Open Source Declarations

Some software files have been licensed under certain open source or third-party licenses. End-user license agreements and open source declarations can be found at: <https://www.extremenetworks.com/support/policies/open-source-declaration/>

About this Document

[Purpose](#) on page 3

[Conventions](#) on page 3

[Documentation and Training](#) on page 5

[Help and Support](#) on page 6

[Send Feedback](#) on page 7

This section discusses the purpose of this document, ways to provide feedback, additional help, and information regarding other Extreme Networks publications.

Purpose

This document provides information on features in VSP Operating System Software (VOSS). VOSS runs on the following product families:

- ExtremeSwitching VSP 4450 Series
- ExtremeSwitching VSP 4900 Series
- ExtremeSwitching VSP 7200 Series
- ExtremeSwitching VSP 7400 Series
- ExtremeSwitching VSP 8200 Series
- ExtremeSwitching VSP 8400 Series
- ExtremeSwitching VSP 8600 Series
- ExtremeSwitching XA1400 Series

Note

VOSS is licensed on the XA1400 Series as a Fabric Connect VPN (FCVPN) application, which includes a subset of VOSS features. FCVPN transparently extends Fabric Connect services over third-party provider networks.

Conventions

To help you better understand the information presented in this guide, the following topics describe the formatting conventions used for notes, text, and other elements.

Text Conventions

The following tables list text conventions that can be used throughout this document.

Table 1: Notes and warnings

Icon	Notice type	Alerts you to...
	Tip	Helpful tips and notices for using the product.
	Note	Useful information or instructions.
	Important	Important features or instructions.
	Caution	Risk of personal injury, system damage, or loss of data.
	Warning	Risk of severe personal injury.

Table 2: Text Conventions

Convention	Description
Angle brackets (< >)	Angle brackets (< >) indicate that you choose the text to enter based on the description inside the brackets. Do not type the brackets when you enter the command. If the command syntax is <code>cfm maintenance-domain maintenance-level <0-7></code> , you can enter <code>cfm maintenance-domain maintenance-level 4</code> .
Bold text	Bold text indicates the GUI object name you must act upon. Examples: <ul style="list-style-type: none"> Click OK. On the Tools menu, choose Options.
Braces ({ })	Braces ({ }) indicate required elements in syntax descriptions. Do not type the braces when you enter the command. For example, if the command syntax is <code>ip address {A.B.C.D}</code> , you must enter the IP address in dotted, decimal notation.

Table 2: Text Conventions (continued)

Convention	Description
Brackets ([])	Brackets ([]) indicate optional elements in syntax descriptions. Do not type the brackets when you enter the command. For example, if the command syntax is <code>show clock [detail]</code> , you can enter either <code>show clock</code> or <code>show clock detail</code> .
Ellipses (...)	An ellipsis (...) indicates that you repeat the last element of the command as needed. For example, if the command syntax is <code>ethernet/2/1 [<parameter> <value>] . . .</code> , you enter <code>ethernet/2/1</code> and as many parameter-value pairs as you need.
Italic Text	Italics emphasize a point or denote new terms at the place where they are defined in the text. Italics are also used when referring to publication titles that are not active links.
Plain Courier Text	Plain Courier text indicates command names, options, and text that you must enter. Plain Courier text also indicates command syntax and system output, for example, prompts and system messages. Examples: <ul style="list-style-type: none"> <code>show ip route</code> <code>Error: Invalid command syntax [Failed] [2013-03-22 13:37:03.303 -04:00]</code>
Separator (>)	A greater than sign (>) shows separation in menu paths. For example, in the Navigation tree, expand the Configuration > Edit folders.
Vertical Line ()	A vertical line () separates choices for command keywords and arguments. Enter only one choice. Do not type the vertical line when you enter the command. For example, if the command syntax is <code>access-policy by-mac action { allow deny }</code> , you enter either <code>access-policy by-mac action allow</code> or <code>access-policy by-mac action deny</code> , but not both.

Documentation and Training

Find Extreme Networks product information at the following locations:

[Current Product Documentation](#)

[Release Notes](#)

[Hardware and software compatibility](#) for Extreme Networks products
[Extreme Optics Compatibility](#)
[Other resources](#) such as white papers, data sheets, and case studies

Extreme Networks offers product training courses, both online and in person, as well as specialized certifications. For details, visit www.extremenetworks.com/education/.

Help and Support

If you require assistance, contact Extreme Networks using one of the following methods:

Extreme Portal

Search the GTAC (Global Technical Assistance Center) knowledge base; manage support cases and service contracts; download software; and obtain product licensing, training, and certifications.

The Hub

A forum for Extreme Networks customers to connect with one another, answer questions, and share ideas and feedback. This community is monitored by Extreme Networks employees, but is not intended to replace specific guidance from GTAC.

Call GTAC

For immediate support: (800) 998 2408 (toll-free in U.S. and Canada) or 1 (408) 579 2826. For the support phone number in your country, visit: www.extremenetworks.com/support/contact

Before contacting Extreme Networks for technical support, have the following information ready:

- Your Extreme Networks service contract number, or serial numbers for all involved Extreme Networks products
- A description of the failure
- A description of any actions already taken to resolve the problem
- A description of your network environment (such as layout, cable type, other relevant environmental information)
- Network load at the time of trouble (if known)
- The device history (for example, if you have returned the device before, or if this is a recurring problem)
- Any related RMA (Return Material Authorization) numbers

Subscribe to Product Announcements

You can subscribe to email notifications for product and software release announcements, Field Notices, and Vulnerability Notices.

1. Go to [The Hub](#).
2. In the list of categories, expand the **Product Announcements** list.
3. Select a product for which you would like to receive notifications.
4. Select **Subscribe**.
5. To select additional products, return to the **Product Announcements** list and repeat steps 3 and 4.

You can modify your product selections or unsubscribe at any time.

Send Feedback

The Information Development team at Extreme Networks has made every effort to ensure that this document is accurate, complete, and easy to use. We strive to improve our documentation to help you in your work, so we want to hear from you. We welcome all feedback, but we especially want to know about:

- Content errors, or confusing or conflicting information.
- Improvements that would help you find relevant information.
- Broken links or usability issues.

To send feedback, do either of the following:

- Access the feedback form at <https://www.extremenetworks.com/documentation-feedback/>.
- Email us at documentation@extremenetworks.com.

Provide the publication title, part number, and as much detail as possible, including the topic heading and page number if applicable, as well as your suggestions for improvement.

New in this Document

[Notice about Feature Support on page 9](#)

The following sections detail what is new in this document.

Extreme Integrated Application Hosting Enhancements

This release includes the ability to perform the following actions in a virtual machine (VM) from EDM. In previous releases, this functionality was available through CLI only:

- copy files
- run commands
- change a user password

For more information, see [Virtual Services Configuration using EDM](#) on page 868.

Fabric Extend Enhancement

In earlier releases, you could not configure the tunnel source address (**ip-tunnel-source-address** command) if the address belonged to a VRF with an attached I-SID. You can now use an *overlay* parameter with this command to bypass this restriction.

For more information, see the following tasks:

- [Configure Fabric Extend](#) on page 1042
- [Configure Fabric Extend Tunnels](#) on page 1162

Fail Open Continuity Mode

Continuity Mode is an enhancement to existing Fail Open VLAN and Fail Open I-SID behavior that shortens the transition to the Fail Open VLAN or Fail Open I-SID. This mode is automatically enabled if you configure Fail Open VLAN or Fail Open I-SID; you cannot disable Continuity Mode. Continuity Mode replaces the Fail Open behavior of previous releases.

For more information, see [Fail Open VLAN with Continuity Mode](#) on page 786 and [Fail Open I-SID with Continuity Mode](#) on page 787.

Multi-area SPB Enhancement

Note

This feature only applies to the VSP 7400 Series.

This release introduces the ability for a Multi-area SPB boundary node to forward traffic from the UNIs to the remote-area and from the remote-area to the UNIs without requiring an established adjacency in the home area.

For more information, see [Configure Multi-area Flags Functionality](#) on page 1125.

RESTCONF APIs Enhancement

In this release, RESTCONF API support is enhanced to include:

- Get all client MAC addresses (mgmt VRF, GRT and user VRF) from the device.
- Get all switch client ARP information.

For more information, see [Representational State Transfer Configuration Protocol \(RESTCONF\) Fundamentals](#) on page 2791.

Universal Hardware Separation

A new document suite is created to separate feature documentation for the universal hardware products (5520 Series, 5420 Series, and 5320 Series). For more information, see [Fabric Engine User Guide](#).

Note

Prior to Fabric Engine 8.6, 5520 Series and 5420 Series platforms ran VOSS. VOSS support ends for these platforms with VOSS 8.5.x.

Notice about Feature Support

This document includes content for multiple hardware platforms across different software releases. As a result, the content can include features not supported by your hardware in the current software release.

If a documented command, parameter, tab, or field does not display on your hardware, it is not supported.

For information about physical hardware restrictions, see your hardware documentation.

Installation and Commissioning Documentation

Use installation and commissioning documentation to install the product hardware and software, and perform the initial configuration.

Table 3: Installation and commissioning documents

Table 4: Installation and commissioning reference documents (continued)

Technical document	Description
<i>Minimum Software Requirements to Support Virtual Services Platform 8400 ESMs</i>	This document provides the minimum software release for each module in the VSP 8400 Series.
<i>Read Me First—Important Notes and Minimum Software Requirements for VSP 8600 Modules</i>	This document provides important information to read before you install modules in the VSP 8600 Series, and also provides the minimum software release for each IOC and SF module.

Zero Touch Capabilities

[Auto-sense on page 14](#)

[IP Phone Support on page 46](#)

[Zero Touch Deployment on page 56](#)

[Zero Touch Provisioning Plus on page 58](#)

[Zero Touch Fabric Configuration on page 61](#)

[Configuration Example to Create an IS-IS Adjacency between the VSP 8600 Series and VOSS Switches on page 65](#)

The switch supports the following zero touch capabilities:

- Auto-sense support for the following features:
 - Fabric Attach (FA)
 - Extensible Authentication Protocol (EAP) and non-EAPoL (NEAP)
 - IP Phones
- Zero Touch Deployment
- Zero Touch Provisioning Plus (ZTP+)
- Zero Touch Fabric Configuration including Auto-sense for network-to-network (NNI) interfaces

Note

For bridged or routed reachability of the management servers (DHCP, RADIUS, Extreme Management Center or ExtremeCloud IQ - Site Engine, or ExtremeCloud IQ) the onboarding I-SID must be manually mapped to the management segment on at least one Backbone Edge Bridge (BEB) in the network prior to zero touch deployments of new switches. Additionally, you must enable a Dynamic Nickname server on at least one node. For more information, see [VOSS Release Notes](#).

Auto-sense

Table 5: Auto-sense product support

Feature	Product	Release introduced
Auto-sense	VSP 4450 Series	VOSS 8.3
	VSP 4900 Series	VOSS 8.3
	VSP 7200 Series	VOSS 8.3
	VSP 7400 Series	VOSS 8.3
	VSP 8200 Series	VOSS 8.3
	VSP 8400 Series	VOSS 8.3
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported
Auto-sense ports can apply Fabric Attach (FA)-specific configuration	VSP 4450 Series	VOSS 8.4.2
	VSP 4900 Series	VOSS 8.4.2
	VSP 7200 Series	VOSS 8.4.2
	VSP 7400 Series	VOSS 8.4.2
	VSP 8200 Series	VOSS 8.4.2
	VSP 8400 Series	VOSS 8.4.2
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

Auto-sense is a port-based functionality that supports zero touch capabilities on the switch. Auto-sense dynamically configures the port to act as an IS-IS NNI, Fabric UNI (Flex-UNI), Fabric Attach (FA), or voice (IP phone) interface, based on the Link Layer Discovery Protocol (LLDP) events. Auto-sense provides global configuration options for IS-IS authentication, FA authentication, and voice configuration for IP phones, on the switch. For more information about IP Phone Support, see [IP Phone Support](#) on page 46.

When a switch boots in Zero Touch Fabric Configuration mode, all ports on the switch automatically operate in Auto-sense mode, unless you manually change the port configuration. For more information on Zero Touch Fabric Configuration, see [Zero Touch Fabric Configuration](#) on page 61.

With Auto-sense functionality, ports on a switch can detect whether they connect to a Shortest Path Bridging (SPB) device, an FA client, FA Proxy, Voice IP devices, or an undefined host:

- If a port connects to an SPB device or an FA client, then the system establishes Fabric architecture.
- If a port connects to any undefined host, then the system moves all untagged traffic on the port to an onboarding service network, also known as the onboarding I-SID.
- If a port operates in Auto-sense mode, Extensible Authentication Protocol (EAP) is enabled globally with a RADIUS configuration, and the Auto-sense port does not detect an SPB or Fabric Attach proxy neighbor, then the system automatically activates EAP and Non-EAP (NEAP) authentication on them, for untagged traffic.

When you manually disable Auto-sense on a specific port, the switch removes the dynamic configuration on that port unless you use an optional parameter to convert the dynamic configuration to a manual configuration. If you do not use the optional parameter, the software removes all Auto-sense state configuration and reverts the port to the default configuration.

If you enable Auto-sense on a port with a conflicting feature configuration, the software automatically deletes the conflicting configuration from the port. Conflicting configurations include the following commands or features:

- **access-diffserv** command
- **flex-uni enable** command
- **mac-security limit-learning** command
- **qos 802.1p-override enable** command
- Other feature configurations on the port:
 - brouter port
 - port tagging (encapsulation) - If a port has encapsulation enabled and you enable Auto-sense, the port remains with encapsulation enabled. Disabling Auto-sense transitions the encapsulation value to disabled. If a port has encapsulation disabled and you enable Auto-sense, port encapsulation is enabled.
 - Extensible Authentication Protocol over LAN (EAPoL)
 - FA
 - IS-IS interface
 - Link Aggregation Control Protocol (LACP) and Virtual Link Aggregation Control Protocol (VLACP)
 - LLDP enable
 - LLDP MED network policies
 - private VLAN
 - MLT member
 - Switched UNI (S-UNI) or Transparent Port UNI (T-UNI) interface
 - VLAN member

Implementation on Upgraded Switches with Existing Configuration

If the switch does not boot in Zero Touch Fabric Configuration mode and you want to use Auto-sense functionality with an existing switch configuration, you must:

- Enable Auto-sense on the applicable port or ports.
- Create a new VLAN 4048. If the existing configuration uses VLAN 4048, you must configure a new VLAN for those original purposes.
- Configure I-SID 15999999 as the Auto-sense onboarding I-SID.
- Assign onboarding I-SID 15999999 to private VLAN 4048.

Auto-Sense Data I-SID

Auto-sense supports global configuration of a data I-SID on the switch, which applies to all Auto-sense enabled ports. You can also configure Auto-sense data I-SID on each port to separate the data traffic into individual port specific data I-SIDs. For example, if device A and device B connect to different Auto-

sense enabled ports and you configure an Auto-sense data I-SID on each port, the switch separates the data traffic of device A from the data traffic of device B. A port-level data I-SID and the global data I-SID can use the same value. The system prioritizes the I-SIDs in the following order:

1. Untagged I-SID assigned per client by EAP/NEAP MHMV
2. Untagged voice I-SID
3. Port data I-SID
4. Global data I-SID
5. Onboarding I-SID

The **show running-config** output includes the configured Auto-sense data I-SID for the port module only if you enable Auto-sense on the port. If you disable Auto-sense on the port, the configuration remains on the switch even though the command output does not include it. If you disable Auto-sense on the port and use the **convert-to-config** parameter, the port remains in the I-SID until you manually remove the data I-SID configuration from the port. If you re-enable Auto-sense on the port, you must reconfigure the data I-SID on the port.

If you remove the Auto-sense data I-SID from a port, then the port uses either the global Auto-sense data I-SID, if one exists, or the Auto-sense onboarding I-SID.

IS-IS Authentication

Auto-sense supports global configuration of IS-IS authentication key on the switch. All ports operating in Auto-sense mode and transitioned to the NNI state, use the global IS-IS authentication key that you configure using the **auto-sense isis hello-auth type** command. For more information, see [Configure Auto-sense IS-IS Authentication](#) on page 27.

FA Configuration

Depending on the device that the Auto-sense port detects, the software can apply different FA-specific configurations that you define:

- You can configure an I-SID for FA clients such as FA wap-type 1, FA camera, and FA open-virtual-switch (OVS). The software prefers the FA I-SID over the onboarding I-SID.
- You can configure a specific I-SID and customer VLAN ID to use as the management I-SID when the port is in the Auto-sense FA PROXY state. If you do not configure a management I-SID, the port uses the onboarding I-SID for untagged traffic.
- You can disable EAPoL authentication requirements for specific FA client types (wap-type1, camera, and ovs).

FA Authentication

Auto-sense supports FA message authentication on switches. You can enable FA message authentication globally on a switch. All ports operating in Auto-sense mode use the global authentication key. A preconfigured authentication key exists on the switch, by default, which you can change. For more information, see [Configure Auto-sense Fabric Attach \(FA\) Authentication](#) on page 35.

Auto-sense Voice Capabilities

Auto-sense voice capabilities are based on the events when the switch detects an IP phone in the network. For more information, see [Auto-sense Voice](#) on page 48.

Loop Prevention

Auto-sense ports between two switches that have transitioned to NNI state are not prone to loops. Any connection can be wired and SPB establishes the shortest path connections. On Auto-sense NNI links BVID information, as well as IS-IS area information, is exchanged enabling Zero Touch Fabric functionality.

Auto-sense ports that connect to non-SPB switches operate in UNI mode, or FA Proxy mode in the case of ERS, EXOS, and Switch Engine switches. In UNI mode, VOSS devices send Spanning Tree BPDU packets emulating root bridge behavior ensuring that any potential UNI loop is broken by the attached spanning tree enabled devices.

For more information on the port states, see [Auto-sense Port States](#) on page 17.

Running Configuration

If you view the running configuration, the global Auto-sense configuration displays under the port module. Use the command **show running-config module port**.

Auto-sense Port States

The system uses a per-interface state to adapt to all Auto-sense events. Each state transition determines background configuration on the port. The system does not display these configurations in the output of the **show running-config** command or in the saved configuration file but if you disable Auto-sense on the port and use the *convert-to-config* parameter, the dynamic configuration becomes a manual configuration and is visible in the **show running-config** output. Use **show auto-sense** commands to monitor the running states of each port.

Port Down State

If you run the **auto-sense enable** command on a port that is disabled or has an inactive link, the port transitions to the Auto-sense Port Down state. This state transitions to the Auto-sense Wait state after the port becomes operational or the link becomes active.

Wait State

The port modifies outgoing LLDP packets to represent the enhanced properties of the port and analyzes incoming LLDP packets for possible transitions to advanced states like network-to-network interface (NNI), Fabric Attach (FA), or VOICE. If the port does not receive LLDP packets, the port transitions to the UNI state.

UNI State

This state grants onboarding and data connectivity to the port if you configure the onboarding I-SID, or a data I-SID in the global Auto-sense configuration or at the port level. The system also applies the

trusted and untrusted Auto-sense global configuration. As with the Wait state, the port continues to monitor received LLDP packets for transitions to other states.

Network Access Control (NAC) support, through EAP/NEAP, is enabled by default on each Auto-sense port, but disabled globally. If you require EAP/NEAP operation on Auto-sense ports, you must globally enable EAP and configure a RADIUS server.

The system performs the following background configurations on port x:

```
flex-uni enable
eapol status auto
eapol multihost radius-non-eap-enable
eapol multihost eap-oper-mode mhm
[qos 802.1p-override enable]
[access-diffserv enable]
on port X interface, if onboarding I-SID Y is configured without data I-SID:
eapol guest i-sid Y
on onboarding I-SID interface, if it is configured without data I-SID:
untagged-traffic port X
on data I-SID interface, if it is configured:
untagged-traffic port X
```

An Auto-sense port in the UNI state remains in PVLAN isolated mode when any additional untagged I-SID is applied to the port. Auto-sense ports support multiple VLAN/I-SIDs and PVLAN/I-SIDs on the same port at any time concurrently. Typically, this operational mode is required when you configure NAC support with Multiple Host Multiple VLAN (MHMV). The software then assigns clients to their VLAN/I-SIDs based on their NAC authentication results.

NNI States

The NNI states are as follows:

- NNI
- NNI onboarding
- NNI IS-IS
- NNI pending

If, while in the Wait state, the port receives a Fabric Connect LLDP packet, the port transitions to the NNI state and adds the IS-IS SPBM instance on the interface. The system tries to establish an IS-IS adjacency and, if successful, transitions the port to the NNI IS-IS state. The port remains in the NNI IS-IS state until the adjacency fails, at which time it returns to the NNI state.

The system performs the following background configurations on port x:

```
isis
isis spbm 1
isis enable
[isis hello-auth ...] inherited from global configuration
```

If the system cannot establish the adjacency, it transitions the port to the NNI onboarding state. The system creates a Switched UNI (S-UNI) with the onboarding I-SID.

The system performs the following background configurations:

```
flex-uni enable
isis
isis spbm 1
isis enable
```

```
[isis hello-auth ...] inherited from global configuration
on onboarding i-sid interface, if it exists:
untagged-traffic port X
```

Fabric Attach (FA) States

The FA states are as follows:

- FA - this state is used for FA capable wireless access points, Camera or OVS devices
- FA PROXY - this state is used for interaction with ERS, EXOS, and Switch Engine switches, which are capable of FA proxy function
- FA PROXY NOAUTH - this state is used for interaction with ERS, EXOS, and Switch Engine switches, which are capable of FA proxy function

LLDP uses the FA TLV to detect FA-capable neighbors.

The port enters the FA state after LLDP detects an access point, an FA client that is not another switch.

The system performs the following background configurations on port x:

```
flex-uni enable
eapol status auto
eapol multihost radius-non-eap-enable
eapol multihost eap-oper-mode mhmv
eapol guest i-sid X
fa enable
on onboarding i-sid interface, if it exists:
untagged-traffic port X
```

If LLDP detects an FA proxy switch such as an ERS, EXOS, or Switch Engine switch that uses FA message authentication, the port transitions to the FA PROXY state.

The system performs the following background configurations on port x:

```
flex-uni enable
fa enable
fa message-authentication
fa management-isid
```

Note

By default, the FA PROXY state uses the onboarding I-SID as the management I-SID but you can override this with a specific I-SID and customer VLAN ID combination.

If the FA proxy switch does not use FA message authentication, the port transitions to the FA PROXY NOAUTH state.

The system performs the following background configurations on port x:

```
flex-uni enable
fa enable
on onboarding i-sid interface, if it exists:
untagged-traffic port X
```

Depending on the device that the Auto-sense port detects, the switch can apply different FA-specific configurations that you define. For more information, see [Auto-sense](#) on page 14.

When a port is in the FA state, the system uses the following priority for untagged traffic:

1. EAP/NEAP assigned I-SID
2. WAP, camera, or open virtual switch (OVS) I-SID
3. Onboarding I-SID
4. Drop

Voice State

If the port detects an LLDP packet from a phone, the port transitions to the VOICE state. A global Auto-sense voice configuration is not required to transition to the VOICE state except a specific voice VLAN shall be signaled to the phone.

For more information on Auto-sense voice, see [Auto-sense Voice](#) on page 48.

DHCP Port Snooping

For zero touch onboarding, if a port answers Dynamic Host Configuration Protocol (DHCP) requests sent by the switch and the port is in the Auto-sense UNI state, the system automatically changes the port's Private VLAN configuration from isolated mode to promiscuous mode.

Without this port type change on the Private VLAN, the other devices in the network cannot receive an IP address through the DHCP server if they are in the Zero Touch Fabric Configuration mode unless you disable Auto-sense on the port and manually change the port from isolated mode to promiscuous mode.

Auto-sense Logical Flowcharts

The system uses a per-interface state to adapt to all Auto-sense events. Each state transition determines background configuration on the port. The system does not display Auto-sense port configurations in the **show running-config** command or in the saved configuration file; instead use the **show auto-sense** commands to show global and port specific Auto-sense information..

The following flowcharts describe the system logic for Auto-sense port state detection, how the system configurations change the logic path, and the Auto-sense configuration results.

Note

The `vlan create` CLI command examples are not applicable for DvR leaf switch configurations. DvR leaf switches create VLANs automatically.

Auto-sense Configuration using CLI

To change the Auto-sense configuration on a port using EDM, see [Configure Basic Port Parameters](#) on page 577.

Enable Auto-sense on Port(s)

**Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to manually enable Auto-sense on a specific port.

**Note**

After a switch boots without a configuration file, Auto-sense is enabled on all ports, by default.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Auto-sense on the port:

```
auto-sense enable
```

Example

Enabling Auto-sense on port 1/2:

```
Switch:1>enable  
Switch:1#configure terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
Switch:1(config)#interface gigabitEthernet 1/2  
Switch:1(config-if)#auto-sense enable  
Warning: Enabling Auto-Sense will default port configurations.
```

Disable Auto-sense on Port(s)

**Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to disable Auto-sense on a specific port. You also have the option to disable Auto-sense on the port but retain the configuration that the system applied dynamically.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable Auto-sense on the port:

```
no auto-sense enable [convert-to-config]
```

Example

Disable Auto-sense on port 1/2 but retain the configuration. The dynamic configuration becomes a manual configuration and is visible in the **show running-config** output and can be saved to the configuration file using the **save config** command.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface interface gigabitEthernet 1/2
Switch:1(config-if)#no auto-sense enable convert-to-config
Switch:1(config-if)#save config
```

Variable Definitions

The following table defines parameters for the **no auto-sense enable** command.

Variable	Value
<i>convert-to-config</i>	Retains the Auto-sense configuration that the system applies dynamically on the specific port. The dynamic configuration becomes a manual configuration and is visible in the show running-config output. If you run the "no auto-sense enable" command without the "convert-to-config" option, then the configuration will be removed from the port and the port returns to the default state where VLAN 1 is assigned.

Configure the Auto-sense Wait Interval

Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

About This Task

Perform this task to configure the time, in seconds, for Auto-sense to wait for a Link Layer Discovery Protocol (LLDP) neighbor to be detected in the Auto-sense wait state before transitioning to the Auto-sense onboarding state.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the Auto-sense wait interval:

```
auto-sense wait-interval <10-120>
```
3. Verify the Auto-sense wait interval information:

```
show auto-sense wait-interval
```

Examples

Configure the Auto-sense wait interval as 50 seconds:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense wait-interval 50
```

Verify the Auto-sense wait-interval information:

```
Switch:1>show auto-sense wait-interval
=====
                        AUTO-SENSE GLOBAL Config
=====
WAIT
INTERVAL
-----
50
-----

0 out of 0 Total Num of AUTO-SENSE entries displayed
=====
```

Variable Definitions

The following table defines parameters for the **auto-sense wait-interval** command.

Variable	Value
<10-120>	Specifies the wait interval, in seconds, for Auto-sense ports. The default value is 35.

Configure Auto-sense IS-IS Authentication

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

Before You Begin

Enable IS-IS globally.

About This Task

Perform this procedure to configure a global IS-IS authentication key for ports that are operating in Auto-sense mode.

Note

If the IS-IS authentication keys on auto-sense ports between two switches do not match, then the auto-sense port state will be auto-sense UNI onboarding, until the keys are matching, then an IS-IS adjacency will be established.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the authentication type for IS-IS hello packets on Auto-sense ports:

```
auto-sense isis hello-auth type {none|simple|hmac-md5|hmac-sha-256}  
[key WORD<1-16>] [key-id <1-255>]
```

Example

Configuring simple authentication for IS-IS hello packets on Auto-sense ports:

```
Switch:1>enable  
Switch:1#configure terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
Switch:1(config)#auto-sense isis hello-auth type simple key Secure
```

Variable Definitions

The following table defines parameters for the **auto-sense isis hello-auth type** command.

Variable	Value
<i>{ none simple hmac-md5 hmac-sha-256 }</i>	<p>Specifies the authentication type for IS-IS hello packets on Auto-sense ports:</p> <ul style="list-style-type: none"> • none • simple - simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet. • hmac-md5 - MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. • hmac-sha-256 - with SHA-256 authentication, the switch adds an hmac-sha-256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. <p>Note: Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate ISIS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key. This feature is in full compliance with RFC 5310.</p> <p>The default authentication type is none.</p>
<i>key WORD<1-16></i>	Specifies the authentication key (password) used by the receiving router to verify the packet.
<i>key-id <1-255></i>	Specifies the key ID.

Configure Auto-sense Access Ports

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to configure ports operating in Auto-sense mode to determine the Layer 3 Quality of Service (QoS) actions the switch performs. The Auto-sense access ports override the Differentiated Services Code Point (DSCP) markings.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure Auto-sense access ports:

```
auto-sense access-diffserv [enable]
```

Example

Configure the Auto-sense access ports:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)#auto-sense access-diffserv enable
```

Variable Definitions

The following table defines parameters for the **auto-sense access-diffserv** command.

Variable	Value
<i>enable</i>	Configures the ports operating in Auto-sense mode to determine the Layer 3 Quality of Service (QoS) actions the switch performs. The Auto-sense access ports override the Differentiated Services Code Point (DSCP) markings. The default configuration is enabled.

Disable Auto-sense DHCP Server Detection

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to disable Dynamic Host configuration Protocol (DHCP) server detection in Auto-sense mode.

Note

By default Auto-sense DHCP server detection is enabled. This ensures automatic detection of the DHCP uplink ports in Zero Touch Deployment.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Disable DHCP server detection:

```
no auto-sense dhcp-detection
```

Example

Enable DHCP server detection:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no auto-sense dhcp-detection
```

Configure the Auto-sense Onboarding I-SID on the Switch**Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to configure the onboarding I-SID for ports that are operating in Auto-sense mode. The onboarding I-SID is typically used to onboard networking devices such as switches and non FA capable access points. By default, the onboarding I-SID provides automatic reachability when switches are booted from factory without a configuration file. For security reasons, the onboarding I-SID forms an isolated PVLAN/ETREE to block any unwanted port to port cross talk.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the onboarding I-SID:

```
auto-sense onboarding i-sid <1-15999999>
```

Example

Configuring the Auto-sense onboarding I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense onboarding i-sid 15000000
```

Variable Definitions

The following table defines parameters for the **auto-sense onboarding** command.

Variable	Value
<i>i-sid</i> <1-15999999>	Specifies the service instance identifier (I-SID). The default onboarding I-SID value is 15999999.

Configure a Auto-sense Global Data I-SID**Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

Before You Begin

- Enable Auto-sense on the port.
- Associate a VLAN with the I-SID before you configure it as the global data I-SID.

About This Task

Perform this task to configure Auto-sense data traffic information for ports that are operating in Auto-sense mode.

Note

This option applies to the auto-sense UNI and voice states only, it replaces the onboarding I-SID and places an (untagged) client device into a pre-defined global data I-SID.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the data service instance identifier (I-SID):

```
auto-sense data i-sid <1-15999999>
```

Example

Configuring the Auto-sense data I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense data i-sid 1000
```

Variable Definitions

The following table defines parameters for the **auto-sense data** command.

Variable	Value
<i>i-sid</i> <1-15999999>	Specifies the service instance identifier (I-SID).

Configure a Auto-sense Port Data I-SID

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

Before You Begin

- Enable Auto-sense on the port.
- Associate a VLAN with the I-SID before you configure it as the data I-SID on the port. This does not apply to a DvR leaf.

About This Task

Perform this procedure to configure a data I-SID on a port.

Note

This option applies to the auto-sense UNI and voice states only, it replaces the onboarding I-SID and places an (untagged) client device into a pre-defined port specific data I-SID.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Auto-sense port data I-SID:

```
auto-sense data i-sid <1-15999999>
```

Example

Configuring the Auto-sense data I-SID for ports 1/1-1/5:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1-1/5
Switch:1(config-if)#auto-sense data i-sid 15000000
```

Variable Definitions

The following table defines parameters for the **auto-sense data** command.

Variable	Value
<i>i-sid</i> <1-15999999>	Specifies the service instance identifier (I-SID).

Configure Layer 2 Trusted Auto-sense Ports**Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to override incoming 802.1p bits on ports that operate in Auto-sense UNI or voice mode.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure Auto-sense ports as Layer 2 untrusted:

```
auto-sense qos 802.1p-override
```

Example

Configure Auto-sense ports as Layer 2 trusted:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense qos 802.1p-override
```

Configure EAPoL Authentication Requirements for Auto-sense Fabric Attach Clients

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

You can disable EAPoL authentication for specific Fabric Attach (FA) client types.

About This Task

By default, authentication is required before the connection is authorized.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure EAPoL authentication requirements from the following choices:
 - For auto-sensed cameras: `auto-sense fa camera eapol status {authorized | auto}`
 - For auto-sensed virtual switches: `auto-sense fa ovs eapol status {authorized | auto}`
 - For auto-sensed wireless access points (WAP): `auto-sense fa wap-type1 eapol status {authorized | auto}`

Variable Definitions

The following table defines parameters for the **auto-sense** commands related to EAPoL authentication for Fabric Attach (FA).

Variable	Value
<code>{authorized auto}</code>	<p>Configures the EAPoL authentication requirement for the specific client type. Choose from the following options:</p> <ul style="list-style-type: none"> • <code>authorized</code> — the port skips EAPoL authentication and authorizes the connection. • <code>auto</code> — authorization depends on the result of EAPoL authentication. <p>By default, authentication is required before the connection is authorized.</p>

Configure Auto-sense Fabric Attach (FA) Authentication

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to configure FA authentication for ports that are operating in Auto-sense mode.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the FA authentication key:

```
auto-sense fa authentication-key WORD<0-32>
```
3. Enable FA message authentication:

```
auto-sense fa message-authentication
```

Example

Configuring FA message authentication globally:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense fa message-authentication
```

Variable Definitions

The following table defines parameters for the **auto-sense fa** command.

Variable	Value
<i>authentication-key</i> <i>WORD<0-32></i>	Specifies the authentication key value.
<i>message-authentication</i>	Enables Fabric Attach (FA) message authentication globally, for ports that operate in Auto-sense mode.

Configure an I-SID for Auto-sense Fabric Attach Clients

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

For Zero Touch Deployment and assignments of dedicated I-SIDs for FA capable cameras, Wireless Access Points, FA proxy switches and Open Virtual Switches (OVS), configure a specific I-SID to use instead of the onboarding I-SID when a port is in an Auto-sense Fabric Attach (FA) state and detects an FA client.

Before You Begin

- Create the I-SID.

- Associate the I-SID with either a platform or private VLAN; this association is not required on a DvR Leaf.

About This Task

You can create only one I-SID of each type.

The FA I-SID can be the same as the voice I-SID because they are used by different Auto-sense port states.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the FA I-SID from the following choices:
 - For auto-sensed cameras: `auto-sense fa camera i-sid <1-15999999>`
 - For auto-sensed FA client switches that do not use FA message authentication, like EXOS or Switch Engine: `auto-sense fa proxy-no-auth i-sid <1-15999999>`
 - For auto-sensed virtual switches: `auto-sense fa ovs i-sid <1-15999999>`
 - For auto-sensed wireless access points (WAP): `auto-sense fa wap-type1 i-sid <1-15999999>`

Variable Definitions

The following table defines parameters for the **auto-sense** commands related to Fabric Attach (FA) I-SIDs.

Variable	Value
<code>i-sid <1-15999999></code>	Specifies the service instance identifier (I-SID).

Configure a Management I-SID for Auto-sense Fabric Attach Proxy Switches

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

Configure a specific I-SID and customer VLAN ID to use as the management I-SID when a port is in the Auto-sense FA PROXY state.

About This Task

The switch creates this I-SID dynamically and uses it instead of the onboarding I-SID.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```

2. Configure the management I-SID:

```
auto-sense fa proxy management i-sid <1-15999999> c-vid <1-4094>
```

Variable Definitions

The following table defines parameters for the **auto-sense fa proxy management** command.

Variable	Value
<i>c-vid</i> <1-4094>	Specifies the customer VLAN ID.
<i>i-sid</i> <1-15999999>	Specifies the service instance identifier (I-SID).

Display Auto-sense Configuration on the Switch

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to display the Auto-sense configuration on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Auto-sense configuration:

```
show auto-sense [access-differv] [data] [dhcp-detection] [eapol] [fa]
[isis] [onboarding] [qos] [voice] [wait-interval]
```
3. Display the Auto-sense status and state on a port:

```
show interfaces gigabitEthernet auto-sense [{slot/port[/sub-port]}[-
slot/port[/sub-port]][,...]]
```

Examples

Display the Auto-sense configuration related to voice:

```
Switch:1>show auto-sense voice
=====
                        AUTO-SENSE VOICE Config
=====
TYPE   LDDP-AUTH  ENABLE  I-SID      C-VID      DSCP      PRIORITY
-----
phone  FALSE          2000    2000      46         6
-----
1 out of 1 Total Num of AUTO-SENSE entries displayed
=====
```

Display the Auto-sense status and state on a range of ports:

```
Switch:1>show interfaces gigabitEthernet auto-sense 1/1-1/5
=====
                        Port Auto-sense
=====
PORT      AUTO-SENSE  AUTO-SENSE  AUTO-SENSE
NUM       STATUS     STATE      PORT-DATA-ISID
-----
```

1/1	Enable	UNI-ONBOARDING	500
1/2	Disable	OFF	
1/3	Disable	OFF	
1/4	Disable	OFF	
1/5	Disable	OFF	

Display the Auto-sense status for Fabric Attach (FA):

```
Switch:1>show auto-sense fa
=====
                        AUTO-SENSE FA Config
=====
MSG-AUTH                MSG-AUTH-KEY
-----
enabled                 ****
-----

=====
                        AUTO-SENSE FA Client specific config
=====
TYPE                    EAPOL STATUS   I-SID  VLANID  C-VID  MGMT  I-SID  MGMT  C-VID
-----
camera                  Auto           100    100     untag  -     -

