure LACP on SPB NNI MLT links or on the Simplified Virtual IST.
- Do not configure ECMP in PIM Simplified vIST scenarios. Running PIM in a Simplified vIST environment with ECMP enabled may lead to incorrect behavior since there are multiple options in terms of choosing the upstream node towards a host or source. For example, since the path chosen cannot be predicted (it is determined by the downstream PIM neighbor), we may end up not adding the Virtual IST MLT port in the PIM mroute's outgoing port list on the joined interface if the PIM Join Prune Message was received on an alternative path, different from the interface the local router considers to be the correct upstream to the source.

Traffic loss can occur in such an environment. Do not enable ECMP in PIM vIST scenarios.

After you disable the **spbm-config-mode** boot flag, you can configure PIM or IGMP Snooping on any VLAN including the vIST VLAN.

To configure the boot flag and Simplified vIST, see [Configuring IP multicast in SMLT topologies](#) on page 1502 or [Configuring multicast on the switch](#) on page 1522.

#### *vIST VLAN IP addresses*

Do not configure an RP or BSR on the vIST VLAN because you cannot ping them outside of the vIST VLAN subnet. When you enter the **ip pim enable** command on the vIST VLAN, the following message displays:

```
WARNING: Please do not use virtual IST VLAN IP address for BSR and RP
related configurations, as unicast packets to virtual IST vlan IP
```

address from outside of virtual IST vlan subnet will be dropped. Use Loopback or CLIP interface IP address for BSR and RP related configurations.

## Overview of IP multicast

IP multicast transmits messages to multiple recipients at the same time. This one-to-many delivery mechanism is similar to broadcasting, except that multicasting transmits to specific groups and broadcasting transmits to all receivers on a network. Because IP multicast transmits only one stream of data to the network where it replicates to many receivers, multicasting saves a considerable amount of bandwidth.

IP multicast services benefit applications such as video conferencing, dissemination of datagram information, and dissemination of mail or news to a large number of recipients.

Multicast protocols use different techniques to discover delivery paths.

A distribution tree is a set of multicast routers and subnetworks that permit the members of a group to receive traffic from a source. The source of the tree depends on the algorithm used by the multicast protocol. The following diagram is an example of a simple distribution tree where S is the multicast source and the arrows indicate the multicast broadcast procedure.

**Figure 136: Multicast distribution tree and broadcasting**

Broadcast and prune methods use multicast traffic to build the distribution tree. Periodically, the source sends or broadcasts data to the extremities of the internetwork to search for active group members. If no local members of the group exist, the router sends a message to the host, removing itself from the distribution tree, and thus pruning the router.

The following diagram illustrates how the host prunes routers from the distribution tree. First, the router sends a message to the source, after which the pruned routers do not receive multicast data.

**Figure 137: Pruning routers from a distribution tree**

Reverse path multicast is based on the concept that a multicast distribution tree is built on the shortest path from the source to each subnetwork that contains active receivers. After a datagram arrives on an interface, the router determines the reverse path to the source of the datagram by examining the routing table of known network sources. If the datagram is not on the optimal delivery tree, the router discards it.

Multicast host groups and their group members enable the IP multicast router to transmit just to those groups interested in receiving the traffic. The switch uses the Internet Group Membership Protocol (IGMP) to learn the existence of host group members on their directly attached subnets. A router communicates with the hosts on a local network by sending IGMP queries. Hosts respond by issuing IGMP reports. For more information about host groups, see [Multicast host groups](#) and [Multicast addresses](#) on page 1436. For more information about IGMP, see [Internet Group Management Protocol](#).

Multicast traffic forwarding transmits frames to all interfaces or subnets for which it receives IGMP reports for the multicast group indicated in the destination IP address. Multicast packets forwarded within the same virtual LAN (VLAN) remain unchanged. The switch does not forward packets to networks that do not use members of the multicast group indicated in the destination IP address.

#### *Multicast host groups*

IP multicast is a method for addressing, routing, and delivering a datagram to a collection of receivers called a host group.

Host groups are permanent or transient, with the following characteristics:

- A permanent host group uses a well-known, administratively assigned IP multicast group address. This address is permanent and defines the group. A permanent host group can consist of zero or more members.

- A transient host group exists only as long as members need its services. IP addresses in the multicast range that are not reserved for permanent groups are available for dynamic assignment to transient host groups.

A host system on an IP network sends a message to a multicast group by using the IP multicast address for the group. To receive a message addressed to a multicast group, however, the host must be a member of the group and must reside on a network where that group is registered with a local multicast router.

An IP multicast host group can consist of zero or more members and places no restrictions on its membership. Host members can reside anywhere, they can join and leave the group at any time, and they can be members of more than one group at the same time.

In general, hosts that are members of the same group reside on different networks. However, a range of multicast addresses (224.0.0.x) is reserved for locally-scoped groups. All message traffic for these hosts typically remains on the local network. Hosts that belong to a group in this address range and that reside in different networks do not receive message traffic for each other.

#### Important

You can apply a special set of filters (global filters) to multicast packets. You can also create, deny, or accept filters to configure the sources that can receive and send data. For more information about how to configure filters, see [Traffic filtering fundamentals](#) on page 3378.

#### *Multicast addresses*

Each host group uses a unique multicast address. To reach all members of the group, a sender uses the multicast address as the destination address of the datagram.

An IP version 4 multicast address is a Class D address (the high-order bits are 1110) from 224.0.0.0 to 239.255.255.255. These addresses are assigned statically for use by permanent groups and dynamically for use by transient groups.

The block of addresses from 224.0.0.1 to 224.0.0.255 is reserved for routing protocols and other low-level protocols. Multicast routers do not forward datagrams with addresses in this range because the time-to-live (TTL) value for the packet is usually 1.

#### *Multicast protocols*

You can use the following protocols to enable multicast routing on a switch:

- Internet Group Management Protocol (IGMP)—learns the existence of host group members on directly attached subnets.
- Multicast Router Discovery (MRDISC) protocol—discovers multicast routers in a Layer 2 bridged domain configured for IGMP snoop.
- Protocol Independent Multicast (PIM)
  - Sparse Mode (PIM-SM) protocol—suitable for implementation on networks sparsely populated by receivers.
  - Source Specific Multicast (PIM-SSM) protocol—uses a one-to-many model where members can receive traffic from one or more specific sources. This protocol is suitable for television channels and other content-distribution applications.

### *Static source groups*

Use static source groups to configure static source-group entries in the PIM-SM, or PIM-SSM multicast routing table. PIM cannot prune these entries from the distribution tree. In other words, even if no receivers for the group exist, the multicast stream for a static source-group entry stays active. PIM never prunes static forwarding entries. If you no longer need the entries, you must manually delete them.

To configure static source groups, you must first globally enable PIM. If you disable PIM, the switch saves all of the configured static source-group entries and deactivates them. After you re-enable PIM, the switch reactivates the static source groups.

Static source groups ensure that the multicast route (mroute) records remain in the distribution tree. After receivers join the group, they do not experience a delay in receiving multicast data because they do not need to graft onto the group, or start a join process in the case of PIM. This timing is essential for applications where the multicast data must send to a receiver as soon as the receiver joins the group, for example, when a switch delivers television channels to receivers. After the receiver turns the channel, which is equivalent to joining a group, the receiver can view the channel immediately.

Static entries result in continuous traffic if the source is active, even if no receivers exist. However, the system does not forward traffic with a static entry if no receivers exist, but forwards it continuously to the switch where the entry is programmed and crosses intermediate switches on the path.

You can configure static source-group entries for a specific source or subnet. If several sources on the same subnet send traffic to the same group, traffic for all these sources flows continuously when using the subnet configuration.

After you configure static source groups, keep the following points in mind:

- If you disable PIM, the switch deactivates all of the static source groups. After you re-enable PIM, the switch activates the static source groups.
- In PIM-SM configuration, the static source-group feature works for both specific source addresses and subnet addresses by using the SrcSubnetMask field.

When the network mask is 255.255.255.255, the full source address is used to match the (S,G) which is the specific source case. When the network mask field is a subnet mask for the source, only the source subnet is used to match (S,G)s.

- In PIM-SSM configurations, static source groups have the following limitations:
  - Subnets: SSM static source groups work only with specific IP addresses. Static source groups cannot work with source subnets, so the mask must use a full 32-bit mask, 255.255.255.255, and the source must use a host address.

### *IP Multicast over Fabric Connect*

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. These extensions, combined with the use of IGMP snooping and querier functions at the edge of the SPBM cloud, efficiently transport IP multicast data by using sub-trees of the VSN shortest path tree per IP multicast group.

## Internet Group Management Protocol

**Table 113: Internet Group Management Protocol product support**

| Feature                                                             | Product         | Release introduced |
|---------------------------------------------------------------------|-----------------|--------------------|
| Internet Group Management Protocol (IGMP), including virtualization | 5420 Series     | VOSS 8.4           |
|                                                                     | 5520 Series     | VOSS 8.2.5         |
|                                                                     | VSP 4450 Series | VSP 4000 4.0       |
|                                                                     | VSP 4900 Series | VOSS 8.1           |
|                                                                     | VSP 7200 Series | VOSS 4.2.1         |
|                                                                     | VSP 7400 Series | VOSS 8.0           |
|                                                                     | VSP 8200 Series | VSP 8200 4.0.1     |
|                                                                     | VSP 8400 Series | VOSS 4.2           |
|                                                                     | VSP 8600 Series | VSP 8600 4.5       |
|                                                                     | XA1400 Series   | Not Supported      |

A host uses IGMP to register group memberships with the local querier router to receive datagrams sent to this router targeted to a group with a specific IP multicast address.

A router uses IGMP to learn the existence of group members on networks to which it directly attaches. The router periodically sends a general query message to each of its local networks. A host that is a member of a multicasting group identifies itself by sending a response.

### *IGMP queries*

When multiple IGMP routers operate on a network, one router is elected to send queries. This elected querier periodically sends host membership queries (also known as general queries) to the attached local subnets. The switch supports queries from all three versions of IGMP.

### *IGMP host reports*

A host that receives a membership query from a local router can respond with a host membership report, one for each multicast group that joins. A host that receives a query delays its reply by a random interval and listens for a reply from other hosts in the same host group. For example, consider a network that includes two host members—host A and host B—of the same multicast group. The router sends out a host membership query on the local network. Both host A and host B receive the query and listen on the network for a host membership report. The delay timer for host B expires first, so it responds to the query with a membership report. Hearing the response, host A does not send a report of its own for the same group.

Each query from a router to a host includes a maximum response time field. IGMP inserts a value  $n$  into this field specifying the maximum time in tenths of a second within which the host must issue a reply. The host uses this value to calculate a random value between 0 and  $n$  tenths of a second for the period that it waits before sending a response. This calculation is true for IGMP versions 2 and 3. For IGMP version 1, this field is 0 but defaults to a value of 100, that is, 10 seconds.

If at least one host on the local network specifies that it is a member of a group, the router forwards to that network all datagrams that bear the multicast address for the group.

Upon initialization, the host can immediately issue a report for each of its supported multicast groups. The router accepts and processes these asynchronous reports the same as requested reports.

After hosts and routers are in a steady state, they communicate in a way that minimizes the exchange of queries and reports. The designated routers establish a path between the IP multicast stream source and the end stations and periodically query the end stations about whether to continue participation. As long as a client continues to participate, all clients, including nonparticipating end stations on the switch port, receive the IP multicast stream.

#### *Host leave messages*

If an IGMPv2 host leaves a group and it is the host that issues the most recent report, it also issues a leave group message. The multicast router on the network issues a group-specific query to determine whether other group members exist on the network. If no host responds to the query, the router assumes that no members belonging to that group exist on that interface.

#### *Fast leave feature*

The switch supports a fast leave feature that is useful for multicast-based television distribution applications. Fast leave relies on an alternative leave process where the switch stops sending traffic for the group immediately after it receives a leave message, without issuing a query to check if other group members exist on the network. Fast leave alleviates the network from additional bandwidth demand after a customer changes television channels.

The switch provides several fast leave processes for IP multicast:

- immediate leave with one user for each interface
- immediate leave with several users for each interface
- standard IGMP leave based on a Last Member Query Interval (LMQI), which you can configure in tenths of seconds

Fast leave modifies the IGMP leave processing mechanism on an IGMP interface. After the system receives an IGMP leave message on a fast leave enabled interface, the switch does not send a group-specific query and immediately stops sending traffic to the leaving member (IGMP host) port. Without fast leave, traffic continues to forward until the group times out. This situation wastes bandwidth if no receiver that requires the group traffic exists.

Fast leave mode provides two options of the fast leave mechanism—single-user mode and multiple-users mode:

- **Single-user mode:** In this mode, the port stops receiving traffic immediately after a group member on that port sends a leave message. Use the single-user mode if each interface port connects to only one IGMP host.
- **Multiple-users mode:** Use this mode if the interface port connects to multiple IGMP hosts. In this case, the port stops receiving traffic after all members leave the IGMP group. The switch removes the leaving IGMP member and, if more group members exist on that port, the switch continues sending traffic to the port.

When operating in multiple-users mode, the switch must use the correct membership information. To support multiple-users mode, multicast receivers on the same interface cannot use IGMP report suppression. If you must use IGMP report suppression, do not use this mode. Instead, use the LMQI

(configurable in units of 1/10ths of seconds) to provide a faster leave process while still sending group-specific queries after the interface receives a leave message.

Fast leave mode applies to all fast-leave enabled IGMP interfaces.

### *IGMP snoop*

The switch provides IP multicast capability and can support all three versions of IGMP to prune group membership for each port within a VLAN. This feature is IGMP snoop.

#### **Important**

IGMP snoop can optimize only local multicast data flow. IGMP snoop does not manage the forwarding state of the multicast tree. You cannot configure a port as a static receiver in an IGMP snoop-enabled VLAN that does not contain at least one dynamic receiver port and forward multicast data.

Use the IGMP snoop feature to optimize the multicast data flow, for a group within a VLAN, to only those ports that are members of the group. The switch builds a database of group members by listening to IGMP reports from each port. The switch suppresses the reports heard by not forwarding them to ports other than the one receiving the report, thus forcing the members to continuously send their own reports. The switch relays group membership from the hosts to the multicast routers and forwards queries from multicast routers to all port members of the VLAN. Furthermore, the switch forwards multicast data only to the participating group members and to the multicast routers within the VLAN.

The multicast routing functionality can coexist with IGMP snoop on the same switch, but you can configure only one of IGMP snoop or an IP multicast routing protocol, excluding IGMP, on the same VLAN.

### *Multicast group trace for IGMP snoop*

Use this feature to monitor the multicast group trace for an IGMP snoop-enabled switch. You can view the multicast group trace from CLI.

Multicast group trace tracks the data flow path of the multicast streams. Group trace tracks information such as the multicast group address, the source address, ingress VLAN and port, and egress VLAN and port.

### *IGMP proxy*

If a switch receives multiple reports for the same multicast group, it does not transmit each report to the multicast upstream router. Instead, the switch consolidates the reports into a single report and forwards the one report. If you add another multicast group or the system receives a query since it last transmitted the report upstream, the system forwards the report onto the multicast router ports. This feature is IGMP proxy.

### *IGMP versions*

The switch supports IGMPv1, IGMPv2, and IGMPv3. IGMPv1 and IGMPv2 are backward compatible and can exist together on a multicast network. The following list describes the purpose for each version:

- IGMPv1 provides the support for IP multicast routing. IGMPv1 specifies the mechanism to communicate IP multicast group membership requests from a host to its locally attached routers. For more information, see RFC1112.

- IGMPv2 extends the features in IGMPv1 by quickly reporting group membership termination to the routing protocol. This feature is important for multicast groups with highly volatile group membership. For more information, see RFC2236.
- IGMPv3 supports the PIM Source Specific Multicast (SSM) protocol, PIM-SM, and snooping. A host can selectively request or filter traffic from individual sources within a multicast group or from specific source addresses sent to a particular multicast group. Multicast routing protocols use this information to avoid delivering multicast packets from specific sources to networks where there are no interested receivers. For more information, see RFC3376.

For the switch implementation of PIM-SSM, each group can use multiple sources.

The following list identifies group records that a report message includes:

- current-state record
- source-list-change record
- filter-mode-change record

A current-state record is sent by a system in response to a query received on an interface. It reports the current reception state of that interface, with respect to a single multicast address.

The Record Type of a current-state record has one of the following two values:

- `MODE_IS_INCLUDE` — Indicates that the interface has a filter mode of include for the specified multicast address. The source address fields in this group record contain the source list of the interface for the specified multicast address.
- `MODE_IS_EXCLUDE` — Indicates that the interface has a filter mode of exclude for the specified multicast address. The source address fields in this group record contain the source list of the interface for the specified multicast address.

Source-List Change Record — The system sends a source-list-change record after a change of source list occurs that does not coincide with a filter-mode change on the interface for a particular multicast address. The interface on which the change occurs sends a report that includes the record. The record type of a source-list-change record can be one of the following two values:

- `ALLOW_NEW_SOURCES` — Indicates that the source address [i] fields in this group record contain a list of the additional sources that the system wishes to hear from, for packets sent to the specified multicast address. If the change was to an include source list, these are the addresses that were added to the list. If the change was to an exclude source list, these are the addresses that were deleted from the list.
- `BLOCK_OLD_SOURCES` — Indicates that the source address [i] fields in this group record contain a list of the sources that the system no longer wishes to hear from, for packets sent to the specified multicast address. If the change was to an include source list, these are the addresses that were deleted from the list; if the change was to an exclude source list, these are the addresses that were added to the list.

If a change of source list results in both allowing new sources and blocking old sources, then two group records are sent for the same multicast address, one of type `ALLOW_NEW_SOURCES` and one of type `BLOCK_OLD_SOURCES`.

Filter Mode — The switch implements the filter-mode-change record. The system sends a filter-mode-change record whenever the filter mode changes (during a change from include to exclude, or from exclude to include) for a particular multicast address. The interface on which the change occurs sends a

report that includes the record. The record type of a filter-mode-change record can be one of the following two values:

- `CHANGE_TO_INCLUDE_MODE` — Indicates that the interface has changed to include filter mode for the specified multicast address. The source address [i] fields in this group record contain the new source list of the interface for the specified multicast address.
- `CHANGE_TO_EXCLUDE_MODE` — Indicates that the interface has changed to exclude filter mode for the specified multicast address. The source address [i] fields in this group record contain the new source list of the interface for the specified multicast address.

After you enable IGMPv3, the following actions occur:

- After you change the version on an interface to or from IGMPv3, the switch experiences a disruption to existing multicast traffic on that interface but traffic does recover. Do not make this change when the system passes multicast traffic.

### *IGMP states*

Multicast routers implementing IGMPv3 keep one state for each group for every port in every attached network. This group state consists of a filter-mode, a list of sources, and various timers. For each attached network running IGMP, a multicast router records the desired reception state for that network. This state consists of a set of records of the following form:

- multicast address
- group timer
- filter mode (source records)

Each source record is of the form source address or source timer. If all sources within a given group are desired, an empty source record list is kept with filter-mode set to EXCLUDE. This means hosts on this network want all sources for this group to be forwarded. This is the IGMPv3 equivalent to a IGMPv1 or IGMPv2 group join.

### *Group timer*

A group timer represents the time for the filter-mode to expire and switch to INCLUDE mode and is used only when a group is in EXCLUDE mode.

Group timers are updated according to the types of group records received. If a group timer is expiring when a router filter-mode for the group is EXCLUDE means, there are no listeners on the attached network in EXCLUDE mode. At this point, a router will transition to INCLUDE filter-mode.

### *Source timer*

A source timer is maintained for every source record. Source timers are updated according to:

- the type and filter-mode of the group record received
- whenever the source is present in a received record for that group.

If a source timer expires with a router filter-mode for the group of INCLUDE, the router concludes that traffic from this particular source is no longer desired on the attached network, and deletes the associated source record.

If a source record has a running timer with a router filter-mode for the group of EXCLUDE, it means that at least one system desires the source. It should therefore be forwarded by a router on the network. If a source timer expires with a router filter-mode for the group of EXCLUDE, the router informs the routing

protocol that there is no receiver on the network interested in traffic from this source. The records are deleted when the group timer expires in the EXCLUDE router filter-mode.

### *Processing IGMP messages for groups in SSM range*

IGMP messages are processed for groups in SSM range in the following scenarios:

1. IGMPv3 interface enabled; PIM-sparse or snooping enabled
  - IGMPv3 reports that contain group records with groups within SSM range are processed with no restrictions.
  - IGMPv2 reports for groups within SSM range translate to IGMPv3 reports with one group record and type IS\_EXCLUDE{NULL}. These reports are processed with no restriction as an IGMPv3 report.
  - IGMPv2 leave for groups within SSM range translate to IGMPv3 reports with one group record and type TO\_INCLUDE{NULL}. These reports are processed with no restriction as an IGMPv3 report.
2. IGMPv3 interface enabled; PIM-SSM or ssm-snooping enabled
  - IGMPv3 reports that contain group records with groups within SSM range received from members in the EXCLUDE mode are discarded (eg. IS\_EXCLUDE and TO\_EXCLUDE messages).
  - IGMPv2 reports for groups within SSM range translate to IGMPv3 reports with one group record and type ALLOW{S1,S2,...}. The source list is obtained from the global ssm-map. If there are no sources in the global ssm-map, the message is discarded. These reports are processed with no restriction as an IGMPv3 report.
  - IGMPv2 leave for groups within SSM range translate to IGMPv3 reports with one group record and type BLOCK{S1,S2,...}. The source list is obtained from the global ssm-map. If there are no sources in the global ssm-map, the message is discarded. These reports are processed with no restriction as an IGMPv3 report.

#### **Note**

In order to accept v2 messages, you must enable the compatibility mode on the IGMPv3 interface.

### *IGMPv3 source-specific forwarding rules*

After a multicast router receives a datagram from a source destined to a particular group, the router must decide to forward the datagram to the attached network. The multicast routing protocol uses IGMPv3 information to forward datagrams to all required sources or groups on a subnetwork.

The following table describes the forwarding suggestions that IGMPv3 makes to the routing protocol. The table also identifies the action taken after the source timer expires, based on the filter mode of the group.

| Group filter-mode | Source-timer value | Action                                                                                                                                             |
|-------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| INCLUDE           | TIMER > 0          | Forward the traffic from the source.                                                                                                               |
| INCLUDE           | TIMER = 0          | Stop forwarding the traffic from the source, and remove the source record. If no more source records exist for the group, delete the group record. |

| Group filter-mode | Source-timer value | Action                                                                                                              |
|-------------------|--------------------|---------------------------------------------------------------------------------------------------------------------|
| INCLUDE           | No source elements | Do not forward the source.                                                                                          |
| EXCLUDE           | TIMER > 0          | Forward the traffic from the source.                                                                                |
| EXCLUDE           | TIMER = 0          | Do not forward the traffic from the source. If no more source records exist for the group, delete the group record. |
| EXCLUDE           | No source elements | Forward the traffic from the source.                                                                                |

### *IGMPv3 explicit host tracking*

IGMPv3 explicit host tracking enables the IGMP to track all the source and group members. To track all the source and group members, the sources that are in the include mode hold a list of members who want to receive traffic from that source.

The members that are in the exclude mode are on hold on the reporter list under the port data. By default, IGMPv3 explicit host tracking is disabled.

#### **Important**

If explicit host tracking is enabled, you cannot downgrade the IGMPv3 interface to IGMPv1 or IGMPv2.

### *IGMPv3 fast leave*

When a BLOCK message is received for a source, you must check if the member that sent this message is the last reporter for the source. If it is the last reporter, delete the source. Else, delete the member. No group and source specific queries are sent.

When a LEAVE message is received, you must check if the member that sent this message is the last reporter for the group. If it is the last reporter, switch to INCLUDE mode if sources are available (if no sources are available the port is deleted). Else, delete the member. No group and source specific queries or group specific queries are sent.

#### **Important**

To use the IGMPv3 fast leave feature, you must first enable the explicit host tracking feature.

### *Synchronization of IGMPv3 over SMLT*

The implementation of IGMPv3 offers support for IGMPv3 over SMLT. The Virtual-IST (vIST) peers must be in sync with the IGMPv3 reports received over SMLT links to ensure effective performance. The vIST protocol ensures the infrastructure to send such information from one vIST peer to the other.

The synchronization of IGMPv3 members and their advertised sources is different from IGMPv1 and IGMPv2. Because of IGMPv3 compatibility mode, you must consider the IGMP member version. If you have version 1 or 2 members, you must synchronize the IGMP information as IGMPv1 or IGMPv2 reports, so the peer can build an accurate database. In particular, if members with version 1 or 2 exist, the group filter mode is exclude and the exclude source list is empty. Also no v1 or v2 member will be present on any source from include list.

Each member sends IGMP reports in the same manner for all IGMP versions. The sending mechanism depends on the SMLT state.

After a vIST peer receives an IGMPv3 report over an SMLT link, it must pass the message to its peer. If the SMLT state is up, the vIST peer sends the message encapsulated in an vIST IGMPv3 message. If the SMLT state is down, the vIST peer sends the message as a plain IGMPv3 report.

In both cases the IGMPv3 message is not altered and the receiving vIST peer processes it as expected in SMLT conditions (translating the receiving port to SMLT port if applicable).

**Note**

If you enable compatibility mode and the member sends an IGMPv1 or IGMPv2 report, the message is either a vIST IGMPv1 or v2 encapsulated Message or a plain IGMPv1 or IGMPv2 report.

After SMLT up or down events occur, the vIST peer must synchronize its IGMPv3 database to its peer, taking into account the new state of the SMLT link.

If you enable IGMP explicit host tracking, each include source stores information for each member that advertises that particular source in an include list. This information is synchronized with the vIST peer.

If you do not enable explicit host tracking, each source from include list contains only information related to the last member that sent an IGMPv3 report. Only this information is synchronized with the vIST peer.

*Backward compatibility*

IGMPv3 for PIM-SSM is backward compatible with IGMPv2. You can configure the switch to operate in v3-only mode or in v2-v3 compatibility mode. If you configure the switch to use v3-only mode, it ignores all v2 and v1 messages except the query message.