=====
```

Auto-sense Configuration using EDM

The following sections provide procedural information to configure Auto-sense on the switch using the Enterprise Device Manager (EDM).

Enable LLDP Authentication of IP Phones

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

Before You Begin

You must enable EAPoL globally.

About This Task

Perform this procedure to enable Link Layer Discovery Protocol (LLDP) authentication of IP phones. The switch authenticates the phone after it receives LLDP packets from the phone.

Auto-sense LLDP authentication applies to Auto-sense ports in the VOICE state. Auto-sense LLDP authentication does not require a global Auto-sense voice configuration.

The system removes the LLDP session for the following reasons:

- You disable EAPoL globally.
- You disable Auto-sense on the port.
- The LLDP neighbor is removed.

If the LLDP authentication configuration exists and one of the following situations occur, the LLDP session is recreated:

- You reenable EAPoL globally.
- You reenable Auto-sense on the port.
- The LLDP neighbor is recreated.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. Select **EapolVoiceLldpAuthEnable**, to enable the EAPoL LLDP authorization for voice Auto-sense ports.
5. Select **Apply**.

Configure Auto-sense Voice Information for IP Phones

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

The switch applies the Auto-sense voice configuration on specific port(s), after it discovers IP phones on the port through LLDP packets.

Before You Begin

If you boot the switch with a configuration file, and not through Zero Touch Fabric Configuration, you must manually enable Auto-sense on specific port(s).

About This Task

Perform this procedure to configure Auto-sense voice information for IP phones. A global Auto-sense voice configuration does not require LAuto-senseLLDP authentication.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **AutoSense**.

3. Select the **Globals** tab.
4. For **Voicelsid**, type the I-SID value.
5. For **VoiceCvid**, type the CVID value associated with the voice I-SID.
6. Select **Apply**.

Disable Auto-sense DHCP Server Detection

**Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to disable DHCP server detection in Auto-sense mode.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. Select **DhcpDetection** to disable DHCP detection.
5. Select **Apply**.

Configure Auto-sense Onboarding I-SID Globally

**Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to configure the onboarding I-SID for ports that are operating in Auto-sense mode.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. For **Onboardingsid**, type I-SID value for the Auto-sense ports.
5. Select **Apply**.

Configure Auto-sense Data I-SID Globally

**Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

Before You Begin

- Enable Auto-sense on the port.
- Associate a VLAN with the I-SID before you configure it as the global data I-SID.

About This Task

Perform this task to configure Auto-sense data traffic information for ports that are operating in Auto-sense mode.

Note

This option applies to the Auto-sense UNI and voice states only; it replaces the onboarding I-SID and places an (untagged) client device into a pre-defined global data I-SID.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. For **Datalsid**, type the data I-SID value used by the Auto-sense ports.
5. Select **Apply**.

Configure Layer 2 Trusted Auto-sense Ports

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to override incoming 802.1p bits on ports that operate in Auto-sense mode.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. Select **Qos8021pOverrideEnable** to override incoming 802.1p bits on ports that operate in Auto-sense mode.
5. Select **Apply**.

Configure Auto-sense IS-IS Authentication

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to configure a global IS-IS authentication key for ports that are operating in Auto-sense mode.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. For **IsisHelloAuthType**, select a type of IS-IS hello authentication.

5. For **IsisHelloAuthKeyId**, type the key ID for IS-IS authentication for the Auto-sense ports.
6. For **IsisHelloAuthKey**, type the key for IS-IS authentication for the Auto-sense ports.
7. Select **Apply**.

Configure Auto-sense Access Ports

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to configure ports operating in Auto-sense mode to determine the Layer 3 QoS actions the switch performs. The Auto-sense access ports override the Differentiated Services Code Point (DSCP) markings.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. Select **AccessDiffservEnable** to enable differentiated serve type as access for Auto-sense ports.
5. Select **Apply**.

Configure Auto-sense for Fabric Attach

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

Perform this procedure for the following purposes:

- Configure Fabric Attach (FA) authentication for ports that are operating in Auto-sense mode.
- For Zero Touch Deployment and assignments of dedicated I-SIDs for FA capable cameras, Wireless Access Points, FA proxy switches and Open Virtual Switches (OVS), you can configure a specific I-SID to use instead of the onboarding I-SID when a port is in an Auto-sense Fabric Attach (FA) state and detects an FA client.
- Configure a specific I-SID and customer VLAN ID to use as the management I-SID when a port is in the Auto-sense FA PROXY state.

Before You Begin

- Create the I-SID.
- Associate the I-SID with either a platform or private VLAN; this association is not required on a DvR Leaf.

About This Task

You can create only one I-SID of each type.

The FA I-SID can be the same as the voice I-SID because they are used by different Auto-sense port states.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. Configure Fabric Attach authentication:
 - a. Select **FaMsgAuthEnable**, to enable FA message authentication.
 - b. For **FaAuthenticationKey**, type the key for FA authentication for the Auto-sense ports.
5. Configure a specific I-SID to use instead of the onboarding I-SID:
 - a. For auto-sensed cameras, type the I-SID in **FaCameralSid**.
 - b. For auto-sensed FA client switches that do not use FA message authentication, like EXOS or Switch Engine, type the I-SID in **FaProxyNoAuthSid**.
 - c. For auto-sensed virtual switches, type the I-SID in **FaVirtualSwitchSid**.
 - d. For auto-sensed wireless access points (WAP), type the I-SID in **FaWapType1Sid**.
6. Configure a specific I-SID and customer VLAN ID to use as the management I-SID:
 - a. In **FaProxyMgmtSid**, type the I-SID.
 - b. In **FaProxyMgmtCvid**, type the customer VLAN ID.
7. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AccessDiffServEnable	Enables or disables the differentiated service type as access for Auto-sense ports. The default is enabled.
Datalsid	Specifies the data I-SID used by the Auto-sense ports.
EapVoiceLldpAuthEnable	Enables the EAPoL LLDP authentication for Auto-sense voice ports. The default is disabled.
FaMsgAuthEnable	Enables or disables the FA message authentication for Auto-sense ports. The default is enabled.
FaAuthenticationKey	Specifies the FA authentication key for Auto-sense ports.

Name	Description
IsisHelloAuthType	<p>Specifies the authentication type for IS-IS hello packets on Auto-sense ports:</p> <ul style="list-style-type: none"> • None • simple - simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet. • hmac-md5 - MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. • hmac-sha256 - with SHA-256 authentication, the switch adds an hmac-sha-256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. <p>Note: Note: Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate ISIS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key. This feature is in full compliance with RFC 5310.</p> <p>The default authentication type is none.</p>
IsisHelloAuthKeyId	Specifies the IS-IS hello authentication number key id for the Auto-sense ports.
IsisHelloAuthKey	Specifies the IS-IS hello authentication number key for the Auto-sense ports. You must configure the IS-IS hello authentication key along with the IS-IS hello authentication type.
OnboardingIsid	Specifies the onboarding I-SID used by the Auto-sense ports.
Qos8021pOverrideEnable	Overrides the incoming 802.1p bits on ports that operate in Auto-sense mode. The default is enabled.
Voicelsid	Specifies the voice I-SID used by Auto-sense ports.
VoiceCvid	Specifies the customer VLAN ID associated with the voice I-SID used by Auto-sense ports. Voice C-Vid is configured for tagged voice traffic only. You must configure the Auto-sense voice customer VLAN ID along with the auto-sense voice I-SID.
DhcpDetection	Enables or disables the DHCP detection in Auto-sense mode. The default is enabled.
FaCameraIsid	Specifies the FA camera I-SID used by auto-sense ports.
FaProxyMgmtIsid	Specifies the FA proxy management I-SID used by auto-sense ports.
FaProxyMgmtCvid	Specifies the FA proxy management Client-VLAN ID (c-vid) used by auto-sense ports.
FaProxyNoAuthIsid	Specifies the FA proxy no-auth I-SID used by auto-sense ports.
FaVirtualSwitchIsid	Specifies the FA virtual-switch I-SID used by auto-sense ports.
FaWapType1Isid	Specifies the FA WAP type-1 I-SID used by auto-sense ports.
FaCameraEapolStatus	Specifies the FA EAPOL status for Camera I-SID used by auto-sense ports.

Name	Description
FaEapolOVSSStatus	Specifies the FA EAPOL status for OVS (Open-Virtual-Switch) I-SID used by auto-sense ports.
FaEapolWap1Status	Specifies the FA EAPOL status for Wap-type-1 I-SID used by auto-sense ports.
WaitInterval	Specifies the wait interval in seconds for the 'WAIT' state of auto-sense's finite state machine.

Auto-sense Port Configuration using EDM

Perform the following procedures to configure Auto-sense on specific ports using the Enterprise Device Manager (EDM).

Enable Auto-sense on Port(s)

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to enable Auto-sense on one or more ports.

If you select more than one port, the format of the tab changes to a table-based tab.

Note

- After a switch boots without a configuration file, Auto-sense is enabled on all ports, by default.
- Auto-sense is disabled by default for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.

Procedure

1. In the **Device Physical View** tab, select one or more ports.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. For **AutoSense**, select enable.
6. Select **Apply**.

Disable Auto-sense on Port(s)

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to disable Auto-sense on one or more ports. You also have the option to disable Auto-sense on the port but retain the configuration that the system applied dynamically. The dynamic configuration becomes a manual configuration and is visible in the **show running-config** output.

If you select more than one port, the format of the tab changes to a table-based tab.

Procedure

1. In the **Device Physical View** tab, select one or more ports.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. For **AutoSense**, select disable.
6. (Optional) Select **AutoSenseKeepAutoConfig** to retain the configuration that the system applies dynamically.
7. Select **Apply**.

Configure an Auto-sense Data I-SID on a Port

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to configure an Auto-sense Data I-SID on a port.

Procedure

1. In the **Device Physical View** tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. For **AutoSenseDatalsid**, type the data I-SID value. The range is 0 to 15999999.
6. Select **Apply**.

IP Phone Support

Table 6: IP Phone product support

Feature	Product	Release introduced
IP Phone Support	VSP 4450 Series	VOSS 8.3
	VSP 4900 Series	VOSS 8.3
	VSP 7200 Series	VOSS 8.3
	VSP 7400 Series	VOSS 8.3
	VSP 8200 Series	VOSS 8.3
	VSP 8400 Series	VOSS 8.3
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

The IP phone support feature focusses on the following key points:

- Works only on the Flex UNI-enabled and Auto-sense ports.
- For Avaya phones, you can choose to configure and send call server and file server Link Layer Discovery Protocol (LLDP) Type-Length-Value (TLV) options through the **lldp vendor-specific** CLI command.
- To reduce configuration overhead, this feature includes the Auto-sense voice mechanism to detect IP phones from LLDP signalling. After the switch detects the phone, this mechanism manages the following tasks:
 - Provides the voice VLAN to the phone, tagging, Differentiated Services Code Point (DSCP), and priority parameters through the LLDP Media Endpoint Discovery (MED) signaling options.
 - Configures a switched UNI for phone traffic and sends it to the Service Instance Identifier (I-SID) that is associated with the voice VLAN.
 - Handles the configuration, whether “trusted” or “untrusted” on the port and priority re-markings.
 - Integrates with the Auto-sense functionality. For more information on Auto-sense, see [Auto-sense](#) on page 14.

**Note**

This feature does not support auto-creation of voice VLAN and MultiLink Trunking (MLT) or Split Multi-Link Trunking (SMLT).

This feature has the following connectivity models:

- Standalone IP phone, which connects to a switch port.
- IP Phone with PC behind it, where the IP Phone has a small inbuilt bridge, and a PC connects to that bridge port.

**Note**

Phone traffic is tagged with the voice VLAN whereas the PC traffic is untagged. However, you can configure the phone to send the traffic as untagged.

The IP phone connectivity supports the following scenarios:

- Call server and file Server LLDP TLV options—These TLVs are Avaya proprietary. Use them only with the Avaya IP phones to detect the IP addresses of a Call server and File Server.
- Phone detection through LLDP messaging—Use the Capabilities and Enabled Capabilities field in the LLDP packet to detect a phone. A “T” capability identifies a phone.
- Auto-sense voice option, without Network Access Control (NAC)—Use this functionality to specify the voice VLAN and voice I-SID in a single CLI command.
- Auto-ISID-Offset—Use this functionality if the voice VLAN is received without an I-SID from a Radius response. The Auto-ISID-Offset functionality determines an I-SID automatically to send the data traffic.
- Auto-sense voice, LLDP authentication, and Non- EAP (NEAP) (MAC authentication) connectivity—If you have enabled NEAP, it authorizes all the MAC addresses received on the port and IP phone. With the LLDP authentication option, a device, such as phone, is trusted and does not require a Remote Authentication Dial-in User (RADIUS) authentication. For this authentication, the Extensible Authentication Protocol (EAP) is notified after a phone is detected and the port is in the Auto-sense voice state. Then, the MAC address of the phone is added to EAP or NEAP host table.

Auto-sense Voice

The Auto-sense voice feature is an addition to the Auto-sense module. Based on the events of the phone discovery in the network, you can use this feature to configure phone devices without manual intervention.

After the switch discovers a Link Layer Discovery Protocol (LLDP) packet with phone capabilities, the port transitions to the "voice" state. The port receives a message on the voice event details.

With the Auto-sense voice feature, you can configure the voice I-SID and the voice VLAN. If you configure the I-SID as untagged, the phone receives VLAN as zero. When you configure Auto-sense voice, switched UNI is configured in VOICE I-SID for each port that is in "voice" state. The switch adds the Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED) policies for voice and voice-signaling Type-Length-Value (TLVs) to the LLDP packet and sends LLDP packets to the phone. It uses the configured voice VLAN and default values for Differentiated Services Code Point (DSCP) (46) and priority (6). After you run the **auto-sense voice** command, a filter is installed to prioritize the traffic that passes through the configured I-SID. The filter applies to traffic that reaches the VOICE I-SID, which implies the voice traffic.

Note

To change the Auto-sense voice configuration on the switch, delete the earlier configured voice I-SID and VLAN entry.

After you configure auto-sense voice, following tasks take place:

- The I-SID <I-SID value> and C-VID <C-VID value> are saved in the control plane.
- The voice I-SID is created.
- The ports that are in the "voice" state process the voice configuration message and begin the dynamic configuration. This configuration includes the following tasks:
 - Creation of voice Switched UNI (S-UNI).
 - Deletion of onboarding and data I-SID, or S-UNI, if you configured auto-sense as "untagged".
 - Addition of LLDP-MED voice and voice-signaling TLVs to the LLDP packet and sending of LLDP packets to the phone.
- The voice filter is updated. After you run the **auto-sense voice** command, a filter is installed to prioritize the traffic that passes through the configured I-SID. The filter applies to the traffic in Voice

I-SID. The traffic that passes through this I-SID is internally prioritized with level 6 and forwarded with a dot1p value of 6, for tagged packets. For the IP packets, the DSCP value of 46 is forwarded.

Note

- To disable Auto-sense on the port but keep the dynamic configurations made by Auto-sense, use the command **no auto-sense enable convert-to-config**. The voice S-UNI loses its Auto-sense origin and has a config origin instead. The LLDP-MED policies installed by Auto-sense are preserved.
- If you use the **no auto-sense voice** command, the system removes the voice S-UNI and the LLDP-MED policies. The voice I-SID is removed if it was installed by using the **auto-sense voice** command. If the I-SID existed before you used the **auto-sense voice** command, the system does not remove the I-SID but the I-SID does lose its Auto-sense origin.
- A port exits the voice state in one of the following scenarios:
 - If the port is down
 - If the LLDP session fails between the switch and the phone
 - If Auto-sense is disabled on the port that connects to the IP phone

After a port exits the voice state, the Switched UNI (S-UNI), LLDP voice and voice-signaling are deleted.

IP Phone Configuration using CLI

Configure Auto-sense Voice Information for IP Phones

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

The switch applies the voice configuration on Auto-sense-enabled ports, after it discovers IP phones on the port through Link Layer Discovery Protocol (LLDP) packets.

Before You Begin

If you boot the switch with a configuration file, and not through Zero Touch Fabric Configuration, you must manually enable Auto-sense on specific ports.

About This Task

Perform this procedure to configure Auto-sense voice information for IP phones.

A global Auto-sense voice configuration does not require Auto-sense LLDP authentication based on the following cases.

- In a non NAC, a phone is classified based on the phones LLDP signaling.
- In a NAC, a phone is authenticated based on EAP/NEAP radius authenticated, or if configured, it is LLDP authenticated

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the customer VLAN ID:

```
auto-sense voice i-sid <1-15999999> c-vid <c-vid>
```
3. Configure the traffic as untagged:

```
auto-sense voice i-sid <1-15999999> untagged
```

Note

The phone receives VLAN ID as 0 and the tagging is configured as "untagged".

Example

Configure VLAN tagging as untagged:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense voice i-sid 1234 untagged
```

Variable Definitions

The following table defines parameters for the **auto-sense voice** command.

Variable	Value
<code>i-sid<1-15999999></code>	Specifies the service instance identifier (I-SID).
<code>c-vid<c-vid></code>	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch.
<code>untagged</code>	Specifies the VLAN tagging type as untagged. Note: The phone receives VLAN ID as 0 and the tagging is configured as "untagged".

Enable Auto-sense LLDP Authentication of IP Phones

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

Before You Begin

- You must enable Extensible Authentication Protocol over LAN (EAPoL) globally.

About This Task

Perform this procedure to enable Link Layer Discovery Protocol (LLDP) authentication of IP phones. The switch authenticates the phone after it receives LLDP packets from the phone if EAP/NEAP is enabled.

Auto-sense LLDP authentication applies to Auto-sense ports in the VOICE state. Auto-sense LLDP authentication does not require a global Auto-sense voice configuration.

The **no auto-sense eapol voice lldp-auth** command removes all Auto-sense LLDP sessions and removes the Auto-sense LLDP authentication configuration.

The system removes the LLDP session for the following reasons:

- You disable EAPoL globally.
- You disable Auto-sense on the port.
- The LLDP neighbor is removed.

If the LLDP authentication configuration exists and one of the following situations occur, the LLDP session is recreated:

- You enable EAPoL globally.
- You enable Auto-sense on the port.
- The LLDP neighbor is recreated.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable LLDP authentication:

```
auto-sense eapol voice lldp-auth
```

Example

Enabling LLDP authentication on the switch:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense eapol voice lldp-auth
```

Variable Definitions

The following table defines parameters for the **auto-sense eapol voice** command.

Variable	Value
<i>lldp-auth</i>	Enables Link Layer Discovery Protocol (LLDP) authentication of IP phones. By default, LLDP authentication of IP phones is disabled on the switch.

Configure LLDP Vendor Specific Information

About This Task

Use this procedure to configure the Link Layer Discovery Protocol (LLDP) vendor-specific information on a call server or a file server.

Note

After you configure LLDP vendor specific call server information, the SIP Proxy of the phone is configured as transport type Transport Layer Security (TLS) port 5061. This option is available depending on the operating system of the call server.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. To configure LLDP vendor-specific information for a call server server, enter:

```
lldp vendor-specific call-server <1-8> <A.B.C.D>
```
3. To configure LLDP vendor-specific information for a file server, enter

```
lldp vendor-specific file-server <1-4> <A.B.C.D>
```

Example

Configure the LLDP vendor-specific information on a call server:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#lldp vendor-specific call-server 1 192.0.2.0
```

Variable Definitions

The following table defines parameters for the **lldp vendor-specific** command.

Variable	Value
<i>call-server</i> <1-8> <A.B.C.D>	Specifies the Link Layer Discovery Protocol (LLDP) vendor specific information on the call server number and the IP address.
<i>file-server</i> <1-4> <A.B.C.D>	Specifies an LLDP vendor specific information on the file server number and the IP address.

View LLDP Vendor Specific Information

About This Task

Use this procedure to view the Link Layer Discovery Protocol (LLDP) vendor-specific information on a call server or a file server.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. To view LLDP vendor-specific information for a call server, enter:

```
show lldp vendor-specific call-server
```
3. To configure LLDP vendor-specific information for a file server, enter

```
show lldp vendor-specific file-server
```

Example

Display the LLDP vendor-specific information on a call server:

```
Switch:1>enable
Switch:1#show lldp vendor-specific call-server
=====
                        LLDP Call-Server
=====
NUM          IP
-----
1            192.0.2.0
2            198.51.100.0
-----
All 2 out of 2 Total Num of call-server entries displayed
```

View LLDP Neighbor Vendor Specific Information

About This Task

Use this procedure to view the remote Link Layer Discovery Protocol (LLDP) vendor-specific information on a call server or a file server.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. To view remote LLDP vendor-specific information for a call server, enter:

```
show lldp neighbor vendor-specific call-server
```
3. To view remote LLDP vendor-specific information for a file server, enter:

```
show lldp neighbor vendor-specific file-server
```

Example

Display remote LLDP vendor-specific information on a file server:

```
Switch:1>enable
Switch:1#show lldp neighbor vendor-specific file-server
=====
                Remote LLDP File-Server IP Addresses
=====
PORT          IP
-----
203           192.0.2.0, 198.51.100.0, 203.0.113.0
-----
All 3 out of 3 Total Num of remote file-server entries displayed
```

Enable LLDP Voice Authentication on a Specific Port**Note**

This procedure does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

About This Task

Perform this procedure to enable Link Layer Discovery Protocol (LLDP) voice authentication of IP phones on a port.

You cannot manually enable LLDP voice authentication on an Auto-sense-enabled port. If the system detects a phone on an Auto-sense port, then “eapol voice lldp-auth” configuration is automatically applied on the port that connects to the phone. This procedure applies to ports with Auto-sense disabled.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable LLDP voice authentication on a specific port:

```
eapol voice lldp-auth
```

Example

Enabling LLDP voice authentication on a specific port:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#eapol voice lldp-auth
```

Variable Definitions

The following table defines parameters for the **eapol voice** command.

Variable	Value
<i>lldp-auth</i>	Enables Link Layer Discovery Protocol (LLDP) voice authentication of IP phones on the selected port. By default, LLDP authentication of IP phones is disabled on the switch.

IP Phone Configuration using EDM

View Vendor Specific Call Server Information

About This Task

Perform this procedure to view inventory attributes for vendor-specific call server information.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > 802_1ab**.
2. Select **Vendor Specific**.
3. Select the **Call Server** tab.

Vendor Specific Call Server Field Descriptions

Use the data in the following table to use the **Call Server** tab.

Name	Description
CallServerNum	Specifies the call server ID.
CallServerAddressType	Specifies the IP address type of the call server.
CallServerAddress	Specifies the IP address of the call server.

View Vendor Specific File Server Information

About This Task

Perform this procedure to view inventory attributes for vendor-specific file server information.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > 802_1ab**.
2. Select **Vendor Specific**.
3. Select the **File Server** tab.

Vendor Specific File Server Field Descriptions

Use the data in the following table to use the **File Server** tab.

Name	Description
FileServerNum	Specifies the file server ID.
FileServerAddressType	Specifies the IP address type of the file server.
FileServerAddress	Specifies the IP address of the file server.

Zero Touch Deployment

Table 7: Zero Touch Deployment product support

Feature	Product	Release introduced
Zero Touch Deployment	VSP 4450 Series	VOSS 8.2
	VSP 4900 Series	VOSS 8.2 VIMs: VIM5-4YE, VIM5-4X, VIM5-4XE, and VIM5-2Y only
	VSP 7200 Series	VOSS 8.2
	VSP 7400 Series	VOSS 8.2
	VSP 8200 Series	VOSS 8.2
	VSP 8400 Series	VOSS 8.2
	VSP 8600 Series	Not supported
	XA1400 Series	VOSS 8.2

For the most current information on switches supported by ExtremeCloud™ IQ, see [ExtremeCloud™ IQ Learning What's New](#).

Zero Touch Deployment enables a switch to be deployed automatically with ExtremeCloud IQ but you still need to onboard the switch on the ExtremeCloud IQ side. When the switch powers on, the Dynamic Host Configuration Protocol (DHCP) Client obtains the IP address and gateway from a DHCP Server, and discovers the Domain Name Server, connecting the switch automatically to Extreme Management Center or ExtremeCloud IQ - Site Engine or to ExtremeCloud IQ cloud management application.

The switch integrates with ExtremeCloud IQ using IQAgent.

Zero Touch Provisioning Plus (ZTP+) provides Extreme Management Center or ExtremeCloud IQ - Site Engine connectivity to the switch.

For more information about ExtremeCloud IQ Agent, see [ExtremeCloud IQ Agent](#) on page 835. For more information about ZTP+, see [Zero Touch Provisioning Plus](#) on page 58.

To use zero touch functionality, your switch must be in a Zero Touch Deployment-ready configuration mode, which means the switch cannot have existing primary or secondary configuration files loaded. Factory shipped switches are Zero Touch Deployment ready because they deploy without configuration files. However, existing switches require manual preparation before Zero Touch Deployment can function.

To prepare an existing switch for Zero Touch Deployment, the switch must boot without a configuration file. Perform one of the following actions:

- Rename existing primary and secondary configuration files. Use the **mv** command to rename the existing configuration files. For example, **mv config.cfg config.cfg.backup**.

This is the preferred option as it ensures that the primary and secondary files are removed while making a backup of them at the same time. This option also ensures that the switch uses the default config.cfg file for the final configuration after it has successfully onboarded.

- Boot from non-existent configuration files. Use the **boot config choice** command to configure the primary and backup configuration files to reference files that do not exist on the switch:

```
boot config choice primary config-file nonexistent1.cfg
```

```
boot config choice primary backup-config-file nonexistent2.cfg
```

This option also works, however, after the switch has successfully onboarded, it does not use the default config.cfg file but uses the alternative configuration file name provided instead, which might not be desired.

- Delete the existing primary and secondary configuration files. Create a backup of these files before you delete them.

Configuration Considerations

The switch configuration depends on whether you use factory default mode or Zero Touch Deployment.

Zero Touch Deployment Configuration

With Zero Touch Deployment, the switch configuration consists of the following:

- The ssh and sshd boot configuration flags are enabled by default.
- All ports are Private VLAN isolated ports, except on the XA1400 Series.
- VLAN 4048 is created as an *onboarding-vlan* for host-only connectivity for In Band management. On all platforms, except the XA1400 Series, all front panel ports are members of VLAN 4048.
- In Band management is enabled.
- Dynamic Host Configuration Protocol (DHCP) client requests are cycled between In Band and Out of Band ports, except on the XA1400 Series and VSP 4450 Series. XA1400 Series and VSP 4450 Series support In Band management only.
- If the switch resets after the IP address is obtained from the DHCP Server, the entire DHCP process does not need to be repeated. Instead, the switch can directly send the DHCP Request to the DHCP Server for the IP stored in the /intflash/dhcp/dhclient.leases file.
- Out of Band management is enabled, except on the XA1400 Series and VSP 4450 Series. XA1400 Series and VSP 4450 Series support In Band management only.
- All ports are administratively enabled, except on the XA1400 Series. Only Port 1/8 is administratively enabled on the XA1400 Series, which means the administrator must plug in and use only port 1/8 for Zero Touch Deployment on an XA1400 Series.
- IQAgent is enabled by default.
- Zero Touch Provisioning Plus (ZTP+) for Extreme Management Center or ExtremeCloud IQ - Site Engine onboarding is enabled by default.
- Initiates Zero Touch Fabric Configuration.
- After the Zero Touch Fabric establishes successfully, the onboarding VLAN 4048 is automatically assigned to onboarding I-SID 15999999.

For information about IQAgent, see [ExtremeCloud IQ Agent](#) on page 835.

Factory Default Mode

The switch continues to support the boot configuration flag **boot config flags factorydefaults** to return an existing switch to factory default configuration.

**Note**

Zero Touch Deployment does not run on a switch returned to factory default configuration in this manner.

For more information, see [Boot Sequence](#) on page 145.

Zero Touch Provisioning Plus

	VSP 8400 Series	VOSS 8.2.5
	VSP 8600 Series	Not Supported
	XA1400 Series	VOSS 8.2.5

With zero touch functionality, switches are automatically discovered on the network within minutes of when they are connected.

Zero Touch Provisioning Plus (ZTP+) enables you to deploy and configure switches in Extreme Management Center or ExtremeCloud IQ - Site Engine with minimal server configuration and intervention. ZTP+ enabled switches send information, such as the serial number, software version, MAC, management IP, and port information to Extreme Management Center or ExtremeCloud IQ - Site Engine automatically.

When the switch powers on, the DHCP Client obtains the IP address and gateway from the DHCP server, discovers the Domain Name Server, and connects the switch to Extreme Management Center or ExtremeCloud IQ - Site Engine.

ZTP+ uses HTTPS for communication between the switch and the Extreme Management Center or ExtremeCloud IQ - Site Engine server. The switch discovers the Extreme Management Center or ExtremeCloud IQ - Site Engine server by resolving the DNS name *extremecontrol.<domain-name>*.

**Important**

This feature requires a Zero Touch Deployment-ready configuration. For more information, see [Zero Touch Deployment](#) on page 56.

ZTP+ Phases of Operation

Zero Touch Provisioning Plus (ZTP+) auto-provisioning occurs in phases after you connect the switch to the network, if the switch is in factory ship state with no valid configuration saved on the device.

Connect

The Connect phase is the first phase of ZTP+ during which the switch connects to the Extreme Management Center or ExtremeCloud IQ - Site Engine server on the network. The Extreme Management Center or ExtremeCloud IQ - Site Engine server is discovered by resolving the DNS name *extremecontrol.<domain-name>*.

If the attempt is successful, the Extreme Management Center or ExtremeCloud IQ - Site Engine server responds with an **Accept** message. When connectivity is established, the switch communicates with the Extreme Management Center or ExtremeCloud IQ - Site Engine server securely and transmits information, such as its serial number, model number. The switch then progresses to the next phase of ZTP+.

Upgrade

After a successful connect to the Extreme Management Center or ExtremeCloud IQ - Site Engine server, the next phase of ZTP+ is the Upgrade phase. This phase verifies that the switch is running the image file version that is currently selected as the reference version on the Extreme Management Center or ExtremeCloud IQ - Site Engine server.

Image file validation is initiated by the switch. After a successful connect, the switch sends an image file upgrade request to the Extreme Management Center or ExtremeCloud IQ - Site Engine server with details on the current image file version. If the image file versions on the switch and the Extreme Management Center or ExtremeCloud IQ - Site Engine server match, no upgrade is initiated, and the switch moves to the next phase of ZTP+. If the Extreme Management Center or ExtremeCloud IQ - Site Engine server detects a different image file version, ZTP+ initiates the .tgz image file download from a specified URL location.

After a successful image upgrade, the switch reboots and reconnects to the Extreme Management Center or ExtremeCloud IQ - Site Engine server. If there are errors in the image upgrade process, an event is added to the server log. The switch then retries the image upgrade.

Configuration

The next phase after the image upgrade is ZTP+ Configuration phase. During this phase, the switch queries the Extreme Management Center or ExtremeCloud IQ - Site Engine server for configuration updates, and initiates auto-provisioning by transmitting information, such as the image version, model name, and serial number. The switch then attempts to apply the configuration that is pushed from the Extreme Management Center or ExtremeCloud IQ - Site Engine server.

If the switch can still communicate with the Extreme Management Center or ExtremeCloud IQ - Site Engine server after the configuration is applied, the new configuration is automatically saved on the switch. The switch can be managed through the Extreme Management Center or ExtremeCloud IQ - Site Engine using Simple Network Management Protocol (SNMP). However, if the configuration that is pushed from the Extreme Management Center or ExtremeCloud IQ - Site Engine server breaks switch connectivity to the Extreme Management Center or ExtremeCloud IQ - Site Engine server, the switch reboots without saving the configuration. After the switch reboots, the ZTP+ onboarding restarts.

Any configurations pushed from the Extreme Management Center or ExtremeCloud IQ - Site Engine server to devices using the initial ZTP+ configuration push are not displayed in the **show log file detail** command output. The logs associated with the Cloud connector are logged internally to `state_machine.txt` and `ztp_plus.txt` files located in `/intflash/cc/cc_logs/`.

Extreme Management Center or ExtremeCloud IQ - Site Engine uses ZTP+ to configure the following items:

- Link Layer Discovery Protocol (LLDP) neighbor discovery

**Note**

Based on the LLDP discovery, port templates can be used on the Extreme Management Center or ExtremeCloud IQ - Site Engine server. Enabling or disabling LLDP is not supported.

- Login
- Network Time Protocol (NTP)
- Ports configuration
- SNMP
- VLANs

**Note**

ZTP+ cannot manage VLAN port membership. With ZTP+, new VLANs are created with no ports. Ports cannot be removed from the onboarding VLAN. Ports cannot be added to another VLAN. VLAN port membership is managed through Auto-sense functionality or through manual configuration after initial onboarding is complete.

ZTP+ Considerations

The following considerations apply to Zero Touch Provisioning Plus (ZTP+) :

- Fabric configurations are not supported with ZTP+. After ZTP+ is configured, Extreme Management Center or ExtremeCloud IQ - Site Engine server can use Simple Network Management Protocol (SNMP) to remotely configure Fabric-related configurations on the switch using SNMP MIBs.
- Only the Out-of-Band (OOB) port or the Management VLAN interface are used to connect the Extreme Management Center or ExtremeCloud IQ - Site Engine server.

**Note**

ZTP+ cannot change the Management VLAN interface. If onboarding started on the Management onboarding VLAN, this cannot be changed while using ZTP+.

Configuring ZTP+ using the CLI

This section provides procedures to configure and manage Zero Touch Provisioning Plus (ZTP+) using the Command Line Interface (CLI).

After your device is onboarded, you have access to Extreme Management Center or ExtremeCloud IQ - Site Engine.

Note

You must configure a Segmented Management Instance to use ZTP+. For more information, see [Segmented Management Instance Configuration using the CLI](#) on page 85.

For information about onboarding switches, see <https://www.extremenetworks.com/support>.

View ZTP+ Status

About This Task

Use this procedure to verify the status of Zero Touch Provisioning Plus (ZTP+) on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Verify that ZTP+ is enabled:

```
show application auto-provision
```

Example

The following is an example output of the **show application auto-provision** command:

```
Switch:1>show application auto-provision

Admin state      : Enabled
Operational state : Running
```

You can use Zero Touch Fabric Configuration to deploy Fabric-capable switches in a plug and play manner with no initial configuration. The switches form a new Fabric automatically or they can connect to an existing Fabric that is Auto-sense-capable, obtain an IP address and Domain Name System (DNS) information from a Dynamic Host Configuration Protocol (DHCP) server using the onboarding I-SID/VLAN, which then permits the system to automatically onboard to the management servers, such as ExtremeCloud IQ or Extreme Management Center or ExtremeCloud IQ - Site Engine, to conduct actual provisioning deployment of the switch. For more information about Auto-sense, see [Auto-sense](#) on page 14.

Zero Touch Fabric Configuration automatically configures Shortest Path Bridging MAC (SPBM) and IS-IS without user intervention if you boot the switch in Zero Touch Deployment-ready configuration mode, meaning you boot without a configuration file. Zero Touch Fabric Configuration uses LLDP to signal Fabric capability and exchanges SPB backbone VLAN IDs information to ensure seamless joining to any existing fabric deployment. The switches use the chassis MAC addresses as their system ID. To ensure participation in the correct area, newly joining ZTF switches listen to IS-IS update packets for area information. A unique nick-name is assigned by a pre-configured nick-name server switch. For more information, see [Zero Touch Deployment](#) on page 56.

Important

To add new Zero Touch Fabric Configuration devices or implement Zero Touch Fabric Configuration on existing devices, the network requires a nickname server and reachability to the DHCP server. How you implement this depends on if the network is a new deployment or an existing Fabric network that you upgrade. In a new deployment, you can meet the network requirements with one node, known as a seed node. In an existing network, functions may already exist on different nodes. For more information, see [VOSS Release Notes](#).

Zero Touch Fabric Configuration uses the port-based Auto-sense features, that enables all ports on the switch, by default, and all ports operate in Auto-sense mode. With the support of Auto-sense, Zero Touch Fabric Configuration onboards all ports on the switch to an existing network, without having to manually enable each port. Auto-sense automatically detects neighbor capabilities and performs the configuration on the port to reach the desired connectivity with the neighbor without user invention.

With Auto-sense functionality, ports on a switch can detect whether they connect to a Shortest Path Bridging (SPB) device, a Fabric Attach (FA) client, FA Proxy, Voice IP devices, or an undefined host, and

then make the necessary configuration. For more information about Auto-sense, see [Auto-sense](#) on page 14.

If you start two nodes in a network without an existing configuration file, then Zero Touch Fabric Configuration, through Auto-sense, dynamically establishes an IS-IS adjacency between them. For more information, see [Establishing IS-IS Adjacencies](#) on page 64.

Default IS-IS Parameters

Zero Touch Fabric Configuration automatically configures the Shortest Path Bridging (SPB) and Intermediate System-to-Intermediate System (IS-IS) infrastructure to enable Fabric architecture on a switch. The system initializes the following items after you start the switch in Zero Touch Fabric Configuration mode:

- Enables Shortest Path Bridging MAC (SPBM).
- Creates a private VLAN 4048.
- Creates the Auto-sense onboarding I-SID 15999999.
- Assigns the Auto-sense onboarding I-SID 15999999 to private VLAN 4048 and also includes the management VLAN.

Note

As a best practice, use the onboarding I-SID for onboarding purposes and, whenever possible, configure a management VLAN or management CLIP on a different I-SID after the onboarding procedures have been successfully completed.

- Enables Auto-sense on all ports.
- Configures Auto-sense access ports and layer 2 trusted Auto-sense ports.
- Creates an SPBM instance.
- Enables IS-IS globally.

Parameter	Default value
SPBM instance	1
Primary B-VLAN	4051
Secondary B-VLAN	4052
Manual area	Initialize to 00.1515.fee1.900d.1515.fee1.900d Note: You can change the manual area dynamically, without disabling IS-IS, only when the area is the Zero Touch Fabric Configuration area. When IS-IS is enabled, you cannot delete the last manual area.
Auto-sense onboarding I-SID	15999999

Establishing IS-IS Adjacencies

Zero Touch Fabric Configuration automatically triggers when the switch boots without a configuration file, the platform enables Intermediate System-to-Intermediate System (IS-IS) without a configured nickname or manual area. The system creates default backbone VLANs (B-VLAN) (4051 and 4052) and IS-IS manual area values. As a result, if you start two nodes in a network without an existing configuration file, then Zero Touch Fabric Configuration dynamically establishes an IS-IS adjacency between them.

The switch uses the Auto-sense functionality with the Zero Touch Fabric Configuration feature to establish the adjacency between two nodes. For more information about how and when the system tries to establish the adjacency, see [Auto-sense Port States](#) on page 17 .

- If you manually configure an SPBM instance on a node, then the system removes the SPBM instance that is dynamically created by Zero Touch Fabric Configuration. The system uses the LLDP Fabric Connect TLV to send user-defined B-VLANs to other nodes in the network. Only the first pair of B-VLANs is learned. If the switch already learned the B-VLANs from neighbor_A, the switch ignores the B-VLANs received from neighbor_B, if those are different.
- If a switch operating in Zero Touch Fabric Configuration mode in the network receives B-VLANs from a neighboring switch, which do not match the default B-VLANs configured through Zero Touch Fabric Configuration, then the switch will perform the following actions:
 - Disables ISIS.
 - Deletes its VLANs.
 - Unassigns the B-VLANs.
 - Assigns the values received through LLDP Fabric Connect TLV.
 - Creates the corresponding VLANs.
 - Re enables ISIS and log a message on the console.

LLDP Fabric Connect TLV

The system uses the Link Layer Discovery Protocol (LLDP) Fabric Connect Type-Length-Value (TLV) to communicate B-VLANs and system IDs between nodes in the SPB cloud. For more information about

LLDP and its interaction with Fabric Attach, see [Link Layer Discovery Protocol \(802.1AB\) Fundamentals](#) on page 2197.

Table 10: LLDP Fabric Connect TLV Format

TLV Type	TLV Length	OUI	Subtype	Fabric Connect Capability	B-VLANs Number	B-VLAN-1	B-VLAN-2	System ID Length	System ID
7 bits	9 bits	3 octets	1 byte	1 byte	1 byte	2 bytes	2 bytes	1 byte	6 bytes

Table 11: LLDP Fabric Connect TLV Field Descriptions

TLV Field	Description
OUI	Specifies the Extreme OID value (0xd88466).
Fabric Connect capability	Fabric Connect capability is enabled on all nodes that support Zero Touch Fabric Configuration. The value is 0 if the LLDP Fabric Connect TLV is not carrying any information in it. By default, the value is set to 1 on all ports.
B-VLANs number	Specifies the number of B-VLANs that the TLV can carry. The LLDP Fabric Connect TLV supports an unlimited number of B-VLANs, but Zero Touch Fabric Configuration sends two B-VLANs through the TLV. The value is 0 if the node is sending default B-VLAN values.
B-VLANs	Specifies the B-VLAN that is user-configured or dynamically learned from a neighbor node in the network.
System ID Length	Specifies the length (in bytes) of the System ID.
System ID	Specifies the IS-IS system ID.

Configuration Example to Create an IS-IS Adjacency between the VSP 8600 Series and VOSS Switches

Link Layer Discovery Protocol (LLDP) stations that connect to a local area network (LAN) advertise the station capabilities to each other, allowing the discovery of physical topology information for network management. When the system enables a switch as a Fabric Attach (FA) server in the Shortest Path Bridging (SPB) network, it receives LLDP messages from the FA Client and the FA Proxy devices using the LLDP Fabric Connect Type-Length-Value (TLV). For more information, see [LLDP Fabric Connect TLV](#) on page 64.

Following are the steps to create an Intermediate-System-to-Intermediate-System (IS-IS) adjacency between the VSP 8600 Series and the VOSS switches.

On the VSP 8600 Series switch:

1. Disable the High Availability-CPU mode.
2. Enable the Shortest path bridging MAC (SPBM) mode.

3. Create an SPBM instance.
4. Create an SPBM B-VLAN.
5. Configure the port linked to the VOSS switch.

On the VOSS switch:

1. Enable the Shortest path bridging MAC (SPBM) mode.
2. Enable Auto-sense on the port linked to the VSP 8600 Series.

Creating an IS-IS adjacency:

On the VSP 8600 Series switch:

```
enable
configure terminal
no boot config flags ha-cpu
boot config flags spbm-config-mode
spbm
router isis
spbm 1
spbm 1 b-vid 100,101 primary 100
spbm 1 nick-name 1.44.66
manual-area c1
exit
vlan create 100 type spbm-bvlan
vlan create 101 type spbm-bvlan
vlan members remove 1 1/3
interface gigabitEthernet 1/3
isis
isis spbm 1
isis enable
router isis enable
```

On the VOSS switch:

```
enable
configure terminal
boot config flags spbm-config-mode
interface gigabitEthernet 1/3
auto-sense enable
1 YYYY-MM-DD HH:MM:SS.622Z Switch - 0x00374589 - 00000000 GlobalRouter FA INFO Fabric Attach Assignments will
be rejected since ISIS is disabled.

XA1400 Series	VOSS 8.2 OOB not supported	

A Management Instance is required to provide access to specific management applications.

With Segmented Management, the Management plane (management protocols) is separated from the Control Plane (routing plane) from a process and data-path perspective. Segmented Management is the only method to manage switches. One or a combination of the following management interface/ management instance types can be used:

- Out-of-Band (OOB) management IP address (IPv4 and IPv6)

- In-band Loopback/circuitless IP (CLIP) management IP address (IPv4 and IPv6)
- In-band management VLAN IP address (IPv4 and IPv6)

**Important**

The Segmented Management Instance provides support for management interfaces that transmit and receive packets directly to and from the system native Linux IP stack. Unlike a traditional management interface, for example, a CLIP in the GRT that is part of the OS networking IP stack, Segmented Management Instance interfaces do not route packets through the OS networking IP stack.

Segmented Management provides better security because you cannot reach the management instance from outside the VRF (in case of CLIP) or outside VLAN/I-SID (in case of management VLAN), and because it has a built-in firewall for the management plane. There is also more predictability with symmetric traffic flows for management traffic originating from and terminating on the switch, for instance:

- Sessions originated from switch (client mode) - Source IP of packets is determined based on Management IP stack routing table weights (configurable).
- Sessions connecting to switch (server mode) - Source IP is derived from session connection and reply will go out on management interface packet.

Migration to Segmented Management Instance

**Important**

VOSS 8.2 introduced changes to Segmented Management Instance that required migration of legacy management interfaces. Before you upgrade to VOSS 8.2 or later from an earlier release, you must consider your management interface configuration and migration scenario requirements. Backup and save your configuration files off the switch before upgrading to this release.

If the switch already runs VOSS 8.2 or later, you can ignore this section. This section does not apply to VSP 8600 Series.

**Important**

Management interface access to the switch can be lost if you do not perform the applicable migration scenarios before upgrading to this release. Loss of management access after an upgrade can result in an automatic roll-back to the previous software version.

You must perform a manual software commit after upgrading from VOSS Release 8.1.5.0 or earlier to VOSS 8.2 or later. Management interface access is required to input the `software commit` CLI command within 10 minutes after the upgrade. If the time expires the system initiates an automatic roll-back to the previous release.

You must ensure the switch runs VOSS 8.1.x before you upgrade to VOSS 8.2 or later to support the **migrate-to-mgmt** functionality.

Note

If the network environment must migrate static IPv6 routes, the switches must run VOSS Release 8.1.2.0 or later before you upgrade to VOSS 8.2 or later.

Not all upgrade paths are validated by Extreme Networks for each new software release. To understand the validated upgrade paths, see [VOSS Release Notes](#).

Ensure you understand the Management Instance interface types before you begin the upgrade and migration. For more information, see [Interface Types](#) on page 75.

You must consider the following legacy management interface migration scenarios before you upgrade to VOSS 8.2 or later:

Table 13: Management Interface Migration Scenarios

Mgmt Interface	Mgmt Scenario	Migration Description
DvR leaf	Automatic migration during upgrade.	DvR leaf settings migrate automatically during the software upgrade process. The DvR inband-mgmt-ip CLIP automatically becomes the new Segmented Management Instance CLIP. Note: Leaf nodes only support the management CLIP as part of the Global Routing Table (GRT).
OOB	Automatic migration during upgrade.	Out-of-Band management settings migrate automatically during the software upgrade process.

Table 13: Management Interface Migration Scenarios (continued)

Mgmt Interface	Mgmt Scenario	Migration Description
CLIP	Specify a Circuitless IP (CLIP) interface for migration to management interface before you upgrade.	<p>You can use this interface type for CLIP management network routing in a Fabric network or Layer 3 routing network.</p> <p>Use the migrate-to-mgmt command in the Loopback Interface Configuration mode of the CLI to specify the CLIP interface for management before starting the software upgrade process.</p> <p>You can designate the IP Shortcut CLIP to migrate to the Management Instance CLIP. After the upgrade, the IS-IS source IP address moves to the Management Instance CLIP. You should configure a new GRT CLIP using a different IP address and assign that as the new IS-IS source IP.</p> <p>Save the configuration before upgrading.</p> <p>Important: Ensure that the management CLIP IP address does not fall into the range of a configured VLAN IP address range as this is not allowed.</p>
VLAN	Specify a VLAN interface for migration to management interface before you upgrade.	<p>You can use this interface type for management of Layer 2 switches or for Zero-Touch onboarding of newly deployed devices. Use the CLIP Management Instance for routed management.</p> <p>Use the migrate-to-mgmt command in the VLAN Interface Configuration mode of the CLI to specify the VLAN interface for management before starting the software upgrade process.</p> <p>Important: Choose a VLAN that does not have an IP interface on it. The upgrade process removes the IP configuration and network connectivity can be impacted.</p> <p>Save the configuration before upgrading. The VLAN Management Instance does not route to or from the GRT.</p>

Table 13: Management Interface Migration Scenarios (continued)

Mgmt Interface	Mgmt Scenario	Migration Description
		Bridged management traffic must ingress on the VLAN or I-SID.

Automatic Migration

Out-of-Band management interface and DVR leaf configurations automatically migrate during the upgrade process. The management port interface, and all associated applications are moved to the Segmented Management Instance .

A DVR leaf has a single management interface that also automatically migrates during the upgrade process to the Segmented Management Instance.

Static Route Migration

When a VLAN designated as management interface or an Out-of-Band management interface migrates to the Segmented Management Instance, static routes might be required for IP reachability. Static routes are always required for Out-of-Band management interfaces but can also be used with in-band VLAN management.

Static route migration is completed by the upgrade process and no commands are necessary to prepare for the migration. The following logic is applied during the upgrade process to the static routes:

- Out-of-Band management interfaces
 - All IPv4 routes in the VRF 512 / mgmtrouter context are moved to the Segmented Management Instance.
 - All IPv6 routes in GRT with a nexthop IP address that exists in the same subnet as the IPv6 address are moved to the Segmented Management Instance.
- In-Band VLAN management
 - All IPv4 routes from the VRF bound to the migrated VLAN and that have a nexthop IP address in the same subnet as the IPv4 address being migrated are moved to the Segmented Management Instance.
 - All IPv6 routes from the VRF bound to the migrated VLAN and that have a nexthop IP address in the same subnet as the IPv6 address being migrated are moved to the Segmented Management Instance.

Important

The IP interface and all routing protocols attached to the original VLAN are deleted post migration.

Consider the following example of In-Band VLAN management. The static route configuration listed below is in the GRT:

```
ip route 192.168.20.0 255.255.255.0 192.168.10.2 weight 1
ip route 192.168.30.0 255.255.0.0 192.168.10.50 weight 1
ip route 192.168.40.0 255.255.255.0 192.168.20.99 weight 1
ip route 192.168.50.0 255.255.255.0 192.168.10.2 weight 1
no ip route 192.168.50.0 255.255.255.0 192.168.10.2 enable
```

The GRT is associated with VLAN 10 with an IP address of 192.168.10.1. This is the VLAN to be migrated. After the upgrade, the 192.168.20.0, 192.168.30.0, and, 192.168.50.0 routes are migrated to the management instance because their nexthop IP address is associated with the 192.168.10.0/24 subnet.

Note

All routes with a nexthop IP address associated with the subnet are migrated. This includes administratively disabled routes. Administratively disabled routes must be manually deleted after the upgrade if the route is not needed.

ECMP static route migration is not supported for the Segmented Management Instance. For an ECMP static route, only the first path in the configuration file migrates.

After upgrading to VOSS Release 8.1.60 or later, any administratively disabled static routes that migrated to the OOB or VLAN Segmented Management Instance subnet become active. Administratively disabled routes must be manually deleted after the upgrade if the route is not needed.

The static route configuration in the Management VLAN configuration block will be the following after the upgrade:

```
mgmt vlan 10
ip address 192.168.10.1/24
ip route 192.168.20.0/24 next-hop 192.168.10.2
ip route 192.168.30.0/16 next-hop 192.168.10.50
ip route 192.168.50.0/24 next-hop 192.168.10.2
```

Segmented Management Instance Migration

You have two command options to change attributes of a Management Instance:

- **convert** command
- **migrate-to-mgmt** command

As a best practice, use the **convert** command.

With the **convert** command, you can dynamically change the attributes of a Management Instance while you actively manage the switch over that same Management Instance without requiring the switch to reboot. This option also has rollback functionality to recover from unwanted changes.

For more information, see the following sections:

- [Dynamic Change Options for Segmented Management Instance Attributes](#) on page 84
- [Change Management Instance Attributes](#) on page 98

You can use the **migrate-to-mgmt** command to move a management VLAN to a different VLAN ID, or a management CLIP to a different VRF. However, if you use this option, you must reboot your switch after you save the configuration changes.

The following is an outline of the steps required for management migration using the **migrate-to-mgmt** command:

1. Configure a new or existing VLAN or CLIP management interface using Interface Configuration mode in the CLI (**interface vlan <vlan_id>** or **interface loopback <clip_id>**) or EDM.

Important

The IP interface and all routing protocols attached to the original VLAN are deleted post migration.

2. Add required routes to reach management services and subnets from the new interface.
3. Test connectivity to the new interface using ping and traceroute, and from the switch to management stations and servers.
4. Use the **migrate-to-mgmt** command from the new interface CLI mode.
5. Save the configuration and reboot.

Note

During boot, the migrate-to-mgmt settings are parsed and override the existing management interface with the new interface.

6. Access and manage the switch from the new interface.

For more information see, [Migrate a VLAN or CLIP IP address to the Segmented Management Instance](#) on page 85 (using CLI) or [Migrate an IP Address to a Segmented Management Instance](#) on page 114 (using EDM).

XA1400 Series Management Migration with a Fabric Extend Source IP VLAN

Before VOSS Release 8.1.60, a single IP address could be used for both routing or management, however Segmented Management Instance separates the routing and management networking stacks. Because **migrate-to-mgmt** can only move an IP from the routing stack to the management stack, see the following scenario for a before and after upgrade process required to manage an XA1400 Series with the Fabric Extend (FE) tunnel Source IP using Segmented Management Instance:

Before upgrading to VOSS Release 8.1.60 or later:

1. Configure a CLIP Management Instance or designate an existing loopback IP for migration.
2. Save configuration and reboot.

After upgrading to VOSS Release 8.1.60 or later:

1. Manage the XA1400 Series using the CLIP Management Instance.
2. Create the VLAN Management Instance with the same VLAN ID and IP address as the FE tunnel source VLAN.
3. Modify the default route or create static routes to the VLAN Management Instance.
4. Manage the XA1400 Series with the VLAN or CLIP Management Instance.

Interface Types

The Management Instance supports the following interface types:

- [CLIP](#) on page 75
- [OOB](#) on page 76
- [VLAN](#) on page 76

You can configure a maximum of three Management Instance interfaces, one of each type.

You can configure the route priority for the Segmented Management Instance. The Source IP default route priority is management CLIP (weight 100), then management VLAN (weight 200), then management OOB interface (weight 300). You can route packets through a different management interface than the default configuration, but you must add a specific static route or change the default weight of the management interface.

Note

If you change the default route weight, the management interface with the lowest weight value becomes the default route for all segmented management interface traffic.

The VSP 8600 Series Segmented Management Instance does not support ACL based filters or use of ping with -Q option to change the internal priority of management traffic.

You can configure the default topology IP for LLDP and SONMP advertisements. Both LLDP and SONMP advertise the same topology IP. SONMP supports only IPv4 addresses. If multiple IPv4 addresses are configured on an OOB or VLAN management interface, the advertised IP priority is static IP address, then DHCP IP address, then link-local IP address.

IPSec is not supported on Segmented Management Instance management interfaces.

CLIP

You can use this interface type for CLIP management network routing in a Fabric network or Layer 3 routing network.

Important

A CLIP Management Instance is not a management CLIP created in the GRT. You must create the CLIP Management Instance using the Segmented Management Instance configuration.

The following list defines the abilities of this interface type:

- You can assign a circuitless management IP (CLIP) address bound to a VRF.
- You can associate only one VRF ID with a CLIP Management Instance IP address.
- The IP address is not bound to a physical network; it does not transmit nor receive IPv4 Address Resolution Protocol (ARP) or IPv6 Neighbor Discovery (ND) messages.
- You do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the associated VRF.
- Packets can ingress on any port or VLAN that belongs to the VRF associated with the CLIP Management Instance.

- You must configure accept policies or configure inter-VRF route redistribution to access the CLIP Management Instance from a different VRF. Inter-VRF access is not permitted with traditional IP routing using OSPF, BGP, or RIP. Packets ingressing the switch from a VLAN that belongs to a different VRF without a configured accept policy will not reach the CLIP Management Instance IP address. For more information, see [Redistribution of CLIP Segmented Management Instance Examples](#) on page 111.
- If you migrate the current IS-IS IP source address to the CLIP Management Instance, after the upgrade the IS-IS source IP address moves to the CLIP Management Instance. You must configure a new GRT CLIP using a different IP address and assign that as the new IS-IS source IP.
- Advertisement of the IPv4 or IPv6 address for the CLIP Management Instance to IS-IS in the GRT occurs automatically. Advertisement of the IPv4 or IPv6 address in the VRF Layer 3 VSN bound to the CLIP Management Instance occurs automatically. You must configure route redistribution to advertise the CLIP Management Instance to different protocols. For more information, see [Redistribution of CLIP Segmented Management Instance Examples](#) on page 111.

OOB

You can use this interface type for OOB management network routing, as an alternative to in-band network routing management.

Note

The OOB Segmented Management Instance is not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

The following list defines the abilities of this interface type:

- You can assign a management IP address bound to the Out-of-Band (OOB) interface.
- You can associate only one OOB interface with an OOB Management Instance IP address.
- The Dynamic Host Configuration Protocol (DHCP) Client can request an IPv4 address for the OOB Management Instance interface.
- You must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.
- You can configure only Layer 3 networking parameters in the Management Instance Configuration mode (**mgmt OOB**) in CLI.
- You can configure only Layer 1 and Layer 2 networking parameters in the mgmtEthernet Interface Configuration mode (**interface mgmtEthernet mgmt**) in CLI.

VLAN

You can use this interface type for management of Layer 2 switches or for Zero-Touch onboarding of newly deployed devices.

For more information on Zero-Touch onboarding, see [Zero Touch Capabilities](#) on page 13.

Note

The VLAN Segmented Management Instance is not supported on VSP 8600 Series.

The following list defines the abilities of this interface type:

- You can assign a Management Instance IP address to an inband VLAN.
- You can associate only one VLAN ID with a VLAN Management Instance IP address.
- The DHCP Client can request an IPv4 address for the VLAN Management Instance interface.
- The interface resides on the physical VLAN segment, behaving as a host for sending and receiving IPv4 ARP and IPv6 ND messages.
- You must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link (other subnets) networks.
- For the VLAN Management Instance to take route priority when used in conjunction with the CLIP Management Instance, you must configure a default route for the VLAN Management Instance with a value lower than 100, or configure static routes for direct communication over the VLAN Management Instance and management networks.
- No internal routing occurs between the VLAN Management Instance and other non Management Instance VLANs. The VLAN Management Instance does not route to or from the GRT. Packets must ingress on one of the ports in the VLAN Management Instance.

Packets sent to the VLAN Management Instance IP address must ingress the switch from a VLAN or NNI port (or contain the VLAN ID) associated with the VLAN Management Instance. The system does not route packets between the network operating system (NOS) routing VLAN and the VLAN Management Instance.

If you configure the same VLAN ID for NOS routing and for the VLAN Management Instance, the NOS routing stack transmits and receives all ARP, ND, and ICMP packets. In this scenario, the packets are only counted and shown in the NOS routing KHI port statistics. The management statistics and KHI management statistics do not count or show the packets.

- You can bind the VLAN Management Instance to an I-SID, which bridges all management traffic to a single I-SID in a Fabric network. Also, other normal VLAN related operations such as VLAN port member changes are valid.
- Bridged management traffic must ingress on the VLAN or I-SID.
- The VLAN Management Instance can be routed by upstream routers.

Coexistence Restrictions

IPv4 and IPv6 address coexistence for both a NOS routing VLAN and VLAN Management Instance is supported, however you must manually match both IP address configurations between the VLANs.

If you configure the VLAN Management Instance with a manual IPv4 address and a DHCP IPv4 address first, you cannot add a IPv4 address to a NOS routing VLAN.

If you configure the VLAN Management Instance with an IPv6 address first, you can only add one IPv6 global address to a NOS routing VLAN.

The following restrictions apply when a VLAN Management Instance coexists with a port-based VLAN or with a brouter port:

- If you want a dual stack IPv4 and IPv6 coexistence between a NOS VLAN and VLAN Management Instance, you must configure the same IPv4 and IPv6 addresses on the VLAN Management Instance and on the NOS VLAN.

You cannot configure the VLAN Management Instance with both IPv4 and IPv6 and configure the NOS VLAN with IPv4 or IPv6 only.

- If you disable NOS routing for IPv4, then you must disable routing for IPv6, and vice versa.

Configuration Example - Coexistence with Port-Based VLAN

The following example shows how the VLAN Management Instance can be configured to share the same IP address as a routing port-based VLAN.

You can configure the NOS VLAN first, and then configure the VLAN Management Instance, or in reverse order. You can remove or add the coexistence at any time.

Note

With the coexistence between NOS routing stack and the VLAN Management Instance, packets sent to the VLAN Management Instance IP address must ingress the switch from a VLAN port (or contain the VLAN ID) associated with the VLAN Management Instance. The system does not route packets between the NOS routing VLAN and the VLAN Management Instance.

IPv4

```
vlan create 10 type port-mstprstp 0
vlan members add 10 1/1
interface vlan 10
ip address 192.0.2.0/24
exit
mgmt vlan 10
ip address 192.0.2.0/24
ip route 0.0.0.0/0 next-hop 192.0.2.1
enable
```

IPv6

```
vlan create 10 type port-mstprstp 0
vlan members add 10 1/1
interface vlan 10
ipv6 interface address 2001:DB8::/32
ipv6 interface enable
exit
mgmt vlan 10
ipv6 address 2001:DB8::/32
ipv6 route 0::0/0 next-hop 2001::1
enable
```

Configuration Example - Coexistence with Port-Based VLAN Zero Touch Deployment

For XA1400 Series branch deployments, the NOS routing IP stack requires the VLAN Management Instance to work in coexistence mode where both the management IP stack and the routing IP stack share the same IP address and default routes. This configuration is required if you need to use the management IP as IPsec source address.

You can manually configure the coexistence as in the preceding example, or you can use the **propagate-to-routing** command to propagate the management VLAN IP and static routes from the management IP stack to the NOS routing IP stack on the same VLAN ID. If you do not include the VRF name, the system uses the existing VRF of the NOS routing VLAN.

IPv4

```
mgmt vlan 10
enable
exit
mgmt dhcp-client vlan
mgmt vlan
propagate-to-routing vrf vrf24
```

Configuration Example - Coexistence with Brouter Port

The following example shows how the VLAN Management Instance can be configured to share the same IP address as a brouter interface.

You must configure the brouter interface before you enable the VLAN Management Instance. When the VLAN Management Instance is enabled, you must disable the VLAN Management Instance before you disable the brouter port.

IPv4

```
interface GigabitEthernet 1/1
no shutdown
brouter port 1/1 vlan 10 subnet 192.0.2.0/24
mgmt vlan 10
ip address 192.0.2.0/24
enable
```

IPv6

```
interface GigabitEthernet 1/1
no shutdown
ipv6 interface vlan 10
ipv6 interface address 2001:DB8::/32
ipv6 interface enable
mgmt vlan 10
ipv6 address 2001:DB8::/32
enable
```

Management Applications

The Segmented Management Instance provides support for management interfaces that transmit and receive packets directly to and from the system native Linux IP stack. Unlike a traditional management interface, for example, a CLIP in the GRT that is part of the networking IP stack, Segmented Management Instance interfaces do not route packets through the networking IP stack.

The following management applications use the Segmented Management Instance directly to transmit or receive packets with segmented management interfaces and addresses.

**Note**

The VSP 8600 Series only supports Ping, Traceroute, and NTPv4.

Segmented Management Instance Applications and Protocols	Client	Server	IPv4	IPv6
Digital Certificates	Yes		Yes	
DHCP Client	Yes		Yes	
DNS	Yes		Yes	Yes
FTP	Yes	Yes	Yes	Yes
HTTP/HTTPS		Yes	Yes	Yes
IQAgent	Yes		Yes	
NTPv4	Yes	Yes	Yes	Yes
OVSDB protocol support for VXLAN Gateway	Yes	Yes	Yes	
Ping	Yes	Yes	Yes	Yes
RADIUS	Yes		Yes	Yes
RADIUS Security (RADSec)	Yes		Yes	Yes
Representational State Transfer Configuration Protocol (RESTCONF)		Yes	Yes	
SSH/SCP/SFTP	Yes (SSH only)	Yes	Yes	Yes
Syslog	Yes		Yes	Yes
TACACS+	Yes		Yes	
Telnet	Yes	Yes	Yes	Yes
TFTP	Yes	Yes	Yes	Yes
Traceroute	Yes	Yes	Yes	Yes

The following management applications do not use the Segmented Management Instance directly to transmit or receive packets, but can integrate with segmented management interfaces and addresses.

Applications and Protocols	IPv4	IPv6
Link Layer Discovery Protocol (LLDP)	Yes	Yes
SynOptics Network Management Protocol (SONMP)	Yes	
Sampled Flow (sFlow)	Yes	
Remote Network Monitoring version 2 (RMON2)	Yes	

Note

The following management applications do not use the Segmented Management Instance and are deprecated in VOSS.

- NTPv3
- Remote Login (rlogin)
- Remote Shell (RSH)

Operational Notes for UDP Management Applications

Management applications that use UDP, such as TFTP, RADIUS dynamic server, or SNMP can have restrictions when multiple Segmented Management Instances are configured with overlapping or asymmetrical routing.

Note

The restrictions listed do not apply to TCP applications or if a single Management Instance is configured.

Asymmetrical routing can occur in any of the following scenarios. For the first two scenarios you can use the OOB or VLAN Management Instance IP address instead of the CLIP Management Instance IP address. Also, use FTP or SCP file transfer as an alternative because those protocols are TCP based.

In the third scenario, you can configure more specific static routes for networks originating UDP client communication to the OOB or VLAN Management Instance IP address if the CLIP Management Instance is also configured.

1. Client communication to the CLIP Management Instance IP address is from the same subnet as the VLAN Management Instance.
2. Client communication to the CLIP Management Instance IP address when specific static routes or default route with higher preference back to the client network exist on OOB Management Instance or VLAN Management Instance.

3. Client communication to the OOB Management Instance IP address or VLAN Management Instance IP address that relies on a default route with a lower preference than the internal default route used by the CLIP Management Instance.
4. Client communication to the CLIP Management Instance IP address is from the same subnet as the OOB Management Instance (even if the OOB port is down).

DHCP Client for Segmented Management Instance

To support Zero Touch Deployment, a DHCP Client is used for the Segmented Management Instance VLAN management interface or Out-of-Band (OOB) management interface. The DHCP Client configuration supports a VLAN mode, OOB mode, and a cycle mode. DHCP Client cycle mode alternates IP address requests between the VLAN management interface and OOB management interface until an IP address is obtained on one of the interfaces. Priority is given to the OOB management interface.

You can also manually configure the DHCP Client to request an IPv4 address from a DHCP server for the In-band VLAN management interface, or the OOB management interface, or to cycle requests until an IP address is obtained on a VLAN or OOB management interface. The DHCP Client supports IPv4 addresses only, and cannot be enabled on multiple management interfaces simultaneously.

Note

If a default route is configured on an OOB or VLAN management interface, and then you configure DHCP so that it replaces the default route, the original default route is restored if you disable DHCP.

However, if the DHCP default route is updated or deleted after it is created by DHCP, the default route will not be replaced by the original route when DHCP is disabled.

DHCP Client Restrictions

DHCP Client for the Segmented Management Instance supports IPv4 addresses only, and cannot be enabled on multiple management interfaces simultaneously. The DHCP Client only supports the in-band VLAN management interface, or the OOB management interface, or to cycle requests on the the VLAN then OOB management interface until an IP address is obtained on one of the interfaces.

Note

The DHCP Client is disabled by default on previously configured or upgraded switches.

The DHCP Client is enabled by default in cycle mode when:

- The switch ships directly from manufacturing with VOSS Release 8.1.60 or later.
- The primary and secondary configuration file is not on the switch.
- The primary and secondary configuration file fail to load on the switch.

The DHCP Client is not available if RMON2 is configured on a Management Instance, and RMON2 is not available if the DHCP Client is configured on a Management Instance.

When DHCP is enabled on a Management Instance interface, the DHCP Client initial broadcast discovery packet and initial response from the DHCP server are not counted or shown in KHI management statistics for the management interface. Only the packets after the DHCP IP address assignment

completes are counted and shown. After an IP address is assigned, a UDP socket opens and packets are counted on the interface.

If you change the DHCP Client configuration between management VLAN, OOB, or cycle, the default route provided by the DHCP server might delete and add with a different nexthop or network. DHCP Client configuration changes can cause interruptions to existing management connections.

DHCP static routes are not saved in the configuration file or displayed in **show running-config**. You can view DHCP static routes with **show mgmt ip route static**. If the DHCP Client adds a default route to an interface, the previous default route is deleted. If you modify a default route created by the DHCP Client, the route type output of **show mgmt ip route static** changes from DHCP to STATIC. You can save the modified to static default route to the configuration file, but on reboot the DHCP Client deletes the modified default route and restores the default static route the DHCP server specifies.

DHCP Option 43

DHCP option 43 requests specific vendor options from the DHCP server. Only sub-option 226 (EXTREME.cloudiq-ip) is supported to change the value of the ExtremeCloud IQ server IP address on the switch.

With the support of DHCP option 43, DHCP can dynamically configure the IP address of a private/non-public ExtremeCloud IQ server for zero touch deployments when the default ExtremeCloud IQ server (hac.extremecloudiq.com) is not desired.

For information about configuring the switch to support ExtremeCloud IQ, see [ExtremeCloud IQ Agent](#) on page 835.

DHCP Option 43 Configuration Examples

This section provides examples to configure DHCP Option 43 on a Linux server and on Windows Server.

ISC DHCP Server configuration on Linux:

```
/etc/dhcp/dhcpd.conf
default-lease-time 60;
max-lease-time 7200;
option space EXTREME;
option EXTREME.cloudiq-ip code 226 = ip-address;

class "Edge-without-POE" {
    match if (option vendor-class-identifier = "EXTREME");
    vendor-option-space EXTREME;
    option EXTREME.cloudiq-ip 10.16.231.131;
}

subnet 30.30.30.0 netmask 255.255.255.0 {
    pool {
        range 30.30.30.10 30.30.30.20;
        allow members of "Edge-without-POE";
    }
    option domain-name-servers 10.1.10.1;
    option domain-name "labs.extremenetworks.com";
    option routers 30.30.30.250;
```

```

        default-lease-time 3600;
    }

```

Windows Server configuration:

1. Go to scope options for defined DHCP pool.
2. Enter the following for Option 43: e2 04 0a 10 e7 83

Value	Description
e2 04	vendor ID prefix (e2 is the hexadecimal value of the code 226 used to identify sub-option EXTREME.cloudiq-ip and 04 the hexadecimal value of the length of an IP address in bytes)
0a 10 e7 83	IP address 10.16.231.131 converted to hexadecimal

Dynamic Change Options for Segmented Management Instance Attributes

You can now dynamically change the attributes of a Management Instance while you actively manage the switch over that same Management Instance without requiring the switch to reboot. For example, if your switch onboards using VLAN 4048, you can change that Management Instance VLAN to a new VLAN.

You can change the following attributes for the Management Instance:

- Management Instance VLAN:
 - VLAN ID
 - IPv4 address
 - default gateway
 - I-SID (on a DvR Leaf)
 - ports-tagged
 - ports-untagged
- Management Instance CLIP
 - IPv4 address
 - vrf
- Management Instance Out-of-Band (OOB)
 - IPv4 address
 - default gateway

Operational Considerations

The following are operational considerations when you change Management Instance attributes using the **convert** command:

- IPv6 is not supported and is removed during conversion, if an IPv6 address exists.
- You cannot change parameters for more than one Management Instance operation at a time. You must issue the **mgmt convert-commit** command before you use the **convert** command for either the same or a different Management Instance.
- If you attempt to change attributes for an existing Management Instance VLAN, you cannot configure ports-tagged, ports-untagged, and I-SID parameters. Make configuration changes to the

existing Management Instance VLAN first before you use the **convert** command. If you change your switch to a DvR leaf node, you can change the I-SID parameter.

- If you attempt to change attributes for a Management Instance VLAN and the VLAN does not exist, a VLAN is automatically created in the background. You can specify ports-tagged, ports-untagged, and I-SID parameters to be associated with this new VLAN. The new VLAN is assigned to the default Spanning Tree Group, which is 0.
- If you attempt to change attributes for a Management Instance VLAN and the VLAN does not exist, and you do not specify ports-tagged, ports-untagged, or I-SID parameters, then this is a special case. If any untagged ports in the old VLAN have dynamic Address Resolution Protocol (ARP) entries then these ports automatically move from the old VLAN to the new VLAN. For example, VLAN 200 has port members 1/1, 1/2, and 1/3. ARP entries are configured on ports 1/1 and 1/2. VLAN 300 is created in the background and only ports 1/1 and 1/2 automatically move to this new VLAN.

If an MLT ID is associated with the old VLAN, the association is removed and re-added to the new Management Instance VLAN ID.

- If you attempt to change the vrf attribute for a Management Instance CLIP but the vrf does not exist, a vrf is automatically created in the background. In order for this vrf to function properly, you must configure either SPBM Layer 3 VSN or IP interfaces and routing protocols.

The best practice is to configure and test vrf connectivity before you use the **convert** command.

- The following applies when you change static routes attributes on a Management Instance VLAN or Management Instance OOB interface:
 - If you provide the static route next-hop gateway, all next-hop gateway direct to the new gateway.
 - If you do not provide the static route next-hop gateway and the new subnet is the same as the old subnet, all routes are re-added as is.
 - If you do not provide a gateway and the new subnet is different, routes are discarded.
- Dynamic routes added by DHCP convert to static routes.

Segmented Management Instance Configuration using the CLI

This section provides procedures to configure segmented management instance using the command line interface (CLI).

Migrate a VLAN or CLIP IP address to the Segmented Management Instance

In releases prior to VOSS release 8.1.60, perform this procedure to identify a pre-existing VLAN or loopback management interface to migrate to the Segmented Management Instance after you upgrade. This action moves the IP interface from the routing stack to the management stack to use with management applications. In releases later than VOSS 8.1.60, you can perform this procedure to migrate a new routing VLAN with a new IP address or a new loopback IP address under a different VRF to the Segmented Management Instance. Alternatively, you can also use the **convert** command. For more information, see [Change Management Instance Attributes](#) on page 98.

Important

Choose a VLAN that does not have an IP interface on it. The upgrade process removes the IP configuration and network connectivity will be impacted.

About This Task

Note

Do not migrate interfaces used for routing purposes, for example, where you configure Layer 3 routing protocols.

This command does not apply to the OOB or mgmtEthernet interface. Releases that support this migration procedure automatically move the IP address on the mgmtEthernet interface from the routing stack to the Segmented Management Instance during the upgrade to this release.

Procedure

1. Enter Interface Configuration mode for either a VLAN or loopback interface:

```
enable

configure terminal

interface vlan <1-4059> or interface loopback <1-256>
```
2. Select the interface address for migration:

```
migrate-to-mgmt
```
3. View the designated interface addresses selected for migration:

```
show mgmt migration
```
4. Save the configuration selected for migration:

```
save config
```

Example

Identify an IP address currently assigned to an inband VLAN to migrate to the Management VLAN. The example assumes you already identified a CLIP address. The VRF column in **show mgmt migration** indicates where the interface is being moved from.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 20
Switch:1(config-if)#migrate-to-mgmt
Switch:1(config-if)#show mgmt migration

=====
Mgmt Migration Information
=====
IFINDEX   DESCR      VRF          IPV4          IPV6

Configure a Segmented Management Instance Using quick-config-mgmt Utility

Use the following procedure to run the quick-config-mgmt utility script to ease the transition to the Segmented Management Instance.

**Note**

XA1400 Series does not support the OOB Management Instance.

**Note**

Product Notice: quick-config-mgmt is not supported on VSP 8600 Series.

The quick-config-mgmt utility recognizes existing configuration. For the OOB Management Instance, you can overwrite the existing configuration only. However, for the VLAN Management Instance, you can overwrite the existing configuration, or you can migrate the existing configuration to a coexistence of IP on both VOSS VLAN and management VLAN.

The quick-config-mgmt utility supports the following:

- IPv4 only
- only one interface at one time
- Out-of-Band management and In-Band VLAN management

About This Task

You can use this procedure to help you transition to a new Segmented Management Instance. You can configure IPv4, static routes, and DHCP support for the Out-of-Band (OOB) Management Instance or for the In-Band VLAN Management Instance. If configuration exists for the interface type you selected, you are prompted to replace the configured interface or to quit the utility.

**Important**

If you configure DHCP, any other running DHCP instance is stopped and a new DHCP instance is created on the interface. This might cause loss of connectivity.

The default values are given in square brackets. You can input your values at the prompt or you can press `Enter` to accept the default values.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enter the following command to start the utility:
`quick-config-mgmt`

**Important**

If DHCP mode cycle is enabled, the following warning message displays to inform you that DHCP client will be disabled, if you continue.

```
Continuing will disable dhcp and may affect your connectivity  
to the DUT. Do you want to continue? y/n [n]:
```

Examples

The following examples show outputs from the **quick-config-mgmt** utility.

Configure the OOB Management Instance:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]:
Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully
```

Replace an existing OOB Management Instance configuration:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]:
MGMT OOB is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [y]:
Please enter management interface type or "q" to quit. [1]:
Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully
```

Configure the In-band port-based VLAN Management Instance by removing parts of or all of the existing VLAN configuration:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
```

```

Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]: 3
MGMT VLAN is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [n]: y
Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
VLAN 2 is already in use.
Do you want to re-use existing vlan configuration? y/n/q: [n]
This option will remove all current config on VLAN 2.
Please enter port to be added to the in-band management VLAN or "q" to quit [1/1]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully

```

Configure the In-band port-based VLAN Management Instance by reusing the existing VLAN configuration:

```

Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]: 3
MGMT VLAN is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [n]: y
Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
VLAN 2 is already in use.
Do you want to re-use existing vlan configuration? y/n/q: [y]
Please enter port to be appended to the in-band management VLAN or leave empty
to keep currently configured ports or "q" to quit []: 1/1
Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully

```

Configure the In-band port-based VLAN Management Instance by reusing the existing VLAN configuration when IP address is configured and coexistence of mgmt and routing on same VLAN is desired:

```

Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
  1 - Out of band management port

```

```

3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]: 3
MGMT VLAN is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [n]: y
Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
VLAN 2 is already in use.
Do you want to re-use existing vlan configuration? y/n/q: [y]
Please enter port to be appended to the in-band management VLAN or leave empty
to keep currently configured ports or "q" to quit []: 1/1
IP address is already configured on VLAN 2.
Do you want to configure co-existence of mgmt and routing on the same vlan? y/n/q: [y]
Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully

```

Configure the In-band port-based VLAN Management Instance by reusing the existing VLAN configuration when IP address is configured but coexistence of mgmt and routing on same VLAN is not desired:

```

Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]: 3
MGMT VLAN is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [n]: y
Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
VLAN 2 is already in use.
Do you want to re-use existing vlan configuration? y/n/q: [y]
Please enter port to be appended to the in-band management VLAN or leave empty
to keep currently configured ports or "q" to quit []: 1/1
IP address is already configured on VLAN 2.
Do you want to configure co-existence of mgmt and routing on the same vlan? y/n/q: [n]
Management interface created successfully

```

Create a Segmented Management Instance

You must create a Management Instance to gain access to specific management applications. After you create the Management Instance, you can add an IP address to it and configure route redistribution to advertise reachability of the Management Instance to the rest of the network.

About This Task

The Management Instance supports different management interface types. When you create the Management Instance, you specify the interface type and the switch automatically creates the appropriate instance ID for that type.

A management VLAN is used for Layer 2 deployments. In a Layer 3 routing or Fabric deployment, use a management CLIP. For Out-of-band Management, use a management OOB.

Each Management Instance supports a IPv4 and IPv6 (global scope) management address for use by management applications.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Create the Management Instance required for your deployment:
 - a. To create a management CLIP:
`mgmt clip [vrf WORD<1-16>]`

Note

If you do not specify a VRF, the management CLIP uses the GRT. You cannot use mgmtrouter as the VRF.

OR

- b. To create a management OOB:
`mgmt oob`

OR

- c. To create a management VLAN and associate it with an existing port-based VLAN:
`mgmt vlan <2-4059>`

3. Enable the Management Instance:
`enable`

Example

Create and enable a Management CLIP:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:clip)#enable
```

Create and enable a Management OOB:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt oob
Switch:1(mgmt:oob)#enable
```

Create and enable a Management VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Switch:1(config)#mgmt vlan 20
Switch:1(mgmt:vlan)#enable
```

Delete a Segmented Management Instance

Use this task to delete a Management Instance. Deleting the Management Instance removes the IP address, and changes the associated VRF for a management CLIP.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Delete the Management Instance:
`no mgmt {clip | oob | vlan}`

Configure the DHCP Client for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure the DHCP Client to obtain an IPv4 address for the Management Instance VLAN interface or Out-of-Band interface.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable and configure the DHCP Client for a management interface:
`mgmt dhcp-client {cycle | oob | vlan}`

Example

The following example configures the DHCP Client to cycle IPv4 requests for the management OOB interface, and then the In-Band management VLAN interface; priority is given to the OOB interface. The system cycles attempts until one management interface receives an IP address from the DHCP server:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt dhcp-client cycle
```

Variable Definitions

The following table defines parameters for the **mgmt dhcp-client** command.

Variable	Value
<i>cycle</i>	DHCP Client cycles IP requests for in-band VLAN and Out-of-Band management interfaces.
<i>oob</i>	DHCP Client requests an IP address for the Out-of-Band management interface.
<i>vlan</i>	DHCP Client requests an IP address for the VLAN management interface.

Configure an IP Address for a Segmented Management Instance

Use this task to add an IPv4 or IPv6 address to a Management Instance.

Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.
- If the DHCP client is configured for a Segmented Management Instance, you must manually disable the client. Configuring an IP address does not automatically disable the DHCP client.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enter the configuration mode for the Management Instance:

```
mgmt {clip | oob | vlan}
```
3. Add an IPv4 address:

```
ip address {A.B.C.D [A.B.C.D] | A.B.C.D/X}
```
4. Add an IPv6 address:

```
ipv6 address WORD<0-255>
```

Example

Add an IPv4 address to the VLAN Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#ip address 192.0.2.12/24
```

Add an IPv4 address to the OOB Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt oob
Switch:1(mgmt:oob)#ip address 192.0.2.12 255.255.255.0
```

Add an IPv6 address to the CLIP Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:clip)#ipv6 address 2001:DB8::1/128
```

Configure a Segmented Management Instance Interface as Default Topology IP

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure a Management Instance with a default topology IP.