If you configure the switch to operate in v2-v3 compatibility mode, the switch supports all IGMPv1, v2, and v3 messages. The switch parses the group address of the messages. If the group address is out of SSM range and it is a v3 message, the switch drops the message; if it is a v2 message, PIM-SM or IGMP snoop processes handle the message.

After the switch receives an IGMPv2 leave message and the group address in it is within SSM range, the switch sends the group-and-source specific query. If the group address is not within the SSM range, the switch sends the group specific query.

According to RFC3376, the multicast router with IGMPv3 can use one of two methods to handle older query messages:

- If an older version of IGMP is present on the router, the querier must use the lowest version of IGMP present on the network.
- If a router that is not explicitly configured to use IGMPv1 or IGMPv2 hears an IGMPv1 query or IGMPv2 general query, it logs a rate-limited warning.

You can configure if the switch dynamically downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning.

In v2-v3 compatibility mode, an IGMPv2 host can only join if you configure a static entry in SSM map and if the interface operates in PIM-SSM mode or IGMP SSM-Snoop mode.

You can use the compatibility mode with Split MultiLink Trunking (SMLT). One core switch sends an SMLT message to the other core switch after it receives an IGMPv3 message. This action synchronizes the IGMP host information.

#### *Implementation of IGMP*

You can enable and disable multicast routing on an interface basis. If you disable multicast routing on an interface, the interface does not generate IGMP queries. If the switch or interface is in IGMP router behavior mode, for example, PIM enabled, you cannot configure IGMP snoop. The switch still learns the group membership and snoops multicast receivers on the switch VLAN or ports.

## IGMP Layer 2 Querier

In a Layer 2 multicast network, you can enable Layer 2 querier on one of the switches in the VLAN. IGMP Layer 2 querier provides the IGMP querier function so that the switch can provide the recurring queries that maintain IGMP groups when you do not use multicast routing for multicast traffic.

#### *Overview*

In a multicast network, if you only need to use Layer 2 switching for the multicast traffic, you do not need multicast routing. However, you must have an IGMP querier on the network for multicast traffic to flow from sources to receivers. A multicast router provides the IGMP querier function. You can also use the IGMP Layer 2 Querier feature to provide a querier on a Layer 2 network without a multicast router.

The Layer 2 querier function originates queries for multicast receivers, and processes the responses accordingly. On the connected Layer 2 VLANs, IGMP snoop continues to provide services as normal. IGMP snoop responds to queries and identifies receivers for the multicast traffic.

You must enable Layer 2 querier and configure an IP address for the querier before it can originate IGMP query messages. If a multicast router exists on the network, the switch automatically disables the Layer 2 querier.

In a Layer 2 multicast network, enable Layer 2 querier on only one of the switches in the VLAN. A Layer 2 multicast domain supports only one Layer 2 querier. No querier election exists.

#### *IGMP Snooping*

IGMP Snooping enables Layer 2 switches in the network to examine IGMP control protocol packets exchanged between downstream hosts and upstream routers.

When Layer 2 switches examine the IGMP control protocol packets, they:

- Generate the Layer 2 MAC forwarding tables used for further switching sessions
- Regulate the multicast traffic to prevent it from flooding the Layer 2 segment of the network

#### *IGMP Layer 2 Querier and IGMP interaction*

IGMP Layer 2 Querier uses IGMP to learn which groups have members on each of the attached physical networks, and it maintains a list of multicast group memberships for each attached network and a timer for each membership. In this case, multicast group memberships means the presence of at least one member of a multicast group on a given attached network, not a list of all of the members.

IGMP Layer 2 Querier can assume one of two roles for each of the attached networks:

- Querier
- Non-Querier

After you enable IGMP Layer 2 Querier, the system assumes it is a multicast router, so it sends the General Query, Group Specific/Group, and Source Specific Query when Leave/BLOCK messages are received. IGMP queries are required to maintain an IGMP group.

**Note**

Group Specific When Leave does not apply to IGMPv1.

### *IGMP Layer 2 Querier limitations*

The following limitations apply to IGMP Layer 2 Querier.

- IGMP Layer 2 Querier is based on IGMP Snoop. If you disable IGMP Snoop, IGMP Layer 2 Querier does not work until you enable IGMP Snoop and IGMP Layer 2 Querier.
- After you enable IGMP Snoop and IGMP Layer 2 Querier on an interface, if the system receives no IGMP query messages, it becomes the querier.

### **IGMP Layer 2 Querier limitations and DvR**

The following limitations apply when you configure IGMP Layer 2 Querier on DvR enabled nodes.

- You can configure IGMP Layer 2 Querier only on the DvR Controllers in a DvR domain. When you configure the following parameters on the Controllers, the configuration is automatically pushed to the DvR Leaf nodes within the domain.
  - IGMP version
  - IGMP query interval
  - IGMP query maximum response time
  - IGMP robustness value
  - IGMP last member query interval
  - IGMP compatibility mode
- You cannot configure IGMP snooping on DvR enabled Layer 2 VSNs.

For more information on DvR, see [Distributed Virtual Routing \(DvR\) Fundamentals](#) on page 681 .

## Multicast access control

Multicast access control is a set of features that operate with standard existing multicast protocols. You can configure multicast access control for an IP multicast-enabled port or VLAN with an access control policy that consists of several IP multicast groups.

You can use this feature to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams). For example, in a television distribution application, instead of applying a filter to each channel (multicast group), you can apply a multicast access policy to a range of channels (groups), thereby reducing the total number of filters and providing a more efficient and scalable configuration. Also, if you want to add or remove television channels from a package, you can modify the multicast access policy; you do not need to change filters for individual

VLANs or ports. Multicast access policies contain an ID and a name (for example, PremiumChannels), the list of IP multicast addresses, and the subnet mask.

Multicast access control is not a regular filtering configuration. Multicast access control is for multicast streams and relies on handling multicast control and initial data to prevent hosts from sending or receiving specified multicast streams; it does not use filters. Also, multicast access control provides a list of multicast groups in one configuration using the same routing policy prefix list configuration. For information about prefix lists, see [Configuring prefix lists](#) on page 2886. You can configure multicast access control and change it dynamically to support changes in the configuration without restarting the protocol. You can change the access capabilities of a user or service subscriber without loss of service.

The following paragraph describes a typical application.

The local cable television company offers three packages; each one includes 35 channels (35 multicast groups). The company configures each package in an access control policy. This policy applies to a set of VLANs or ports to prevent users from viewing the channels on those VLANs. Use the same policy to prevent users from sending traffic to those groups (also known as spoofing) by specifying the deny-tx option for that port. After you define the packages, you can use them for access policy configuration. You can easily change the package by changing the group range, without changing all the port configurations.

The multicast access control functionality applies to an IP multicast application where you must control user access. You can use it in financial-type applications and other enterprise applications, such as multicast-based video conferencing.

Six types of multicast access control policies exist:

- deny-tx
- deny-rx
- deny-both
- allow-only-tx
- allow-only rx
- allow-only-both

The tx policies control the sender and ingress interface for a group; the rx policies control the receivers and egress interface for a group.

#### *deny-tx*

Use the deny-tx access policy to prevent a matching source from sending multicast traffic to the matching group on the interface where you configure the deny-tx access policy. Configure this policy on the ingress interface to the multicast source. The deny-tx access policy performs the opposite function of the allow-only-tx access policy. Therefore, the deny-tx access policy and the allow-only-tx access policy cannot exist on the same interface at the same time.

For example, in [Figure 138](#), a VLAN 1, the ingress VLAN, uses a deny-tx access policy. This policy prevents multicast traffic sent by Sender from forwarding from VLAN 1 to a receiver, consequently preventing Receiver 1 and Receiver 2 from receiving data from the multicast group. You can create receive-only VLANs, such as VLAN 1, with the deny-tx policy.

**Figure 138: Data flow using deny-tx policy**

*deny-rx*

Use the deny-rx access policy to prevent a matching group from receiving IGMP reports from the matching receiver on the interface where you configure the deny-rx access policy. The deny-rx access policy performs the opposite function of the allow-only-rx access policy. Therefore, the deny-rx access policy and the allow-only-rx access policy cannot exist on the same interface at the same time.

For example, in [Figure 139](#), a VLAN 2 uses a deny-rx access policy, preventing IGMP reports sent by Receiver 1 from receiving on VLAN 2. You can deny a multicast group access to a specific VLAN or receiver using the deny-rx policy.

**Figure 139: Data flow using deny-rx policy**

*deny-both*

Use the deny-both access policy to prevent a matching IP address from both sending multicast traffic to, and receiving IGMP reports from, a matching receiver on an interface where you configure the deny-both policy. You can use this policy to eliminate all multicast activity for a receiver or source in a specific multicast group. The deny-both access policy performs the opposite function of the allow-only-both access policy. Therefore, the deny-both access policy and the allow-only-both access policy cannot exist on the same interface at the same time.

For example, in [Figure 140](#), a VLAN 2 uses a deny-both access policy, preventing VLAN 2 from receiving IGMP reports sent by Receiver 2, and preventing multicast traffic sent by Sender 2 from forwarding from VLAN 2. You can prevent certain VLANs from participating in an activity involving the specified multicast groups with the deny-both policy.

**Figure 140: Data flow using deny-both policy**

#### *allow-only-tx*

Use the *allow-only-tx* policy to allow only the matching source to send multicast traffic to the matching group on the interface where you configure the *allow-only-tx* policy. The interface discards all other multicast data it receives. The *allow-only-tx* access policy performs the opposite function of the *deny-tx* access policy. Therefore, the *allow-only-tx* access policy and the *deny-tx* access policy cannot exist on the same interface at the same time.

#### *allow-only-rx*

Use the *allow-only-rx* policy to allow only the matching group to receive IGMP reports from the matching receiver on the interface where you configure the *allow-only-rx* access policy. The interface discards all other multicast data it receives. The *allow-only-rx* access policy performs the opposite function of the *deny-rx* access policy. Therefore, the *allow-only-rx* access policy and the *deny-rx* access policy cannot exist on the same interface at the same time.

#### *allow-only-both*

Use the *allow-only-both* policy to allow only the matching IP address to both send multicast traffic to, and receive IGMP reports from, the matching receiver on the interface where you configure the *allow-only-both* access policy. The interface discards all other multicast data and IGMP reports. The *allow-only-both* access policy performs the opposite function of the *deny-both* access policy. Therefore, the *allow-only-both* access policy and the *deny-both* access policy cannot exist on the same interface at the same time.

#### *Host addresses and masks*

When you configure multicast access policies, you must specify the host (IP) address and host (subnet) mask of the host to filter (the host that sends multicast traffic).

You can use the host subnet mask to restrict access to a portion of the host network. For example, if you configure the host subnet mask as 255.255.255.255, you use the full host address. To restrict access to a portion of the network of a host, use a subnet mask such as 255.255.255.0. Access control applies to the specified subnet only.

## Multicast stream limitation feature

You can configure the multicast stream limitation feature to limit the number of multicast groups that can join a VLAN. By limiting the number of concurrent multicast streams, a service provider can, for example, protect the bandwidth on a specific interface and control access to multicast streams.

Use multicast stream limitation in an environment where you want to limit users to a certain number of multicast streams simultaneously. For example, a television service provider can limit the number of television channels a user can watch at a time. (To a television service provider, a multicast stream is synonymous with a television channel.) If a user purchases a service contract for two single-tuner television receivers, they can use two channels flowing at the same time, but not a third. The service provider can control the bandwidth usage in addition to preventing users from watching more than the allowed number of channels at a point in time.

You can enable the multicast stream limitation feature on the switch by using one of the following methods:

- for each interface—This limitation controls the total number of streams for all clients on this router port.
- for each VLAN—This limitation controls the total number of streams for all clients on this VLAN. This method is equivalent to the interface stream limitation.
- for each VLAN port—This limitation controls the number of streams for all clients on this VLAN port. This method is equivalent to the interface port stream limitation.

You can configure the maximum number of streams for each limit independently. After the number of streams meets the limit, the interface drops additional join reports for new streams. The maximum number of streams for each limit is 65535 and the default is 4.

## Multicast Router Discovery protocol

The Multicast Router Discovery (MRDISC) protocol can automatically discover multicast-capable routers. By listening to multicast router discovery messages, Layer 2 devices can determine where to send multicast source data and IGMP host membership reports. This feature is useful in a Layer 2 bridging domain that you configure for IGMP snoop.

IGMP multicast router discovery consists of three message types that discover multicast routers on the network:

- Multicast router advertisements: routers advertise that IP multicast forwarding is enabled on an interface.
- Multicast router solicitations: routers solicit a response of multicast router advertisements from all multicast routers on a subnet.
- Multicast router termination messages: a router terminates its multicast routing functions.

Multicast routers send multicast router advertisements periodically on all interfaces where you enable multicast forwarding. Multicast routers also send advertisements in response to multicast router solicitations.

Multicast router solicitations transmit to the IGMP-MRDISC all-routers multicast group that uses a multicast address of 224.0.0.2. Multicast router solicitations do not transmit if a router needs to discover multicast routers on a directly attached subnet.