Note

You can only configure one Management Instance interface as the default topology IP.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enter the configuration mode for the Management Instance:
`mgmt {clip | oob | vlan}`
3. Configure the Management Instance as the default topology IP.
`force-topology-ip`

Example

The following example configures the Segmented Management Instance VLAN as the default topology IP:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#force-topology-ip
```

Configure Static Routes for a Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure static routes for Management Instances.

About This Task

For the Management Instance CLIP, you do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the VRF. For more information about

how to associate a VRF with the CLIP interface, see [Create a Segmented Management Instance](#) on page 90.

For the Management Instance OOB and VLAN, you must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.

You can configure up to 100 IPv4 and IPv6 static routes.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter the configuration mode for the Management Instance:

```
mgmt {clip | oob | vlan}
```

3. Configure a static route:

```
ip route <A.B.C.D A.B.C.D | A.B.C.D/X> next-hop <A.B.C.D> [weight <1-65535>]
```

OR

```
ipv6 route WORD<0-255> [next-hop WORD<0-255>] [weight <1-65535>]
```

Example

Add a static route to configure routing for a Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#ip route 192.0.2.2/24 next-hop 198.51.100.1
```

Variable definitions

The following table defines parameters for the **ip route** and **ipv6 route** commands.

Variable	Value
<A.B.C.D A.B.C.D A.B.C.D/X>	Specifies the IP address and mask in one of the following formats: <ul style="list-style-type: none"> • A.B.C.D A.B.C.D • A.B.C.D/X
next-hop <A.B.C.D> Or next-hop WORD<0-255>	Specifies the next hop address for the static route. Use an IP in the same subnet as the management VLAN IP address.

Variable	Value
<code>weight <1-65535></code>	Specifies the static route cost. The default is 100 for CLIP, 200 for VLAN, and 300 for OOB. The management CLIP uses an internal static route with a weight of 100. If you use both CLIP and VLAN and need to force all default traffic out the management VLAN interface, configure a default static route with a weight lower than 100.
<code>WORD<0-255></code>	Specifies the IPv6 address.

Configure Fragmented ICMP Packet Filtering on a Segmented Management Instance

Note
This procedure does not apply to VSP 8600 Series.

About This Task

Use this task to enable fragmented ICMP packet filtering on a Segmented Management Instance.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enter the configuration mode for the Management Instance:

```
mgmt {clip | oob | vlan}
```
3. Enable fragmented ICMP packet filtering:
 - For IPv4:

```
ip icmp drop-fragments
```
 - For IPv6:

```
ipv6 icmp drop-fragments
```

Note
The **ipv6 icmp drop-fragments** command does not apply to XA1400 Series.

View Fragmented ICMP packet filtering Statistics on a Segmented Management Instance

Note
This procedure does not apply to VSP 8600 Series.

About This Task

Use this task to view Fragmented ICMP packet filtering details on a Management Instance.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View Fragmented ICMP packet filtering:

- For IPv4:

```
show mgmt ip icmp [clip | oob | vlan]
```

- For IPv6:

```
show mgmt ipv6 icmp [clip | oob | vlan]
```

**Note**

This command does not apply to XA1400 Series.

Variable Definitions

The following table defines parameters for the **show mgmt ip icmp** command.

Variable	Value
<i>clip</i>	Displays the IPv4 or IPv6 ICMP information specific to the management CLIP.
<i>oob</i>	Displays the IPv4 or IPv6 ICMP information specific to the management OOB.
<i>vlan</i>	Displays the IPv4 or IPv6 ICMP information specific to the management VLAN.

Configure MAC-offset for a Management VLAN Instance

Use this task to configure MAC-offset for a Management VLAN instance.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter the MAC-offset for a Management VLAN instance:

```
mgmt vlan mac-offset <MAC-offset>
```

**Note**

Different hardware platforms support different ranges.

Example

Configure the MAC-offset for the Management VLAN instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#mac-offset <0-511>
```

Variable Definitions

The following table defines parameters for the **mgmt vlan** interface.

Variable	Value
<i>mac-offset</i> <MAC-offset>	Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help.

Configure Management VLAN and VOSS Routing VLAN Coexistence Through Propagation

Note

This procedure only applies to XA1400 Series.

For XA1400 Series branch deployments, the VOSS routing IP stack requires the VLAN Management Instance to work in coexistence mode where both the management IP stack and the routing IP stack share the same IP address and default routes. This is required for an IPsec source address.

About This Task

You can manually configure the coexistence or you can use the **propagate-to-routing** command to propagate the management VLAN IP and static routes from the management IP stack to the VOSS routing IP stack on the same VLAN ID. If you do not include the VRF name, the system uses the existing VRF of the VOSS routing VLAN.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enter the configuration mode for the Management Instance VLAN:

```
mgmt vlan
```
3. Configure the coexistence:

```
propagate-to-routing [vrf WORD<0-16>]
```

Change Management Instance Attributes

Note

This procedure does not apply to VSP 8600 Series.

Use this task to change the IP address, VLAN, VRF, or default gateway for a Management Instance while you actively manage the switch over the same instance.

Important

Change the parameters in the following order:

1. VLAN or VRF
2. ports-tagged, ports-untagged-, or I-SID
3. IP address or default gateway

About This Task

You cannot change parameters for more than one Management Instance operation at a time.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter the configuration mode for the Management Instance:

```
mgmt {clip | oob | vlan}
```

3. Use one of the following Management Instances interfaces to configure the new values:

- a. Configure new Management Instance VLAN parameters:

```
convert [vlan <1-4059>] [i-sid <1-16777215>] [ports-tagged {slot/
port[/sub-port] [-slot/port[/sub-port]][, ...]}] [ports-untagged {slot/
port[/sub-port] [-slot/port[/sub-port]][, ...]}] [ip {<A.B.C.D/X>|
<A.B.C.D> <A.B.C.D>}] [gateway <A.B.C.D>] [rollback <0-3600>]
```

Important

After you configure the new values, the existing Management Instance VLAN is deleted and connectivity to the switch can be lost. You must reconnect to the switch before you can issue the `mgmt convert-commit` command.

- b. Configure new Management Instance OOB parameters:

```
convert [ip {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>}] [gateway <A.B.C.D>]
[rollback <0-3600>]
```

- c. Configure new Management Instance CLIP parameters:

```
convert [vrf WORD <1-16>] [ip {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>}]
[rollback <0-3600>]
```

Note

If the VRF does not exist before you issue the **convert** command, the VRF is automatically created in the background. For this VRF to function properly, you must configure either SPBM Layer 3 VSN or IP interfaces and routing protocols.

- Log on to Global Configuration mode to commit the parameter changes:

```
mgmt convert-commit
```

Note

Commit the change within 120 seconds (default) of issuing the `mgmt convert-commit` command. Otherwise, the configuration changes automatically roll back to the previous configuration.

Examples

The following examples show the change options attributes for a Management Instance VLAN:

Convert a management VLAN to a new VLAN ID:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300
```

```
Switch1:(mgmt:vlan)#1 2021-09-24T21:41:54.627Z 4902 CP1 - 0x003c8677 -

Convert on mgmt vlan
instance: Mgmt convert executed successfully

.
<reconnect to switch...>
Login: rwa
Password: ***

Mgmt convert: Please issue 'mgmt convert commit' before 120 seconds rollback timer
expires otherwise mgmt vlan
config change will be reverted
```

Convert a management VLAN to new IP address in the same subnet and in the same VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert ip 10.10.10.30/24
```

Convert a management VLAN to new IP address in a different subnet.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert ip 11.11.11.30/24 gateway 11.11.11.1
```

Convert a management VLAN to new VLAN ID with specified port or ports:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300 ports-untagged 1/2 ports-tagged 1/4
```

Convert a management VLAN to new VLAN ID with a specified I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300 i-sid 4300
```

Convert a management VLAN to new VLAN ID with a new IP address and default Gateway:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300 ip 11.11.11.30/24 gateway 11.11.11.1
```

Convert a management VLAN with all options:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300 ports-untagged 1/2 ports-tagged 1/4 i-sid 43000
ip 11.11.11.30/24 gateway 11.11.11.1
```

Convert a management VLAN to new I-SID (DvR Leaf only):

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert i-sid 4000
```

Convert a management VLAN with a faster rollback option (default is 120 seconds):

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300 rollback 60
```

Convert a management VLAN with no rollback option:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300 rollback 0
```

The following examples show the change options attributes for Management Instance CLIP.

Convert a management CLIP from one VRF to another VRF. The IP address is the same:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:clip)#convert vrf blue
```

```
WARNING: the specified vrf does not exist - connectivity to the mgmt clip will be lost
until l3vsn or
ip interfaces for the given vrf are provisioned.
Continue with this operation (y/n) ? n
```

Note

If the VRF does not exist before you issue the **convert** command, the VRF is automatically created in the background. In order for this VRF to function properly, you must configure either SPBM Layer 3 VSN or IP interfaces and routing protocols.

Convert a management CLIP to a new IP address. The VRF is the same:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:vlan)#convert ip 30.30.30.100/32
```

Convert a management CLIP to new IP address and VRF:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:vlan)#convert vrf blue ip 30.30.30.100/32
```

The following examples show the change options attributes for Management Instance Out-Of-Band (OOB):

Convert a management OOB to a new IP address in the same subnet:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt oob
Switch:1(mgmt:vlan)#convert ip 20.20.20.100/24
```

Convert a management OOB IP address to a different subnet:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt oob
Switch:1(mgmt:vlan)#convert ip 21.21.21.100/24 gateway 21.21.21.1
```

Variable Definitions

The following table defines parameters for the **convert** command.

Variable	Value
<A.B.C.D A.B.C.D A.B.C.D/X>	Specifies the IP address and subnet mask. This parameter applies to the following Management Instance interface types: <ul style="list-style-type: none"> • CLIP • OOB • VLAN
<A.B.C.D>	Specifies the gateway IP address. This parameter applies to the following Management Instance interface types: <ul style="list-style-type: none"> • OOB • VLAN
<1-16777215>	Specifies the service instance identifier (I-SID). This parameter applies to the Management Instance VLAN interface type. Note: You can specify the I-SID for a switch not configured as a DvR Leaf node.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<0-3600>	Specifies the time in seconds between when the command is issued and when the command changes automatically roll back to the previous configuration. The default is 120 seconds. To disable the rollback, enter 0.
<2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. This parameter applies to the Management Instance VLAN interface type only.
WORD<0-16>	Specifies the vrf name. This parameter applies to the Management Instance CLIP interface type only.

View Segmented Management Instance Information

Use this task to view Management Instance information.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. View general configuration information:

```
show mgmt interface [clip | oob | vlan]
```

3. View operational routes for the Management Instance:

```
show mgmt ip route [clip | oob | vlan]
```

OR

```
show mgmt ipv6 route [clip | oob | vlan]
```

Note

Routes with a type of LOCAL have a metric equal to 1.

4. View configured static routes for the Management Instance:

```
show mgmt ip route static [vlan | oob | clip]
```

OR

```
show mgmt ipv6 route static [vlan | oob | clip]
```

Note

Routes with a type of LOCAL have a metric equal to 256.

5. View the ARP or Neighbor Discovery cache information for the Management Instance:

```
show mgmt ip arp [clip | oob | vlan]
```

OR

```
show mgmt ipv6 neighbor [clip | oob | vlan]
```

Example

```
Switch:1>show mgmt interface vlan
```

```

View IP Address Information for a Segmented Management Instance

Use this task to view the IP address information for a Management Instance.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View Segmented Management Instance IP address information:

```
show mgmt ip [<clip | oob | vlan>]
```

OR

```
show mgmt ipv6 [<clip | oob | vlan>]
```
3. View Segmented Management Instance topology IP address information:

```
show mgmt topology-ip
```

Example

```
Switch:1>#show mgmt ip vlan
```

```

View Segmented Management Instance Statistics

Use this task to view Management Instance statistics.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View general Segmented Management Instance statistics:
`show mgmt statistics [clip | oob | vlan]`
3. View ICMP statistics for the Management Instance:

Note

This step does not apply to VSP 8600 Series.

```
show mgmt ip icmp-statistics
```

OR

```
show mgmt ipv6 icmp-statistics
```

4. View IP statistics for the Management Instance:

Note

This step does not apply to VSP 8600 Series.

```
show mgmt ip ip-statistics
```

OR

```
show mgmt ipv6 ip-statistics
```

- View the TCP connections for the Management Instance:

**Note**

This step does not apply to VSP 8600 Series.

```
show mgmt ip tcp-connections
```

OR

```
show mgmt ipv6 tcp-connections
```

- View the TCP statistics for the Management Instance:

**Note**

This step does not apply to VSP 8600 Series.

```
show mgmt ip tcp-statistics
```

OR

```
show mgmt ipv6 tcp-statistics
```

- View the UDP endpoints for the Management Instance:

**Note**

This step does not apply to VSP 8600 Series.

```
show mgmt ip udp-endpoints
```

OR

```
show mgmt ipv6 udp-endpoints
```

- View the UDP statistics for the Management Instance:

**Note**

This step does not apply to VSP 8600 Series.

```
show mgmt ip udp-statistics
```

OR

```
show mgmt ipv6 udp-statistics
```

- Enter Privileged EXEC mode:

```
enable
```

- (Optional) Clear all of the statistics for the Management Instance:

```
clear mgmt statistics
```

Examples

```
Switch:1>show mgmt statistics

Redistribution of CLIP Segmented Management Instance Examples

The CLIP Management Instance is added as a LOCAL route in the Control Processor Route Table Manager table and change list infrastructure. Existing route redistribution mechanisms redistribute local routes into the desired routing protocols within the associated VRF or across VRF instances.

Redistribute IPv4 CLIP Management Instance to OSPF in GRT

```
router ospf
 redistribute direct
 redistribute direct enable
 exit
 ip ospf apply redistribute direct
```

Redistribute IPv6 CLIP Management Instance to OSPF in GRT

```
router ospf
 ipv6 redistribute direct
 ipv6 redistribute direct enable
 ipv6 ospf apply redistribute direct
```

Redistribute IPv4 CLIP Management Instance to OSPF in VRF

```
router vrf red
 ip ospf redistribute direct
 ip ospf redistribute direct enable
 exit
 ip ospf apply redistribute direct vrf red
```

Redistribute IPv6 CLIP Management Instance to OSPF in VRF

```
router vrf red
 ipv6 ospf redistribute direct
 ipv6 ospf redistribute direct enable
 exit
 ipv6 ospf apply redistribute direct vrf red
```

Redistribute IPv4 CLIP Management Instance to BGP in GRT

```
router bgp
 redistribute direct
 redistribute direct enable
 ip bgp apply redistribute direct
```

Redistribute IPv6 CLIP Management Instance to BGP in GRT

```
router vrf
 redistribute ipv6-direct
 redistribute ipv6-direct enable
 ipv6 bgp apply redistribute direct
```

Redistribute IPv4 CLIP Management Instance to BGP in VRF

```
router vrf red
 ip bgp redistribute direct
 ip bgp redistribute direct enable
 exit
 ip bgp apply redistribute direct vrf red
```

Redistribute IPv6 CLIP Management Instance to BGP in VRF

```
router vrf red
 ip bgp redistribute ipv6-direct
 ip bgp redistribute ipv6-direct enable
 exit
 ipv6 bgp apply redistribute direct vrf red
```

Accept Policy for IPv4 CLIP Management Instance in GRT to VRF Red (I-SID 200)

```
#grt-->vrf
router vrf red
isis accept i-sid 0
isis accept i-sid 0 enable
isis redistribute direct
isis redistribute direct enable
exit
isis apply accept vrf red
isis apply redistribute direct vrf red

#vrf-->grt
router isis
accept i-sid 200
accept i-sid 200 enable
exit
isis apply accept
```

Accept Policy for IPv6 CLIP Management Instance in GRT to VRF Red (I-SID 200)

```
#grt-->vrf
router vrf red
ipv6 isis accept i-sid 0
ipv6 isis accept i-sid 0 enable
ipv6 isis redistribute direct
ipv6 isis redistribute direct enable
exit
ipv6 isis apply accept vrf red
ipv6 isis apply redistribute direct vrf red

#vrf-->grt
router isis
ipv6 accept i-sid 200
ipv6 accept i-sid 200 enable
exit
ipv6 isis apply accept
```

Accept Policy for IPv4 CLIP Management Instance in VRF Blue (I-SID 300) to GRT

```
#vrf --> grt
router isis
accept i-sid 300
accept i-sid 300 enable
redistribute direct
redistribute direct enable
exit
isis apply accept
isis apply redistribute direct

#grt --> vrf
router vrf blue
isis accept i-sid 0
isis accept i-sid 0 enable
exit
isis apply accept vrf blue
```

Accept Policy for IPv6 CLIP Management Instance in VRF Blue (I-SID 300) to GRT

```
#vrf --> grt
router isis
ipv6 accept i-sid 300
ipv6 accept i-sid 300 enable
```

```
ipv6 redistribute direct
ipv6 redistribute direct enable
exit
ipv6 isis apply accept
ipv6 isis apply redistribute direct

#grt --> vrf
router vrf blue
ipv6 isis accept i-sid 0
ipv6 isis accept i-sid 0 enable
exit
ipv6 isis apply accept vrf blue
```

Segmented Management Instance Configuration for VOSS using EDM

Note

This section does not apply to VSP 8600 Series.

This section provides procedures to configure segmented management instance using the EDM.

Migrate an IP Address to a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

In releases prior to VOSS release 8.1.60, perform this procedure to identify a pre-existing VLAN or loopback management interface to migrate to the Segmented Management Instance after you upgrade. This action moves the IP interface from the routing stack to the management stack to use with management applications. In releases later than VOSS 8.1.60, you can perform this procedure to migrate a new routing VLAN with a new IP address or a new loopback IP address under a different VRF to the Segmented Management Instance. Alternatively, you can also use the **convert** command.

Important

Choose a VLAN that does not have an IP interface on it. The upgrade process removes the IP configuration and network connectivity will be impacted.

About This Task

You cannot migrate interfaces used for routing purposes, for example, where you configure Layer 3 routing protocols.

This command does not apply to the OOB or mgmtEthernet interface. Releases that support this migration procedure automatically move the IP address on the mgmtEthernet interface from the routing stack to the Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Migrate** tab.

5. Select **Insert**.
6. Select the instance type, either **clip** or **vlan**.
7. Specify the existing VLAN or loopback ID.
8. Select **Insert**.

Migrate field descriptions

Use the data in the following table to use the **Migrate** tab.

Name	Description
InstanceId	Specifies the interface instance to migrate.
InterfaceIndex	Shows the interface index of the identified interface.
InterfaceType	Shows the interface type.
Description	Shows the interface description.
VlanId	Specifies the VLAN ID for a port-based VLAN.
LoopbackId	Specifies the loopback ID.
VrfName	Shows the VRF associated with the loopback interface.
IpAddress	Shows the IPv4 address to migrate.
IpMask	Shows the subnet mask for the IPv4 address.
Ipv6Address	Shows the IPv6 address to migrate.
Ipv6PrefixLength	Shows the prefix length for the IPv6 address.

Configure a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

You must create a Management Instance to gain access to specific management applications.

About This Task

The Management Instance supports different management interface types. When you create the Management Instance, you specify the interface type and the switch automatically creates the appropriate instance ID for that type.

In a Layer 2 routing deployment, use a management VLAN. In a Layer 3 routing or Fabric deployment, use a management CLIP. To separate management network from Layer 2 and Layer 3, use a management OOB.

Each Management Instance supports a IPv4 and IPv6 (global scope) management address for use by management applications.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Interface** tab.
5. Select **Insert**.
6. In the **Instanceld** field, select the type of Management Instance to create.
7. (Optional) For a CLIP Management Instance, in the **VrfName** field, type the VRF name to associate with the CLIP instance.

Note

If you want to associate the GRT with the CLIP instance, type **GlobalRouter** in the **VrfName** field. You cannot use `mgmtrouter` as the VRF.

8. For a VLAN Management Instance, in the **VlanId** field, type the VLAN ID to associate the management VLAN with an existing port-based VLAN.
9. For an OOB Management Instance, in the **OOBIndex** field, select the interface port number to associate for Out-of-Band management.
10. Select the **State** check box to enable the instance.
11. To specify the interface as the default topology IP for LLDP advertisements, select **InterfaceTopologyIpFlag**.
12. To administratively enable RMON for the interface, select **RmonAdminEnable**.
13. For a DvR Leaf node, in the **Isid** field, type the I-SID value to associate with the Management Instance VLAN.
14. Select **Insert**.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
Instanceld	Indicates the Management Instance type associated with this entry.
InterfaceType	Indicates the interface type.
VlanId	Specifies the VLAN ID to associate with the management VLAN.
OOBIndex	Specifies the interface ID to associate with the management OOB.
VrfName	Specifies the VRF name to associate with the management CLIP .
State	Indicates if the interface is enabled for this instance. The default is disabled.
InterfaceMacAddr	Indicates the MAC address for the interface.
InterfaceName	Indicates the interface name.
InterfaceTopologyIpFlag	Specifies if the interface is the default topology source IP.

Name	Description
ZtpOn	Identifies the Zero Touch Provisioning status for the interface.
RmonAdminEnable	Specifies if RMON is administrative enabled for the interface.
RmonOperEnable	Indicates the RMON operational status for the interface.
RmonIpAddress	Indicates the RMON IP address for the interface.
MacOffset	Translates the IP address into a MAC address.
DropIcmpFragEnable Note: Exception: Not supported on VSP 8600 Series and XA1400 Series.	Enables IPv4 Fragmented ICMP packet filtering on the Management Instance. The default is disabled.
DropIcmpv6FragEnable Note: Exception: Not supported on VSP 8600 Series and XA1400 Series.	Enables IPv6 Fragmented ICMP packet filtering on the Management Instance. The default is disabled.
Isid Note: Exception: Not supported on VSP 8600 Series.	Specifies the I-SID number that associated with the Management Instance VLAN for the DvR Leaf node. For non DvR node, the default I-SID value is 0 and this value cannot be edited.

Configure DHCP Client for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure a DHCP Client on a management interface.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Mgmt Instance**.
2. Select **Mgmt**.
3. Select the **Dhcp** tab.
4. In the **Client** field, select an option to configure the DHCP Client.
5. Select **Apply**.

Dhcp Field Descriptions

Use the data in the following table to use the **Dhcp** tab.

Name	Description
Client	Specifies the DHCP client configuration: <ul style="list-style-type: none"> • oob - DHCP Client on the Out-of-Band management interface. • vlan - DHCP Client on the VLAN management interface. • cycle - DHCP Client cycles between in-band and Out-of-Band management interfaces until an IP address is obtained on one management interface. • disable - DHCP Client is disabled.
ClientPreferredInterface	Shows the DHCP Client preferred management interface when in cycle mode. On reboot, the system first attempts to acquire a DHCP IP address on the preferred interface.

View IPv4 ARP Information for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv4 Address Resolution Protocol (ARP) information.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpArp** tab.

IpArp Field Descriptions

Use the data in the following table to use the **IpArp** tab.

Name	Description
Address	Shows the IPv4 address of the ARP entry.
Instance	Shows the Management Instance ID.
IntfName	Shows the Management Instance interface name for the ARP entry.
MacAddr	Shows the MAC address for the ARP entry.
State	Shows the state of the ARP entry. The state can be one of the following: <ul style="list-style-type: none"> • reachable • stale • permanent • failed • delay

View IPv6 ND Information for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv6 Neighbor Discovery (ND) information.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6Neighbor** tab.

Ipv6Neighbor Field Descriptions

Use the data in the following table to use the **Ipv6Neighbor** tab.

Name	Description
Addr	Shows the IPv6 address of the neighbor entry.
Instance	Shows the Management Instance ID.
IntfName	Shows the Management Instance interface name for the neighbor entry.
MacAddr	Shows the MAC address for the neighbor entry.
State	Shows the state of the neighbor entry. The state can be one of the following: <ul style="list-style-type: none"> • reachable • stale • permanent • failed • delay

Configure IPv4 Static Routes for a Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure IPv4 static routes for Management Instances.

About This Task

For the Management Instance CLIP, you do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the VRF. For more information about how to associate a VRF with the CLIP interface, see [Configure a Segmented Management Instance](#) on page 115.

For the Management Instance OOB and VLAN, you must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.

You can configure up to 100 IPv4 and IPv6 static routes.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpStaticRoute** tab.
5. Select **Insert**.
6. For the **Instance**, select the type of Management Instance interface.
7. Type the destination IP address and mask.
8. Type the next hop IP address.
9. Type a metric value.
10. Select **Insert**.

IpStaticRoute Field Descriptions

Use the data in the following table to use the **IpStaticRoute** tab.

Name	Description
Instance	Specifies the Management Instance.
DestAddr	Specifies the destination IP address.
DestMask	Specifies the destination mask.
NextHop	Specifies the next hop address for the static route. Use an IP address in the same subnet as the management VLAN IP address.
IntfName	Specifies the Management Instance interface name for the route entry.
Metric	Specifies the static route cost. The default is 200. The management CLIP uses an internal static route with a weight of 100. If you use both CLIP and VLAN and need to force all default traffic out the management VLAN interface, configure a default static route with a weight lower than 100.
State	Shows if the route is active or inactive.

Configure IPv6 Static Routes for a Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure IPv6 static routes for Management Instances.

About This Task

For the Management Instance CLIP, you do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the VRF. For more information about

how to associate a VRF with the CLIP interface, see [Configure a Segmented Management Instance](#) on page 115.

For the Management Instance OOB and VLAN, you must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.

You can configure up to 100 IPv4 and IPv6 static routes.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6StaticRoute** tab.
5. Select **Insert**.
6. For the **Instance**, select the type of Management Instance interface.
7. Type the destination IPv6 address and prefix length.
8. Type the next hop IPv6 address.
9. Type a metric value.
10. Select **Insert**.

Ipv6StaticRoute Field Descriptions

Use the data in the following table to use the **Ipv6StaticRoute** tab.

Name	Description
Instance	Specifies the Management Instance.
DestAddr	Specifies the destination IP address.
DestPrefixLen	Specifies the destination prefix length.
NextHop	Specifies the next hop address for the static route. Use an IP address in the same subnet as the management VLAN IP address.
IntfName	Specifies the Management Instance interface name for the route entry.
Metric	Specifies the static route cost. The default is 200. The management CLIP uses an internal static route with a weight of 100. If you use both CLIP and VLAN and need to force all default traffic out the management VLAN interface, configure a default static route with a weight lower than 100.
State	Shows if the route is active or inactive.

View IPv4 Operational Routes for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv4 operational routes.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpRoute** tab.

IpRoute Field Descriptions

Use the data in the following table to use the **IpRoute** tab.

Name	Description
DestAddr	Shows the destination address of the route entry.
DestMask	Shows the destination mask of the route entry.
Metric	Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 1.
Instance	Shows the Management Instance ID.
NextHop	Shows the next hop for the route entry.
IntfName	Shows the Management Instance interface name for the route entry.
Type	Shows the type of route entry.

View IPv6 Operational Routes for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv6 operational routes.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6Route** tab.

Ipv6Route Field Descriptions

Use the data in the following table to use the **Ipv6Route** tab.

Name	Description
DestAddr	Shows the destination address of the route entry.
PrefixLen	Shows the destination prefix length of the route entry.
Metric	Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 256.
Instance	Shows the Management Instance ID.
NextHop	Shows the next hop for the route entry.
IntfName	Shows the Management Instance interface name for the route entry.
Type	Shows the type of route entry.

View Topology IP for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view the default topology IP address for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **TopologyIp** tab.

TopologyIp Field Descriptions

Use the data in the following table to use the **TopologyIp** tab.

Name	Description
AddrType	Shows the IP address type for the topology IP.
Addr	Shows the IP address for the topology IP.
InterfaceName	Shows the interface name of the identified interface for the topology IP.
InstanceId	Specifies the interface instance for the topology IP.

Configure an IP Address for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure and view IPv4 address information for a Segmented Management Instance.

Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.
- If the DHCP client is configured for a Segmented Management Instance, you must manually disable the client. Configuring an IP address does not automatically disable the DHCP client.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpAddress** tab.
5. Select **Insert**.
6. Select the Segmented Management Instance interface type.
7. Type the address information.
8. Select **Insert**.

IpAddress Field Descriptions

Use the data in the following table to use the **IpAddress** tab.

Name	Description
Instanceld	Specifies the interface instance.
Address	Specifies IPv4 address for the interface instance. Ensure that the management CLIP IP address does not fall into the range of a configured VLAN IP address range as this is not allowed.
Mask	Specifies the subnet mask of the IP address.
AddrOrigin	Shows the IP address origin.
IntfName	Shows the interface name.

Configure an IPv6 Address for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure or view IPv6 address information for a Segmented Management Instance.

Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6Address** tab.
5. Select **Insert**.
6. Select the Segmented Management Instance interface type.
7. Type the address information.
8. Select **Insert**.

Ipv6Address Field Descriptions

Use the data in the following table to use the **Ipv6Address** tab.

Name	Description
InstanceId	Specifies the interface instance.
Address	Specifies the IPv6 address for the interface instance. Ensure that the management CLIP IP address does not fall into the range of a configured VLAN IP address range as this is not allowed.
PrefixLength	Specifies the prefix length for the IPv6 address.
AddrOrigin	Shows the IPv6 address origin.
IntfName	Shows the interface name.
DadStatus	Shows the IPv6 DAD status of the address.

View Segmented Management Instance Statistics

**Note**

This procedure does not apply to VSP 8600 Series.

View operational statistics for the Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Interface** tab.
5. Select a Management Instance by placing the cursor in a cell within the applicable row.
6. Select **Graph**.

Interface Counters Field Descriptions

Use the data in the following table to use the **Interface Counters** tab.

Name	Description
RxPkts	Counts the packets received on the Segmented Management Instance.
RxError	Counts the packets received with errors on the Segmented Management Instance.
RxDrop	Counts the packets received and dropped on the Segmented Management Instance.
TxPkts	Counts the packets transmitted on the Segmented Management Instance.
TxError	Counts the packets transmitted with errors on the Segmented Management Instance.
TxDrop	Counts the packets dropped before transmission on the Segmented Management Instance.

View IP Address Statistics for a Segmented Management Instance

**Note**

This procedure does not apply to VSP 8600 Series.

Use this task to view IP address statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

IP Field Descriptions

Use the data in the following table to use the **IP** tab.

Name	Description
InReceives	Shows the inbound packet statistics.
InHdrErrors	Shows the inbound packets with header errors statistics.
InAddrErrors	Shows the inbound packets with address errors statistics.
InUnknownProtos	Shows the inbound packets with unknown protocols statistics.

Name	Description
InDiscards	Shows the inbound packets discarded statistics.
InDelivers	Shows the inbound packets delivered statistics.
OutRequests	Shows the outbound packet requests statistics.
OutDiscards	Shows the outbound packets discarded statistics.
OutNotRoutes	Shows the outbound packets with no routes statistics.
ForwDatagrams	Shows the forwarded datagram packets statistics.
ReasmTimeout	Shows the packet reassembly timeouts statistics.
ReasmReqds	Shows the packet reassembly requests statistics.
ReasmOKs	Shows the successfully reassembled packets statistics.
ReasmFails	Shows the failed reassembled packets statistics.
FragOKs	Shows the successfully fragmented packets statistics.
FragFails	Shows the failed fragmented packets statistics.
FragCreates	Shows the fragments created statistics.

View IPv6 Address Statistics for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

Use this task to view IPv6 address statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IPv6** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

IPv6 Field Descriptions

Use the data in the following table to use the **IPv6** tab.

Name	Description
InReceives	Shows the inbound packet statistics.
InHdrErrors	Shows the inbound packets with header errors statistics.

Name	Description
InAddrErrors	Shows the inbound packets with address errors statistics.
InUnknownProtos	Shows the inbound packets with unknown protocols statistics.
InDiscards	Shows the inbound packets discarded statistics.
InDelivers	Shows the inbound packets delivered statistics.
InTooBigErrors	Shows the inbound packets too big errors statistics.
InNoRoutes	Shows the inbound packets with no routes statistics.
InTruncatedPkts	Shows the inbound packets truncated statistics.
InMcastPkts	Shows the inbound multicast packets statistics.
InOctets	Shows the inbound octets statistics.
InMcastOctets	Shows the inbound multicast octets statistics.
InBcastOctets	Shows the inbound broadcast octets statistics.
InNoECTPkts	Shows the inbound packets with no Explicit Congestion Notification (ECN) statistics.
InECT1Pkts	Shows the inbound packets with ECT(1) statistics.
InECT0Pkts	Shows the inbound packets with ECT(0) statistics.
InCEPkts	Shows the inbound packets with Congestion Encountered (CE) statistics.
OutRequests	Shows the outbound packet requests statistics.
OutDiscards	Shows the outbound packets discarded statistics.
OutNoRoutes	Shows the outbound packets with no routes statistics.
OutForwDatagrams	Shows the forwarded datagram packets statistics.
OutMcastPkts	Shows the outbound multicast packets statistics.
OutOctets	Shows the outbound octets statistics.
OutMcastOctets	Shows the outbound multicast octets statistics.
OutBcastOctets	Shows the outbound broadcast octets statistics.
ReasmTimeout	Shows the packet reassembly timeouts statistics.
ReasmReqds	Shows the packet reassembly requests statistics.
ReasmOKs	Shows the successfully reassembled packets statistics.
ReasmFails	Shows the failed reassembled packets statistics.
FragOKs	Shows the successfully fragmented packets statistics.
FragFails	Shows the failed fragmented packets statistics.
FragCreates	Shows the fragments created statistics.

View IP ICMP Statistics for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IP ICMP statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP-ICMP** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

IP-ICMP Field Descriptions

Use the data in the following table to use the **IP-ICMP** tab.

Name	Description
InMsgs	Shows the inbound messages statistics.
InErrors	Shows the inbound errors statistics.
InCsumErrors	Shows the inbound checksum errors statistics.
InDestUnreachs	Shows the inbound destination unreachable statistics.
InTimeExcds	Shows the inbound time exceeded statistics.
InParmProbs	Shows the inbound parameter problems statistics.
InSrcQuenchs	Shows the inbound source quenchs statistics.
InRedirects	Shows the inbound redirects statistics.
InEchos	Shows the inbound echos statistics.
InEchoReps	Shows the inbound echo replies statistics.
InTimestamps	Shows the inbound timestamps statistics.
InTimestampsReps	Shows the inbound timestamp replies statistics.
InAddrMasks	Shows the inbound address masks statistics.
InAddrMaskReps	Shows the inbound address mask replies statistics.
OutMsgs	Shows the outbound messages statistics.
OutErrors	Shows the outbound errors statistics.
OutDestUnreachs	Shows the outbound destination unreachable statistics.
OutTimeExcds	Shows the outbound time exceeded statistics.
OutParmProbs	Shows the outbound parameter problems statistics.

Name	Description
OutSrcQuenches	Shows the outbound source quenches statistics.
OutRedirects	Shows the outbound redirects statistics.
OutEchos	Shows the outbound echos statistics.
OutEchoReps	Shows the outbound echo replies statistics.
OutTimestamps	Shows the outbound timestamps statistics.
OutTimestampReps	Shows the outbound timestamps replies statistics.
OutAddrMasks	Shows the outbound address masks statistics.
MsgInType0	Shows the inbound Type0 messages statistics.
MsgOutType8	Shows the outbound Type8 messages statistics.

View IPv6 ICMP Statistics for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv6 ICMP statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IPv6-ICMP** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

IPv6-ICMP Field Descriptions

Use the data in the following table to use the **IPv6-ICMP** tab.

Name	Description
InMsgs	Shows the inbound messages statistics.
InErrors	Shows the inbound errors statistics.
InCsumErrors	Shows the inbound checksum errors statistics.
InDestUnreachs	Shows the inbound destination unreachable statistics.
InTimeExcds	Shows the inbound time exceeded statistics.
InParmProbs	Shows the inbound parameter problems statistics.
InPktTooBigs	Shows the inbound packets too big statistics.
InRedirects	Shows the inbound redirects statistics.
InEchos	Shows the inbound echos statistics.

Name	Description
InEchoReplies	Shows the inbound echo replies statistics.
InGroupMembQueries	Shows the inbound group member queries statistics.
InGroupMembResponses	Shows the inbound group member responses statistics.
InGroupMembReductions	Shows the inbound group member reductions statistics.
InRouterSolicits	Shows the inbound router solicits statistics.
InRouterAdvertisements	Shows the inbound router advertisements statistics.
InNeighborSolicits	Shows the inbound neighbor solicits statistics.
InNeighborAdvertisements	Shows the inbound neighbor advertisements statistics.
InMLDv2Reports	Shows the inbound MLDv2 reports statistics.
InType134	Shows the inbound type134 statistics.
InType136	Shows the inbound type136 statistics.
OutMsgs	Shows the outbound messages statistics.
OutErrors	Shows the outbound errors statistics.
OutDestUnreachs	Shows the outbound destination unreachable statistics.
OutTimeExcds	Shows the outbound time exceeded statistics.
OutParmProbs	Shows the outbound parameter problems statistics.
OutPktTooBigs	Shows the outbound packets too big statistics.
OutRedirects	Shows the outbound redirects statistics.
OutEchos	Shows the outbound echos statistics.
OutEchoReps	Shows the outbound echo replies statistics.
OutGroupMembQueries	Shows the outbound group member queries statistics.
OutGroupMembResponses	Shows the outbound group member responses statistics.
OutGroupMembReductions	Shows the outbound group member reductions statistics.
OutRouterStatistics	Shows the outbound router statistics
OutRouterAdvertisements	Shows the outbound router advertisements statistics.
OutNeighborSolicits	Shows the outbound neighbor solicits statistics.
OutNeighborAdvertisements	Shows the outbound neighbor advertisements statistics.
OutMLDv2Reports	Shows the outbound MLDv2 reports statistics.

Name	Description
OutType133	Shows the outbound Type133 statistics.
OutType135	Shows the outbound Type135 statistics.
OutType143	Shows the outbound Type143 statistics.

View UDP Statistics for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view UDP statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP/IPv6 UDP** tab.

IP/IPv6 UDP Field Descriptions

Use the data in the following table to use the **IP/IPv6 UDP** tab.

Name	Description
IPVersion	Shows the IP address version as ipv4 or ipv6.
InDatagrams	Shows the input datagram statistics.
NoPorts	Shows the number of ports statistics.
InErrors	Shows the input errors statistics.
OutDatagrams	Shows the output datagram statistics.
IgnoredMulti	Show the ignored multiport statistics.
RcvbufErrors	Shows the received buffer errors statistics.
SndbufErrors	Shows the send buffer errors statistics.
InCsumErrors	Shows the input checksum errors statistics.
Clear	Specifies to clear the statistics. Default is false.

View TCP Statistics for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view TCP statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP/IPv6 TCP** tab.

IP/IPv6 TCP Field Descriptions

Use the data in the following table to use the **IP/IPv6 TCP** tab.

Name	Description
IPVersion	Shows the IP address version as ipv4 or ipv6.
ActiveOpens	Shows the active open TCP connections statistics.
PassiveOpens	Shows the passive open TCP connections statistics.
AttemptFails	Shows the TCP connection attempt failures statistics.
EstabResets	Shows the TCP connection established resets statistics.
InSegs	Shows the input segments statistics.
OutSegs	Shows the output segments statistics.
RetransSegs	Shows the retransmit segments statistics.
InErrs	Shows the input checksum errors statistics.
OutRsts	Shows the output resets statistics.
InCsumErrors	Shows the input checksum errors statistics.
Clear	Specifies to clear the statistics. Default is false.

View TCP Connections and UDP Endpoints Statistics for a Segmented Management Instance

**Note**

This procedure does not apply to VSP 8600 Series.

Use this task to view TCP connections and UDP endpoints statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP/IPv6 Socket (TCP/UDP)** tab.

IP/IPv6 Socket (TCP/UDP) Field Descriptions

Use the data in the following table to use the **IP/IPv6 Socket (TCP/UDP)** tab.

Name	Description
IPVersion	Shows the IP address version as ipv4 or ipv6.
Type	Shows the connection type as tcp or udp.
Index	Shows the index ID for the connection.
State	Shows the link state for the connection.
RecvQ	Shows the connection received quantity.
SendQ	Shows the connection sent quantity.
LocalAddressAndPort	Shows the local IP address and port.
PeerAddressAndPort	Shows the peer IP address and port.

Segmented Management Instance Configuration for VSP 8600 Series using EDM

Note

This section only applies to VSP 8600 Series.

This section provides procedures to configure segmented management instance using the EDM.

Configure a Segmented Management Instance

Note

This procedure only applies to VSP 8600 Series.

You must create a Management Instance to gain access to specific management applications.

About This Task

The Management Instance supports different management interface types. When you create the Management Instance, you specify the interface type and the switch automatically creates the appropriate instance ID for that type.

In a Layer 3 routing or Fabric deployment, use a management CLIP.

Each Management Instance supports a single IPv4 and IPv6 (global scope) management address for use by management applications.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtInterface** tab.
4. Select **Insert**.
5. Select the type of Management Instance to create.

- (Optional) For a CLIP Management Instance, in the **VrfName** field, type the VRF name to associate with the CLIP instance.

**Note**

If you want to associate the GRT with the CLIP instance, type **GlobalRouter** in the **VrfName** field. You cannot use `mgmtrouter` as the VRF.

If you specify a non-default VRF, you must enable Layer 3 VSN to achieve IPv6 CLIP connectivity.

- Select the **State** check box to enable the instance.
- Select **Insert**.

MgmtInterface field descriptions

Use the data in the following table to use the **MgmtInterface** tab.

Name	Description
InstanceId	Shows a value that identifies the Management Instance type associated with this entry.
InterfaceType	Indicates the interface type.
VlanId	Specifies the ID of a port based VLAN to associate with a particular management IP instance, if the management VLAN interface is supported.
OoBIfIndex	Specifies the interface index of the OOB port to associate with a particular management IP instance, if the management OOB interface is supported.
VrfName	Specifies the VRF name to associate with the management CLIP .
State	Indicates if the interface is enabled for this instance. The default is disabled.
InterfaceMacAddr	Shows the MAC address for the interface.
InterfaceName	Shows the interface name.

Configure a Segmented Management Instance IP Address

**Note**

This procedure only applies to VSP 8600 Series.

After you create the Management Instance, you can add an IP address to it, and then configure route redistribution to advertise reachability of the Management Instance to the rest of the network.

Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.

Procedure

- In the navigation pane, expand **Configuration > Edit**.
- Select **Mgmt Instance**.

3. Select the **MgmtAddress** tab.

**Tip**

If you create the interface and assign an IP address during the same EDM session, you may need to select **Refresh** on the **MgmtAddress** tab before you see the new interface to configure.

4. To assign an IPv4 address:
 - a. Select the **IpAddress** field, and then type the IPv4 address value.
 - b. Select the **IpMask** field, and then type the IPv4 Mask value.
5. To assign an IPv6 address:
 - a. Select the **Ipv6Address** field, and then type the IPv6 address value.
 - b. Select the **Ipv6PrefixLength** field, and then type the IPv6 prefix value.
6. Select **Apply**.

MgmtAddress Field Descriptions

Use the data in the following table to use the **MgmtAddress** tab.

Name	Description
InstanceId	Shows a value that identifies the Management Instance type associated with this entry.
IpAddress	Specifies the IPv4 management address.
IpMask	Specifies the subnet mask of the IPv4 management address.
Ipv6Address	Specifies the IPv6 management address. Each Management Instance supports a single IPv6 management address for use by management applications.
Ipv6PrefixLength	Specifies the prefix length of the IPv6 management address. It is /128 for a loopback interface.
Ipv6LinkLocalAddr	Shows the automatically generated link local address.
InterfaceName	Shows the interface name.

View IPv4 Operational Routes for a Segmented Management Instance

**Note**

This procedure only applies to VSP 8600 Series.

Use this task to view IPv4 operational routes.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtIpRoute** tab.

MgmtIpRoute Field Descriptions

Use the data in the following table to use the **MgmtIpRoute** tab.

Name	Description
DestAddr	Shows the destination address of the route entry.
DestMask	Shows the destination mask of the route entry.
Metric	Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 256.
Instance	Shows the Management Instance ID.
NextHop	Shows the next hop for the route entry.
IntfName	Shows the Management Instance interface name for the route entry.
Type	Shows the type of route entry.

View IPv6 Operational Routes for a Segmented Management Instance

Note

This procedure only applies to VSP 8600 Series.

Use this task to view IPv6 operational routes.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtIpv6Route** tab.

MgmtIpv6Route Field Descriptions

Use the data in the following table to use the **MgmtIpv6Route** tab.

Name	Description
DestAddr	Shows the destination address of the route entry.
PrefixLen	Shows the destination prefix length of the route entry.
Metric	Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 256.
Instance	Shows the Management Instance ID.
NextHop	Shows the next hop for the route entry.

Name	Description
IntfName	Shows the Management Instance interface name for the route entry.
Type	Shows the type of route entry.

Migrate an IP Address to a Segmented Management Instance

Note

This procedure only applies to VSP 8600 Series.

Use this procedure to designate an existing VLAN or loopback IP address as a Segmented Management Instance. This action moves the IP interface from the VOSS routing stack to the management stack to use with management applications.

About This Task

You cannot migrate interfaces used for routing purposes, for example, where you configure Layer 3 routing protocols.

This command does not apply to the OOB or mgmtEthernet interface. Releases that support this migration procedure automatically move the IP address on the mgmtEthernet interface from the routing stack to the Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtMigrate** tab.
4. Select **Insert**.
5. Select the instance type, either **clip** or **vlan**.
6. Specify the existing VLAN or loopback ID.
7. Select **Insert**.

MgmtMigrate field descriptions

Use the data in the following table to use the **MgmtMigrate** tab.

Name	Description
Instanceld	Specifies the interface instance to migrate.
InterfaceIndex	Shows the interface index of the identified interface.
InterfaceType	Shows the interface type.
Description	Shows the interface description.
VlanId	Specifies the VLAN ID for a port-based VLAN.
LoopbackId	Specifies the loopback ID.

Name	Description
VrfName	Shows the VRF associated with the loopback interface.
IpAddress	Shows the IPv4 address to migrate.
IpMask	Shows the subnet mask for the IPv4 address.
Ipv6Address	Shows the IPv6 address to migrate.
Ipv6PrefixLength	Shows the prefix length for the IPv6 address.

View Segmented Management Instance Statistics

Note

This procedure only applies to VSP 8600 Series.

View operational statistics for the Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **Mgmt Instance** tab.
4. Select a Management Instance by placing the cursor in a cell within the applicable row.
5. Select **Graph**.

Interface Counters Field Descriptions

Use the data in the following table to use the **Interface Counters** tab.

Name	Description
RxPkts	Counts the packets received on the Segmented Management Instance.
RxError	Counts the packets received with errors on the Segmented Management Instance.
RxDrop	Counts the packets received and dropped on the Segmented Management Instance.
TxPkts	Counts the packets transmitted on the Segmented Management Instance.
TxError	Counts the packets transmitted with errors on the Segmented Management Instance.
TxDrop	Counts the packets dropped before transmission on the Segmented Management Instance.

Basic Administration

[Fundamentals](#) on page 140

[Basic Configuration](#) on page 162

[Verification](#) on page 188

[Basic Administration Procedures using CLI](#) on page 192

[Basic administration procedures using EDM](#) on page 208

[Boot parameter configuration using the CLI](#) on page 210

[Run-time process management using CLI](#) on page 225

[Hardware status using EDM](#) on page 233

The following topics provide instructions to perform basic configuration of, and administrative tasks for, the switch and software.

Examples and network illustrations may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

Fundamentals

This section includes the minimum, but essential, configuration steps to:

- provide a default, starting point configuration
- establish basic security on the node

For more information about hardware specifications and installation procedures, see the following documents:

advanced-feature-bandwidth-reservation Boot Flag

Table 14: Advanced Feature Bandwidth Reservation product support

Feature	Product	Release introduced
Advanced Feature Bandwidth Reservation Note: If your switch does not have this boot flag, it is because the hardware reserves the bandwidth automatically with no user interaction.	VSP 4450 Series	Not Supported
	VSP 4900 Series	Not Supported
	VSP 7200 Series	Not Supported
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	Not Supported
	VSP 8400 Series	Not Supported
	VSP 8600 Series	Not Supported
	XA1400 Series	VOSS 8.0.50 XA1480 only- demonstration feature

The switch enables the **boot config flags advanced-feature-bandwidth-reservation** command by default to use advanced features on the switch. If you disable the **boot config flags advanced-feature-bandwidth-reservation** command and attempt to enable an advanced feature, the switch displays an error message to explain why the advanced feature failed to start, and to remind you that you must enable this boot configuration flag for that advanced feature.

Important

If you change the configuration, you must save the configuration, and then reboot the switch for the change to take effect.

If you disable this feature and save the configuration, any configuration for advanced features remains saved in the configuration file but is not used.

VSP 7400 Series

By default, this boot configuration flag is enabled with the low level option.

When disabled, you can use all ports for Layer 2 or Layer 3 forwarding of standard unicast and multicast features. Use this mode if you are not configuring advanced features. The syntax for disabling this boot configuration flag is **no boot config flags advanced-feature-bandwidth-reservation**.

When enabled, also known as Full Feature mode, the switch supports advanced features by reassigning some of the front panel ports to be loopback ports. The following advanced features require loopback ports:

- Fabric Extend
- SPB
- SMLT
- vIST
- VXLAN Gateway
- Fabric RSPAN (Mirror to I-SID)

- Application Telemetry
- IS-IS Accept Policies
- Segmented Management Instance CLIP interface

**Note**

Full Feature mode does not support PIM.

The syntax for enabling the boot flag for this mode is: **boot config flags advanced-feature-bandwidth-reservation [low | high]**.

The *high* level parameter means that the switch reserves the maximum bandwidth for the advanced features.

The *low* level parameter means that the switch reserves less bandwidth to support minimum functionality for advanced features.

After the switch reserves the appropriate ports to become loopback ports, the ports are no longer visible in the output when you enter **show interfaces gigabitEthernet**.

**Important**

If you change the configuration, you must save the configuration, and then reboot the switch for the change to take effect.

If you disable this feature and save the configuration, any configuration for advanced features remains saved in the configuration file but is not used.

The following table lists the ports reserved as loopback ports:

Product	Reserved loopback ports
VSP 7432CQ	Low reserves ports 1/31 and 1/32. High reserves ports 1/29, 1/30, 1/31, and 1/32.
VSP 7400-48Y	Low reserves ports 1/55 and 1/56. High reserves ports 1/53, 1/54, 1/55, and 1/56

**Important**

You must ensure your configuration does not include reserved ports before you enable this feature. If the configuration includes reserved ports after you enable this feature and restart the switch, the switch stops loading the configuration.

XA1400 Series**Note**

Product Notice: This feature is available in demo mode only on XA1480 and supports low level parameter configuration automatically, which cannot be modified.

When disabled, all I-SID bindings are removed and the switch can only operate as a Backbone Core Bridge (BCB). The syntax for disabling this boot configuration flag is: **no boot config flags advanced-feature-bandwidth-reservation**.

When enabled, the switch reserves CPU cores for Backbone Edge Bridge (BEB) functionality. The syntax for enabling the boot flag for this mode is: **boot config flags advanced-feature-bandwidth-reservation low**.

spbm-config-mode boot flag

Table 15: spbm-config-mode product support

Feature	Product	Release introduced
spbm-config-mode (boot config flags spbm-config-mode)	VSP 4450 Series	VOSS 4.1
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0.1
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	Not Supported

Shortest Path Bridging (SPB) and Protocol Independent Multicast (PIM) cannot interoperate with each other on the switch at the same time. To ensure that SPB and PIM stay mutually exclusive, the software uses a boot flag called **boot config flags spbm-config-mode**.

- The **boot config flags spbm-config-mode** flag is enabled by default. This enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface.
- If you disable the boot flag, save the configuration, and then reboot with the saved configuration. When the flag is disabled, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

Important

After you change the **boot config flags spbm-config-mode** flag, you must save the configuration, and then reboot the switch for the change to take effect.

For more information about this boot flag and Simplified vIST, see [IP Multicast](#) on page 1456.

nni-mstp boot config flag

Table 16: nni-mstp boot flag product support

Feature	Product	Release introduced
nni-mstp boot flag (boot config flags nni-mstp)	VSP 4450 Series	VOSS 6.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 6.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.0
	VSP 8400 Series	VOSS 6.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

The nni-mstp boot flag changes the default behavior of the MSTP on SPBM NNI ports. The Common and Internal Spanning Tree (CIST) is disabled automatically on the NNI, and the NNI ports can only be members of backbone VLANs (B-VLAN).

- During startup, if you have non-B-VLAN on SPBM NNI ports in your configuration file, the system sets the nni-mstp flag to true (if it was not already set to true) and enables MTSP on SPBM NNI ports, and all other configurations remain the same. Save your configuration file. If you do not save your configuration, you continue to see the following message on reboot:

Warning

Detected brouter and/or vlans other than BVLANS on NNI ports. Setting the boot config flag nni-mstp to true. Saving configuration avoids repetition of this warning on reboot.

Note

When the nni-mstp flag is set to true, only MSTI 62 is disabled on the SPBM NNI ports. You can add the SPBM NNI ports to any VLAN.

- If you configure the nni-mstp boot configuration flag to false (default), the system checks to make sure that the SPBM NNI ports do not have brouter (IPv4 or IPv6) or non-SPBM VLANs configured. The nni-mstp flag is then set to false. Save your configuration file, and reboot the switch for the configuration change to take effect.

Note

Ensure that all SPBM NNI ports in non-B-VLAN are removed prior to setting the nni-mstp flag to false.

Example: Configuring nni-mstp to true

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags nni-mstp
Warning: Please save the configuration and reboot the switch for this configuration to
take effect.
Switch:1(config)#
```