Multicast router termination messages transmit after a router terminates its multicast routing functions. Other non-IP forwarding devices, such as Layer 2 switches, can send multicast router solicitations to solicit multicast router advertisements.

To function MRDISC on IGMP snoop interface, you must explicitly enable MRDISC. The Solicitation messages are sent only if IGMP snoop and MRDISC are enabled on the switch.

## Multicast flow distribution over MLT

MultiLink Trunking (MLT) is a mechanism to distribute multicast streams over a multilink trunk and achieve an even distribution of the streams. The distribution is based on source-subnet and group addresses. In applications like television distribution, multicast traffic distribution is particularly important because the bandwidth requirements are substantial when you use a large number of television streams.

The switch enables this feature by default and you can not change the configuration.

### *Traffic distribution*

Traffic distribution distributes the streams on the multilink trunk links if an MLT configuration change occurs. For example, you can add or delete ports.

This feature distributes active streams according to the distribution algorithm on the multilink trunk links. This distribution can cause minor traffic interruptions. To minimize the effect of distribution of multicast traffic on the multilink trunks, the implementation does not move the streams to the appropriate links at the same time. Instead, it distributes a few streams at every time tick of the system.

To that end, after a multilink trunk port becomes inactive, this feature distributes all the streams on the multilink trunk ports based on the assignment provided by the distribution algorithm.

By default, distribution is enabled and you can not change the configuration.

For more information about MLT, see [MultiLink Trunking](#) on page 2337 .

## Multicast virtualization

Multicast provides simplified extension of internal video and data delivery to remote locations.

Virtualized multicast enables multiple VPN routing instances on devices and supports various unicast routing protocols so that you can provide the services of many virtual routers from one physical device.

You can configure multicast routing support with the Virtual Routing and Forwarding (VRF) Lite feature and you can use VRF Lite to emulate many virtual routers with one router.

Multicast virtualization support includes:

- IGMP snooping
- IGMP in Layer 2 virtual services networks (VSN)
- IGMP in Layer 3 VSNs

To implement multicast virtualization, you must perform the following tasks:

1. Create a VRF. For more information about how to create and configure a VRF, see [Create a VRF Instance](#) on page 3815.
2. Create a VLAN and associate it with the VRF.
3. Enable one of the following: IGMP snooping on the VLAN, Layer 2 VSN, or Layer 3 VSN.

If you use IGMP snooping on the VLAN, ensure the IGMP version on the multicast hosts or other network devices is either the same as the version on the VLAN, or enable compatibility mode.

Multicast virtualization does not support PIM. The switch supports IGMP with PIM only in the Global Router.

#### *VRF Lite background*

VRF Lite provides independent IPv4 forwarding instances and independent routing instances (contexts), which can reside on the same or different VLANs and ports.

While forwarding and routing instances are mapped to IP interfaces, incoming traffic is classified into a VLAN and IP interface and, depending on the IP interface, routed context traffic is forwarded.

## Protocol Independent Multicast-Sparse Mode

**Table 114: Protocol Independent Multicast - Sparse Mode product support**

| Feature                                                      | Product         | Release introduced |
|--------------------------------------------------------------|-----------------|--------------------|
| Protocol Independent Multicast-Sparse Mode (PIM-SM) for IPv4 | 5420 Series     | VOSS 8.4           |
|                                                              | 5520 Series     | VOSS 8.2.5         |
|                                                              | VSP 4450 Series | VOSS 4.1           |
|                                                              | VSP 4900 Series | VOSS 8.1           |
|                                                              | VSP 7200 Series | VOSS 4.2.1         |
|                                                              | VSP 7400 Series | VOSS 8.0           |
|                                                              | VSP 8200 Series | VOSS 4.0.1         |
|                                                              | VSP 8400 Series | VOSS 4.2           |
|                                                              | VSP 8600 Series | VSP 8600 4.5       |
|                                                              | XA1400 Series   | Not Supported      |

PIM-SM, as defined in RFC2362, supports multicast groups spread out across large areas of a company or the Internet. PIM-SM sends multicast traffic only to routers that specifically join a multicast group. This technique reduces traffic flow over WAN links and overhead costs for processing unwanted multicast packets.

Dense-mode protocols use a flood-and-prune technique, which is efficient with densely-populated receivers. However, for sparsely populated networks, PIM-SM is more efficient because it sends multicast traffic only to those routers that belong to a specific multicast group and that choose to receive the traffic.

PIM-SM is independent of a specific unicast routing protocol, but it does require the presence of a unicast routing protocol, such as Routing Information Protocol (RIP) or Open Shortest Path First (OSPF). PIM-SM uses the information from the unicast routing table to create and maintain multicast trees that enable PIM-enabled routers to communicate.

Typically, a PIM-SM network consists of several multipoint data streams, each targeted to a small number of LANs in the internetwork. For example, customers whose networks consist of multiple hosts

on different LANs can use PIM-SM to simultaneously access a video data stream, such as video conferencing, on a different subnet.

**Important**

In some cases, PIM stream initialization can take several seconds.

*Hosts*

A host is a source, a receiver, or both:

- A source, also known as a sender, sends multicast data to a multicast group.
- A receiver receives multicast data from one or several sources that sends data to a multicast group.

*PIM-SM domain*

PIM-SM operates in a domain of contiguous routers on which PIM-SM is enabled.

Each PIM-SM domain requires the following routers:

- designated router (DR)
- rendezvous point (RP) router
- bootstrap router (BSR)

Although a PIM-SM domain can use only one active RP router and one active BSR, you can configure additional routers as a candidate RP (C-RP) router and as a candidate BSR (C-BSR). Candidate routers provide backup protection in case the primary RP router or BSR fails.

As a redundancy option, you can configure several RPs for the same group in a PIM domain. As a load sharing option, you can have several RPs in a PIM-SM domain map to different groups. The switch devices use the hash function defined in the PIM-SM standard to elect the active RP.

*Designated router*

The designated router (DR), the router with the highest IP address on a LAN, performs the following tasks:

- sends register messages to the RP router on behalf of directly connected sources
- sends join and prune messages to the RP router on behalf of directly connected receivers
- maintains information about the status of the active RP router for local sources in each multicast group

**Important**

The DR is not a required configuration. Switches act automatically as the DR for directly attached sources and receivers.

*Rendezvous point router*

PIM-SM builds a shared multicast distribution tree within each domain, and the RP router is at the root of this shared tree. Although you can physically locate the RP anywhere on the network, it must be as close to the source as possible. Only one active RP router exists for a multicast group.

At the RP router, receivers meet new sources. Sources use the RP to identify themselves to other routers on the network; receivers use the RP to learn about new sources.

The RP performs the following tasks:

- registers a source that wants to announce itself and send data to group members
- joins a receiver that wants to receive data for the group
- forwards data to group

### **Candidate rendezvous point router**

You can configure a set of routers as C-RP routers that serve as backup to the RP router. If an RP fails, all the routers in the domain apply the same algorithm to elect a new RP from the group of C-RP routers. To make sure that the routers use a complete list of C-RP routers, the C-RP router periodically sends unicast advertisement messages to the BSR. The most common implementation is to configure a PIM-SM router as both a C-RP router and a C-BSR.

The switch devices use the hash function defined in the PIM-SM standard to elect the active RP.

### **Static rendezvous point router**

You can configure a static entry for an RP router with static RP. This feature avoids the process of selecting an active RP from the list of candidate RPs and dynamically learning about RPs through the BSR mechanism. Static RP-enabled switches cannot learn about RPs through the BSR because the switch loses all dynamically learned BSR information and ignores BSR messages. After you configure static RP entries, the switch adds them to the RP set as if they were learned through the BSR.

#### **Important**

In a PIM domain with both static and dynamic RP switches, the static RP switches cannot use a local interface configured as an RP.

When you configure a PIM static RP in a switch, the next hop of the unicast route toward the PIM static RP must be a PIM neighbor. The PIM protocol fails to work, due to a route change, if the next hop toward an already configured static RP becomes a non-PIM neighbor. If a PIM neighbor cannot reach the configured RP, the RP does not activate and its state remains invalid.

A static RP-enabled switch can communicate with switches from other vendors that do not use the BSR mechanism. Some vendors use either early implementations of PIM-SM v1 that do not support the BSR or proprietary mechanisms like the Cisco Auto-RP. For a network to work properly with static RP, you must map all the switches in the network (including switches from other vendors) to the same RP or RPs, if several RPs exist in the network.

To avoid a single point of failure, you can also configure redundant static RPs.

Use the static RP feature when you do not need dynamic learning mode, typically in small networks, or for security reasons, where RPs are forced to devices in the network so that they do not learn other RPs.

### **Static RP configuration considerations**

Before you can configure a static RP, you must enable PIM-SM and enable static RP.

After you meet these prerequisites, keep in mind the following configuration considerations:

- You cannot configure a static RP-enabled switch as a BSR or as a C-RP router.
- All dynamically learned BSR information is lost. However, if you disable static RP, the switch loses the static RP information and regains the BSR functionality.
- Static RPs do not age, that is, they cannot time out.
- Switches do not advertise static RPs, so, if a new PIM neighbor joins the network, it does not know about the static RP unless you configure it with that static RP.
- Configure all the switches in the network (including switches from other vendors) to map to the same RP.
- In a PIM domain with both static and dynamic RP switches, the static RP switches cannot use a local interface configured as an RP.
- To avoid a single point of failure, you can configure redundant static RPs for the same group prefix. If you use a mix of vendor switches across the network, you must ensure that all switches and routers use the same active RP because other vendors can use different algorithms to elect the active RP. The switch devices use the hash function defined in the PIM-SM standard to elect the active RP; other vendors can use the lowest IP address to elect the RP.

**Important**

To reduce convergence times, create only one static RP for each group. The more static RPs you configure for redundancy, the more time PIM requires to rebuild the mroute table and associate RPs.

- Static RP configured on the switch is active as long as the switch uses a unicast route to the static RP network. If the switch loses this route, the static RP is invalidated and the hash algorithm remaps all affected groups. If the switch regains this route, the static RP is validated and the hash algorithm remaps the affected groups.

### *Bootstrap router*

The BSR receives RP router advertisement messages from the candidate RPs. The BSR adds the RP router with its group prefix to the RP set. Only one BSR exists for each PIM-SM domain.

The BSR periodically sends bootstrap messages containing the complete RP set to all routers in the domain. The BSR ensures that all PIM-SM routers send join, prune, and register packets.

Within a PIM-SM domain, you can configure a small set of routers as C-BSRs. The C-BSR with the highest configured priority becomes the BSR for the domain. If two C-BSRs use equal priority, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher priority to the domain, it automatically becomes the new BSR.

**Important**

Configure C-BSRs on routers that are central to all candidate RPs.

### *Shared trees and shortest-path trees*

A PIM-SM domain uses shared trees and shortest-path trees to deliver data packets to group members. This section describes both trees.

### Shared trees

Group members in a PIM-SM domain receive the first packet of data from sources across a shared tree. A shared tree consists of a set of paths that connect all members of a multicast group to the RP. PIM creates a shared tree when sources and receivers send messages toward the RP.

### Shortest-path trees

After receiving a certain number of packets from the RP, the DR changes from a shared tree to an SPT. Switching to an SPT creates a direct route between the receiver and the source. The switch changes to the SPT after it receives the first packet from the RP.

Figure 141 shows a shared tree and an SPT.

**Figure 141: Shared tree and shortest-path tree**

#### *Receiver joining a group*

The following steps describe how a receiver joins a multicast group:

1. A receiver multicasts an IGMP host membership message to the group that it wants to join.
2. After the last-hop router (the DR), normally the PIM router with the highest IP address for that VLAN, receives the IGMP message for a new group join, the router looks up the associated elected RP with responsibility for the group.
3. After it determines the RP router for the group, the last-hop router creates a (\*,G) route entry in the multicast forwarding table and sends a (\*,G) join message to the RP. After the last-hop router receives data packets from the RP, if the multicast packet arrival rate exceeds the DR threshold, the

last-hop router switches to the SPT by sending an (S,G) join message to the source. (S denotes the source unicast IP address, and G denotes the multicast group address.)

4. If the last-hop router switches to the SPT, the following actions occur:
  - All intermediate PIM routers along the path to the source create the (S,G) entry.
  - To trim the shared tree, the router sends an (S,G) prune message to the RP.

#### *Receiver leaving a group*

Before it leaves a multicast group, a receiver sends an IGMP leave message to the DR. If all directly connected members of a multicast group leave or time out, and no downstream members remain, the DR sends a prune message upstream and PIM-SM deletes the route entry after that entry times out.

When the system ages PIM mroutes, it does not clear the (S,G) entry for an inactive route immediately after the expiration period. Topology and hardware conditions can affect the polling interval and cause an inactive route to remain for up to 12-15 minutes.

#### *Source sending packets to a group*

The following steps describe how a source sends multicast packets to a group:

1. A source directly attached to a VLAN bridges the multicast data to the DR. The DR for the VLAN (the router with the highest IP address) encapsulates each packet in a register message and sends a unicast message directly to the RP router to distribute to the multicast group.
2. If a downstream group member chooses to receive multicast traffic, the RP router sends a join or prune message toward the source DR and forwards the data down the RP tree after it obtains the data natively.
3. After the receiver DR obtains the first packet, it switches to the shortest-path tree (SPT) and continues receiving data through the SPT path.
4. If no downstream members want to receive multicast traffic, the RP router sends a register-stop message (for the source) to the DR.

The DR starts the register suppression timer after it receives the first register-stop message. During the register suppression timeout period (the default is 60 seconds), the following events occur:

- The DR for the source sends a probe packet to the RP router before the register suppression timer expires. The probe packet prompts the RP router to determine whether new downstream receivers joined the group.
- If no new receivers joined the group, the RP router sends another register-stop message to the DR for the source, and its register suppression timer restarts.
- After the RP router no longer responds with a register-stop message to the source DR probe message, the register suppression timer expires and the DR sends encapsulated multicast packets to the RP router. The RP router uses this method to tell the DR that new members joined the group.

The RP sends a register-stop message to the DR immediately after it receives the first multicast data packet.

### Required elements for PIM-SM operation

For PIM-SM to operate, the following elements must exist in the PIM-SM domain:

- You must enable an underlying unicast routing protocol for the switch to provide routing table information to PIM-SM.
- You must configure an active BSR to send bootstrap messages to all PIM-v2 configured switches and routers to enable them to learn group-to-RP mapping. If you configure several BSRs in a network, an active BSR is elected based on priority and IP address (if priority is equal, the BSR with the higher IP address is elected).
- You must include an RP to perform the following tasks:
  - manage one or several IP multicast groups
  - become the root for the shared tree to these groups
  - accept join messages from receiver switches for groups that it manages
  - elect an active RP based on priority and IP address (if priority is equal, the RP with the higher IP address is elected)

### PIM-SM simplified example

Figure 142 shows a simplified example of a PIM-SM configuration.

**Figure 142: PIM-SM simplified example**

In the sample configuration, the following events occur:

1. The BSR distributes RP information to all switches in the network.
2. R sends an IGMP membership report to S4.
3. Acting on this report, S4 sends a (\*,G) join message to RP.
4. S sends data to G.

5. The DR (S1 in this example) encapsulates the data that it unicasts to RP (S2) in register messages.
6. S2 decapsulates the data, which it forwards to S4.
7. S4 forwards the data to R.
8. If the packet rate exceeds the DR threshold, S4 sends S1 an (S,G) join message.
9. S1 forwards data to S4. After S4 receives data from S1, it prunes the stream from the RP.

**Important**

[Figure 142](#) on page 1459 is a simplified example and is not the best design for a network if you locate the source and receiver as shown. In general, place RPs as close as possible to sources.

### *PIM-SM Static Source Groups*

You can configure static source groups as static source-group entries in the PIM-SM multicast routing table. PIM-SM cannot prune these entries from the distribution tree. For more information about static source groups, see [Static source groups](#) on page 1437.

## Join and prune messages

The DR sends join and prune messages from a receiver toward an RP for the group to either join the shared tree or remove (prune) a branch from it. A single message contains both a join and a prune list. This list includes a set of source addresses that indicate the shortest-path trees or the shared trees that the host wants to join. The DR sends join and prune messages hop-by-hop to each PIM router on the path to the source or the RP.

## Register and register-stop messages

The DR sends register messages to the RP for a directly connected source. The register message informs the RP of a new source, causing the RP to send join or prune messages back toward the DR of the source, which forwards the data down the RP tree after it obtains the data natively. After the receiver DR obtains the first packet, it switches to the shortest-path tree (SPT) and continues receiving data through the SPT path.

The DR stops sending encapsulated packets to the RP after it receives a register-stop message. This traffic stops without delay because the RP sends a register-stop message immediately after it receives the first multicast data packet, and joins the shortest-path tree.

## PIM-SMLT

IP multicast routing support with Split MultiLink Trunking (SMLT) builds a virtual switch that represents the two switches of the split multilink trunk core.

When switches use PIM in the core, they need to exchange protocol-related updates as part of the interswitch trunking (IST) protocol. IST hides the fact that the edge switch attaches to two physical switches.

PIM-SMLT can work in triangular, square, and full mesh configurations with Layer 3 IP multicast. However, PIM-SSM in square or full mesh SMLT topologies is not supported.

The following rules apply:

- If a VLAN receives traffic from the IST link, it cannot forward on the split multilink trunk link or the edge for the same VLAN.
- If one side of the SMLT link toward the receiver is down, such that the traffic cannot be forwarded directly down the SMLT link from the router on which traffic is ingressing, the IST Peer **MUST** forward that traffic it receives over the IST link down its side of the SMLT toward the receiver. The decision of whether the IST Peer needs to forward traffic received over the IST to SMLT receivers is made in the datapath, which has full knowledge of the remote SMLT link state.
- Traffic can use the IST to route between VLANs if the forwarding decision for the multicast protocol requires that the other side of the core forwards the multicast traffic (follow the IP multicast routing and forwarding rules for routed traffic). Other VLANs that are not part of SMLT continue to behave in the same way.
- To create a temporary default route pointing to a peer IST, you must enable PIM on the IST VLAN.
- In a scaled multicast environment, if you must reconfigure the members of an MLT link, either SMLT or IST, by removing the ports from the MLT membership list, you must first shutdown the port by using the **shutdown** command at the port configuration level. Let the unicast and multicast traffic subside, and then remove the port from the MLT membership list. If you reconfigure the MLT without first shutting down the port, it can lead to excessive hardware updates to multicast forwarding records and can result in high utilization of the CPU.

#### Note

In a scaled PIM over Simplified vIST deployment, disabling all the PIM interfaces (**no ip routing**) causes the VLACP ports to bounce. With no user intervention, the packets start getting processed again in approximately 10 seconds. VLACP enables the ports and full functionality is restored.

SMLT provides for fast failover in all cases, but does not provide a functionality similar to Routed SMLT (RSMLT).

#### Important

You must enable square SMLT globally before you configure square or full-mesh configurations.

#### *Traffic delay with PIM while restarting peer SMLT switches*

If you restart peer SMLT switches, you can lose, or experience a delay in, PIM traffic. The local and remote SMLT links must be up to forward traffic. If a remote SMLT link is down, you can experience a traffic delay.

PIM uses a DR to forward data to receivers on a VLAN. If you restart the DR in an SMLT VLAN, you can lose data because of the following actions:

- If the DR is down, the non-DR switch assumes the role and starts forwarding data.
- After the DR comes back up, it takes priority (higher IP address) to forward data so the non-DR switch stops forwarding data.
- The DR is not ready to forward traffic due to protocol convergence and because it takes time to learn the RP set and create the forwarding path. This situation can result in a traffic delay of 2 to 3 minutes because the DR learns the RP set after Open Shortest Path First (OSPF) converges.

A workaround to this delay is to configure the static RP router on the peer SMLT switches. This feature avoids the process of selecting an active RP router from the list of candidate RPs and dynamically learning about RPs through the BSR mechanism. After the DR comes back up, traffic resumes as soon as OSPF converges. This workaround reduces the traffic delay to approximately 15 to 65 seconds.

## Protocol Independent Multicast-Source Specific Multicast

**Table 115: Protocol Independent Multicast-Source Specific Mode product support**

| Feature                                     | Product         | Release introduced |
|---------------------------------------------|-----------------|--------------------|
| PIM-Source Specific Mode (PIM-SSM) for IPv4 | 5420 Series     | VOSS 8.4           |
|                                             | 5520 Series     | VOSS 8.2.5         |
|                                             | VSP 4450 Series | VOSS 4.1           |
|                                             | VSP 4900 Series | VOSS 8.1           |
|                                             | VSP 7200 Series | VOSS 4.2.1         |
|                                             | VSP 7400 Series | VOSS 8.0           |
|                                             | VSP 8200 Series | VOSS 4.0.1         |
|                                             | VSP 8400 Series | VOSS 4.2           |
|                                             | VSP 8600 Series | VSP 8600 4.5       |
|                                             | XA1400 Series   | Not Supported      |

Source Specific Multicast optimizes PIM-SM by simplifying the many-to-many model. Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

SSM only builds source-based SPTs. Whereas PIM-SM always joins a shared tree first, and then switches to the source tree, SSM eliminates the need to start with a shared tree by immediately joining a source through the SPT. SSM avoids using an RP and RP-based shared trees, which can be a potential problem.

Until now only one channel for one group was allowed to exist in ssm map. From now on multiple channels for the members of the SSM group are allowed to be configured in this map.

This configuration is ideal for applications like television channel distribution and other content-distribution businesses. Banking and trade applications can also use SSM as it provides more control over the hosts receiving and sending data over their networks.

When a v2 report in SSM range is received it is translated to an igmpv3 report message with one group record with type ALLOW and the source lists copied from the igmp ssm map static entries and passed to igmpv3 module. When a v2 leave in SSM range is received it is translated to an igmpv3 report message with one group record with type BLOCK and the source lists copied from the igmp ssm map static entries and passed to igmpv3 module. This behaviour is displayed only when PIM-SSM mode is enabled.

SSM applications use IP addresses reserved by the Internet Assigned Numbers Authority (IANA) in the 232/8 range (232.0.0.0 to 232.255.255.255). SSM recognizes packets in this range and controls the behavior of multicast routing devices and hosts that use these addresses. When a source (S) transmits

IP datagrams to an SSM destination address (G), a receiver can receive these datagrams by subscribing to the (S,G) channel.

A channel is a source-group (S,G) pair where S is the source that sends to the multicast group and G is an SSM group address. SSM defines channels on an individual or multiple source basis, which enforces the one-to-many concept of SSM applications. In an SSM channel, each group is associated with multiple sources.

### *SSM features*

PIM-SM requires a unicast protocol to forward multicast traffic within the network to perform the Reverse Path Forwarding (RPF) check. PIM-SM uses the information from the unicast routing table to create and maintain the shared and shortest multicast tree that PIM-enabled routers use to communicate. The unicast routing table must contain a route to every multicast source in the network as well as routes to PIM entities like the RPs and BSR.

SSM uses only a subset of the PIM-SM features such as the SPT, DR, and some messages (hello, join, prune, and assert). However, some features are unique to SSM. These features, described in the following sections, are extensions of the IGMP and PIM protocols.

### *PIM-SSM architecture*

The following diagram illustrates how the PIM-SSM architecture requires routers to perform the following actions:

- support IGMPv3 source-specific host membership reports and queries at the edge routers
- initiate PIM-SSM (S,G) joins directly and immediately after receiving an IGMPv3 join report from the designated router
- restrict forwarding to SPTs within the SSM address range by all PIM-SSM routers

**Figure 143: PIM-SSM architecture**

The following rules apply to Layer 3 devices with SSM enabled:

- Receive IGMPv3 membership join reports in the SSM range and, if no entry (S,G) exists in the SSM channel table, create one.
- Receive IGMPv2 membership join reports, but only for groups that already use a static (S,G) entry in the SSM channel table.
- Send periodic join messages to maintain a steady SSM tree state.
- Use standard PIM-SM SPT procedures for unicast routing changes, but ignore rules associated with the SPT for the (S,G) route entry.
- Receive prune messages and use standard PIM-SM procedures to remove interfaces from the source tree.
- Forward data packets to interfaces from the downstream neighbors that sent an SSM join, or to interfaces with locally attached SSM group members.
- Drop data packets that do not use an exact-match lookup (S,G) in their forwarding database for S and G.

### *PIM-SSM Static Source Groups*

You can configure static source group entries in the PIM-SSM multicast routing table with static source groups. PIM-SSM cannot prune these entries from the distribution tree. For more information about static source groups, see [Static source groups](#) on page 1437.

### *Implementation of SSM and IGMP*

The following sections describe how the switch implements PIM-SSM and IGMP.

#### **SSM range**

The standard SSM range is 232/8, but you can extend the range to include an IP multicast address. Although you can configure the SSM range, you cannot configure it for all multicast groups (224/4 or 224.0.0.0/240.0.0.0 or 224.0.0.0/255.0.0.0).

You can extend the SSM range to configure existing applications without changing their group configurations.

#### **SSM channel table**

You can use the SSM channel to manually configure (S,G) entries that map existing groups to their sending source. These table entries apply to the whole switch, not for each interface, and both IGMPv2 and IGMPv3 hosts use the SSM channel table.

The following rule applies to an SSM channel table for an individual switch:

- You can map one source to multiple groups.
- You can allow multiple sources to the same group.

#### **Important**

Different switches can use different mappings for groups to sources, for example, different channels map differently even if they are on the same network.

#### **SSM and IGMPv2**

SSM-configured switches can accept reports from IGMPv2 hosts on IGMPv2 interfaces if the group uses an SSM channel table entry. However, the IGMPv2 host groups must exist in the SSM range defined on the switch, which is 232/8 by default.

- After the SSM switch receives an IGMPv2 report for a group that is in the SSM channel table, it joins the specified source immediately.
- After the SSM switch receives an IGMPv2 report for a group that uses an enabled static SSM channel table entry, it triggers PIM-SSM processing as if it received an equivalent IGMPv3 report.
- After the SSM switch receives an IGMPv2 report for a group out of the SSM range, it processes the report as if it is in PIM-SM mode.