System Connections

Connect the serial console interface (an RJ-45 jack) to a PC or terminal to monitor and configure the switch. The port uses a RJ-45 connector that operates as data terminal equipment (DTE). Some switches also provide a USB port or micro USB port for serial console interface connectivity. See your hardware documentation for available ports.

The default communication protocol settings for the console port are:

- Baud rate:
 - VSP 4450 Series — 9600
 - VSP 4900 Series — 115200
 - VSP 7200 Series — 9600
 - VSP 7400 Series — 115200
 - VSP 8200 Series — 9600
 - VSP 8400 Series — 9600
 - VSP 8600 Series — 115200
 - XA1400 Series — 115200
- 8 data bits
- 1 stop bit
- No parity
- No flow control.

To use the console port, you need a terminal or teletypewriter (TTY)-compatible terminal, or a portable computer with a serial port and terminal-emulation software.

Depending on the hardware platform, the console port can display as console port or 10101.

Boot Sequence

Table 17: Linux kernel version product support

Feature	Product	Release introduced
Important: For VSP 4450 Series, VSP 7200 Series, VSP 8200, and VSP 8400 Series, kernel version 4.9 has special upgrade considerations the first time you upgrade to a release that supports it. You must first upgrade to a stepping-stone release, 6.1.x , before you upgrade to the release with the new kernel.	VSP 4450 Series	4.9 as of VOSS 7.0
	VSP 4900 Series	5.4 as of VOSS 8.6
	VSP 7200 Series	4.9 as of VOSS 7.0
	VSP 7400 Series	5.4 as of VOSS 8.6
	VSP 8200 Series	4.9 as of VOSS 7.0
	VSP 8400 Series	4.9 as of VOSS 7.0
	VSP 8600 Series	4.9 as of VSP 8600 8.0
	XA1400 Series	5.4 as of VOSS 8.6

The switch goes through a boot sequence before it becomes fully operational. After you turn on power to the switch, the system starts.

The boot sequence consists of the following stages:

- [Loading Linux](#) on page 146
- [Loading the Primary Release](#) on page 147
- [Deploying Zero Touch](#) on page 147 or [Loading the Configuration File](#) on page 147

The following figure shows a summary of the boot sequence.

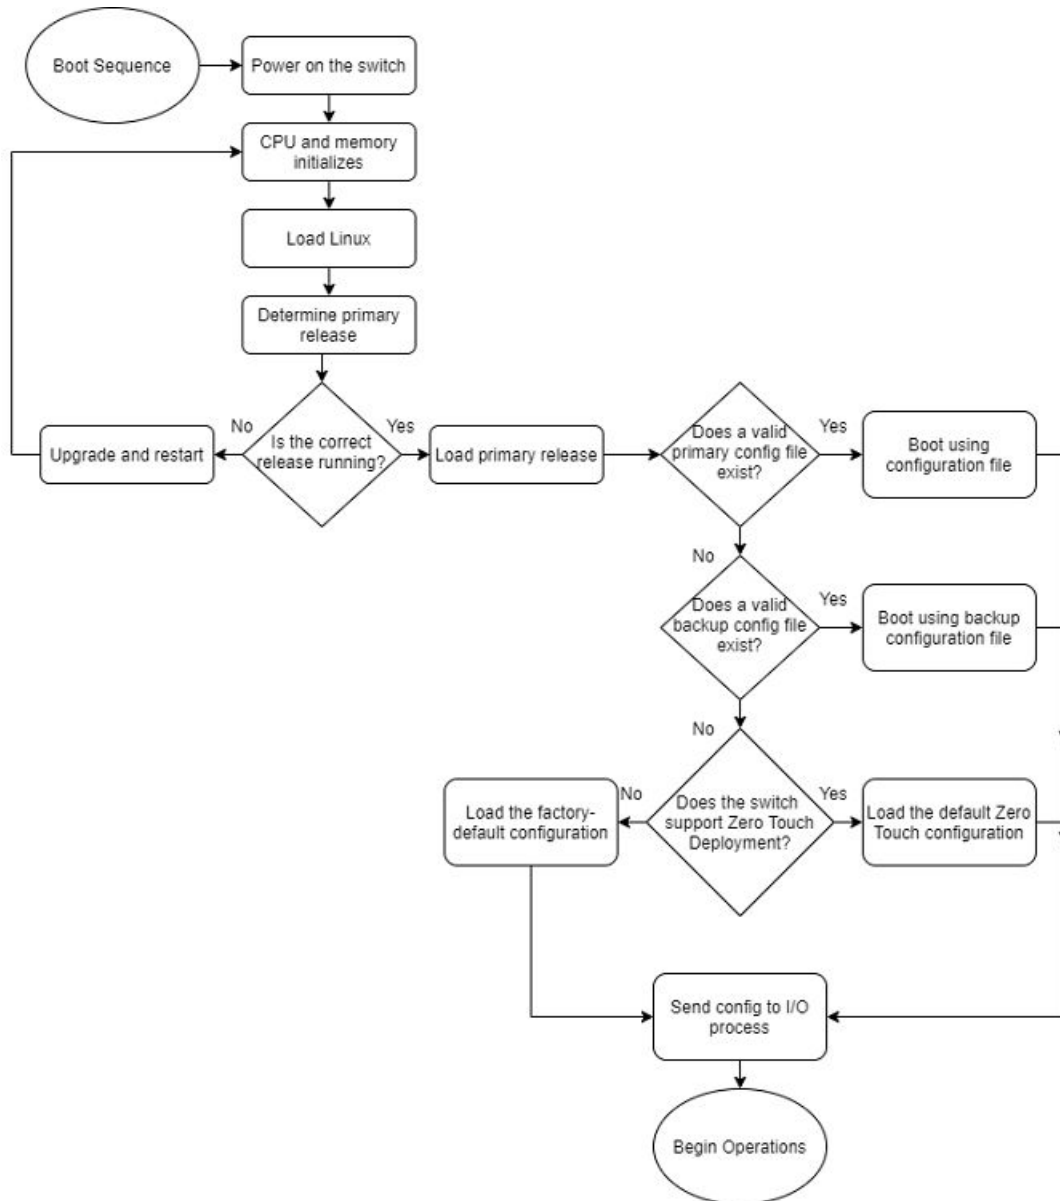

Figure 9: Boot Sequence

Loading Linux

Depending on the Linux kernel used, the boot image is stored either in a boot flash partition, Secure Digital (SD), or Solid State Drive (SSD) flash card. The boot image includes the boot loader, and the Linux kernel and applications.

The boot location contains two versions of the boot image: a committed version (the primary release) and a backup version. A committed version is one that is marked as good (if you can start the system using that version). The system automatically uses the backup version if the system fails the first time you start with a new version.

Loading the Primary Release

The switch can install a maximum of six releases but can only load one of two—a primary (committed) release or a backup release.

The system saves software image files to the `/intflash/release/` directory.

After loading the primary release, the CPU and basic system devices, such as the console port, initializes. Depending on the hardware platform, the console port displays as console or 10101. At this stage, the I/O ports are not available; the system does not initialize the I/O ports until the port sends configuration data.

Deploying Zero Touch

Important

Zero Touch Deployment does not function if primary or secondary configuration files exist.

After the system loads the primary release and the switch is in a Zero Touch Deployment-ready configuration mode, the switch automatically deploys without intervention.

For more information, see [Zero Touch Deployment](#) on page 56.

Loading the Configuration File

After the system loads the primary release, it identifies the location and file name of the primary configuration file. You can save this file in internal flash.

If the primary configuration file does not exist, the system looks for the backup configuration file, as identified by `version.cfg`. If this file does not exist, the system initiates Zero Touch functionality on the switch that enables Zero Touch Fabric Configuration. For more information, see [Zero Touch Fabric Configuration](#) on page 61.

Note

Exception: for VSP 8600 Series and XA1400 Series, if the configuration file does not exist, the system loads the factory-default configuration, which is the equivalent of using the **boot config flags factorydefaults** command.

The switch configuration consists of higher-level functionality, including:

- Chassis configuration
- Port configuration
- Virtual LAN (VLAN) configuration
- Routing configuration
- IP address assignments
- Remote monitoring (RMON) configuration

The default switch configuration in Zero Touch Fabric Configuration mode includes the following:

- Shortest Path Bridging MAC (SPBM) instance is created.
- Intermediate System-to-Intermediate System (IS-IS) is enabled.
- All ports are enabled and operating in Auto-sense mode.
- The switch issues DHCP requests on the out-of-band (OOB) management port and the management VLAN.

The default switch configuration in factory default mode includes the following:

- A single, port-based default VLAN with a VLAN identification number of 1
- No interface assigned IP addresses
- Traffic priority for all ports configured to normal priority
- All ports as untagged ports
- Default communication protocol settings for the console port. For more information about these protocol settings, see [System Connections](#) on page 145.

Configuration File Statements

In the configuration file, statements preceded by both the number sign (#) and exclamation point (!) load prior to the general configuration parameters. Statements preceded by only the number sign are comments meant to add clarity to the configuration; they do not load configuration parameters. The following table illustrates the difference between these two statement formats.

Table 18: Configuration file statements

Sample statement	Action
# software version : 8.6.0.0	Adds clarity to the configuration by identifying the software version.
#!no boot config flags sshd	Configures the flag to the false condition, prior to loading the general configuration.

Boot Sequence Modification

You can change the boot sequence in the following ways:

- Change the primary designations for file sources.
- Change the file names from the default values. You can store several versions of the configuration file and specify a particular one by file name. The specified configuration file only gets loaded when the chassis starts. To load a new configuration file, you need to restart the system.
- Start the system without loading an existing configuration file so that the system uses the factory default configuration. You can do this by running the **boot config flags factorydefaults** command.

The factorydefaults boot flag removes the runtime, primary, and backup configuration files, resets all local default user account passwords, and removes all digital certificates. The Radsec, IPsec, IKE, OSPF, SNMP, SSL, SSH, OVSDb, and NTP files are also removed. The CLI displays a warning that the configurations, passwords, and files will be reset, and the system logs an informational message. The configuration and file removals occur during the next boot sequence when the factorydefaults boot

flag is enabled. After the switch reboots, the security mode setting is retained. To enable Zero Touch Onboarding after a factorydefaults boot, reboot the switch again without saving a configuration.

- Start the system in Zero Touch Deployment mode, which includes Zero Touch Fabric Configuration. For more information, see [Zero Touch Deployment](#) on page 56.

Runtime

After the switch is operational, you can use the runtime commands to perform configuration and management functions necessary to manage the system. These functions include the following

- Resetting or restarting the switch
- Adding, deleting, and displaying address resolution protocol (ARP) table entries
- Pinging another network device
- Viewing and configuring variables for the entire system and for individual ports
- Configuring and displaying MultiLink Trunking (MLT) parameters
- Creating and managing port-based VLANs or policy-based VLANs

To access the runtime environment you need a connection from a PC or terminal to the switch. You can use a direct connection to the switch through the console port or remotely through Telnet, rlogin, or Secure Shell (SSH) sessions.

Note

rlogin is only supported on VSP 8600 Series.

Important

Before you attempt to access the switch using one of the preceding methods, ensure you first enable the corresponding daemon flags.

System logon

After the platform boot sequence is complete, the system opens the logon prompt. The following table shows the default values for logon and password for console and Telnet sessions.

Note

With enhanced secure mode enabled, the person in the role-based authentication level of administrator configures the login and password values for the other role-based authentication levels. The administrator initially logs on to the switch using the default login of `admin` and the default password of `admin`. After the initial login, the switch prompts the administrator to create a new password.

Table 19: Access levels and default logon values

Access level	Description	Default logon	Default password
Read-only	Permits view-only configuration and status information. Is equivalent to Simple Network Management Protocol (SNMP) read-only community access.	ro	ro
Layer 1 read/write	View most switch configuration and status information and change physical port settings.	l1	l1
Layer 2 read/write	View and change configuration and status information for Layer 2 (bridging and switching) functions.	l2	l2
Layer 3 read/write	View and change configuration and status information for Layer 2 and Layer 3 (routing) functions.	l3	l3
Read/write	View and change configuration and status information across the switch. You cannot change security and password settings. This access level is equivalent to SNMP read/write community access.	rw	rw
Read/write/all	Permits all the rights of read/write access and the ability to change security settings, including CLI and web-based management user names and passwords and the SNMP community strings.	rwa	rwa

System flags

After you enable or disable certain modes and functions, you need to save the configuration and restart the switch for your change to take effect. This section lists parameters and indicates if they require a switch restart.

The following table lists parameters you configure in the CLI using the **boot config flags** command. For information on system flags and their configuration, see [Configure Boot Flags](#) on page 212.

**Note**

Flag support can vary across hardware models.

Table 20: Boot config flags

CLI flag	Restart
<i>advanced-feature-bandwidth-reservation</i>	Yes
Note: Exception: Only supported on VSP 7400 Series and XA1480.	
<i>block-snmp</i>	No
<i>debug-config</i>	Yes
<i>debugmode</i>	Yes
<i>dvr-leaf-mode</i>	No
Note: The switch does not require a restart when you enable the dvr-leaf-mode flag, as long as there is no unsupported configuration on the switch.	
<i>enhancedsecure-mode</i>	Yes
<i>factorydefaults</i>	Yes
<i>flow-control-mode</i>	Yes
Note: Exception: Not supported on VSP 8600 Series.	
<i>ftpd</i>	No
<i>ha-cpu</i>	Yes, the standby CPU restarts automatically. Modifying this flag does not require a system restart.
Note: Exception: Only supported on VSP 8600 Series.	
<i>hsecure</i>	Yes
<i>linate-directed-broadcast</i>	Yes
Note: Exception: Only supported on VSP 4450 Series.	
<i>ipv6-egress-filter</i>	Yes
Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	

Table 20: Boot config flags (continued)

CLI flag	Restart
<i>ipv6-mode</i> Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Yes
<i>logging</i>	No
<i>nmi-mstp</i> Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	Yes
<i>reboot</i>	No
<i>rlogind</i> Note: Exception: Only supported on VSP 8600 Series.	No
<i>savetostandby</i> Exception: Only supported on VSP 8600 Series.	No
<i>spanning-tree-mode</i>	Yes
<i>spbm-config-mode</i>	Yes
<i>sshd</i>	No
<i>telnetd</i>	No
<i>tftpd</i>	No
<i>trace-logging</i>	No
<i>urpf-mode</i> Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	Yes
<i>verify-config</i>	Yes
<i>vrf-scaling</i>	Yes
<i>vxlan-gw-full-interworking-mode</i> Exception: Only supported on VSP 7200 Series, VSP 7400 Series , VSP 8200 Series, and VSP 8400 Series.	Yes

Secure and Nonsecure Protocols

The following table describes the secure and nonsecure protocols that the switch supports.

Table 21: Secure and nonsecure protocols for IPv4 and IPv6

Nonsecure protocols	Default status	Equivalent secure protocols	Default status
FTP and Trivial FTP	Disabled	Secure Copy (SCP) and Secure File Transfer Protocol (SFTP)	Disabled
<p>Note: File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.</p>			
Telnet	Disabled	Secure Shell version 2 (SSHv2)	Disabled
SNMPv1, SNMPv2	Enabled	SNMPv3	Enabled
rlogin	Disabled	SSHv2	Disabled
<p>Note: Exception: only supported only on VSP 8600 Series.</p>			
HTTP	Disabled	HTTPS Important: Take the appropriate security precautions within the network if you use HTTP. You must use the web-server enable command in CLI before you can access EDM.	Enabled

Client and Server Support

Table 22: Client and Server product support

Feature	Product	Release introduced	Release deprecated
File Transfer Protocol (FTP) server and client (IPv4)	VSP 4450 Series	VSP 4000 4.0	Not Applicable
	VSP 4900 Series	VOSS 8.1	Not Applicable
	VSP 7200 Series	VOSS 4.2.1	Not Applicable

	VSP 8600 Series	VSP 8600 6.1
	XA1400 Series	VOSS 8.1

The client-server model partitions tasks between servers that provide a service and clients that request a service.

For active CLI clients, users initiate a client connection from the switch to another device.

Note

Both FTP and TFTP clients are supported by the switch. The switch does not launch FTP and TFTP clients explicitly as a separate command; you can launch them through the CLI **copy** command. If you have configured the username through the **boot config host** command, the FTP client is used to transfer files to and from the switch using the CLI **copy** command; If you have not configured the username, the TFTP client is used to transfer files to and from the switch using the CLI **copy** command.

Configuring the `boot config flags ftpd` or `boot config flags tftpd` enables the FTP or TFTP Servers on the switch.

For non-active clients, the client exists on the switch and the switch console initiates the request, with no intervention from users after the initial setup. For instance, Network Time Protocol (NTP) is a non active client. The switch initiates the client request to the central server to obtain the up-to-date time.

Password encryption

The platform stores passwords in encrypted format and not in the configuration file.

Important

For security reasons, configure the passwords to values other than the factory defaults.

Enterprise Device Manager

The switch includes Enterprise Device Manager (EDM), an embedded graphical user interface (GUI) that you can use to manage and monitor the platform through web-based access without additional installations.

For more information about EDM, see [Enterprise Device Manager](#) on page 261.

Enterprise Device Manager access

To access EDM, enter one of the following addresses in your web browser:

- `http://<A.B.C.D>`
- `https://<A.B.C.D>`

Where <A.B.C.D> is the device IP address.

Ensure you use a supported browser version. For more information about supported browsers, see [Supported Browsers](#) on page 262.

Important

- You must enable the web server from CLI to enable HTTP access to the EDM. If you want HTTP access to the device, you must also disable the web server secure-only option. The web server secure-only option, allowing for HTTPS access to the device, is enabled by default. Take the appropriate security precautions within the network if you use HTTP.
- EDM access is available to read-write users only.

If you experience any issues while connecting to the EDM, check the proxy settings. Proxy settings may affect EDM connectivity to the switch. Clear the browser cache and do not use proxy when connecting to the device. This should resolve the issue.

Default user name and password

The following table contains the default user name and password that you can use to log on to the switch using EDM. For more information about changing the passwords, see [Change Passwords](#) on page 3060.

Table 24: EDM default username and password

Username	Password
admin	password

Important

The default passwords and community strings are documented and well known. As a best practice, change the default passwords and community strings immediately after you first log on. For more information about changing user names and passwords, see [Change Passwords](#) on page 3060.

TLS server for secure HTTPS

Table 25: TLS server for secure HTTPS product support

Feature	Product	Release introduced
Note: VOSS Releases 6.0 and 6.0.1 do not support this feature.	VSP 4450 Series	VOSS 5.1.2
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.1.2
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.1.2
	VSP 8400 Series	VOSS 5.1.2
	VSP 8600 Series	VSP 8600 6.1
	XA1400 Series	VOSS 8.0.50

This feature enhances communications security by implementing Mocana NanoSSL to secure HTTPS server using Transport Layer Security (TLS) cryptographic protocol.

The following are the key properties of Secure web server with TLS:

- This feature can be implemented on a maximum of only 10 concurrent client connections.
- The switch supports version TLS 1.2 and above by default. You can explicitly configure TLS 1.0 and TLS 1.1 version support using CLI or EDM.
- This feature replaces SSL 3.0 with TLS. SSL 3.0 is not supported.

- TLS server does not support RC4, DES, TDES, and MD5 based cipher suites.
- The minimum password length for the web server is 8 characters, by default. You can change this using CLI or EDM.

For information about the certificate order priority when the Transport Layer Security (TLS) server and switch connect, see [Certificate Order Priority](#) on page 3007.

IP Address for the Management Port

At startup, the system loads the runtime configuration file, which is stored in the internal flash of the CPU. If the file is present, the system assigns the IP address for the management port from that file.

You can configure an IP address for the management port if one is not in the configuration file. For more information, see [Configure an IP Address for the Management Port](#) on page 545. This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management](#) on page 67.

Basic Configuration

Connect a Terminal

Before You Begin

- To use the console port, you need the following equipment:
 - A terminal or Teletypewriter (TTY)-compatible terminal, or a portable computer with a serial port and terminal-emulation software.
 - A specific cable with an RJ-45 or USB connector for the console port on the switch. The other end of the cable must use a connector appropriate to the serial port on the computer or terminal.
- To comply with emissions regulations and requirements, you must shield the cable that connects to the console port.

Note

If you are using the VSP 4900 Series USB console port with a terminal running Windows 10, you must install the CP210x USB to UART Bridge Virtual COM Port (VCP) driver from Silicon Labs before you connect to the terminal.

About This Task

Connect a terminal to the serial console interface to monitor and configure the system directly.

Procedure

1. Configure the terminal protocol as follows:
 - 9600 baud or 115200 baud, depending on the hardware platform.
 - 8 data bits
 - 1 stop bit
 - No parity
 - No flow control

2. Connect the RJ-45 or USB cable to the console port on the switch.
3. Connect the other end of the cable to the terminal or computer serial port.
4. Turn on the terminal.
5. Log on to the switch.

Changing passwords

Configure new passwords for each access level, or change the logon or password for the different access levels of the switch. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change encrypted passwords.

If you enable the `hsecure` flag, after the aging time expires, the system prompts you to change your password. If you do not configure the aging time, the default is 90 days.

If you enable enhanced secure mode with the `boot config flags enhancedsecure-mode` command, you enable new access levels, along with stronger password complexity, length, and minimum change intervals. For more information on system access fundamentals and configuration, see [System access fundamentals](#) on page 3311.

Before You Begin

- You must use an account with read-write-all privileges to change passwords. For security, the switch saves passwords to a hidden file.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Change a password:
`cli password WORD<1-20> {layer1|layer2|layer3|read-only|read-write|read-write-all}`
3. Enter the old password.
4. Enter the new password.
5. Re-enter the new password.
6. Configure password options:
`password [access-level WORD<2-8>] [aging-time day <1-365>] [default-lockout-time <60-65000>] [lockout WORD<0-46> time <60-65000>] [min-passwd-len <10-20>] [password-history <3-32>]`

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Change a password:
```

```
Switch:1(config)# cli password rwa read-write-all
```

Enter the old password: ***

Enter the new password: ***

Re-enter the new password: ***

Set password to an access level of read-write-all and the expiration period for the password to 60 days:

```
Switch:1(config)#password access-level rwa aging-time 60
```

Variable Definitions

Use the data in the following table to use the **cli password** command.

Variable	Value
<i>layer1 layer2 layer3 read-only read-write read-write-all</i>	Changes the password for the specific access level.
<i>WORD<1-20></i>	Specifies the user logon name.

Use the data in the following table to use the **password** command.

Variable	Value
<i>access-level WORD<2-8></i>	Permits or blocks this access level. The available access level values are as follows: <ul style="list-style-type: none"> • layer1 • layer2 • layer3 • read-only • read-write • read-write-all
<i>aging-time day <1-365></i>	Configures the expiration period for passwords in days, from 1-365. The default is 90 days.
<i>default-lockout-time <60-65000></i>	Changes the default lockout time after three invalid attempts. Configures the lockout time, in seconds, and is in the 60-65000 range. The default is 60 seconds. To configure this option to the default value, use the default operator with the command.
<i>lockout WORD<0-46> time <60-65000></i>	Configures the host lockout time. <ul style="list-style-type: none"> • <i>WORD<0-46></i> is the host IPv4 or IPv6 address. • <i><60-65000></i> is the lockout-out time, in seconds, in the 60-65000 range. The default is 60 seconds.

Variable	Value
<code>min-passwd-len <10-20></code>	Configures the minimum length for passwords in high-secure mode. The default is 10 characters. To configure this option to the default value, use the default operator with the command.
<code>password-history <3-32></code>	Specifies the number of previous passwords the switch stores. You cannot reuse a password that is stored in the password history. The default is 3. To configure this option to the default value, use the default operator with the command.

Configuring system identification

Configure system identification to specify the system name, contact person, and location of the switch.

Procedure

1. Log on as rwa.
2. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
3. Change the system name:

```
sys name WORD<0-255>
```
4. Configure the system contact:

```
snmp-server contact WORD<0-255>
```
5. Configure the system location:

```
snmp-server location WORD<0-255>
```

Example

Change the system name, configure the system contact, and configure the system location:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys name Floor3Lab2
Floor3Lab2:1(config)#snmp-server contact http://companyname.com
Floor3Lab2:1(config)#snmp-server location "12 Street, City, State, Zip"
```

Variable Definitions

Use the data in the following table to use the system-level commands.

Variable	Value
<code>contact WORD<0-255></code>	Identifies the contact person who manages the node. To include blank spaces in the contact, use quotation marks (") around the text.
<code>location WORD<0-255></code>	Identifies the physical location of the node. To include blank spaces in the location, use quotation marks (") around the text.
<code>name WORD<0-255></code>	Configures the system or root level prompt name for the switch. <code>WORD<0-255></code> is an ASCII string from 1-255 characters (for example, LabSC7 or Closet4).

Configuring the CLI Banner

Configure the logon banner to display a message to users before authentication and configure a system login message-of-the-day in the form of a text banner that displays after each successful logon.

About This Task

You can use the custom logon banner to display company information, such as company name and contact information. For security, you can change the default logon banner of the switch, which contains specific system information, including platform type and software release.

Use the custom message-of-the-day to update users on a configuration change, a system update or maintenance schedule. For security purposes, you can also create a message-of-the-day with a warning message to users that, "Unauthorized access to the system is forbidden."

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the switch to use a custom banner or use the default banner:

```
banner <custom|static>
```

3. Create a custom banner:

```
banner WORD<1-80>
```

Note

To enter multiple lines for a message, use the **banner** command before each new line of the message. To provide a string with spaces, include the text in quotation marks.

4. Create the message-of-the-day:

```
banner motd WORD<1-1516>
```

Note

To enter multiple lines for a message, use the **banner motd** command before each new line of the message. To provide a string with spaces, include the text in quotation marks.

5. Enable the custom message-of-the-day:

```
banner displaymotd
```
6. Save the configuration:

```
save config
```
7. Display the banner information:

```
show banner
```
8. Logon again to verify the configuration.
9. (Optional) Disable the banner:

```
no banner [displaymotd] [motd]
```

Example

Configure the custom banner to “Company, www.Companyname.com.” and configure the message of the day to “Unauthorized access to this system is forbidden. Please logout now.”

```
Switch:1> enable
Switch:1#configure terminal
Switch:1(config)# banner custom
Switch:1(config)# banner Company
Switch:1(config)# banner www.Companyname.com
Switch:1(config)# banner motd "Unauthorized access to this system is forbidden"
Switch:1(config)# banner motd "Please logout now"
Switch:1(config)#banner displaymotd
Switch:1(config)#show banner
Company
www.company.com
                defaultbanner : false
                custom banner :

                displaymotd : true
                custom motd :
Unauthorized access to this system is forbidden
Please logout now
```

Variable definitions

Use the data in the following table to use the **banner** command.

Variable	Value
<i>custom</i>	Disables the use of the default banner.
<i>static</i>	Activates the use of the default banner.
<i>WORD <1-80></i>	Adds lines of text to the CLI logon banner.
<i>motd WORD<1-1516></i>	Create the message of the day. To provide a string with spaces, include the text in quotation marks (“”).
<i>displaymotd</i>	Enable the custom message of the day.

Configure the Date

Configure the calendar time in the form of month, day, year, hour, minute, and second.

About This Task

Log on as rwa to perform this procedure.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Configure the date:

```
clock set <MMddyyyyhhmmss>
```
3. Verify the configuration:

```
show clock
```

Example

Configure the date and time, and then verify the configuration.

```
Switch:1>enable
Switch:1#clock set 19042014063030
Switch:1#show clock
Wed Mar 19 06:30:32 2014 EDT
```

Variable Definitions

Use the data in the following table to use the **clock set** command.

Variable	Value
<i>MMddyyyyhhmmss</i>	Specifies the date and time in the format month, day, year, hour, minute, and second.

Enable Remote Access Services

Before You Begin

- When you enable the rlogin flag, you must configure an access policy to specify the user name of who can access the switch. For more information about the access policy commands, see [Access Policies for Services](#) on page 2995.

Note

Rlogin is only supported on VSP 8600 Series.

About This Task

Enable the remote access service to provide multiple methods of remote access.

File Transfer Protocol (FTP), Trivial File Transfer Protocol (TFTP) and Telnet server support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable the access service:

```
boot config flags {ftpd | rlogind | sshd | telnetd | tftpd}
```
3. Repeat as necessary to activate the desired services.
4. Save the configuration.

Example

Enable the access service for Telnet:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags telnetd
```

Variable Definitions

The following table defines parameters for the **boot config flags** command.

Variable	Value
<p><i>advanced-feature-bandwidth-reservation [low high]</i></p> <p>Note: Exception: only supported on VSP 7400 Series and XA1480.</p>	<p>Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work. The default is enabled with low level.</p> <ul style="list-style-type: none"> • The high level means that the switch reserves the maximum bandwidth for the advanced features. • The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features. <p>If you change this parameter, you must restart the switch.</p>
<i>block-snmp</i>	Activates or disables Simple Network Management Protocol management. The default value is false (disabled), which permits SNMP access.

Variable	Value
<i>debug-config [console] [file]</i>	<p>Enables you to debug the configuration file during loading configuration at system boot up. The default is disabled. You do not have to restart the switch after you enable debug-config, unless you want to immediately debug the configuration. After you enable debug-config and save the configuration, the debug output either displays on the console or logs to an output file the next time the switch reboots.</p> <p>The options are:</p> <ul style="list-style-type: none"> • debug-config [console]—Displays the line-by-line configuration file processing and result of the execution on the console while the device loads the configuration file. • debug-config [file]— Logs the line-by-line configuration file processing and result of the execution to the debug file while the device loads the configuration file. The system logs the debug config output to /intflash/debugconfig_primary.txt for the primary configuration file. The system logs the debug config output to /intflash/debugconfig_backup.txt for the backup configuration, if the backup configuration file loads.
<i>debugmode</i>	<p>Enables a TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. Works on console connection only. The default is disabled.</p> <p>Important: Do not change this parameter unless directed by technical support.</p>
<i>dvr-leaf-mode</i>	<p>Enables an SPB node to be configured as a DvR Leaf.</p> <p>A node that has this flag set cannot be configured as a DvR Controller.</p> <p>The boot flag is disabled by default.</p>

Variable	Value
<code>enhancedsecure-mode {jitc non-jitc}</code>	<p>Enables enhanced secure mode in either the Joint Interoperability Test Command (JITC) or non-JITC sub-modes.</p> <p>Note: As a best practice, enable the enhanced secure mode in the non-JITC sub-mode, because the JITC sub-mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting.</p> <p>When you enable enhanced secure mode in either the JITC or non-JITC sub-modes, the switch provides role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use.</p>
<code>factorydefaults</code>	<p>Specifies whether the switch uses the factory default settings at startup. The default value is disabled. This flag is automatically reset to the default setting after the CPU restarts. If you change this parameter, you must restart the switch.</p> <p>Note: The factorydefaults flag deletes the runtime, primary and backup configuration files, local password files, authentication keys, and certificates. After a factory default, you must change the password on first login.</p>
<code>flow-control-mode</code> Note: Exception: not supported on VSP 8600 Series.	<p>Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.</p> <p>The default is disabled.</p>
<code>ftpd</code>	<p>Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the <code>tftpd</code> flag is disabled.</p>
<code>ha-cpu</code> Note: Exception: only supported on VSP 8600 Series.	<p>Activates or disables High Availability-CPU (HA-CPU) mode. Switches with two CPUs use HA mode to recover quickly from a failure of one of the CPUs.</p> <p>If you enable or disable HA mode, the secondary CPU resets automatically to load settings from the saved configuration file.</p>

Variable	Value
<p><i>hsecure</i></p>	<p>Activates or disables High Secure mode. The hsecure command provides the following password behavior:</p> <ul style="list-style-type: none"> • 10 character enforcement • The password must contain a minimum of 2 uppercase characters, 2 lowercase characters, 2 numbers, and 2 special characters. • Aging time • Failed login attempt limitation <p>The default value is disabled. If you enable High Secure mode, you must restart the switch to enforce secure passwords. If you operate the switch in High Secure mode, the switch prompts a password change if you enter invalid-length passwords.</p>
<p><i>ipv6-egress-filter</i></p> <p>Note: Exception: not supported on VSP 8600 Series and XA1400 Series.</p>	<p>Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch.</p>
<p><i>ipv6-mode</i></p> <p>Note: Exception: not supported on VSP 4450 Series, VSP 8600 Series, and XA1400 Series.</p>	<p>Enables IPv6 mode on the switch.</p>
<p><i>linerate-directed-broadcast {true false}</i></p> <p>Note: Exception: only supported on VSP 4450 Series.</p>	<p>Enables or disables support for IP Directed Broadcast in hardware without requiring CPU intervention. Setting this boot flag will put port 1/46 into loopback mode, making it unusable for external connections, so you need to move any existing connections on this port first. After setting this boot flag, save the configuration, and then restart the switch. The default value is disabled.</p> <p>Important: The software cannot be upgraded or downgraded to a software release that does not contain this directed broadcast hardware assist functionality without first disabling this feature and saving the configuration.</p>

Variable	Value
<p><i>logging</i></p>	<p>Activates or disable system logging. The default value is enabled. The system names log files according to the following:</p> <ul style="list-style-type: none"> • The system displays the file names in 8.3 (log.xxxxxxx.sss) format. • The first 6 characters of the file name contain the last three bytes of the chassis base MAC address. • The next two characters in the file name specify the slot number of the CPU that generated the logs. • The last three characters in the file name are the sequence number of the log file. <p>The system generates multiple sequence numbers for the same chassis and same slot if the system reaches the maximum log file size.</p>
<p><i>nni-mstp</i></p> <p>Note: Exception: not supported on VSP 8600 Series and XA1400 Series.</p>	<p>Enables MSTP and VLAN configuration on NNI ports. The default is disabled.</p> <p>Note: Spanning Tree is disabled on all NNIs.</p> <p>You cannot add an SPBM NNI port or MLT port to any non SPBM B-VLAN. You cannot add additional C-VLANs to a brouter port.</p>
<p><i>reboot</i></p>	<p>Activates or disables automatic reboot on a fatal error. The default value is activated.</p> <p>Important: Do not change this parameter unless directed by technical support.</p>
<p><i>rlogind</i></p> <p>Note: Exception: rlogin and rsh are only supported on VSP 8600 Series.</p>	<p>Activates or disables the rlogin and rsh server. The default value is disabled.</p>
<p><i>savetostandby</i></p> <p>Note: Exception: only supported on VSP 8600 Series.</p>	<p>Activates or disables automatic save of the configuration file to the standby CPU. The default value is enabled. If you operate a dual CPU system, enable this flag for ease of operation.</p>
<p><i>spanning-tree-mode</i> <mstp rstp></p>	<p>Specifies the Multiple Spanning Tree Protocol or Rapid Spanning Tree Protocol mode. If you do not specify a protocol, the switch uses the default mode. The default mode is mstp. If you change the spanning tree mode, you must save the current configuration and restart the switch.</p>

Variable	Value
<i>spbm-config-mode</i>	Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. Use the no operator so that you can configure PIM and IGMP. The boot flag is enabled by default. To set this flag to the default value, use the default operator with the command.
<i>sshd</i>	Activates or disables the SSHv2 server service. The default value is disabled.
<i>syslog-rfc5424-format</i>	Controls the format of the syslog output and logging. By default, the switch uses the RFC5424 format. If the RFC based format is disabled, the older format is used.
<i>telnetd</i>	Activates or disables the Telnet server service. The default is disabled.
<i>tftpd</i>	Activates or disables Trivial File Transfer Protocol server service. The default value is disabled.
<i>trace-logging</i>	Activates or disables the creation of trace logs. The default value is disabled. Important: Do not change this parameter unless directed by technical support.
<i>urpf-mode</i> Note: Exception: not supported on VSP 8600 Series and XA1400 Series.	Enables Unicast Reverse Path Forwarding (uRPF) globally. You must enable uRPF globally before you configure it on a port or VLAN. The default is disabled.

Variable	Value
<i>verify-config</i>	<p>Activates syntax checking of the configuration file. The default is enabled.</p> <ul style="list-style-type: none"> Primary config behavior: When the verifyconfig flag is enabled, the primary config file is pre-checked for syntax errors. If the system finds an error, the primary config file is not loaded, instead the system loads the backup config file. <p>If the verify-config flag is disabled, the system does not pre-check syntax errors. When the verify-config flag is disabled, the system ignores any lines with errors during loading of the primary config file. If the primary config file is not present or cannot be found, the system tries to load the backup file.</p> <ul style="list-style-type: none"> Backup config behavior: If the system loads the backup config file, the system does not check the backup file for syntax errors. It does not matter if the verify-config flag is disabled or enabled. With the backup config file, the system ignores any lines with errors during the loading of the backup config file. <p>If no backup config file exists, the system defaults to factory defaults.</p> <p>As a best practice, disable the verify-config flag.</p>
<i>vrf-scaling</i>	<p>Increases the maximum number of VRFs and Layer 3 VSNs that the switch supports. This flag is disabled by default.</p> <p>Important: If you enable both this flag and the spbmconfig-mode flag, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see VOSS Release Notes.</p>
<p><i>vxlan-gw-full-interworking-mode</i></p> <p>Note: Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.</p>	<p>Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vIST. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag.</p> <p>The no operator is the default Base Interworking Mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments. For more information about feature support, see VOSS Feature Support Matrix.</p>

Using Telnet to Log on to the Device

About This Task

Use Telnet to log on to the device and remotely manage the switch.

Procedure

1. From a PC or terminal, start a Telnet session:
`telnet <ipv4 or ipv6 address>`
2. Enter the logon and password when prompted.

Example

```
C:\Users\jsmith>telnet 192.0.2.40
Connecting to 192.0.2.40.....
Login:rwa
Password:rwa
```

Enable the Web Management Interface

About This Task

Note

DEMO FEATURE - Read Only User for EDM is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

Enable the web management interface to provide management access to the switch using a web browser.

HTTP and HTTPS, and FTP support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Important

To enable HTTP access to the device, you must disable the web server secure-only option. To enable HTTPS access to the device, the web server secure-only option is enabled by default. The TFTP server supports both IPv4 and IPv6 TFTP clients.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable the web server:
`web-server enable`
3. To enable the secure-only option (for HTTPS access), enter:
`web-server secure-only`
4. (Optional) To disable the secure-only option (for HTTP access), enter:
`no web-server secure-only`

- Configure the username and the access password:

```
web-server password rwa WORD<1-20>
```

Important

The default passwords and community strings are documented and well known. Change the default passwords and community strings immediately after you first log on.

- Enter and confirm your password.

- Enable read-only user:

```
web-server read-only-user enable
```

- Save the configuration:

```
save config
```

- Display the web server status:

```
show web-server
```

Example

Enable the secure-only web-server.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#web-server enable
Switch:1(config)#web-server secure-only
Switch:1(config)#web-server read-only-user enable
Switch:1(config)#web-server password rwa smith2
Enter the New password : *****
Re-enter the New password : *****
Password changed.
Switch:1(config)#web-server password ro jones6
Enter the New password : *****
Re-enter the New password : *****
Password changed.

Switch:1(config)#show web-server

```

Variable Definitions

Use the data in the following table to use the **web-server** command.

Variable	Value
<i>def-display-rows</i> <10-100>	Configures the number of rows each page displays, between 10 and 100.
<i>enable</i>	Enables the web interface. To disable the web server, use the no form of this command: no web-server [enable]
<i>help-tftp</i> <WORD/0-256>	Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/ peer:/ [<dir>]. The path can use 0-256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> • 192.0.2.1:/help • 192.0.2.1:/
<i>http-port</i> <80-49151>	Configures the web server HTTP port. The default port is 80.
<i>https-port</i> <443-49151>	Configure the web server HTTPS port. The default port is 443.
<i>inactivity-timeout</i> <30-65535>	Configures the web-server session inactivity timeout. The default is 900 seconds (15 minutes).
<i>password</i> {ro rwa} WORD<1-20>	Configures the logon and password for the web interface.
<i>password min-passwd-len</i> <1-32>	Configures the minimum password length. By default, the minimum password length is 8 characters.
<i>read-only-user</i>	Enables read-only user for the web server. Note: read-only-user enable is available for demonstration purposes on some products. For more information, see VOSS Feature Support Matrix .

Variable	Value
<code>secure-only</code>	Enables secure-only access for the web server.
<code>tls-min-ver<tlsv10 tlsv11 tlsv12></code>	<p>Configures the minimum version of the TLS protocol supported by the web-server. You can select among the following:</p> <ul style="list-style-type: none"> • <code>tlsv10</code> – Configures the version to TLS 1.0. <p>Note: <code>tlsv10</code> is not supported in enhanced secure mode.</p> <ul style="list-style-type: none"> • <code>tlsv11</code> – Configures the version to TLS 1.1. • <code>tlsv12</code> – Configures the version to TLS 1.2 <p>The default is <code>tlsv12</code>.</p>

Enable the Web Server RO User

About This Task

Note

DEMO FEATURE - Read Only User for EDM is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

Perform this procedure to enable the web server RO user, which is disabled by default after a software upgrade.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable the read-only user:

```
web-server read-only-user enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Enable the default ro username:

```
Switch1:(config)#web-server read-only-user enable
```

Display the output of the **show web-server command** with the ro username enabled:

```
Switch:1(config)#show web-server
Web Server Info :

      Status                : on
      Secure-only           : enabled
      TLS-minimum-version   : tlsv12
```

```

RO Username Status      : enabled
RO Username             : jones6
RO Password             : *****
RWA Username           : smith2
RWA Password           : *****
Def-display-rows       : 30
Inactivity timeout     : 900 sec
Html help tftp source-dir :
HttpPort               : 80
HttpsPort              : 443

```

Configure the TLS Protocol Version

The switch by default supports version TLS 1.2 and above. You can explicitly configure TLS 1.0 and TLS 1.1 version support using CLI.

About This Task

Disable the web server before changing the TLS version. By disabling the web server, other existing users with a connection to the web server are not affected from changing to a different version after you run the **tls-min-ver** command.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Disable the web server:

```
no web-server enable
```
3. Set the TLS protocol version:

```
web-server tls-min-ver [tlsv10 | tlsv11 | tlsv12]
```
4. Enable the web server:

```
web-server enable
```
5. Verify the protocol version:

```
show web-server
```

Example

```

Switch> enable
Switch# configure terminal
Switch(config)# web-server tls-min-ver tlsv12

```

Verify the protocol version.

```
Switch:1(config)#show web-server
```

Web Server Info :

```

Status : off

                TLS_RSA_WITH_AES_256_CBC_SHA256
TLS_RSA_WITH_AES_256_CBC_SHA
                TLS_RSA_WITH_AES_128_CBC_SHA256
TLS_RSA_WITH_AES_128_CBC_SHA

```

Variable Definitions

Use the data in the following table to use the **web-server** command.

Variable	Value
<code>def-display-rows <10-100></code>	Configures the number of rows each page displays, between 10 and 100.
<code>enable</code>	Enables the web interface. To disable the web server, use the no form of this command: <code>no web-server [enable]</code>
<code>help-tftp <WORD/0-256></code>	Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/ peer:/ [<dir>]. The path can use 0-256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> 192.0.2.1:/help 192.0.2.1/

Variable	Value
<code>http-port <80-49151></code>	Configures the web server HTTP port. The default port is 80.
<code>https-port <443-49151></code>	Configure the web server HTTPS port. The default port is 443.
<code>inactivity-timeout<30-65535></code>	Configures the web-server session inactivity timeout. The default is 900 seconds (15 minutes).
<code>password {ro rwa} WORD<1-20></code>	Configures the logon and password for the web interface.
<code>password min-passwd-len<1-32></code>	Configures the minimum password length. By default, the minimum password length is 8 characters.
<code>read-only-user</code>	Enables read-only user for the web server. Note: read-only-user enable is available for demonstration purposes on some products. For more information, see VOSS Feature Support Matrix .
<code>secure-only</code>	Enables secure-only access for the web server.
<code>tls-min-ver<tlsv10 tlsv11 tlsv12></code>	Configures the minimum version of the TLS protocol supported by the web-server. You can select among the following: <ul style="list-style-type: none"> • <code>tlsv10</code> – Configures the version to TLS 1.0. Note: <code>tlsv10</code> is not supported in enhanced secure mode. <ul style="list-style-type: none"> • <code>tlsv11</code> – Configures the version to TLS 1.1. • <code>tlsv12</code> – Configures the version to TLS 1.2 The default is <code>tlsv12</code> .

Access the Switch Through the Web Interface

Before You Begin

You must enable the web server using CLI.

About This Task

Monitor the switch through a web browser from anywhere on the network. The web interface uses a 15-minute timeout period. If no activity occurs for 15 minutes, the system logs off the switch web interface, and you must re-enter the password information.

Hypertext Transfer Protocol (HTTP) and Hypertext Transfer Protocol Secure (HTTPS) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Note

By default the web server is configured with the secure-only option, which requires you to use HTTPS to access EDM. To access EDM using HTTP, you must disable the secure-only option. For more information about configuring the secure-only option, see [Enable the Web Management Interface](#) on page 176.

Procedure

1. Start your web browser.
2. Type the switch IP address as the URL in the web address field.
3. In the **User Name** box, type `admin` and in the **Password** box, type `password`.
4. Select **Login**.

Configuring the minimum version of the TLS protocol

Use the following procedure to configure the minimum version of the TLS protocol.

Earlier releases used a self-signed certificate generated using the OpenSSL API, and this self-signed certificate was installed in `/inflash/.ssh`. The self-signed certificate is now generated with the Mocana API.

Disable the web server before changing the TLS version. By disabling the web server, other existing users with a connection to the web server are not affected by changing to a different version.

The switch by default supports version TLS 1.2 and above. You can explicitly configure TLS 1.0 and TLS 1.1 version support.

Procedure

1. In the navigation tree, open the following folders: **Configuration > Security > Control Path**.
2. Select **General** and then select **Web** tab.
3. In the **TlsMinimumVersion** field, select the TLS version you want to configure as the minimum on the system.

Web Field Descriptions

Use the data in the following table to use the **Web** tab.

Name	Description
WebRWAUserName	Specifies the RWA username from 1-20 characters. The default is admin.
WebRWAUserPassword	Specifies the password from 1-32 characters. The default is 12345678.

Name	Description
WebROEnable Note: Exception: not supported on VSP 8600 Series.	Enables the web server read-only (RO) user, which is disabled by default after a software upgrade.
WebEncryptionType	Specifies the ciphers for preset version of TLS for the web server.
WebCertSubjectName	Specifies the digital certificate subject Name used as identity certificate in the web server.
WebCertCAName	Specifies the digital certificate CA trustpoint name used for the certificate in the web server.
WebROUserName Note: Product Notice: For VSP 8600 Series the web server RO username must be enabled in CLI.	Specifies the RO username. The default is user.
WebROUserPassword	Specifies the password from 1-32 characters. The default is password.
MinimumPasswordLength	Configures the minimum password length. By default, the minimum password length is 8 characters.
HttpPort	Specifies the HTTP port for web access. The default value is 80.
HttpsPort	Specifies the HTTPS port for web access. The default value is 443.
SecureOnly	Controls whether the secure-only option is enabled. The default is enabled.
InactivityTimeout	Specifies the idle time (in seconds) to wait before the EDM login session expires. The default value is 900 seconds (15 minutes).
TlsMinimumVersion	Configures the minimum version of the TLS protocol supported by the web-server. You can select from the following options: <ul style="list-style-type: none"> • <code>tlsv10</code> – Configures the version to TLS 1.0. • <code>tlsv11</code> – Configures the version to TLS 1.1. • <code>tlsv12</code> – Configures the version to TLS 1.2 The default is <code>tlsv12</code> .
InUseCertType Note: Exception: not supported on VSP 8600 Series.	Shows if the certificate is self-signed or user-installed. Note: Product Notice: For VSP 8600 Series use the show web-server command in CLI to view this information.

Name	Description
HelpTftp/Ftp_SourceDir	Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/peer:/ [<dir>]. The path can use 0–256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> • 192.0.2.1:/Help • 192.0.2.1:/
DefaultDisplayRows	Configures the web server display row width between 10–100. The default is 30.
LastChange	Shows the last web-browser initiated configuration change.
NumHits	Shows the number of hits to the web server.
NumAccessChecks	Shows the number of access checks performed by the web server.
NumAccessBlocks	Shows the number of access attempts blocked by the web server.
LastHostAccessBlockedAddressType	Shows the address type, either IPv4 or IPv6, of the last host access blocked by the web server.
LastHostAccessBlockedAddress	Shows the IP address of the last host access blocked by the web server.
NumRxErrors	Shows the number of receive errors the web server encounters.
NumTxErrors	Shows the number of transmit errors the web server encounters.
NumSetRequest	Shows the number of set-requests sent to the web server.

Saving the configuration

Save the configuration to a file to retain the configuration settings.

About This Task

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Note

If you use File Transfer Protocol (FTP) or Trivial File Transfer Protocol (TFTP), ensure that you enable the FTP or TFTP server.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Save the running configuration:

```
save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]
```

Example

```
Switch:1> enable
```

Save the file to the default location:

```
Switch:1# save config
```

Variable Definitions

Use the data in the following table to use the **save config** command.

Variable	Value
<i>backup</i> WORD<1-99>	Saves the specified file name and identifies the file as a backup file. WORD uses one of the following formats: <ul style="list-style-type: none"> • a.b.c.d:<file> • /intflash/<file> The file name, including the directory structure, can include up to 99 characters.
<i>file</i> WORD<1-99>	Specifies the file name in one of the following formats: <ul style="list-style-type: none"> • a.b.c.d:<file> • /intflash/<file> The file name, including the directory structure, can include up to 99 characters.
<i>verbose</i>	Saves the default and current configuration. If you omit this parameter, the command saves only parameters you change.

Backing up configuration files

Before and after you upgrade your switch software, make copies of the configuration files. If an error occurs, use backup configuration files to return the switch to a previous state.

Before You Begin

- If you use File Transfer Protocol (FTP) or Trivial File Transfer Protocol (TFTP), ensure that you enable the FTP or TFTP server. File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

About This Task

Keep several copies of backup files.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Determine the configuration file names:

```
show boot config choice
```
3. Save the configuration files. Assuming the files use the default file names, enter:

```
save config
```
4. Copy the files to a safe place:

```
copy /intflash/config.cfg /intflash/config_backup.cfg
```

```
copy /intflash/config.cfg a.b.c.d:/dir/config_backup.cfg
```

Example

Determine the configuration file names, save the configuration files, and copy the files to a safe place.

```
Switch:1>enable
Switch:1#show boot config choice
choice primary config-file "/intflash/config.cfg"
choice primary backup-config-file "/intflash/config.cfg"
Switch:1#save config
Switch:1#copy /intflash/config.cfg 00:11:f9:5b:10:42/dir/config_backup.cfg
Do you want to continue? (y/n)
y
```

Resetting the platform

About This Task

Reset the platform to reload system parameters from the most recently saved configuration file.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Reset the switch:

```
reset [-y]
```

Example

Reset the switch:

```
Switch:1>enable
Switch:1#reset
Are you sure you want to reset the switch? (y/n)
y
```

Variable Definitions

Use the data in the following table to use the **reset** command.

Variable	Value
-y	Suppresses the confirmation message before the switch resets. If you omit this parameter, you must confirm the action before the system resets.

Remove a Software Build

Use the following procedure to remove a software build for the switch.

Note

A maximum of 6 software releases can be installed on the switch. When the limit is reached, you are prompted to remove one release before you can proceed with adding and activating a new software release.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Remove the software build:
`software remove WORD<1-99>`

Example

Remove the software build:

```
Switch:1>enable
Switch:1#software remove w.x.y.z
```

Verification

Verify Boot Configuration Flags

Verify the boot configuration flags to verify boot configuration settings. Boot configuration settings only take effect after you reset the system. Verification of these parameters is essential to minimize system downtime and the resets to change them.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Verify the flags:
`show boot config flags`

Example

Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
```

```

flags ha-cpu true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags linerate-directed-broadcast false
flags logging true
flags nni-mstp false
flags reboot true
flags rlogind false
flags savetostandby true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
flags vxlan-gw-full-interworking-mode false

```

Verify the Software Release

About This Task

Use CLI to verify your installed software. It is important to verify your software version before you place a device into a production environment.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Verify the software release:
show software detail

Example

The following is an example of the output of the `show software detail` command.

```

Switch:1#show software detail

Verifying the software version on the slots

Note

This procedure only applies to VSP 8600 Series.

About This Task

Use CLI to verify the software version running on each slot.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Verify the software version running on each slot:
show software slot

Example

The following is an example of the output of the **show software slot** command.

```
Switch:1#show software slot
```

```

=====
                        Software running on chassis
=====

SF 2     VOSS8600.voss_4.5.0.0int011

```

Display local alarms

View local alarms to monitor alarm conditions.

Local alarms are raised and cleared by applications running on the switch. Local alarms are an automatic mechanism run by the system that do not require any additional user configuration. The raising and clearing of local alarms also creates a log entry for each event. Check alarms occasionally to ensure no alarms require additional operator attention.

For more information, see [Alarm Database](#) on page 3503.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display local alarms:

```
show alarm database
```

Example

Display local alarms:

Note

The switches that support SF cards display warning messages when SFIs are down.

```
Switch:1#show alarm database
```

SLOT	ALARM ID	EVENT CODE	ALARM TYPE	ALARM STATUS	SEVERITY	FREQ	CREATION TIME	UPDATED TIME	CLEARED TIME	REASON

Basic Administration Procedures using CLI

The following section describes common procedures that you use while you configure and monitor the switch operations using the Command Line Interface (CLI).

Note

Unless otherwise stated, to perform the procedures in this section, you must log on to the Privileged EXEC mode in the CLI. For more information about how to use CLI, see [CLI Procedures](#) on page 251.

Restarting the platform

Before You Begin

Note

The command mode is key for this command. If you are logged on to a different command mode, such as Global Configuration mode, rather than Privileged EXEC mode, the system displays different options for this command.

About This Task

Restart the switch to implement configuration changes or recover from a system failure. When you restart the system, you can specify the boot config file name. If you do not specify a boot source and file, the boot command uses the configuration files on the primary boot device defined by the `boot config choice` command.

After the switch restarts normally, it sends a cold trap within 45 seconds after the restart.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Restart the switch:
`boot [config WORD<1-99>] [-y]`

Important

If you enter the `boot` command with no arguments, you cause the switch to start using the current boot choices defined by the `boot config choice` command.

If you enter a boot command and the configuration file name without the directory, the device uses the configuration file from `/intflash/`.

Example

```
Switch:1> enable
```

Restart the switch:

```
Switch:1# boot config /intflash/config.cfg
```

```
Switch:1# Do you want to continue? (y/n)
```

```
Switch:1# Do you want to continue? (y/n) y
```

Variable Definitions

The following table defines parameters for the **boot** command.

Variable	Value
<code>config WORD<1-99></code>	Specifies the software configuration device and file name in one of the following formats: <ul style="list-style-type: none"> • <code>/intflash/ <file></code> The file name, including the directory structure, can include up to 99 characters.
<code>-y</code>	Suppresses the confirmation message before the switch restarts. If you omit this parameter, you must confirm the action before the system restarts.

Resetting the platform

About This Task

Reset the platform to reload system parameters from the most recently saved configuration file.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Reset the switch:
`reset [-y]`

Example

```
Switch:1> enable
```

Reset the switch:

```
Switch:1# reset
```

```
Are you sure you want to reset the switch? (y/n) y
```

Variable Definitions

The following table defines parameters for the **reset** command.

Variable	Value
-y	Suppresses the confirmation message before the switch resets. If you omit this parameter, you must confirm the action before the system resets.

Shutting Down the System

Use the following procedure to shut down the system.

Caution

Before you unplug the AC power cord, always perform the following shutdown procedure.

This procedure:

- Flushes any pending data to ensure data integrity.
- Ensures the completion of recent configuration save actions, thus preventing the system from inadvertently booting up with incorrect configuration.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Shut down the system:
`sys shutdown`

- Before you unplug the power cord, wait until you see the following message:

```
System Halted, OK to turn off power
```

Example

Shut down a running system.

```
Switch:1#sys shutdown
Are you sure you want shutdown the system? Y/N (y/n) ? y
CP1 [05/08/14 15:47:50.164] 0x00010813 00000000 GlobalRouter HW INFO System shutdown

Configure the Default Ping and Traceroute Context

About This Task

Ping commands and traceroute commands execute in Global Router (GRT) context by default. You can configure ping commands and traceroute commands to execute in management (mgmt) context or in Virtual Router Forwarding (vrf) context.

Note

This procedure is not supported on VSP 8600 Series.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Configure the default ping command and traceroute command context:

```
sys default-ping-context {grt | mgmt | vrf}
```

Variable Definitions

The following table defines parameters for the **sys default-ping-context** command.

Variable	Value
grt	Specifies Global Routing Table (grt) context as the default context for ping commands and traceroute commands. The default configuration is grt as the default context.
mgmt	Specifies management (mgmt) context as the default context for ping commands and traceroute commands. The default configuration is grt as the default context.
vrf	Specifies Virtual Router Forwarding (VRF) context as the default context for ping commands and traceroute commands. The default configuration is grt as the default context.

Calculate and Verify the MD5 Checksum for a File on the Switch

Perform this procedure to verify that the software files are downloaded properly to the switch. The MD5 checksum for each release is available on the Extreme Networks Support website.

Before You Begin

- Download the MD5 checksum to an intermediate workstation or server where you can open and view the contents.
- Download the image file to the switch.

About This Task

Calculate and verify the MD5 checksum after you download software files.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the list of files:

```
ls *.tgz
```
3. Calculate the MD5 checksum for the file:

```
file-checksum md5 WORD<1-99>
```
4. Compare the number generated for the file on the switch with the number that displays in the MD5 checksum on the workstation or server. Ensure that the MD5 checksum of the software suite matches the system output generated from calculating the MD5 checksum from the downloaded file.

Example

View the contents of the MD5 checksum on the workstation or server:

```
3242309ad6660ef09be1b945be15676d VSP8200.4.0.0.0_edoc.tar
d000965876dee2387f1ca59cf081b9d6 VSP8200.4.0.0.0_mib.txt
897303242c30fd944d435a4517f1b3f5 VSP8200.4.0.0.0_mib.zip
2fbd5eab1c450d1f5feae865b9e02baf VSP8200.4.0.0.0_modules.tgz

8ce39996a131de0b836db629b5362a8a VSP8200.4.0.0.0_oss-notice.html
80bfe69d89c831543623aaad861f12aa VSP8200.4.0.0.0.tgz
```

```
a63a1d911450ef2f034d3d55e576eca0 VSP8200.4.0.0.0.zip
62b457d69cedd44c21c395505dcf4a80 VSP8200v400_HELP_EDM_gzip.zip
```

Calculate the MD5 checksum for the file on the switch:

```
Switch:1>ls *.tgz
-rw-r--r-- 1 0 0 44015148 Dec 8 08:18 VSP8200.4.0.0.0.tgz
-rw-r--r-- 1 0 0 44208471 Dec 8 08:19 VSP8200.4.0.1.0.tgz
Switch:1>file-checksum md5 VSP8200.4.0.0.0.tgz
MD5 (VSP8200.4.0.0.0.tgz) = 80bfe69d89c831543623aaad861f12aa
```

Variable Definitions

The following table defines parameters for the **file-checksum md5** command:

Variable	Value
<i>WORD</i> <1-99>	Specifies the file name.

Calculate and Verify the MD5 Checksum for a File on a Client Workstation

Perform this procedure on a Unix or Linux machine to verify that the software files downloaded properly. The MD5 checksum for each release is available on the Extreme Networks Support website.

About This Task

Calculate and verify the MD5 checksum after you download software files.

Procedure

1. Calculate the MD5 checksum of the downloaded file:

```
$ /usr/bin/md5sum <downloaded software-filename>
```

Typically, downloaded software files are in the form of compressed Unix file archives (.tgz files).
2. Verify the MD5 checksum of the software suite:

```
$ more <md5-checksum output file>
```
3. Compare the output that displays on the screen. Ensure that the MD5 checksum of the software suite matches the system output generated from calculating the MD5 checksum from the downloaded file.

Example

Calculate the MD5 checksum of the downloaded file:

```
$ /usr/bin/md5sum VSP4K.4.0.40.0.tgz
02c7ee0570a414becf8ebb928b398f51 VSP4K.4.0.40.0.tgz
```

View the MD5 checksum of the software suite:

```
$ more VSP4K.4.0.40.0.md5
285620fdclce5ccd8e5d3460790c9fe1 VSP4000v4.0.40.0.zip
a04e7c7cef660bb412598574516c548f VSP4000v4040_HELP_EDM_gzip.zip
ac3d9cef0ac2e334cf94799ff0bdd13b VSP4K.4.0.40.0_edoc.tar
29fa2aa4b985b39843d980bb9d242110 VSP4K.4.0.40.0_mib_sup.txt
```

```
c5f84beaf2927d937fcbe9dd4d4c7795 VSP4K.4.0.40.0_mib.txt

02c7ee0570a414becf8ebb928b398f51 VSP4K.4.0.40.0.tgz
```

Calculating the File Checksum

About This Task

Perform the following procedure to calculate or compare the MD5 or SHA512 digest for a specific file. The **file-checksum** command calculates the MD5 or SHA512 digest for files on the internal flash and either shows the output on screen or stores the output in a file that you specify. The **file-checksum** command compares the calculated MD5 or SHA512 digest with that in a checksum file on flash, and the compared output displays on the screen. By verifying the MD5 or SHA512 checksum, you can verify that the file is transferred properly to the switch.

Important

- If the MD5 key file parameters change, you must remove the old file and create a new file.
- Use the **file-checksum** command with reserved files (for example, a password file) only if you possess sufficient permissions to access these files.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Calculate the file checksum:

```
file-checksum {md5 | sha512} WORD<1-99> [-a] [-c] [-f WORD<1-99>] [-r]
```

Example

```
Switch:1>file-checksum md5 password -a -f password.md5
```

Variable Definitions

The following table defines parameters for the **file-checksum** command.

Variable	Value
<i>md5</i>	Calculates or compares the MD5 digest for a specific file.
<i>sha512</i>	Calculates or compares the SHA512 digest for a specific file.
<i>-a</i>	Adds data to the output file instead of overwriting it. You cannot use the <i>-a</i> option with the <i>-c</i> option.