#### **Deleting or Disabling an ssm-map with IGMPv1 or IGMPv2**

Before you disable or delete an ssm-map, always send IGMPv1 or IGMPv2 leave messages from hosts that operate using IGMPv1 or IGMPv2. If you do not perform this action, receiving and processing reports in SSM range on an IGMP interface enabled with IGMPv1 or IGMPv2 can lead to unexpected behavior.

Consider the following configuration scenario:

- A device is PIM-enabled, running in SSM mode, with IGMPv1 or IGMPv2 configured on the interface.
- IGMPv1 and IGMPv2 hosts send IGMPv1 or IGMPv2 reports for groups in SSM range.

The following table identifies the expected behaviors in this scenario.

**Table 116: Expected behaviors for ssm-map configuration**

| Action                                                      | Expected behavior                                                              |
|-------------------------------------------------------------|--------------------------------------------------------------------------------|
| You do not configure an ssm-map for the group in SSM range. | IGMPv1 and IGMPv2 reports are not processed.                                   |
| You do configure an ssm-map for the group in SSM range.     | IGMPv1 and IGMPv2 reports are processed and the group in SSM range is learned. |

**SSM and IGMPv3**

The switch supports IGMPv3 for SSM. With IGMPv3, a host can selectively request or filter traffic from sources within the multicast group. IGMPv3 is an interface-level configuration.

**Important**

IGMPv3 works without PIM-SSM or SSM-snoop enabled on the interface.

The following rules apply to IGMPv3-enabled interfaces:

- Send only IGMPv3 (source-specific) reports for addresses in the SSM range.
- Accept IGMPv3 reports.
- Drop IGMPv2 reports.

The IGMPv2 report mentioned in [SSM and IGMPv2](#) on page 1465 is processed because it is an IGMPv2 report received on an IGMPv2 interface. If an IGMPv2 interface receives an IGMPv3 report, it drops the report even if PIM-SSM is enabled and the entry is in the SSM channel table. The IGMP versions must match.

- Discard IGMP packets with a group address out of the SSM range.

The switch implements IGMPv3 in one of two modes: dynamic and static.

In dynamic mode, the switch learns about new (S,G) pairs from IGMPv3 reports and adds them to the SSM channel table. If you do not enable dynamic mode and an IGMPv3-enabled interface receives a report that includes a group not listed in the SSM channel table, it ignores the report.

In static mode, you can statically configure (S,G) entries in the SSM channel table. If an IGMPv3-enabled interface receives a report that includes a group not listed in the SSM channel table, it ignores the report. The interface also ignores the report if the group is in the table, but the source or mask does not match what is in the table.

**Important**

After you enable IGMPv3, changes to the query interval and robustness values on the querier switch propagate to other switches on the same VLAN through IGMP query.

Both IGMPv2 and IGMPv3 hosts use the SSM channel table:

- An IGMPv2 host (with an IGMPv2 VLAN) must use an existing SSM channel entry if the group is in the SSM range.
- If you enable dynamic learning for an IGMPv3 host, the SSM channel automatically learns the group. Otherwise, the SSM channel also needs a static entry.

The following table summarizes how a switch in PIM-SSM mode works with IGMP if you disable IGMPv3 compatibility. In the following table, references to matching a static SSM channel entry assumes that the entry is enabled. If an entry is disabled, it is treated as though it is disallowed.

**Table 117: PIM-SSM interaction with IGMPv2 and v3 with IGMPv3 compatibility disabled**

| Host        | VLAN        | SSM range          | Action                                                                                                                                                   |
|-------------|-------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| IGMPv2 host | IGMPv3 VLAN | In or out of range | Drop report.                                                                                                                                             |
| IGMPv3 host | IGMPv2 VLAN | In or out of range | Drop report.                                                                                                                                             |
| IGMPv2 host | IGMPv2 VLAN | In range           | If the report matches an existing static SSM channel entry, create (S,G).<br>If the report does not match an existing static SSM channel entry, drop it. |
| IGMPv2 host | IGMPv2 VLAN | Out of range       | Ignore the SSM channel table and process the report as if it is in PIM-SM mode.                                                                          |
| IGMPv3 host | IGMPv3 VLAN | Out of range       | Process the report.                                                                                                                                      |
| IGMPv3 host | IGMPv3 VLAN | In range           | Dynamic enabled. Create (S,G).                                                                                                                           |
| IGMPv3 host | IGMPv3 VLAN | In range           | Dynamic disabled and matches an existing SSM channel entry. Create (S,G).                                                                                |
| IGMPv3 host | IGMPv3 VLAN | In range           | Dynamic disabled and does not match an existing SSM channel entry. Drop report.                                                                          |

The following table summarizes how a switch in PIM-SSM mode works with IGMP if you enable IGMPv3 compatibility.

**Table 118: PIM-SSM interaction with IGMPv2 and v3 with IGMPv3 compatibility enabled**

| Host        | VLAN        | SSM range    | Action                                                                                                                                                   |
|-------------|-------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| IGMPv2 Host | IGMPv3 VLAN | In range     | If the report matches an existing static SSM channel entry, create (S,G).<br>If the report does not match an existing static SSM channel entry, drop it. |
| IGMPv2 Host | IGMPv3 VLAN | Out of range | Process the report as in PIM-SM mode.                                                                                                                    |

If an IGMPv3 group report enters the VLAN port and the port must discard one or more of the groups in that packet after the application of IGMP access controls, the port drops the entire packet and does not forward it on to other ports of the VLAN.

If an IGMPv3 interface receives an IGMPv2 or v1 query, the interface backs down to IGMPv2 or v1. As a result, the interface flushes all senders and receivers on the interface.

### *Configuration limitations*

Run PIM-SSM on either all switches in the domain or only on the edge routers. If you use a mix of PIM-SSM and PIM-SM switches in the domain, run PIM-SSM on all the edge routers and run PIM-SM on all the core routers.

#### **Important**

A PIM domain with edge routers running PIM-SM and core routers running PIM-SSM does not operate properly. If you prefer or require a mixed PIM-SM and PIM-SSM topology, run PIM-SSM on the edge switches and PIM-SM in the core. Ensure a valid RP configuration exists for groups that exist outside of the SSM range. If a valid RP configuration exists, the SSM switches process the joins in SM mode. If no RP exists, the SSM switches drop the reports.

Static source groups cannot conflict with SSM channels. If you configure a static source group or an SSM channel, the switch performs a consistency check to make sure no conflicts exist. You can map one group (G) to different sources or multiple groups to a single source for both static source group and an SSM channel.

## PIM passive interfaces

You can configure the PIM interface as active or passive. The default is active. With an active interface, you can configure transmit and receive PIM control traffic. A passive interface drops all PIM control traffic, thereby reducing the load on the system. This feature is useful when you use a high number of PIM interfaces and these interfaces connect to end users, not to other switches.

A PIM passive interface does not transmit and drops messages of the following type:

- hello
- join
- prune
- register
- register-stop
- assert
- candidate-RP-advertisement
- bootstrap

If a PIM passive interface receives these types of messages, it drops them and the switch logs a message, detailing the type of protocol message and the IP address of the sending device. These log

messages help to identify the device that performs routing on the interface, which is useful if you must disable a device that does not operate correctly.

#### Important

A device can send register and register-stop messages to a PIM passive interface, but these messages cannot be sent out of that interface.

The PIM passive interface maintains information about hosts, through IGMP, that are related to senders and receivers, but the interface does not maintain information about PIM neighbors. You can configure a BSR or an RP on a PIM passive interface.

You can also use the PIM passive interface feature as a security measure to prevent routing devices from becoming attached and participating in the multicast routing of the network.

#### Important

Before you change the state (active or passive) of a PIM interface, disable PIM on that interface. This action prevents instability in the PIM operations, especially when neighbors exists or the interface receives streams. After you disable PIM, the switch loses traffic for approximately 80 seconds.

## Multicast route statistics

**Table 119: Mroute statistics product support**

| Feature                                               | Product         | Release introduced |
|-------------------------------------------------------|-----------------|--------------------|
| Multicast route (mroute) statistics for IPv4 and IPv6 | 5420 Series     | VOSS 8.4           |
|                                                       | 5520 Series     | VOSS 8.2.5         |
|                                                       | VSP 4450 Series | Not Supported      |
|                                                       | VSP 4900 Series | VOSS 8.1           |
|                                                       | VSP 7200 Series | VOSS 5.1           |
|                                                       | VSP 7400 Series | VOSS 8.0           |
|                                                       | VSP 8200 Series | VOSS 5.1           |
|                                                       | VSP 8400 Series | VOSS 5.1           |
|                                                       | VSP 8600 Series | Not Supported      |
|                                                       | XA1400 Series   | Not Supported      |

The multicast route statistics feature provides statistics for multicast streams through the switch. Using the Command Line Interface (CLI), Simple Network Management Protocol (SNMP) or Enterprise Device Manager (EDM), you can track the number of senders sending multicast streams to a particular group address. You can also obtain a count of the packets or bytes being received for a particular multicast group address and the average size of the frames. Multicast route statistics are supported for both IPv4 and IPv6 group addresses.

Determining the route statistics is especially useful when debugging a multicast network and also when administering the network.

### *Multicast route statistics and DvR*

When you enable or clear IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

For more information on DvR, see [Distributed Virtual Routing \(DvR\) Fundamentals](#) on page 681.

## IP multicast network design

Use multicast routing protocols to efficiently distribute a single data source among multiple users in the network. This section provides information about how to design networks that support IP multicast routing.

For more design guidelines, conceptual, and configuration information about IP Multicast over Fabric Connect, see [IP Multicast over Fabric Connect](#) on page 1437.

### *Multicast scalability design rules*

The following section lists the design rules to increase multicast route scaling.

#### **Important**

The switch does not support High Availability (HA).

The switch software supports the following:

- Protocol-Independent Multicast (PIM)
- Split MultiLink Trunking (SMLT) and Routed-SMLT (RSMLT)

#### **Multicast scalability design rules**

1. Whenever possible, use simple network designs that do not use VLANs that span several switches. Instead, use routed links to connect switches.
2. Whenever possible, group sources sending to the same group in the same subnet. The switch uses a single egress forwarding pointer for all sources in the same subnet sending to the same group. Be aware that these streams have separate hardware forwarding records on the ingress side.
3. Do not configure multicast routing on edge switch interfaces that do not contain multicast senders or receivers. By following this rule, you:
  - Provide secure control over multicast traffic that enters or exits the interface.
  - Reduce the load on the switch, as well as the number of routes. This improves overall performance and scalability.
4. Avoid initializing many (several hundred) multicast streams simultaneously. Initial stream setup is a resource-intensive task, and initializing a large number can increase the setup time. In some cases, this delay can result in stream loss.
5. Whenever possible, do not connect IP multicast sources and receivers by using VLANs that interconnect switches (see the following figure). In some cases, this can result in excessive hardware record use. By placing the source on the interconnected VLAN, traffic takes two paths to the destination, depending on the reverse path forwarding (RPF) checks and the shortest path to the source.

For example, if a receiver is on VLAN 1 on switch S1 and another receiver is on VLAN 2 on switch S1, traffic can be received from two different paths to the two receivers, which results in the use of two

forwarding records. If the source on switch S2 is on a different VLAN than VLAN 3, traffic takes a single path to switch S1 where the receivers are located.

**Figure 144: IP multicast sources and receivers on interconnected VLANs**

#### *IP multicast address range restrictions*

IP multicast routers use D class addresses, which range from 224.0.0.0 to 239.255.255.255. Although you can use subnet masks to configure IP multicast address ranges, the concept of subnets does not exist for multicast group addresses. Consequently, the usual unicast conventions—where you reserve the all 0s subnets, all 1s subnets, all 0s host addresses, and all 1s host addresses—do not apply.

Internet Assigned Numbers Authority (IANA) reserves addresses from 224.0.0.0 through 224.0.0.255 for link-local network applications. Multicast-capable routers do not forward packets with an address in this range. For example, Open Shortest Path First (OSPF) uses 224.0.0.5 and 224.0.0.6, and Virtual Router Redundancy Protocol (VRRP) uses 224.0.0.18 to communicate across local broadcast network segments.

IANA also reserves the range of 224.0.1.0 through 224.0.1.255 for well-known applications. IANA assigns these addresses to specific network applications. For example, the Network Time Protocol (NTP) uses 224.0.1.1, and Mtrace uses 224.0.1.32. RFC1700 contains a complete list of these reserved addresses.

Multicast addresses in the 232.0.0.0/8 (232.0.0.0 to 232.255.255.255) range are reserved only for source-specific multicast (SSM) applications, such as one-to-many applications. While this range is the publicly reserved range for SSM applications, private networks can use other address ranges for SSM.

Finally, addresses in the range 239.0.0.0/8 (239.0.0.0 to 239.255.255.255) are administratively scoped addresses; they are reserved for use in private domains. Do not advertise these addresses outside the private domain. This multicast range is analogous to the 10.0.0.0/8, 172.16.0.0/20, and 192.168.0.0/16 private address ranges in the unicast IP space.

In a private network, only assign multicast addresses from 224.0.2.0 through 238.255.255.255 to applications that are publicly accessible on the Internet. Assign addresses in the 239.0.0.0/8 range to multicast applications that are not publicly accessible.