Variable	Value
<code>-c</code>	<p>Compares the checksum of the specified file with the MD5 checksum present in the checksum file name. You can specify the checksum file name using the <code>-f</code> option. If the checksum filename is not specified, the file <code>/intflash/checksum.md5</code> is used for comparison.</p> <p>If the supplied checksum filename and the default file are not available on flash, the system displays the following error message on the switch: Error: Checksum file <code><filename></code> not present.</p> <p>The <code>-c</code> option also</p> <ul style="list-style-type: none"> calculates the checksum of the specified files compares the checksum with all keys in the checksum file, even if filenames do not match displays the output of comparison
<code>-f</code>	<p>Stores the result of MD5 checksum to a file on internal flash.</p> <p>If the output file specified with the <code>-f</code> option is reserved filenames on the switch, the command fails with the error message: Error: Invalid operation.</p> <p>If the output file specified with the <code>-f</code> option is files for which to compute MD5 checksum, the command fails with the error message: Switch:1# md5 *.cfg -f config.cfg Error: Invalid operation on file <code><filename></code></p> <p>If the checksum filename specified by the <code>-f</code> option exists on the switch (and is not one of the reserved filenames), the system displays the following message on the switch: File exists. Do you wish to overwrite? (y/n)</p>
<code>-r</code>	<p>Reverses the output. Use with the <code>-f</code> option to store the output to a file.</p> <p>You cannot use the <code>-r</code> option with the <code>-c</code> option.</p>
<code>WORD<1-99></code>	Specifies the file name.

Resetting system functions

About This Task

Reset system functions to reset all statistics counters on the console port. Depending on your hardware platform, the console port displays as console or 10101.

Procedure

- Enter Privileged EXEC mode:
`enable`

2. Reset system functions:

```
sys action reset {console|counters}
```

Example

```
Switch:1> enable
```

Reset the statistics counters:

```
Switch:1# sys action reset counters
```

```
Are you sure you want to reset system counters (y/n)? y
```

Variable Definitions

The following table defines parameters for the **sys action** command.

Variable	Value
<code>reset {console counters}</code>	Reinitializes the hardware universal asynchronous receiver transmitter (UART) drivers. Use this command only if the console connection does not respond. Resets all the statistics counters in the switch to zero. Resets the console port.

Sourcing a Configuration

Source a configuration to merge a script file into the running configuration or verify the syntax of a configuration file.

About This Task

The **source** CLI command is intended for use with a switch that is running with a factory default configuration to quick load a pre-existing configuration from a file. If you source a configuration file to merge that configuration into a running configuration, it can result in operational configuration loss if the sourced configuration file contains any configuration that has dependencies on or conflicts with the running configuration. Use the source command to merge smaller portions of a configuration into the existing configuration.

Not all CLI commands are included in configuration files. Typical examples include, but are not limited to some operational and security-related commands. Ensure that you understand what configuration options are included or not included in a configuration file, when you use that file to build new configurations.

The operational modes in the boot configuration file must be configured for some features (for example, **spbm-config-mode true/false**). Before sourcing a configuration file, you need to configure the **boot config flag**, save the configuration, and reboot the system. After the reboot, you can source the configuration file without fail.

Important

Do not source a verbose configuration (`verbose.cfg`) with the `debug stop` option. The sourcing process cannot complete if you use these two options with a verbose configuration.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Source a configuration:

```
source WORD<1-99> [debug] [stop] [syntax]
```

Example

```
Switch:1> enable
```

Debug the script output:

```
Switch:1# source testing.cfg debug
```

Variable Definitions

The following table defines parameters for the **source** command.

Variable	Value
<i>debug</i>	Debugs the script by outputting the configuration commands to the screen.
<i>stop</i>	Stops the sourcing of a configuration if an error occurs.
<i>syntax</i>	Checks the syntax of the configuration file. This parameter does not load the configuration file; only verifies the syntax. If you use this parameter with the <i>stop</i> parameter (source WORD<1-99> stop syntax), the output displays on screen and verification stops if it encounters an error. If you use this parameter with the <i>debug</i> parameter (source WORD<1-99> debug syntax), the output does not stop if it encounters an error; you must review the on-screen output to verify if an error exists. If you use this parameter by itself, it does not output to the screen or stop on error; it shows an error message, <i>syntax errors in script</i> , to indicate if errors exist in the configuration file.
<i>WORD<1-99></i>	Specifies a filename and location in one of the following format: <ul style="list-style-type: none"> • a.b.c.d:<file> • /intflash/<file> <file> is a string.

Using the USB Device

The following sections describe common procedures that you can use with the USB device.

Save a File to an External USB Device

Use the following procedure to save the configuration file or log file to an external USB device.

Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Save the file to an external USB device:
 - a. To save the configuration file to an external USB device, enter:

```
save config file WORD<1-99>
```
 - b. To save the log file to an external USB device, enter:

```
save log file WORD<1-99>
```

Example

```
Switch:1#save config file /usb/test.cfg
CP-1: Save config to file /usb/test.cfg successful.
WARNING: Choice Primary Node Config file is "/intflash/soak.cfg".

Switch:1#
Switch:1#save log file /usb/test.log

Save log to file /usb/test.log successful.
Save log to file /usb/test.log successful.
Switch:1#
```

Variable definitions

The following table defines parameters for the `save` command.

Variable	Value
config file <i>WORD<1-99></i>	Specifies the software configuration device and configuration file name in one of the following formats: <ul style="list-style-type: none"> • a.b.c.d:<file> • /intflash/<file> • /usb/<file> The file name, including the directory structure, can include up to 99 characters.
log file <i>WORD<1-99></i>	Specifies the software configuration device and log file name in one of the following formats: <ul style="list-style-type: none"> • a.b.c.d:<file> • /intflash/<file> • /usb/<file> The file name, including the directory structure, can include up to 99 characters.

Back Up and Restore the Compact Flash to an External USB Device

Perform this procedure to back up and restore the contents of the internal compact flash to a USB flash device without entering multiple **copy** commands. This procedure is useful if you want to copy the complete compact flash contents to another chassis.

Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

Before You Begin

-  **Important**
Disable logging using the command: `no boot config logging`.
- You must have a USB storage device ready to use that is at least 2 GB. The switch supports USB 1 and 2.

About This Task

The system verifies that the USB flash device has enough available space to perform the backup operation. If the USB flash device does not have enough available space, the system displays an error message. The backup command uses the following filepath on the USB flash device: `/usb/intflash/intflashbackup_yyyymmddhhmmss.tgz`.

The backup action can take up to 10 minutes.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Backup the internal flash to USB:
`backup intflash`
3. Restore the data to the internal flash:
`restore intflash`

Example

```
Switch:1#backup intflash
```

```
Warning: Command will backup all data from /intflash to /usb/intflash.
It will take a few minutes and may cause high CPU utilization.

Are you sure you want to continue? (y/n) ? y

For file system /intflash:
 7252475904 total bytes on the filesystem
 990920704 used bytes on the filesystem
6261555200 free bytes on the filesystem

For file system /usb:
2021216256 total bytes on the filesystem
 12038144 used bytes on the filesystem
2009178112 free bytes on the filesystem

cd /intflash ; /bin/tar -czvf /usb/intflash/intflashbackup_20140610074501.tgz *
; /bin/sync
```

```
Info: Backup /intflash to filename /usb/intflash/intflashbackup_20140610074501.tgz is
complete!

Do you want to stop the usb? (y/n) ? n
```

Copy Configuration and Log Files from a USB Device to Intflash

Copy configuration and log files from an external USB device to the internal Flash memory.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Copy configuration or log files from the USB device to Intflash:
copy /usb/<srcfile> /intflash/<destfile>

Example

```
Switch:1#enable
```

```
Switch:1#copy /usb/test.cfg /intflash/test.cfg
```

Variable Definitions

The following table defines parameters for the `copy` command.

Variable	Value
<destfile>	Specifies the name of the configuration or log file when copied to the internal Flash memory. The destination file name must be lower case and have a file extension of .cfg or .log. For example, test.cfg or test.log. The file name, including the directory structure, can include up to 255 characters.
<srcfile>	Specifies the name of the configuration or log file on the USB device. For example, test.cfg or test.log. The file name, including the directory structure, can include up to 255 characters.

Display the Contents of a USB File

Use the following procedure to view content of a USB file.

Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display content of a USB file:
more WORD<1-99>

Example

```
Switch:1#enable
```

```
Switch:1#more /usb/test.cfg
```

Variable definitions

The following table defines parameters for the `more` command.

Variable	Value
<i>WORD</i> <1-99>	Specifies the file name in the following format: <ul style="list-style-type: none"> • /usb/<file> The file name, including the directory structure, can include up to 99 characters.

Move a File to or from a USB Device

Use the following procedure to move a file from the internal Flash memory (Intflash) to an external USB device, or from a USB device to Intflash.

**Caution**

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Move a file to a safe location:
 - a. To move a file from Intflash to a USB device:

```
mv /intflash/<srcfile> /usb/<destfile>
```
 - b. To move a file from a USB device to Intflash:

```
mv /usb/<srcfile> /intflash/<destfile>
```

Example

```
Switch:1#enable
Switch:1#mv /intflash/test.cfg /usb/test.cfg

Switch:1#enable
Switch:1#mv /usb/test.cfg /intflash/test.cfg
```

Variable Definitions

The following table defines parameters for the `mv` command.

Variable	Value
<destfile>	Specifies the name of the configuration or log file when moved to the USB device. The destination file name must be lower case and have a file extension of <code>.cfg</code> or <code>.log</code> . For example, <code>test.cfg</code> or <code>test.log</code> . The file name, including the directory structure, can include up to 255 characters.
<srcfile>	Specifies the name of the configuration or log file on the internal flash memory. For example, <code>test.cfg</code> or <code>test.log</code> . The file name, including the directory structure, can include up to 255 characters.

Delete a file from a USB Device

Use the following procedure to delete a file from an external USB device.

Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Delete a file from a USB device:
`delete WORD<1-255>`

Example

```
Switch:1#enable
```

```
Switch:1#delete /usb/test.cfg
Are you sure (y/n) ? y
```

Variable Definitions

The following table defines parameters for the `delete` command.

Variable	Value
<code>WORD<1-255></code>	Specifies the file name in the following format: <ul style="list-style-type: none"> • <code>/usb/<file></code>

Back Up Configuration Files to ZIP

Table 26: Extreme Management Center or ExtremeCloud IQ - Site Engine backup configuration ZIP file product support

Feature	Product	Release introduced
Extreme Management Center or ExtremeCloud IQ - Site Engine backup configuration ZIP file For more information, see Extreme Management Center or ExtremeCloud IQ - Site Engine documentation.	VSP 4450 Series	VOSS 6.1.2
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 6.1.2
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.1.2
	VSP 8400 Series	VOSS 6.1.2
	VSP 8600 Series	VSP 8600 6.1
	XA1400 Series	VOSS 8.0.50

Extreme Management Center or ExtremeCloud IQ - Site Engine has a configuration backup feature with a requirement to be able to backup configuration related files. Release 6.1.2 introduces new CLI commands to backup configuration related files and package them into a single zip file, or to restore configuration files that were backed up.

Note

License files are not backed up.

Backing up configuration files to a ZIP file

About This Task

Use this procedure to back up configuration files.

Important

Only the RWA user can use the **backup** command.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Use the backup command:
`backup configure WORD<1-99>`

Example

```
Switch:1>enable
Switch:1#backup configure /intflash/backup02072018

Successfully backed up config /intflash to /intflash/backup02072018.tgz
```

*Restoring configuration files from a ZIP file***About This Task**

Use the following procedure to restore previously backed up configuration files.

Before You Begin

- Download the backup file to the /intflash directory.
- If restoring the configuration files on a new switch, you must do one of the following:
 - Disable ISIS on the old switch .
 - Power the old switch down.
 - Remove the old switch from the network.
- If restoring the configuration files on a different switch, use the “isis dup-detection-temp-disable” command on the new switch to suspend duplicate detection prior to its insertion into the existing SPBM topology.

**Important**

This must be done after the original unit has been completely removed or isolated from the SPBM topology.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Run the restore command to restore the configuration files.

```
restore configure WORD<1-99>
```

Example

```
Switch:1>enable
Switch:1#restore configure /intflash/backup02072018.tgz

Warning: Command will restore your backup setup and access files
The current files will be overwritten.

Are you sure you want to continue? (y/n) ?y

Restore /intflash from /intflash/backup02072018.tgz is complete!
Reboot is required for the new configuration to be effective
```

Basic administration procedures using EDM

The following section describes common procedures that you use while you configure and monitor the switch operations using Enterprise Device Manager (EDM).

Reset the Platform**About This Task**

Reset the platform to reload system parameters from the most recently saved configuration file. Use the following procedure to reset the device using EDM.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **System** tab.
5. Locate **ActionGroup4** near the bottom of the screen.
6. Select **softReset** from **ActionGroup4**.
7. Click **Apply**.

Show the MTU for the System

About This Task

Perform this procedure to show the MTU configured for the system.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click on the **Chassis** tab.
5. Verify the selection for the MTU size.

Save the Configuration

About This Task

After you change the configuration, you must save the changes on the device. Save the configuration to a file to retain the configuration settings.

**Note**

When you logout of the EDM interface, a dialog box automatically prompts if you want to save the configuration. If you want to save the configuration, click **OK**. If you want to close without saving the configuration, click **Cancel**. If you no longer see the prompt, clear your browser cache, restart your browser and reconnect.

Procedure

1. In the Device Physical View tab, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **System** tab.
5. (Optional) Specify a filename in **ConfigFileName**.
If you do not specify a filename, the system saves the information to the default file.
6. In **ActionGroup1**, select **saveRuntimeConfig**.
7. Click **Apply**.

Boot parameter configuration using the CLI

Use the procedures in this section to configure and manage the boot process.

Modify the Boot Sequence

About This Task

Modify the boot sequence to prevent the switch from using the factory default settings or, conversely, to prevent loading a saved configuration file.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Bypass the loading of the switch configuration file and load the factory defaults:
`boot config flags factorydefaults`
3. Use a configuration file and not the factory defaults:
`no boot config flags factorydefaults`

Important

If the switch fails to read and load a saved configuration file after it starts, check the log file to see if the log file indicates that the `factorydefaults` setting was enabled, before you investigate other options.

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags factorydefaults
```

Configuring the remote host logon

Before You Begin

- The FTP server must support the FTP passive (PASV) command. If the FTP server does not support the passive command, the file transfer is aborted, and then the system logs an error message that indicates that the FTP server does not support the passive command.

About This Task

Configure the remote host logon to modify parameters for FTP and TFTP access. The defaults enable TFTP transfers. If you want to use FTP as the transfer mechanism, you need to change the password to a non-null value.

Important

`tftp-debug` should be used exclusively to transfer small files less than 1MB in size. Using it for larger files might cause unwanted behavior, such as transfer failure.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Define conditions for the remote host logon:
boot config host {ftp-debug|password WORD<0-16>|tftp-debug|tftp-hash|
tftp-rexmit <1-120>|tftp-timeout <1-120>|user WORD<0-16>}
3. Save the changed configuration.

Example

```
Switch:1> enable

Switch:1# configure terminal

Enable console tftp/tftpd debug messages:

Switch:1# boot config host tftp-debug

Switch:1# save config
```

Changing the primary or secondary boot configuration files

About This Task

Change the primary or secondary boot configuration file to specify which configuration file the system uses to start.

Configure the primary boot choices.

You have a primary configuration file that specifies the full directory path and a secondary configuration file that also contains the full directory path.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Change the primary boot choice:
boot config choice primary {backup-config-file|config-file} WORD<0-
255>
3. Save the changed configuration.
4. Restart the switch.

Example

```
Switch:1> enable

Switch:1# configure terminal
```

Specify the configuration file in internal flash memory as the primary boot source:

```
Switch:1(config)# boot config choice primary config-file /intflash/
config.cfg
```

```
Switch:1(config)# save config
```

```
Switch:1(config)# reset
```

Variable Definitions

The following table defines parameters for the **boot config** command.

Variable	Value
<i>{backup-config-file config-file}</i>	Specifies that the boot source uses either the configuration file or a backup configuration file.
<i>WORD<0-255></i>	Identifies the configuration file. <i>WORD<0-255></i> is the device and file name, up to 255 characters including the path, in one of the following format: <ul style="list-style-type: none"> • a.b.c.d:<file> • /usb/<file> • /intflash/<file> To set this option to the default value, use the default operator with the command.

Configure Boot Flags

Before You Begin

- If you enable the hsecure flag, you cannot enable the flags for the web server or SSH password-authentication.

Important

After you change certain configuration parameters using the **boot config flags** command, you must save the changes to the configuration file.

About This Task

Configure the boot flags to enable specific services and functions for the chassis.

Note

Flag support can vary across hardware models.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```

2. Enable boot config flag(s) on the switch using the **boot config flags** command.

Enable the following flags, as needed:

- *advanced-feature-bandwidth-reservation [low | high]*
- *block-snmp*
- *debug-config [file]*
- *debugmode*
- *dvr-leaf-mode*
- *enhancedsecure-mode <jitc|non-jitc>*
- *factorydefaults*
- *flow-control-mode*
- *ftpd*
- *ha-cpu*
- *hsecure*
- *ipv6-egress-filter*
- *ipv6-mode*
- *linerate-directed-broadcast*
- *logging*
- *nmi-mstp*
- *reboot*
- *rlogind*
- *savetostandby*
- *spanning-tree-mode <mstp|rstp>*
- *spbm-config-mode*
- *sshd*
- *syslog-rfc5424-format*
- *telnetd*
- *tftpd*
- *trace-logging*
- *urpf-mode*
- *verify-config*
- *vrf-scaling*
- *vxlan-gw-full-interworking-mode*

3. Save the changed configuration.

4. Restart the switch.

Example

Activate High Secure mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags hsecure
```

```
Switch:1(config)#save config
Switch:1(config)#reset
```

Variable Definitions

The following table defines parameters for the **boot config flags** command.

Variable	Value
<p><i>advanced-feature-bandwidth-reservation [low high]</i></p> <p>Note: Exception: only supported on VSP 7400 Series and XA1480.</p>	<p>Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work. The default is enabled with low level.</p> <ul style="list-style-type: none"> The high level means that the switch reserves the maximum bandwidth for the advanced features. The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features. <p>If you change this parameter, you must restart the switch.</p>
<i>block-snmp</i>	<p>Activates or disables Simple Network Management Protocol management. The default value is false (disabled), which permits SNMP access.</p>
<i>debug-config [console] [file]</i>	<p>Enables you to debug the configuration file during loading configuration at system boot up. The default is disabled. You do not have to restart the switch after you enable debug-config, unless you want to immediately debug the configuration. After you enable debug-config and save the configuration, the debug output either displays on the console or logs to an output file the next time the switch reboots.</p> <p>The options are:</p> <ul style="list-style-type: none"> <code>debug-config [console]</code>—Displays the line-by-line configuration file processing and result of the execution on the console while the device loads the configuration file. <code>debug-config [file]</code>— Logs the line-by-line configuration file processing and result of the execution to the debug file while the device loads the configuration file. The system logs the debug config output to <code>/intflash/debugconfig_primary.txt</code> for the primary configuration file. The system logs the debug config output to <code>/intflash/debugconfig_backup.txt</code> for the backup configuration, if the backup configuration file loads.

Variable	Value
<i>debugmode</i>	<p>Enables a TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. Works on console connection only. The default is disabled.</p> <p>Important: Do not change this parameter unless directed by technical support.</p>
<i>dvr-leaf-mode</i>	<p>Enables an SPB node to be configured as a DvR Leaf. A node that has this flag set cannot be configured as a DvR Controller. The boot flag is disabled by default.</p>
<i>enhancedsecure-mode {jitc non-jitc}</i>	<p>Enables enhanced secure mode in either the Joint Interoperability Test Command (JITC) or non-JITC sub-modes.</p> <p>Note: As a best practice, enable the enhanced secure mode in the non-JITC sub-mode, because the JITC sub-mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting.</p> <p>When you enable enhanced secure mode in either the JITC or non-JITC sub-modes, the switch provides role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use.</p>
<i>factorydefaults</i>	<p>Specifies whether the switch uses the factory default settings at startup. The default value is disabled. This flag is automatically reset to the default setting after the CPU restarts. If you change this parameter, you must restart the switch.</p> <p>Note: The factorydefaults flag deletes the runtime, primary and backup configuration files, local password files, authentication keys, and certificates. After a factory default, you must change the password on first login.</p>

Variable	Value
<p><i>flow-control-mode</i></p> <p>Note: Exception: not supported on VSP 8600 Series.</p>	<p>Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.</p> <p>The default is disabled.</p>
<p><i>ftpd</i></p>	<p>Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the <i>tftpd</i> flag is disabled.</p>
<p><i>ha-cpu</i></p> <p>Note: Exception: only supported on VSP 8600 Series.</p>	<p>Activates or disables High Availability-CPU (HA-CPU) mode. Switches with two CPUs use HA mode to recover quickly from a failure of one of the CPUs.</p> <p>If you enable or disable HA mode, the secondary CPU resets automatically to load settings from the saved configuration file.</p>
<p><i>hsecure</i></p>	<p>Activates or disables High Secure mode. The hsecure command provides the following password behavior:</p> <ul style="list-style-type: none"> • 10 character enforcement • The password must contain a minimum of 2 uppercase characters, 2 lowercase characters, 2 numbers, and 2 special characters. • Aging time • Failed login attempt limitation <p>The default value is disabled. If you enable High Secure mode, you must restart the switch to enforce secure passwords. If you operate the switch in High Secure mode, the switch prompts a password change if you enter invalid-length passwords.</p>
<p><i>ipv6-egress-filter</i></p> <p>Note: Exception: not supported on VSP 8600 Series and XA1400 Series.</p>	<p>Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch.</p>
<p><i>ipv6-mode</i></p> <p>Note: Exception: not supported on VSP 4450 Series, VSP 8600 Series, and XA1400 Series.</p>	<p>Enables IPv6 mode on the switch.</p>

Variable	Value
<p><i>linate-directed-broadcast</i> {true false}</p> <p>Note: Exception: only supported on VSP 4450 Series.</p>	<p>Enables or disables support for IP Directed Broadcast in hardware without requiring CPU intervention. Setting this boot flag will put port 1/46 into loopback mode, making it unusable for external connections, so you need to move any existing connections on this port first. After setting this boot flag, save the configuration, and then restart the switch. The default value is disabled.</p> <p>Important: The software cannot be upgraded or downgraded to a software release that does not contain this directed broadcast hardware assist functionality without first disabling this feature and saving the configuration.</p>
<p><i>logging</i></p>	<p>Activates or disable system logging. The default value is enabled. The system names log files according to the following:</p> <ul style="list-style-type: none"> • The system displays the file names in 8.3 (log.xxxxxxx.sss) format. • The first 6 characters of the file name contain the last three bytes of the chassis base MAC address. • The next two characters in the file name specify the slot number of the CPU that generated the logs. • The last three characters in the file name are the sequence number of the log file. <p>The system generates multiple sequence numbers for the same chassis and same slot if the system reaches the maximum log file size.</p>
<p><i>nni-mstp</i></p> <p>Note: Exception: not supported on VSP 8600 Series and XA1400 Series.</p>	<p>Enables MSTP and VLAN configuration on NNI ports. The default is disabled.</p> <p>Note: Spanning Tree is disabled on all NNIs.</p> <p>You cannot add an SPBM NNI port or MLT port to any non SPBM B-VLAN. You cannot add additional C-VLANs to a brouter port.</p>
<p><i>reboot</i></p>	<p>Activates or disables automatic reboot on a fatal error. The default value is activated.</p> <p>Important: Do not change this parameter unless directed by technical support.</p>

Variable	Value
<p><i>rlogind</i></p> <p>Note: Exception: rlogin and rsh are only supported on VSP 8600 Series.</p>	<p>Activates or disables the rlogin and rsh server. The default value is disabled.</p>
<p><i>savetostandby</i></p> <p>Note: Exception: only supported on VSP 8600 Series.</p>	<p>Activates or disables automatic save of the configuration file to the standby CPU. The default value is enabled. If you operate a dual CPU system, enable this flag for ease of operation.</p>
<p><i>spanning-tree-mode</i> <mstp rstp></p>	<p>Specifies the Multiple Spanning Tree Protocol or Rapid Spanning Tree Protocol mode. If you do not specify a protocol, the switch uses the default mode. The default mode is mstp. If you change the spanning tree mode, you must save the current configuration and restart the switch.</p>
<p><i>spbm-config-mode</i></p>	<p>Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. Use the no operator so that you can configure PIM and IGMP. The boot flag is enabled by default. To set this flag to the default value, use the default operator with the command.</p>
<p><i>sshd</i></p>	<p>Activates or disables the SSHv2 server service. The default value is disabled.</p>
<p><i>syslog-rfc5424-format</i></p>	<p>Controls the format of the syslog output and logging. By default, the switch uses the RFC5424 format. If the RFC based format is disabled, the older format is used.</p>
<p><i>telnetd</i></p>	<p>Activates or disables the Telnet server service. The default is disabled.</p>
<p><i>tftpd</i></p>	<p>Activates or disables Trivial File Transfer Protocol server service. The default value is disabled.</p>
<p><i>trace-logging</i></p>	<p>Activates or disables the creation of trace logs. The default value is disabled.</p> <p>Important: Do not change this parameter unless directed by technical support.</p>
<p><i>urpf-mode</i></p> <p>Note: Exception: not supported on VSP 8600 Series and XA1400 Series.</p>	<p>Enables Unicast Reverse Path Forwarding (uRPF) globally. You must enable uRPF globally before you configure it on a port or VLAN. The default is disabled.</p>

Variable	Value
<i>verify-config</i>	<p>Activates syntax checking of the configuration file. The default is enabled.</p> <ul style="list-style-type: none"> Primary config behavior: When the verifyconfig flag is enabled, the primary config file is pre-checked for syntax errors. If the system finds an error, the primary config file is not loaded, instead the system loads the backup config file. <p>If the verify-config flag is disabled, the system does not pre-check syntax errors. When the verify-config flag is disabled, the system ignores any lines with errors during loading of the primary config file. If the primary config file is not present or cannot be found, the system tries to load the backup file.</p> <ul style="list-style-type: none"> Backup config behavior: If the system loads the backup config file, the system does not check the backup file for syntax errors. It does not matter if the verify-config flag is disabled or enabled. With the backup config file, the system ignores any lines with errors during the loading of the backup config file. <p>If no backup config file exists, the system defaults to factory defaults.</p> <p>As a best practice, disable the verify-config flag.</p>
<i>vrf-scaling</i>	<p>Increases the maximum number of VRFs and Layer 3 VSNs that the switch supports. This flag is disabled by default.</p> <p>Important: If you enable both this flag and the spbmconfig-mode flag, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see VOSS Release Notes.</p>
<p><i>vxlan-gw-full-interworking-mode</i></p> <p>Note: Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.</p>	<p>Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vIST. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag.</p> <p>The no operator is the default Base Interworking Mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments. For more information about feature support, see VOSS Feature Support Matrix.</p>

Specify the Primary CPU and the Standby Delay

Note

This procedure only applies to VSP 8600 Series.

Specify the primary CPU to designate which CPU becomes the primary after the switch performs a full power cycle. This procedure applies only to hardware with two CPUs.

About This Task

Configure the standby delay to set the number of seconds a standby CPU waits before trying to become the primary CPU. The standby delay applies when two CP modules boot at the same time. The designated standby CP waits for the configured number of seconds before attempting to assert itself as the primary. Only one CP can be the primary in a chassis.

Caution

If you configure the standby delay to too short a value, the configured standby CP can become a primary. If you configure the standby delay to too long, it can delay the standby CP asserting itself and continue booting when the designated CP is inserted, but fails booting.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. View the current configuration for the primary CPU:
`show boot config master`
3. Specify the slot of the primary CPU:
`boot config master <1-2>`
4. Save the changed configuration.
5. Configure the number of seconds a standby CPU waits before trying to become the primary CPU:
`boot config delay <0-255>`
6. Save the changed configuration.
7. Restart the switch.

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Specify the slot number, either 1 or 2, for the primary CPU:

```
Switch:1(config)# boot config master 2
Switch:1(config)# save config
```

Specify the number of seconds a standby CPU waits before trying to become the primary CPU:

```
Switch:1(config)# boot config delay 30
Switch:1(config)# save config
Switch:1(config)# reset
```

Variable Definitions

The following table defines parameters for the **boot config master** command.

Variable	Value
<1-2>	Specifies the slot number, either 1 or 2, for the primary CPU. The default value is slot 1.

Reserve Bandwidth for Advanced Features

Use this procedure if you want the switch to support advanced features. When you enable this boot flag, you need to save and reboot with the new configuration.

Before You Begin

Product Notice: For VSP 7400 Series, you must ensure your configuration does not include reserved ports before you enable this feature. If the configuration includes reserved ports after you enable this feature and restart the switch, the switch stops loading the configuration.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable the boot flag:

```
boot config flags advanced-feature-bandwidth-reservation [low | high]
```
3. Save the configuration, and then reboot the switch.

Important

A change to the advanced-feature-bandwidth-reservation boot flag requires a reboot for the change to take effect.

4. Verify the boot flag configuration:

```
show boot config flags
```
5. Verify that the switch reserved the ports as loopback ports. Reserved ports are not visible in the output of the following command:

Note

This step only applies to VSP 7400 Series.

```
show interfaces gigabitEthernet
```

Example

Enable this feature to the low level.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags advanced-feature-bandwidth-reservation low
Warning: Please note that the configuration for the following ports 1/31-1/32
```

```

will be removed from the configuration file.
Are you sure you want to continue (y/n) ? y
Warning: Please save the configuration and reboot the switch
for this to take effect.
Flag advanced-feature-bandwidth-reservation is changed to enable (low).

```

Display Advanced Feature Bandwidth Reservation Ports

Note

This procedure only applies to VSP 7400 Series.

After you configure the **advanced-feature-bandwidth-reservation** boot flag and reboot with the new configuration, you can use the following procedure to verify that the switch reserved ports for configuring advanced features.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Advanced Feature Bandwidth Reservation mode and reserved ports:

```
show sys-info
```

Example

```

Switch#show sys-info

General Info :

SysDescr      : Switch1 (w.x.y.z)   BoxType: Switch1
SysName       : Switch1
.
.
.

Advanced Feature Bandwidth Reservation:
-----

Reservation Mode : low
Port Usage Info  : 1/31 and 1/32 are not available to use

```

Display the Boot Configuration

About This Task

Display the configuration to view current or changed settings for the boot parameters.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. View the configuration:

```
show boot config <choice|flags|general|host|master|running-config
[verbose]|sio>
```

Example

Show the current boot configuration. (If you omit `verbose`, the system only displays the values that you changed from their default value.):

```
Switch:1>enable

Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.

Switch:1#(config)#show boot config running-config
#
#Mon Feb 13 13:32:58 2017 EST
#
boot config flags debug-config file
boot config flags debugmode
boot config flags ftpd
no boot config flags spbm-config-mode
boot config flags sshd
boot config flags telnetd
boot config flags tftpd
no boot config flags verify-config
boot config choice primary backup-config-file "/intflash/config.cfg"
#boot config sio console baud 115200
```

Variable Definitions

The following table defines parameters for the **show boot config** command.

Variable	Value
<i>choice</i>	Shows the current boot configuration choices.
<i>flags</i>	Shows the current flag settings.
<i>general</i>	Shows system information.
<i>host</i>	Shows the current host configuration.
<i>master</i>	Shows the master information.
<i>running-config</i> <i>[verbose]</i>	Shows the current boot configuration. If you use <i>verbose</i> , the system displays all possible information. If you omit <i>verbose</i> , the system displays only the values that you changed from their default value.
<i>sio</i>	Specifies the current configuration of the serial ports.

Configure Serial Port Devices

Configure the serial port devices to define connection settings for the console port. Depending on your hardware platform the console port displays as console or 10101.

Note

These commands do not apply on all hardware platforms.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. View the current baud rate configuration:
`show boot config sio`
3. Change the console baud rate:
`boot config sio console baud <9600-115200> <1-8>|<SF1-SF3>`
4. Save the changed configuration.
5. Restart the switch.

Example

```
Switch:1>enable
Switch:1#config terminal
Switch:1(config)#show boot config sio
sio console baud 115200 2
sio console baud 115200 5
sio console baud 115200 8
sio console baud 115200 SF1
sio console baud 115200 SF3
```

Configure the baud rate to 9600 for the console port in IOC module slot 2:

```
Switch:1(config)#boot config sio console baud 9600 2
Switch:1(config)#show boot config sio
sio console baud 9600 2
sio console baud 115200 5
sio console baud 115200 8
sio console baud 115200 SF1
sio console baud 115200 SF3
```

Variable Definitions

The following table defines parameters for the **boot config sio console** command.

Variable	Value
<code>baud <9600-115200></code>	<p>Configures the baud rate for the port from one of the following:</p> <ul style="list-style-type: none"> • 9600 • 19200 • 38400 • 57600 • 115200 <p>The default value differs depending on hardware platform:</p> <ul style="list-style-type: none"> • VSP 4450 Series — 9600 • VSP 4900 Series — 115200 • VSP 7200 Series — 9600 • VSP 7400 Series — 115200 • VSP 8200 Series — 9600 • VSP 8400 Series — 9600 • VSP 8600 Series — 115200 • XA1400 Series — 115200
<code><1-8> <SF1-SF3></code> Note: Exception: only supported on VSP 8600 Series.	<p>Configures the individual console baud rate for the IOC modules in slots 1 through 8 or the switch fabric (SF) modules in slots SF1 through SF3.</p>

Run-time process management using CLI

Configure and manage the run-time process using the Command Line Interface (CLI).

Configuring the time zone

About This Task

Configure the time zone to use an internal system clock to maintain accurate time. The time zone data in Linux includes daylight changes for all time zones up to the year 2038. You do not need to configure daylight savings.

The default time zone is Coordinated Universal Time (UTC).

Important

In October 2014, the government of Russia moved Moscow from UTC+4 into the UTC+3 time zone with no daylight savings.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the time zone by using the following command:

```
clock time-zone WORD<1-10> WORD<1-20> WORD<1-20>
```

3. Save the changed configuration.

Example

Configure the system to use the time zone data file for Vevay:

```
Switch:1(config)# clock time-zone America Indiana Vevay
```

Variable Definitions

The following table defines parameters for the **clock time-zone** command.

Variable	Value
<i>WORD<1-10></i>	Specifies a directory name or a time zone name in /usr/share/zoneinfo, for example, Africa, Australia, Antarctica, or US. To see a list of options, enter <code>clock time-zone</code> at the command prompt without variables.
<i>WORD<1-20></i> <i>WORD<1-20></i>	The first instance of <i>WORD<1-20></i> is the area within the timezone. The value represents a time zone data file in /usr/share/zoneinfo/ <i>WORD<1-10></i> /, for example, Shanghai in Asia. The second instance of <i>WORD<1-20></i> is the subarea. The value represents a time zone data file in /usr/share/zoneinfo/ <i>WORD<1-10></i> / <i>WORD<1-20></i> /, for example, Vevay in America/Indiana. To see a list of options, enter <code>clock time-zone</code> at the command prompt without variables.

Configure the Run-time Environment

About This Task

Configure the run-time environment to define generic configuration settings for CLI sessions.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Change the login prompt:

```
login-message WORD<1-1513>
```
3. Change the password prompt:

```
passwordprompt WORD<1-1510>
```
4. Configure the number of supported rlogin sessions:

```
max-logins <0-8>
```

Note

This step only applies to VSP 8600 Series.

5. Configure the number of supported inbound Telnet sessions:

```
telnet-access sessions <0-8>
```

6. Configure the idle timeout period before automatic logoff for CLI and Telnet sessions:

```
cli timeout <30-65535>
```

7. Configure the number of lines in the output display:

```
terminal length <8-64>
```

8. Configure scrolling for the output display:

```
terminal more <disable|enable>
```

Example

```
Switch:1>enable  
Switch:#configure terminal
```

Use the default option to enable use of the default logon string:

```
Switch:(config)#default login-message
```

Use the default option before this parameter to enable use of the default string:

```
Switch:(config)#default passwordprompt
```

Configure the allowable number of inbound remote CLI logon sessions:

```
Switch:(config)#max-logins 5
```

Configure the allowable number of inbound Telnet sessions:

```
Switch:(config)#telnet-access sessions 8
```

Configure the timeout value, in seconds, to wait for a Telnet or CLI login session before terminating the connection:

```
Switch:(config)#cli timeout 900
```

Configure the number of lines in the output display for the current session:

```
Switch:(config)#terminal length 30
```

Configure scrolling for the output display:

```
Switch:(config)#terminal more disable
```

Variable Definitions

The following table defines parameters for the **login-message** command.

Variable	Value
<i>WORD</i> <1-1513>	Changes the CLI logon prompt. <ul style="list-style-type: none"> • <i>WORD</i><1-1513> is an American Standard Code for Information Interchange (ASCII) string from 1-1513 characters. • Use the default option before this parameter, <code>default login-message</code>, to enable use of the default logon string. • Use the no operator before this parameter, <code>no login-message</code>, to disable the default logon banner and display the new banner.

Use the data in the following table to use the **passwordprompt** command.

Variable	Value
<i>WORD</i> <1-1510>	Changes the CLI password prompt. <ul style="list-style-type: none"> • <i>WORD</i><1-1510> is an ASCII string from 1-1510 characters. • Use the default option before this parameter, <code>default passwordprompt</code>, to enable using the default string. • Use the no operator before this parameter, <code>no passwordprompt</code>, to disable the default string.

Use the data in the following table to use the **max-logins** command.

Variable	Value
<0-8>	Configures the allowable number of inbound remote CLI logon sessions. The default value is 8.
Note: Exception: only supported on VSP 8600 Series.	

Use the data in the following table to use the **telnet-access sessions** command.

Variable	Value
<0-8>	Configures the allowable number of inbound Telnet sessions. The default value is 8.

Use the data in the following table to use the **cli time-out** command.

Variable	Value
<30-65535>	Configures the timeout value, in seconds, to wait for a Telnet or CLI login session before terminating the connection.

Use the data in the following table to use the **terminal** command.

Variable	Value
<8-64>	Configures the number of lines in the output display for the current session. To configure this option to the default value, use the default operator with the command. The default is value 23.
<i>disable enable</i>	Configures scrolling for the output display. The default is enabled. Use the no operator to remove this configuration. To configure this option to the default value, use the default operator with the command. no

Configuring CLI logging

About This Task

Use CLI logging to track all CLI commands executed and for fault management purposes. The CLI commands are logged to the system log file as CLILOG module.

Note

The platform logs CLILOG and SNMPLOG as INFO. Normally, if you configure the logging level to WARNING, the system skips all INFO messages. However, if you enable CLILOG and SNMPLOG the system logs CLI Log and SNMP Log information regardless of the logging level you set. This is not the case for other INFO messages.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Enable CLI logging:
clilog enable
3. Disable CLI logging:
no clilog enable
4. Ensure that the configuration is correct:
show clilog
5. View the CLI log:
show logging file module clilog

- View the CLI log.

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#cliolog enable
```

Variable Definitions

The following table defines parameters for the **cliolog** commands.

Variable	Value
<i>enable</i>	Activates CLI logging. To disable, use the <code>no cliolog enable</code> command.