Although you can use a multicast address you choose on your own private network, it is generally not good design practice to allocate public addresses to private network entities. Do not use public addresses for unicast host or multicast group addresses on private networks.

### Multicast MAC Address Mapping Considerations

Like IP, Ethernet has a range of multicast MAC addresses that natively support Layer 2 multicast capabilities. While IP has a total of 28 addressing bits available for multicast addresses, Ethernet has only 23 addressing bits assigned to IP multicast. The Ethernet multicast MAC address space is much larger than 23 bits, but only a subrange of that larger space is allocated to IP multicast. Because of this difference, 32 IP multicast addresses map to one Ethernet multicast MAC address.

IP multicast addresses map to Ethernet multicast MAC addresses by placing the low-order 23 bits of the IP address into the low-order 23 bits of the Ethernet multicast address 01:00:5E:00:00:00. Thus, more than one multicast address maps to the same Ethernet address (see the following figure). For example, all 32 addresses 224.1.1.1, 224.129.1.1, 225.1.1.1, 225.129.1.1, 239.1.1.1, 239.129.1.1 map to the same 01:00:5E:01:01:01 multicast MAC address.

**Figure 145: Multicast IP address to MAC address mapping**

Most Ethernet switches handle Ethernet multicast by mapping a multicast MAC address to multiple switch ports in the MAC address table. Therefore, when you design the group addresses for multicast applications, take care to efficiently distribute streams only to hosts that are receivers.

The VSP 4450 Series devices switch IP multicast data based on the IP multicast address, not the MAC address, and thus, do not have this issue.

As an example, consider two active multicast streams using addresses 239.1.1.1 and 239.129.1.1. Suppose that two Ethernet hosts, receiver A and receiver B, connect to ports on the same switch and only want the stream addressed to 239.1.1.1. Suppose also that two other Ethernet hosts, receiver C and receiver D, also connect to the ports on the same switch as receiver A and B, and want to receive the stream addressed to 239.129.1.1. If the switch uses the Ethernet multicast MAC address to make forwarding decisions, then all four receivers receive both streams—even though each host only wants one stream. This transmission increases the load on both the hosts and the switch. To avoid this extra load, ensure that you manage the IP multicast group addresses used on the network.

The VSP 4450 Series devices do not forward IP multicast packets based on multicast MAC addresses—even when bridging VLANs at Layer 2. Thus, the platform does not encounter this problem. Instead, the platform internally maps IP multicast group addresses to the ports that contain group members.

When an IP multicast packet is received, the lookup is based on the IP group address, regardless of whether the VLAN is bridged or routed. While the problem described in the previous example does not affect the VSP 4450 Series devices, other switches in the network can be affected. This problem is particularly true of pure Layer 2 switches.

In a network that includes multiple hardware platforms, the easiest way to ensure that this issue does not arise is to use only a consecutive range of IP multicast addresses that correspond to the lower-order 23 bits of that range. For example, use an address range from 239.0.0.0 through 239.127.255.255. A group address range of this size can still easily accommodate the needs of even the largest private enterprise.

### *Dynamic multicast configuration changes*

You must not perform dynamic multicast configuration changes when multicast streams flow in a network. For example, do not change the routing protocol that runs on an interface, or the IP address, or the subnet mask for an interface until multicast traffic ceases.

For such changes, ensure that you temporarily stop all multicast traffic. If the changes are necessary and you have no control over the applications that send multicast data, you can disable the multicast routing protocols before you perform the change. For example, consider disabling multicast routing before making interface address changes. In all cases, these changes result in traffic interruptions because they affect neighbor-state machines and stream-state machines.

In addition, when removing port members of an MLT group you must first disable the ports. Changing the group set without first shutting the ports down can result in high-CPU utilization and processing in a scaled multicast environment due to the necessary hardware reprogramming on the multicast records.

### *IGMPv3 backward compatibility*

IGMPv3 for PIM is backward compatible with IGMPv1/v2. According to RFC3376, the multicast router with IGMPv3 can use one of two methods to handle older query messages:

- If an older version of IGMP is present on the router, the querier must use the lowest version of IGMP present on the network.
- If a router that is not explicitly configured to use IGMPv1 or IGMPv2, detects an IGMPv1 query or IGMPv2 general query, it logs a rate-limited warning.

You can configure the IGMP version of an interface to version 3 regardless of the PIM or snooping mode.

You can configure whether the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning.

#### **Note**

If you enable the explicit host tracking option on an IGMPv3 interface, you cannot downgrade to IGMPv1 or IGMPv2. You must disable explicit host tracking to downgrade the IGMP version.

### *TTL in IP multicast packets*

The switch treats multicast data packets with a time-to-live (TTL) of 1 as expired packets and sends them to the CPU before dropping them. To avoid this issue, ensure that the originating application uses a hop count large enough to enable the multicast stream to traverse the network and reach all destinations without reaching a TTL of 1. Ensure that you use a TTL value of 33 or 34 to minimize the effect of looping in an unstable network.

### *Multicast MAC filtering*

Certain network applications require multiple hosts to share a multicast MAC address. Instead of flooding all ports in the VLAN with this multicast traffic, you can use Multicast MAC filtering to forward traffic to a configured subset of the ports in the VLAN. This multicast MAC address is not an IP multicast MAC address.

At a minimum, map the multicast MAC address to a set of ports within the VLAN. In addition, if traffic is routed on the local host, you must configure an Address Resolution Protocol (ARP) entry to map the shared unicast IP address to the shared multicast MAC address. You must configure an ARP entry because the hosts can also share a virtual IP address, and packets addressed to the virtual IP address need to reach each host.

Ensure that you limit the number of such configured multicast MAC addresses to a maximum of 100. This number is related to the maximum number of possible VLANs you can configure, because for every multicast MAC filter that you configure the maximum number of configurable VLANs reduces by one. Similarly, configuring large numbers of VLANs reduces the maximum number of configurable multicast MAC filters downward from 100.

Although you can configure addresses starting with 01.00.5E, which are reserved for IP multicast address mapping, do not enable IP multicast with streams that match the configured addresses. This configuration can result in incorrect IP multicast forwarding and incorrect multicast MAC filtering.

### *Guidelines for multicast access policies*

Use the following guidelines when you configure multicast access policies:

- Use masks to specify a range of hosts. For example, 10.177.10.8 with a mask of 255.255.255.248 matches hosts addresses 10.177.10.8 through 10.177.10.15. The host subnet address and the host mask must be equal to the host subnet address. An easy way to determine this is to ensure that the mask has an equal or fewer number of trailing zeros than the host subnet address. For example, 3.3.0.0/255.255.0.0 and 3.3.0.0/255.255.255.0 are valid. However, 3.3.0.0/255.0.0.0 is not.
- Apply receive-access policies to all eligible receivers on a segment. Otherwise, one host joining a group makes that multicast stream available to all.
- Receive access policies are initiated after the switch receives reports with addresses that match the filter criteria.
- Transmit access policies apply after the switch receives the first packet of a multicast stream.

Multicast access policies can apply to a routed PIM interface if Internet Group Management Protocol (IGMP) reports the reception of multicast traffic.

The following rules and limitations apply to IGMP access policy parameters when you use them with IGMP instead of PIM:

- The static member parameter applies to IGMP snooping and PIM on both interconnected links and edge ports.
- The Static Not Allowed to Join parameter applies to IGMP snooping and PIM on both interconnected links and edge ports.
- For multicast access control, the denyRx parameter applies to IGMP snooping and PIM. The DenyTx and DenyBoth parameters apply only to IGMP snooping.

### *Split-subnet and multicast*

The split-subnet issue arises when you divide a subnet into two unconnected sections in a network. This division results in the production of erroneous routing information about how to reach the hosts on that subnet. The split-subnet problem applies to all types of traffic, but it has a larger impact on a PIM-SM network.

To avoid the split-subnet problem in PIM networks, ensure that the RP router is not in a subnet that can become a split subnet. Also, avoid having receivers on this subnet. Because the RP is an entity that must be reached by all PIM-enabled switches with receivers in a network, placing the RP on a split-subnet can impact the whole multicast traffic flow. Traffic can be affected even for receivers and senders that are not part of the split-subnet.

### *Protocol Independent Multicast-Sparse Mode guidelines*

Protocol Independent Multicast-Sparse Mode (PIM-SM) uses an underlying unicast routing information base to perform multicast routing. PIM-SM builds unidirectional shared trees rooted at a RP router for each group and can also create shortest-path trees for each source.

### **PIM-SM and PIM-SSM Scalability**

For more information on interface scaling, see the [VOSS Release Notes](#).

The software does not support virtualized PIM. PIM is supported in the Global Routing Table only.

Interfaces that run PIM must also use a unicast routing protocol (PIM uses the unicast routing table), which puts stringent requirements on the system. With a high number of interfaces, take special care to reduce the load on the system.

Use few active IP routed interfaces. You can use IP forwarding without a routing protocol enabled on the interfaces, and enable only one or two with a routing protocol. You can configure proper routing by using IP routing policies to announce and accept routes on the switch. Use PIM passive interfaces on the majority of interfaces.

#### **Important**

For information on the maximum values for total PIM interfaces and active interfaces, see the [VOSS Release Notes](#). If you configure the maximum number of active interfaces, all remaining interfaces must be passive.

When you use PIM-SM, the number of routes can scale up to the unicast route limit because PIM uses the unicast routing table to make forwarding decisions. For higher route scaling, use OSPF instead of Routing Information Protocol (RIP).

As a general rule, a well-designed network does not have many routes in the routing table. For PIM to work properly, ensure that all subnets configured with PIM are reachable and that PIM uses the information in the unicast routing table. For the RPF check, to correctly reach the source of any multicast traffic, PIM requires the unicast routing table.

### PIM General Requirements

Design simple PIM networks where VLANs do not span several switches.

PIM relies on unicast routing protocols to perform its multicast forwarding. As a result, include in your PIM network design, a unicast design where the unicast routing table has a route to every source and receiver of multicast traffic, as well as a route to the RP router and Bootstrap router (BSR) in the network. Ensure that the path between a sender and receiver contains PIM-enabled interfaces. Receiver subnets are not always required in the routing table.

Use the following guidelines:

- Ensure that every PIM-SM domain is configured with an RP, either by static definition or via BSR.
- Ensure that every group address used in multicast applications has an RP in the network.
- As a redundancy option, you can configure several RPs for the same group in a PIM domain.
- As a load sharing option, you can have several RPs in a PIM-SM domain map to different groups.
- In order to configure an RP to cover the entire multicast range, configure an RP to use the IP address of 224.0.0.0 and the mask of 240.0.0.0.
- Configure an RP to handle a range of multicast groups by using the mask parameter. For example, an entry for group value of 224.1.1.0 with a mask of 255.255.255.192 covers groups 224.1.1.0 to 224.1.1.63.
- In a PIM domain with both static and dynamic RP switches, you cannot configure one of the (local) interfaces for the static RP switches as the RP. For example, in the following scenario:

```
(static RP switch) Sw1 ----- Sw2 (BSR/Cand-RP1) -----Sw3
```

You cannot configure one of the interfaces on switch Sw1 as static RP because the BSR cannot learn this information and propagate it to Sw2 and Sw3. PIM requires that you consistently configure RP on all the routers of the PIM domain, so you can only add the remote interface Candidate-RP1 (Cand-RP) to the static RP table on Sw1.

- If a switch needs to learn an RP-set, and has a unicast route to reach the BSR through this switch, you cannot enable or configure static RP on a switch in a mixed mode of candidate RP and static RP switches. For examples, see the following two figures.

**PIM and Shortest Path Tree Switchover**

When an IGMP receiver joins a multicast group, PIM on the leaf router first joins the shared tree. After the first packet is received on the shared tree, the router uses the source address information in the packet to immediately switch over to the shortest path tree (SPT).

To guarantee a simple, yet high-performance implementation of PIM-SM, the switch does not support a threshold bit rate in relation to SPT switchover. Intermediate routers (that is, not directly connected IGMP hosts) do not switch over to the SPT until directed to do so by the leaf routers.

Other vendors can offer a configurable threshold, such as a certain bit rate at which the SPT switch-over occurs. Regardless of their implementation, no interoperability issues with the switch result. Switching to and from the shared and shortest path trees is independently controlled by each downstream router. Upstream routers relay joins and prunes upstream hop-by-hop, building the desired tree as they go.

Because a PIM-SM compatible router already supports shared and shortest path trees, no compatibility issues arise from the implementation of configurable switchover thresholds.

### **PIM Traffic Delay and SMLT Peer Reboot**

PIM uses a designated router (DR) to forward data to receivers on the DR VLAN. The DR is the router with the highest IP address on a LAN. If this router is down, the router with the next highest IP address becomes the DR. However, if the VLAN is an SMLT VLAN, the DR is not a factor in determining which switch forwards the data down to the receiver. Either aggregate switch can forward data to the receiver, because the switches act as one. The switch that forwards depends on where the source is located (on another SMLT/vIST link or on a non-SMLT/non-vIST link) and whether either side of the receiver SMLT link is up or down. If the forwarder switch is rebooted, traffic loss occurs until protocol convergence is completed.

Consider the following cases:

- If the source is on an SMLT link that is not the receiver SMLT, the switch that directly received the data on its side of the source SMLT link forwards it down to the receiver on the receiver SMLT regardless of which switch is the DR for the receiver VLAN. The forwarding switch sends a copy of the data over the vIST link to the peer switch, which drops the data because it knows that the remote SMLT is up and therefore the remote peer has already forwarded the data. If the forwarding switch goes down, the other switch receives the data directly over its source SMLT link and takes over forwarding to the receivers. After the original switch comes back up, the original switch again receives the data directly over its source SMLT. The original switch may not be ready to forward the data because of the protocol reconvergence, so the original switch loses traffic until reconvergence is complete.
- If the source is not learned on another SMLT link or the vIST link on each aggregate switch; they have a route to the source which is not on an SMLT or across the vIST. The switches must choose which one forwards the data down the receiver SMLT link; which one is the designated forwarder, so that duplicate data does not occur. The highest IP address is the designated forwarder. If the designated forwarder becomes disabled, the other takes over. When it is reenabled, the other switch sees that it is no longer the highest IP address and it sees that the remote SMLT link comes up. The other switch then assumes that the vIST peer is capable of being the designated forwarder and it stops forwarding down to the receivers. If the original switch is not ready to forward the data due to reconvergence, traffic loss occurs.

In either case, configuring a static RP helps the situation. To avoid this traffic delay, a workaround is to configure a static RP on the peer SMLT switches. This configuration avoids the process of selecting an active RP router from the list of candidate RPs, and also of dynamically learning about RPs through the BSR mechanism. Then, when the DR comes back, traffic resumes as soon as OSPF converges. This workaround reduces the traffic delay.

### **Circuitless IP for PIM-SM**

Use CLIP to configure a resilient RP and BSR for a PIM network. When you configure an RP or BSR on a regular interface, if it becomes nonoperational, the RP and BSR also become nonoperational. This status results in the election of other redundant RPs and BSRs, and can disrupt IP multicast traffic flow in the network. As a best practice for multicast networks design, always configure the RP and BSR on a CLIP interface to prevent a single interface failure from causing these entities to fail.

Also, configure redundant RPs and BSRs on different switches such that these entities are on CLIP interfaces. For the successful setup of multicast streams, ensure that a unicast route exists to all CLIP

interfaces from all locations in the network. A unicast route is mandatory because, for proper RP learning and stream setup on the shared RP tree, every switch in the network needs to reach the RP and BSR. You can use PIM-SM CLIP interfaces only for RP and BSR configurations, and are not intended for other purposes.

Do not configure non-SMLT IGMP leaf ports on a router to be one of the redundant RP CLIP devices. It is possible that these IGMP hosts can become isolated from the multicast data stream(s).

If you configure dual-redundant RPs (vIST peers with the same CLIP interface IP address used for the RP), the topology in the following figure does not work in link-failure scenarios. Use caution if you design a network with this topology where the vIST peers are PIM enabled, and the source and receiver edges are Layer 2.

Consider an example where one of the peers, vIST-A, is the PIM DR for the source VLAN, and the source data is hashed to vIST-A from the Layer 2 source edge. vIST-A forwards traffic to the receiver edge using the SMLT link from vIST-A to the receiver edge. If the SMLT link fails, vIST-A does not forward traffic over the vIST link to vIST-B, and the receiver edge does not receive the data.

In this topology, the receiver edge sends an IGMP membership report for a group, which is recorded on both vIST peers as an IGMP LEAF on the receiver SMLT port on the receiver VLAN.

Because both of the vIST peers are the RP for the group, they do not send a (\*,g) PIM JOIN message toward the other RP. The (\*,g) PIM mroute does not record the vIST port as a JOIN port on either vIST device. The PIM (\*,g) mroute records only a LEAF on the SMLT receiver port.

Because the source is local (Layer 2 edge), there is no PIM (s,g) JOIN message toward the source and the (s,g) PIM mroute does not record the vIST port as a JOIN port on either vIST device. The PIM (s,g) mroute records only a LEAF on the SMLT receiver port.

If the source is hashed to vIST-A, the PIM DR for the incoming VLAN, traffic is forwarded to the receiver correctly. vIST-A does not forward traffic over the vIST to vIST-B, because no JOIN exists on the vIST port. If the receiver SMLT link from the vIST-A peer is down, the traffic is not forwarded to vIST-B, and is not received by the receiver edge. Traffic resumes after the link is restored. If the source data hashes to the non-DR peer, vIST-B, no problem occurs because the non-DR always forwards traffic to the DR.

A similar situation exists in this topology when vIST-A is both the RP and the DR for the Layer 2 receiver edge. The vIST port is not in the outgoing port list because there is no JOIN message from the peer toward the source (which is not PIM enabled). Therefore, if the SMLT link from vIST-A to the receiver edge is down, the system does not forward traffic to the peer vIST-B and down to the receiver.

You can avoid the preceding problems with this topology by performing one of the following actions:

- Enable PIM on the source edge.

The vIST peers send PIM joins toward the source and the JOIN is recorded on the vIST port for the (s,g). Data is forwarded to the peer.

- Do not configure dual redundant RPs.

One vIST peer is the RP for a group.

- Do not configure one vIST peer as both the DR for the source VLAN and the RP for the receiver group.

The system forwards the traffic to the RP or to the DR, depending on which peer receives the source, and, if the SMLT link to the receiver goes down there will be no data loss.

### **PIM-SM and Static RP**

Use static RP to provide security, interoperability, and redundancy for PIM-SM multicast networks. Consider if the administrative ease derived from using dynamic RP assignment is worth the security risks involved. For example, if an unauthorized user connects a PIM-SM router that advertises itself as a candidate RP (C-RP), it can possibly take over new multicast streams that otherwise distribute through an authorized RP. If security is important, use static RP assignment.

You can use the static RP feature in a PIM environment with devices that run legacy PIM-SMv1 and Cisco Auto-RP. For faster convergence, you can also use static RP in a PIM-SMv2 environment. If you configure static RP with PIM-SMv2, the BSR is not active.

### **Static RP and Auto-RP**

Some legacy PIM-SMv1 networks use the auto-RP protocol. Auto-RP is a Cisco proprietary protocol that provides equivalent functionality to the legacy platform supported PIM-SM RP and BSR. You can use the static RP feature to interoperate in this environment. For example, in a mixed-vendor network, you can use auto-RP among routers that support the protocol, while other routers use static RP. In such a network, ensure that the static RP configuration mimics the information that is dynamically distributed to guarantee that multicast traffic is delivered to all parts of the network.

In a mixed auto-RP and static RP network, ensure that the legacy platform does not serve as an RP because it does not support the auto-RP protocol. In this type of network, the RP must support the auto-RP protocol.

### **Static RP and RP Redundancy**

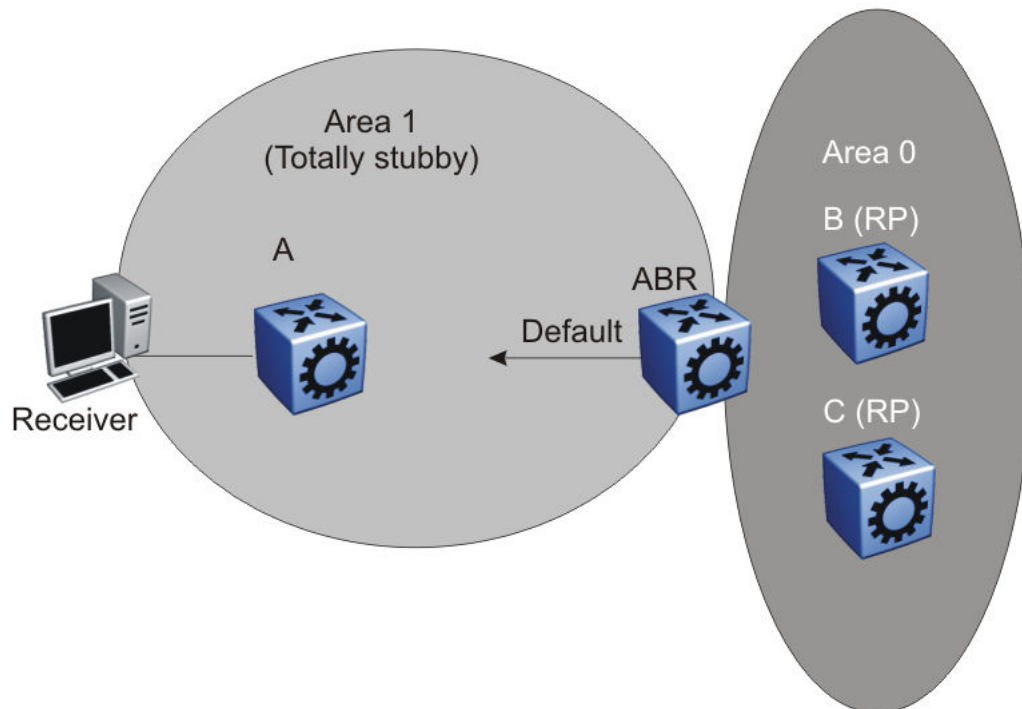

You can provide RP redundancy through static RPs. To ensure consistency of RP selection, implement the same static RP configuration on all PIM-SM routers in the network. In a mixed vendor network, ensure that the same RP selection criteria is used among all routers. For example, to select the active RP for each group address, the switch uses a hash algorithm defined in the PIM-SMv2 standard. If a router from another vendor selects the active RP based on the lowest IP address, then the inconsistency prevents stream delivery to certain routers in the network.

If a group address-to-RP discrepancy occurs among PIM-SM routers, network outages occur. Routers that are unaware of the true RP cannot join the shared tree and cannot receive the multicast stream.

Failure detection of the active RP is determined by the unicast routing table. As long as the RP is considered reachable from a unicast routing perspective, the local router assumes that the RP is fully functional and attempts to join the shared tree of that RP.

The following figure shows a hierarchical OSPF network where a receiver is in a totally stubby area. If RP B fails, PIM-SM router A does not switch over to RP C because the injected default route in the unicast routing table indicates that RP B is still reachable.

Because failover is determined by unicast routing behavior, carefully consider the unicast routing design, as well as the IP address you select for the RP. Static RP failover performance depends on the convergence time of the unicast routing protocol. For quick convergence, ensure that you use a link state protocol, such as OSPF. For example, if you use RIP as the routing protocol, an RP failure can take minutes to detect. Depending on the application, this situation can be unacceptable.

Static RP failover time does not affect routers that have already switched over to the SPT; failover time only affects newly-joining routers.

### Unsupported Static RP Configurations

If you use static RP, you disable dynamic RP learning. The following figure shows an unsupported configuration for static RP. In this example because of inter-operation between static RP and dynamic RP, no RP exists at switch 2. However, (S,G) creation and deletion occurs every 210 seconds at switch 16.

Switches 10, 15, and 16 use static RP, whereas switch 2 uses dynamic RP. The source is at switch 10, and the receivers are switches 15 and 16. The RP is at switch 15 locally. The receiver on switch 16 cannot receive packets because its SPT goes through switch 2.

Switch 2 is in a dynamic RP domain, so it cannot learn about the RP on switch 15. However, (S, G) records are created and deleted on switch 16 every 210 seconds.

### Rendezvous Point Router Considerations

You can place an RP on a switch when VLANs extend over several switches. However, when you use PIM-SM, ensure that you do not span VLANs on more than two switches.

Use static group-range-to-RP mappings in an SMLT topology as opposed to RP set learning using the Bootstrap Router (BSR) mechanism. Static RP allows for faster convergence in box failure, reset and HA failover scenarios, whereas there are inherent delays in the BSR mechanism as follows:

- When a router comes back up after a failover or reset, to accept and propagate (\*,g) join requests from surrounding routers (either PIM join messages or local IGMP membership reports) to the RP, a PIM router must determine the address of the RP for each group for which they desire (\*,g) state. The PIM router must know the unicast route to the RP address. The route to the RP address is learned by using a unicast routing protocol such as OSPF, and the RP address is either statically configured or dynamically learned using the BSR mechanism.
- When a box comes up after a reset, if the RP is not statically configured, it must wait for the BSR to select the RP from candidate RP routers, and then propagate the RP set hop-by-hop to all PIM routers. This must be done before a join message can be processed. If the PIM router receives a join message before it learns the RP set, it drops the join message, and the router waits for another join or prune message to arrive before it creates the multicast route and propagates the join message to the RP. The default Join/Prune timer is 60 seconds, and because of this and the delays inherent in BSR RP-set learning, significant multicast traffic interruptions can occur. If the RP is statically configured, the only delay is in the unicast routing table convergence and the arrival of the Join/Prune messages from surrounding boxes.

### Layer 3 Multicast Extended VLANS

Avoid using a Layer 3 multicast extended VLAN topology without SMLT.

Do not connect non-SMLT PIM routers in a linear fashion on the same VLAN. This topology is called an extended VLAN. Unlike a shared VLAN topology where all routers on the same VLAN are physically one hop away from each other, a VLAN router at one end of the extended VLAN has one or more routers in between it and the router at the far end of the extended VLAN. The following figure shows an extended VLAN.