Configure System Parameters

About This Task

Configure individual system-level switch parameters to configure global options for the switch.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Change the system name:

```
sys name WORD<0-255>
```
- Enable support for Jumbo frames:

```
sys mtu <1522-9600>
```
- Enable the User Datagram Protocol (UDP) checksum calculation:

```
udp checksum
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Configure the system, or root level, prompt name for the switch:

```
Switch:1(config)# sys name Floor3Lab2
```

Variable Definitions

The following table defines parameters for the **sys** command.

Variable	Value
<i>clipId-topology-ip</i> Note: Exception: Only supported on VSP 8600 Series	Configures the topology ip from the available CLIP. <i>WORD</i> <1–256>specifies the Circuitless IP interface id.
<i>control tcp-timestamp</i>	Enables or disables TCP Timestamp.
<i>force-msg</i>	Adds forced message control pattern. <i>WORD</i> <4–4> Enter force message pattern.
<i>force-topology-ip-flag</i> Note: Exception: Only supported on VSP 8600 Series	Flags set to force choice of topology flag. <i>enable</i>
<i>msg-control</i>	Configures system message control feature.
<i>mtu</i> <1522–9600>	Configures Jumbo frame support for the data path. The value can be either 1522, 1950 (default), or 9600 bytes.
<i>name</i> <i>WORD</i> <0–255>	Configures the system, or root level, prompt name for the switch. <i>WORD</i> <0–255> is an ASCII string from 0–255 characters (for example, LabSC7 or Closet4).
<i>power</i>	Enables power to specified slot(s).
<i>security-console</i>	Enables the security console.
<i>software</i>	Configures software configuration.
<i>priv-exec-password</i>	Enables authentication for the Privileged EXEC CLI command mode.

Configuring system message control

About This Task

Configure system message control to suppress duplicate error messages on the console, and to determine the action to take if they occur.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure system message control action:

```
sys msg-control action <both|send-trap|suppress-msg>
```
3. Configure the maximum number of messages:

```
sys msg-control max-msg-num <2–500>
```

4. Configure the interval:

```
sys msg-control control-interval <1-30>
```
5. Enable message control:

```
sys msg-control
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Configure system message control to suppress duplicate error messages on the console and send a trap notification:

```
Switch:1(config)# sys msg-control action both
```

Configure the number of occurrences of a message after which the control action occurs:

```
Switch:1(config)# sys msg-control max-msg-num 2
```

Configure the message control interval in minutes:

```
Switch:1(config)# sys msg-control control-interval 3
```

Enable message control:

```
Switch:1(config)# sys msg-control
```

Variable Definitions

The following table defines parameters for the **sys msg-control** command.

Variable	Value
<i>action</i> <both send-trap suppress-msg>	Configures the message control action. You can either suppress the message or send a trap notification, or both. The default is suppress.
<i>control-interval</i> <1-30>	Configures the message control interval in minutes. The valid options are 1-30. The default is 5.
<i>max-msg-num</i> <2-500>	Configures the number of occurrences of a message after which the control action occurs. To configure the maximum number of occurrences, enter a value from 2-500. The default is 5.

Extending system message control

About This Task

Use the force message control option to extend the message control feature functionality to the software and hardware log messages.

To enable the message control feature, you must specify an action, control interval, and maximum message number. After you enable the feature, the log messages, which get repeated and cross the

maximum message number in the control interval, trigger the force message feature. You can either suppress the message or send a trap notification, or both.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the force message control option:

```
sys force-msg WORD<4-4>
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Configure the force message control option. (If you specify the wildcard pattern (****), then all messages undergo message control:

```
Switch:1(config)# sys force-msg ****
```

Variable Definitions

The following table defines parameters for the **sys force-msg** command.

Variable	Value
<i>WORD<4-4></i>	Adds a forced message control pattern, where <i>WORD<4-4></i> is a string of 4 characters. You can add a four-byte pattern into the force-msg table. The software and the hardware log messages that use the first four bytes that match one of the patterns in the force-msg table undergo the configured message control action. You can specify up to 32 different patterns in the force-msg table, including a wildcard pattern (****) as well. If you specify the wildcard pattern, all messages undergo message control.

Hardware status using EDM

This section provides methods to check the status of basic hardware in the chassis using Enterprise Device Manager (EDM).

Configure Polling Intervals

About This Task

Enable and configure polling intervals to determine how frequently EDM polls for port and LED status changes or detects the hot swap of installed ports.

Procedure

1. In the navigation pane, expand **Configuration > Device**.
2. Click **Preference Setting**.
3. Enable polling or hot swap detection.
4. Configure the frequency to poll the device.
5. Click **Apply**.

Preference Setting field descriptions

Use the data in the following table to use the **Preference Setting** tab.

Name	Description
Enable	Enables polling for port and LED status changes. The default is disabled.
Poll Interval	Specifies the polling interval, if enabled. The default is 60 seconds.
Enable	Detects the hot swap of installed ports. The default is disabled.
Detection per Status Poll Intervals	Specifies the number of poll intervals for detection, if enabled. The default is 2 intervals.

View Module Information

View the administrative status for modules in the chassis.

About This Task

This command is not available for hardware platforms with fixed configurations. It is only available for platforms where the user can install modules in slots.

Procedure

1. In the Device Physical View tab, select a module slot.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Card**.
4. Click the **Card** tab.

Card field descriptions

Use the data in the following table to use the **Card** tab.

Name	Description
CardType	Displays the model number of the module.
CardDescription	Shows a description of the installed module.
SerialNum	Shows the serial number for the installed module.
PartNumber	Shows the part number.
CardAssemblyDate	Shows the date the module was assembled.

Name	Description
CardHWConfig	Shows the hardware revision.
AdminStatus	Changes the administrative status for the module.
OperStatus	Shows the operational status for the module.
PowerManagementPriority	Specifies the slot priority for power management as either high or low.

View Module Storage Usage

Note

This procedure only applies to VSP 8600 Series.

View the storage usage for modules in the chassis.

About This Task

You cannot perform this procedure on hardware platforms with fixed configurations. It is only available for platforms where you can install modules in slots.

Procedure

1. In the Device Physical View tab, select a module slot.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Card**.
4. Select the **Storage Usage** tab.

Storage Usage Field Descriptions

Use the data in the following table to use the **Storage Usage** tab.

Name	Description
IntflashBytesUsed	Specifies the number of bytes used in internal flash memory.
IntflashBytesFree	Specifies the number of bytes available for use in internal flash memory.
IntflashNumFiles	Specifies the number of files in internal flash memory.
UsbBytesUsed	Specifies the number of bytes used in USB device.
UsbBytesFree	Specifies the number of bytes available for use in USB device.
UsbNumFiles	Specifies the number of files in USB device.

View Power Supply Parameters

Perform this procedure to view information about the operating status of the power supplies.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.

2. Click **Power Supply**.

Details Field Descriptions

Use the data in the following table to use the **Details** tab.

Name	Description
Id	Specifies the ID number. This field is not supported on all hardware platforms.
Type	Describes the type of power used.
Description	Provides a description of the power supply.
SerialNumber	Specifies the power supply serial number.
HardwareRevision	Specifies the hardware revision number.
PartNumber	Specifies the power supply part number.
PowerSupplyOperStatus	Specifies the status of the power supply as one of the following: <ul style="list-style-type: none"> • on (up) • off (down)
InputLineVoltage	Displays the input line voltage: <ul style="list-style-type: none"> • low 110v—power supply connected to a 110 Volt source • high 220v—power supply connected to a 220 Volt source • ac110vOr220v—power supply connected to a 110 Volt or 220 Volt source
OutputWatts	Displays the output power of this power supply.
InputOperLineVoltage	Displays the operating input line voltage. If the power supplies in a chassis are not of identical input line voltage values, the operating line voltage shows the low 110v value. This field is not supported on all hardware platforms.
InputPower	Displays the input power of this power supply. This field is not supported on all hardware platforms.

View Power Supply Information

Note

This procedure only applies to VSP 8600 Series.

About This Task

Perform this procedure to view information about the operating status of the power supplies.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Power Supply Information**.

Details Field Descriptions

Use the data in the following table to use the **Details** tab.

Name	Description
Id	Specifies the ID number. This field is not supported on all hardware platforms.
Type	Describes the type of power used.
Description	Provides a description of the power supply.
SerialNumber	Specifies the power supply serial number.
HardwareRevision	Specifies the hardware revision number.
PartNumber	Specifies the power supply part number.
PowerSupplyOperStatus	Specifies the status of the power supply as one of the following: <ul style="list-style-type: none"> on (up) off (down)
InputLineVoltage	Displays the input line voltage: <ul style="list-style-type: none"> low 110v—power supply connected to a 110 Volt source high 220v—power supply connected to a 220 Volt source ac110vOr220v—power supply connected to a 110 Volt or 220 Volt source
OutputWatts	Displays the output power of this power supply.
InputOperLineVoltage	Displays the operating input line voltage. If the power supplies in a chassis are not of identical input line voltage values, the operating line voltage shows the low 110v value. This field is not supported on all hardware platforms.
InputPower	Displays the input power of this power supply. This field is not supported on all hardware platforms.

View System Temperature Information

View information about the temperature for each sensor on the device.

The system triggers an alarm when one of the zones exceeds the threshold temperature value.

Note

This procedure does not apply to all hardware models.

Procedure

1. In the Device Physical View tab, select the chassis.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **System Temperature** tab.

System Temperature field descriptions

Use the data in the following table to use the **System Temperature** tab.

Name	Description
SensorIndex	Specifies the range of sensors on the device.
SensorDescription	Specifies the name of the sensor.
Temperature (degrees celsius)	Specifies the sensor temperature measured in Celsius degrees.
WarningThreshold	Specifies the temperature value of the warning threshold for the sensor. When the temperature crosses the warning threshold a warning message is generated.
CriticalThreshold	Species the temperature value of the critical threshold for the sensor. When the temperature crosses the critical threshold, a critical message is generated or the system shuts down, depending on hardware capability.
Status	Specifies the current temperature status based on the warning and critical thresholds.

View Chassis Temperatures

You can view information about the temperature on the chassis.

**Note**

This procedure only applies to the VSP 8600 Series.

About This Task

The system triggers an alarm when one of the zones exceeds the threshold temperature value, and clears the alarm after the zone temperature falls below the threshold value.

When an elevated temperature triggers a temperature alarm, the fan speed increases, and the LED color changes on the front panel of the switch.

Procedure

1. In the Device Physical View tab, select the chassis.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Chassis**.
4. Select the **Temperature** tab.

Temperature field descriptions

Use the data in the following table to use the **Temperature** tab.

Name	Description
CpuTemperature	Current CPU temperature in Celsius.
MacTemperature	Current MAC component temperature in Celsius.
Phy1Temperature	Current PHY 1 component temperature in Celsius. This field does not apply on all hardware platforms.
Phy2Temperature	Current PHY 2 component temperature in Celsius. This field does not apply on all hardware platforms.

Command Line Interface

[Command Line Interface Fundamentals](#) on page 240
[CLI Procedures](#) on page 251

Table 27: Command Line Interface product support

Feature	Product	Release introduced
Command Line Interface (CLI)	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 4200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50

Command Line Interface Fundamentals

This section describes the Command Line Interface (CLI).

CLI is an industry standard command line interface that you can use for single-device management.

CLI Command Modes

CLI command modes provide specific sets of CLI commands. When you log onto the switch, you are in User EXEC mode with limited commands. While in a higher mode, you can access most commands from lower modes, except if they conflict with commands of your current mode.

There are two categories of CLI commands: show commands and configuration commands. You can use show commands from multiple command modes with the same results; they show the same configuration information regardless of the command mode. Configuration command results, however, might be dependent on the command mode from which a configuration command is used. For example, an **enable** command used in Global Configuration mode will enable a feature globally for all devices, and the same command used from one of the interface command modes will enable a feature for a specific interface only.

The following figure illustrates the navigation paths for the various command modes:

Figure 10: CLI Command Mode Navigation

Your user authorization credentials determine what commands are available to you in Privileged EXEC mode and all higher-level modes. See [System Access](#) on page 3311 for more information.

To navigate from higher-level modes to lower-level modes, use the following commands:

- **exit** to navigate from a higher-level mode to a lower-level mode, down to Privileged EXEC mode
- **end** to navigate from any command mode directly to Privileged EXEC mode
- **disable** to navigate from Privileged EXEC mode to User EXEC mode
- **logout** to terminate the CLI session from any command mode

The following table describes the various command modes, including the CLI command to access each mode, the command prompt that displays in each mode, and a description of the purpose of the mode.

Note

Some command modes are hardware dependent. If any of the following commands modes do not display on your hardware, they are not supported or applicable.

Table 28: CLI Command Mode Summary

Command mode	Command to access mode	Prompt displayed in mode	Description
User EXEC	None required; default mode	>	View configuration settings and connection status.
Privileged EXEC	enable	#	Configure limited device-wide settings.
	Note: Depending on feature configuration, you can be prompted to enter a username and password to access Privileged EXEC mode. For more information, see Authentication for Privileged EXEC Command Mode on page 251.		
Global Configuration	configure {terminal network}	(config) #	From a terminal or TFTP server, configure device-wide global parameters on a running configuration, or specify the filename of a configuration file.
GigabitEthernet Interface Configuration	interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/subport]] [,...]}	(config-if) #	Configure chassis operations and features on a physical port.
MLT Interface Configuration	interface mlt <1-512>	(config-mlt) #	Configure an MLT interface.
mgmtEthernet Interface Configuration	interface mgmtEthernet <mgmt mgmt2>	(config-if) #	Configure a dedicated physical management port (if supported on your hardware).

Table 28: CLI Command Mode Summary (continued)

Command mode	Command to access mode	Prompt displayed in mode	Description
Loopback Interface Configuration	<code>interface loopback <1-256></code>	<code>(config-if) #</code>	Configure a loopback CLIP interface.
VLAN Interface Configuration	<code>interface vlan <1-4059></code>	<code>(config-if) #</code>	Configure port-based, policy-based, private, or SPBM B-VLANs
Logical Interface Configuration	<code>logical-intf isis <1-255></code>	Layer 2: <code>(config-isis- <1-255>) #</code> Layer 3: <code>(config-isis- <1-255>- <A.B.C.D>) #</code>	Configure a logical Layer 2 or Layer 3 interface.
BGP Router Configuration	<code>router bgp</code>	<code>(router-bgp) #</code>	Configure device-wide BGP routing protocol settings.
RIP Router Configuration	<code>router rip</code>	<code>(config-rip) #</code>	Configure device-wide RIP routing protocol settings.
OSPF Router Configuration	<code>router ospf</code>	<code>(config-ospf) #</code>	Configure device-wide OSPF routing protocol settings.
IS-IS Router Configuration	<code>router isis</code>	<code>(config-isis) #</code>	Configure device-wide IS-IS routing protocol settings.
VRF Router Configuration	<code>router vrf WORD<1-16></code>	<code>(router-vrf) #</code>	Configure a VRF instance, including the built-in Management VRF (accessed with router vrf MgmtRouter command).
VRRP Router Configuration	<code>router vrrp</code>	<code>(config-vrrp) #</code>	Configure device-wide VRRP protocol settings.
Application Configuration	<code>application</code>	<code>(config-app) #</code>	Configure custom applications, such as SLA Monitor or RESTCONF.
Management Instance Configuration	<code>mgmt <clip oob vlan></code>	<code>(mgmt:clip) #</code> or <code>(mgmt:oob) #</code> or <code>(mgmt:vlan) #</code>	Configure a segmented management CLIP, Out-of-Band (OOB), or VLAN instance.
Elan I-SID Configuration	<code>i-sid <1-16777215> [elan]</code>	<code>(elan:<1-16777215>) #</code>	Add ports and traffic to a Switched UNI I-SID on a GigabitEthernet or MLT interface.

Table 28: CLI Command Mode Summary (continued)

Command mode	Command to access mode	Prompt displayed in mode	Description
Elan-Transparent Configuration	i-sid <1-16777215> elan-transparent	(elan- tp:<1-16777215>) #	Add ports and MLT interfaces to an Elan-Transparent based service.
OVSDB Configuration	ovsdb	(config-ovsdb) #	Configure OVSDB protocol support for VXLAN Gateway.
Route-Map Configuration	route-map WORD<1-64> <1-65535>	(route-map) #	Configure device-wide or VRF instance-specific route map policy settings.
DHCP-guard Configuration	ipv6 fhs dhcp- guard policy WORD<1-64>	(config- dhcpguard) #	Configure DHCPv6 for advertised address-based, prefix-based, and preference-based filtering.
RA-guard Configuration	ipv6 fhs ra-guard policy WORD<1-64>	(config-raguard) #	Configure RA Guard for advertised IPv6 and MAC address-based, IPv6 prefix-based, preference-based, hop count limit-based, and default router preference-based filtering.
VXLAN Configuration	vnid <1-16777215> i-sid <1- 16777215>	(vxlan:<1-1677721 5>) #	Associate port or MLT interface VLANs, configure VXLAN endpoints and untagged traffic.
MKA Profile Configuration	macsec mka profile WORD<1-16>	(mka-profile) #	Configure replay protection and confidentiality offset for an MKA profile.
BFD Router Configuration	router bfd	(router-bfd) #	Configure device-wide BFD settings.

Special CLI Command Modes

A special CLI command mode provides a set of specific CLI commands that are different from the standard CLI command modes and the CLI commands available in them. For example, a set of CLI commands that are specifically introduced to configure services on a Virtual Machine (VM) through a specific CLI command mode.

Note

Special CLI command modes are hardware dependent. If they do not display on your hardware, they are not supported or applicable.

The following table describes the special command mode.

Table 29: Special CLI Command Mode Summary

Special command mode	Command mode navigation	Command to access mode	Prompt displayed in mode	Description
Fabric IPsec Gateway	Accessible from Privileged EXEC	virtual-service WORD<1-128> console Note: Type CTRL+Y to exit the console.	FIGW>	Configure services like IPsec, fragmentation and reassembly, and to manage the Fabric IPsec Gateway VM.
IS-IS Router Remote Configuration	Accessible from Global Configuration	router isis remote	config-isis-remote>	Configure the Multi-area SPB parameters like area virtual node, Shortest Path Bridging MAC (SPBM), manual area and so on.

Default User Names and Passwords for CLI

The following table contains the default user names and passwords that you can use to log on to the switch using the command line interface (CLI). For more information about how to change passwords, see [Security](#) on page 2991.

Table 30: CLI default user names and passwords

User name	Password	Description
rwa	rwa	read-write-all
rw	rw	read-write
ro	ro	read-only
l1	l1	layer 1
l2	l2	layer 2
l3	l3	layer 3

You can create up to a maximum of 10 CLI users for each role. For more information, see [Multiple CLI Users for Each Role](#) on page 3316.

If you enable enhanced secure mode, the user names and passwords are different than the default values documented in the preceding table. For more information on enhanced secure mode, see [Enhanced Secure Mode](#) on page 3317.

Important

The default passwords and community strings are documented and well known. As a best practice, change the default passwords and community strings immediately after you first log on. For more information about how to change user names and passwords, see [Security](#) on page 2991.

Documentation convention for the port variable

Commands that require you to enter one or more port numbers on the switch use the parameter `{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}` in the syntax. The following table specifies the rules for using `{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`.

Syntax	How to use
<code>{slot/port[/sub-port]}</code>	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. For example, 1/1 indicates the first port on slot 1. 1/41/1 indicates the first channel on slot 1, port 41.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. For example, 1/1-1/3 indicates ports 1 to 3 on slot 1, or 1/41/1,1/41/3 indicates the first and third channels of slot 1, port 41.

Command completion

The CLI provides potential command completions to the command string. Completions are provided by using a question mark (?) or by using the CLI autocompletion feature.

? command completion

The ? command completion is available for any valid command. By typing a command and using a ? as the last argument in the command, the system returns a list of possible command completions from the point of the ?. A short description is provided with each possible completion.

If you enter the following command:

```
Switch:1(config-isis)#redistribute ?
```

CLI provides a list of completions for the **redistribute ?** command.

```
Switch:1(config-isis)#redistribute ?
  direct      isis redistribute direct command
  ospf        isis redistribute ospf command
  rip         isis redistribute rip command
  static      isis redistribute static command
```

All the parameters listed under `redistribute` indicate sub-context commands.

You must use one of the available completions, and if necessary, use the command completion help again to find the next completion.

```
Switch:1(config-isis)#redistribute direct ?
  enable      Enable isis redistribute direct command
  metric      Isis route redistribute metric
  metric-type Set isis redistribute metric type
  route-map   Set isis redistribute direct route-policy
  subnets    Set isis redistribute subnets
<cr>
```

When you see `<cr>` (Carriage Return/Enter Key) in the list with the additional choices, this means that no additional parameters are required to execute the CLI command. However, the additional choices listed could be peer commands or sub-context commands.

For example, the parameters listed under **`redistribute direct ?`** are peer commands. You can enter these peer commands on the same line as the root command, for example **`redistribute direct enable`**. However, the `<cr>` indicates that you can also enter the **`redistribute direct`** command only and this command does not require any additional parameters at this level.

CLI autocompletion

CLI autocompletion is a feature that you can use to automatically fill in the unique parts of a command string rather than typing the entire command. Autocompletion makes the CLI experience easier and prevents mistakes in spelling that force you to re-enter the command.

Autocompletion completes the token in the command as soon as it becomes unique.

The `Tab` key autocompletes the command without executing the command, and places the cursor immediately after the last character. The `Enter` key autocompletes the command and executes it.

To enable redistribution of ISIS direct routes,

```
Switch:1(config-isis)#redistribute direct
```

When you use `redistribute ?`, you see four possible sub-context commands.

```
direct
static
ospf
rip
```

If you type the following without pressing `Enter`:

```
Switch:1(config-isis)#redistribute direct m
```

and press the `Tab` key, the system completes the command to the following point:

```
redistribute direct metric
```

Two possible completions exist. You can type `-t`, and then press `Tab` to finish the command:

```
Switch:1(config-isis)#redistribute direct metric-type
```

default command operator

You can reset the modified configuration of a command to the default configuration by using the default operator. For more information about the default value for each command, see [VOSS CLI Commands Reference](#).

Use the ? command completion along with the default keyword in each configuration mode, to view the list of commands that support the default operator. For more information, see [Command completion](#) on page 246.

Examples

Configure **csnp-interval** to its default value. The default value of **csnp-interval** is 10 seconds.

```
Switch:1>show isis

Switch:1(config-mlt)#default ip ?
Default IP configurations on MLT interface
  arp-inspection  Default arp inspection configuration
  dhcp-snooping   Default dhcp snooping configuration
Switch:1(config-mlt)#default ip arp-inspection ?
<cr>

```

no command operator

You can use the **no** operator in a command to negate a configuration. Based on the functionality of the command, you can perform negations, such as disable, delete, remove, or reset to the default configuration. For more information about the **no** operator for each command, see [VOSS CLI Commands Reference](#).

Use the ? command completion along with the **no** keyword to view the list of commands that support the **no** operator in each configuration mode. For more information, see [Command completion](#) on page 246.

Negate the automatic virtual link that provides automatic dynamic backup link for OSPF traffic.

```

Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router ospf
Switch:1(config-ospf)#no auto-vlink

```

Remove an IP address configuration from VLAN.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 3
Switch:1(config-if)#no ip address 192.0.2.4
```

View the commands that can negate a configuration in RIP router configuration mode.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router rip
Switch:1(config-rip)#no ?
Negate a command or set its defaults
ipv6          Disable ipv6 configurations
network       Disable rip on an ip network
redistribute  To disable/delete redistribute globally
Switch:1(config-rip)#no network ?
{A.B.C.D} Network ip address
Switch:1(config-rip)#no network 192.0.2.4 ?
<cr>
```

GREP with CLI show command

You can use Global Regular Expression Print (GREP) with **show** commands to filter the output based on match criteria.

Enter the **show** command followed by the pipe (|) character, followed by the GREP filter command. The **show** command output contains only the lines that match the GREP filter pattern.

Note

The **show fulltech** command does not support GREP filters.

The following GREP filter commands are supported.

GREP filter function	Description
<i>begin</i>	Displays the output of a command starting from the first line, which matches the given pattern.
<i>count</i>	Counts the number of lines in the output of a command.
<i>exclude</i>	Displays only the output lines which do not match the given pattern. The lines matching the pattern are discarded.
<i>head</i>	Limits the output of a command to the first few lines. If a number is not specified then only the first 10 lines display.
<i>include</i>	Displays only the output lines which match the given pattern.

GREP filter function	Description
<i>no-more</i>	Temporarily disables pagination for the output of an CLI command. When the lines of output exceed the terminal length, you are not prompted to continue or quit but the entire output of the command continues to be displayed. The effect is similar to setting terminal length 0 but only for the current command.
<i>tail</i>	Limits the output of a command to the last few lines. If a number is not specified then only the last 10 lines display.

Timestamp in show command outputs

The output for all CLI show commands includes a timestamp header to indicate when the command output was generated. This information can be helpful when communicating with Support.

The following command output shows a timestamp example.

```
Switch:1#show alarm statistics
*****
                Command Execution Time: Wed Nov 07 19:55:15 2018 UTC
*****

=====
                        ALARM STATISTICS
=====
PERSISTENT PERSISTENT PERSISTENT PERSISTENT DYNAMIC DYNAMIC DYNAMIC DYNAMIC
ALARM      ACTIVE      CLEARED    WRPRD     ALARM     ACTIVE     CLEARED    WRPRD
0           0           0          0         11        8          3          0
```

Authentication for Privileged EXEC Command Mode

For enhanced security, you can request user authentication to enter Privileged EXEC command mode. When you configure password authentication, the switch prompts you to enter a username and password to access Privileged EXEC command mode from User EXEC command mode. You use the same username and password used to Telnet or SSH to the switch.

For more information about configuring Privileged EXEC authentication, see [Authentication for Privileged EXEC Command Mode](#) on page 2998.

CLI Procedures

This section contains information about common CLI tasks. You can access CLI during runtime to manage the switch.

Logging on to the software

Before You Begin

- The first time you connect to the switch, you must log on to CLI using the direct console port.

About This Task

After you first connect to CLI you can log on to the software using the default user name and password. For more information about the default user names and passwords, see [Default User Names and Passwords for CLI](#) on page 245.

Procedure

1. At the login prompt, enter the user name.
2. At the password prompt, enter the password.

View the Configuration

You can view the running configuration using the show command.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. View the running configuration:
`show running-config`

Example

```
VSP-8284XSQ:1#show running-config
Preparing to Display Configuration...
#
# Sat Mar 13 14:35:01 2021 UTC
# box type           : VSP-8284XSQ

```
#
config terminal

#
# BOOT CONFIGURATION
#

boot config flags ftpd
boot config flags sshd
boot config flags telnetd

#boot config sio console baud 9600 1
# end boot flags
```

Saving the configuration

After you change the configuration, you must save the changes to the module. Save the configuration to a file to retain the configuration settings.

About This Task

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Save the running configuration:
`save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]`

Example

Save the configuration to the default location:

```
Switch:1#save config
```

Identify the file as a backup file and designate a location to save the file:

```
Switch:1#save config backup 198.51.100.1/configs/backup.cfg
```

Variable definitions

Use the data in the following table to use the **save config** command.

Variable	Value
<i>backup</i> WORD<1-99>	Saves the specified file name and identifies the file as a backup file. WORD<1-99> uses one of the following formats: <ul style="list-style-type: none"> a.b.c.d:<file> /intflash/<file> The file name, including the directory structure, up to 1 to 99 characters.
<i>file</i> WORD<1-99>	Specifies the file name in one of the following formats: <ul style="list-style-type: none"> /intflash/<file> a.b.c.d:<file> The file name, including the directory structure, up to 1 to 99 characters.
<i>verbose</i>	Saves the default and current configuration. If you omit this parameter, the command saves only parameters you change.
<i>standby</i> WORD<1-99>	Specifies the standby file name in the following format: <ul style="list-style-type: none"> /intflash/<file> The file name, including the directory structure, up to 1 to 99 characters.

Configure the Web Server

Note

DEMO FEATURE - Read Only User for EDM is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

Perform this procedure to enable and manage the web server using the Command Line Interface (CLI). After you enable the web server, you can connect to EDM.

HTTP and FTP support both IPv4 and IPv6 addresses, with no difference in functionality or configuration. The TFTP server supports both IPv4 and IPv6 addresses. The TFTP client is not supported, only the server.

About This Task

This procedure assumes that you use the default port assignments. You can change the port number used for HTTP and HTTPS.

Important

To enable HTTP access to the device, you must disable the web server secure-only option. To enable HTTPS access to the device, the web server secure-only option is enabled by default.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable the web server:
`web-server enable`
3. Disable the secure-only option (for HTTP access) :
`no web-server secure-only`
4. Enable the secure-only option (for HTTPS access) :
`web-server secure-only`
5. Enable read-only user:
`web-server read-only-user enable`
6. Display the web server status:
`show web-server`

Example

```
Switch:1(config)#show web-server
Web Server Info :

      Status                : off
      Secure-only            : enabled
      TLS-minimum-version    : tlsv12
      RO Username Status     : disabled
      RO Username            : user
      RO Password            : *****
      RWA Username           : admin
      RWA Password           : *****
      Def-display-rows      : 30
      Inactivity timeout     : 900 sec
      Html help tftp source-dir :
      HttpPort               : 80
      HttpsPort              : 443

                      TLS_RSA_WITH_AES_256_CBC_SHA256
TLS_RSA_WITH_AES_256_CBC_SHA
                      TLS_RSA_WITH_AES_128_CBC_SHA256
TLS_RSA_WITH_AES_128_CBC_SHA

```

Variable Definitions

Use the data in the following table to use the **web-server** command.

Variable	Value
<code>def-display-rows <10-100></code>	Configures the number of rows each page displays, between 10 and 100.
<code>enable</code>	Enables the web interface. To disable the web server, use the no form of this command: <code>no web-server [enable]</code>
<code>help-tftp <WORD/0-256></code>	Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/peer:/ [<dir>]. The path can use 0-256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> • 192.0.2.1:/help • 192.0.2.1/
<code>http-port <80-49151></code>	Configures the web server HTTP port. The default port is 80.
<code>https-port <443-49151></code>	Configure the web server HTTPS port. The default port is 443.
<code>inactivity-timeout<30-65535></code>	Configures the web-server session inactivity timeout. The default is 900 seconds (15 minutes).
<code>password {ro rwa} WORD<1-20></code>	Configures the logon and password for the web interface.
<code>password min-passwd-len<1-32></code>	Configures the minimum password length. By default, the minimum password length is 8 characters.
<code>read-only-user</code>	Enables read-only user for the web server. Note: read-only-user enable is available for demonstration purposes on some products. For more information, see VOSS Feature Support Matrix .

Variable	Value
<code>secure-only</code>	Enables secure-only access for the web server.
<code>tls-min-ver<tlsv10 tlsv11 tlsv12></code>	<p>Configures the minimum version of the TLS protocol supported by the web-server. You can select among the following:</p> <ul style="list-style-type: none"> • <code>tlsv10</code> – Configures the version to TLS 1.0. <p>Note: <code>tlsv10</code> is not supported in enhanced secure mode.</p> <ul style="list-style-type: none"> • <code>tlsv11</code> – Configures the version to TLS 1.1. • <code>tlsv12</code> – Configures the version to TLS 1.2 <p>The default is <code>tlsv12</code>.</p>

Using GREP CLI show command filters

Use the following GREP filters to output only the command lines specified by the filter.

Procedure

1. Count the number of lines in the output:
`<CLI command> | count`
2. Display the output of a command starting from the first line that matches the given pattern:
`<CLI command> | begin WORD<0-255> [field <number>] [ignore-case] [header <number>]`
3. Display only the output lines that match the given pattern:
`<CLI command> | include <pattern> [field <number>] [ignore-case] [header <number>]`
4. Display only the output lines that do not match the given pattern:
`<CLI command> | exclude <pattern> [field <number>] [ignore-case] [header <number>]`
5. Temporarily disable pagination for the output of a CLI command:
`<CLI command> | no-more`

There is no prompt to continue or to quit when the lines of output exceed the terminal length.

6. Limit the output of a command to the first few lines:

```
<CLI command> | head [<number>]
```

If a number is not specified, the first 10 lines display.

7. Limit the output of a command to the last few lines:

```
<CLI command> | tail [<number>] [from-line <number>] [header <number>]
```

If a number is not specified, the last 10 lines display.

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Count the number of lines in the output:

```
Switch1:#show vlan basic | count
Count: 17 lines
```

Display only the output lines that match the given pattern:

```
Switch:1(config)#show vlan basic | include byPort field 3 header 6
```

```

INST_ID PROTOCOLID  SUBNETADDR  SUBNETMASK  VRFID
-----
6   VLAN6        private   40  none      N/A        N/A         0
7   VLAN7        private   41  none      N/A        N/A         0
```

Display the output of a command starting from the first line that matches the given pattern:

```
Switch:1(config)#show vlan basic | begin 8 header 6
```

```
=====
```

```
                                Vlan Basic
```

```
=====
```

VLAN		MSTP					
ID	NAME	TYPE	INST_ID	PROTOCOLID	SUBNETADDR	SUBNETMASK	VRFLID
8	VLAN-8	byPort	8	none	N/A	N/A	0
9	VLAN-9	byPort	9	none	N/A	N/A	0
11	VLAN-11	byPort	11	none	N/A	N/A	0
12	VLAN-12	byPort	12	none	N/A	N/A	0
20	VLAN-20	byPort	0	none	N/A	N/A	0

Display the entire output of the command:

```
Switch:1(config)#show vlan basic | no-more
```

```
=====
```

```
                                Vlan Basic
```

```
=====
```

VLAN		MSTP					
ID	NAME	TYPE	INST_ID	PROTOCOLID	SUBNETADDR	SUBNETMASK	VRFLID
1	Default	byPort	0	none	N/A	N/A	0
3	VLAN3	byPort	3	none	N/A	N/A	0
4	VLAN4	byPort	4	none	N/A	N/A	0
5	VLAN5	byPort	5	none	N/A	N/A	0
6	VLAN6	private	40	none	N/A	N/A	0
7	VLAN7	private	41	none	N/A	N/A	0
8	VLAN-8	byPort	8	none	N/A	N/A	0
9	VLAN-9	byPort	9	none	N/A	N/A	0
11	VLAN-11	byPort	11	none	N/A	N/A	0
12	VLAN-12	byPort	12	none	N/A	N/A	0
20	VLAN-20	byPort	0	none	N/A	N/A	0

Display only the first few lines of output:

```
Switch:1(config)#show vlan basic | head 9
```

```
=====
```

```
                                Vlan Basic
```

```
=====
```

VLAN		MSTP					
ID	NAME	TYPE	INST_ID	PROTOCOLID	SUBNETADDR	SUBNETMASK	VRFLID
1	Default	byPort	0	none	N/A	N/A	0
3	VLAN3	byPort	3	none	N/A	N/A	0

Display only the last few lines of output:

```
Switch:1(config)#show vlan basic | tail 8 header 6
```

```
=====
```

```
                                Vlan Basic
```

```
=====
```

VLAN		MSTP					
ID	NAME	TYPE	INST_ID	PROTOCOLID	SUBNETADDR	SUBNETMASK	VRFLID
8	VLAN-8	byPort	8	none	N/A	N/A	0
9	VLAN-9	byPort	9	none	N/A	N/A	0
11	VLAN-11	byPort	11	none	N/A	N/A	0

```

12  VLAN-12      byPort      12      none      N/A      N/A      0
20  VLAN-20      byPort      0        none      N/A      N/A      0

Switch:1(config)#show vlan basic | tail from-line 15 header 6

=====
                                Vlan Basic
=====
VLAN
ID  NAME          TYPE          MSTP
  9  VLAN-9        byPort        9         none      N/A      N/A      0

 20  VLAN-20       byPort        0         none      N/A      N/A      0

```

Variable definitions

The GREP filters use the following parameters:

Parameter	Description
<i>field</i> <number>	Specifies the field in each line to match against the pattern. Fields are separated by white spaces and are counted starting with 1 for the left-most field. If the output is formatted as a table, whitespaces are not counted as fields.
<i>from-line</i> <number>	Specifies the remaining output starting with a given line.
<i>head</i> <number>	Specifies the number of lines to keep from the beginning of the output.
<i>header</i> <number>	Specifies a number of lines from the start of the output to display unchanged before trying to match the pattern. This parameter is useful to keep the header of a table intact. This filter skips the header lines.
<i>ignore-case</i>	Specifies letters to match in the pattern regardless of case.
<number>	Specifies the number of lines of output to keep, either from the beginning of the output or from the end of the output.
<pattern>	Specifies the regular expression to match against each line of output. Use quotations if the parameter contains spaces.

Enterprise Device Manager Fundamentals

This section details Enterprise Device Manager (EDM).

EDM is a web-based graphical user interface (GUI) you can use to configure a single switch. EDM runs from the switch and you can access it from a web browser. You do not need to install additional client software, and you can access it with all operating systems.

Supported Browsers

Use the following browser versions to access Enterprise Device Manager (EDM):

- Microsoft Edge 97
- Microsoft Internet Explorer 11+
- Mozilla Firefox 96
- Google Chrome 97
- Safari 15.3

Important

For optimal performance, use Mozilla Firefox or Google Chrome.

Enterprise Device Manager Access

To access EDM, open `http://<deviceip>/login.html` or `https://<deviceip>/login.html` from Microsoft Edge, Microsoft Internet Explorer, Google Chrome, or Mozilla Firefox. Ensure you use a supported browser version.

Important

You must enable the web server from CLI (see [Configure the Web Server](#) on page 254) to enable HTTP access to EDM. For HTTP access to the device, you must also disable the web server secure-only option. The web server secure-only option, allowing for HTTPS access to the device, is enabled by default. As a best practice, take the appropriate security precautions within the network if you use HTTP

If you experience issues while connecting to EDM, check the proxy settings. Proxy settings can affect EDM connectivity to the switch. Clear the browser cache and do not use proxy when connecting to the device.

Default User Name and Password for EDM

The following table contains the default user name and password that you can use to log on to the switch using EDM. For more information about changing the passwords, see [Security](#) on page 2991.

Table 32: EDM default username and password

Username	Password
admin	password

For information about creating CLI accounts for each user role on the switch, see [Multiple CLI Users for Each Role](#) on page 3316.

Important

The default passwords and community strings are documented and well known. Change the default passwords and community strings immediately after you first log on. For more information about changing user names and passwords, see [Security](#) on page 2991.

Device Physical View

After you access EDM, the system displays a real-time physical view of the front panel of the device on the **Device Physical View** tab in the content pane. From the front panel view, you can view fault, configuration, and performance information for the device or a single port.

You can use the device view to determine the operating status of the various ports in your hardware configuration. You can also use the device view to perform management tasks on specific objects. In the device view, you can select a port or the entire chassis. EDM outlines the selected object in yellow.

The conventions on the device view are similar to the actual device appearance. The port LEDs and the ports are color-coded to provide status. Green indicates the module or port is up and running, red indicates the module or port is disabled, dark pink indicates a protocol is down, and amber indicates an enabled port that is not connected to anything. For information about LED behavior, see your hardware documentation.

EDM Window

The following list identifies the different sections of the EDM window:

- Navigation pane—Located on the left side of the window, the navigation pane displays all the available command tabs in a tree format. A row of buttons at the top of the navigation pane provides a quick method to perform common functions.
- Content pane—Located on the right side of the window, the content pane displays the tabs and dialog boxes where you can view or configure parameters on the switch.
- Menu bar—Located at the top of the content pane, the menu bar shows the most recently accessed primary tabs and their respective secondary tabs.
- Toolbar—Located just below the menu bar, the toolbar provides quick access to the most common operational commands such as Apply, Refresh, and Help.

The following figure shows an example of two tabs open in the content pane of the EDM window.

Figure 11: EDM window

Navigation Pane

You can use the navigation pane to see what commands are available and to quickly browse through the command hierarchy. A row of buttons at the top of the navigation pane provides a quick method to perform common functions.

Note

For module-based chassis, menu options related to a specific module are activated only after you install and select the required module.

The following table describes the buttons that display at the top of the navigation pane.

Table 33: Navigation pane buttons

Button	Name	Description
	Save Config	Saves the running configuration.
	Refresh Status	Refreshes the Device Physical View.
	Edit	Edits the selected item in the Device Physical View.
	Graph	Opens the graph options for the selected item in the Device Physical View.
	Help Setup Guide	Opens instructions about how to install the Help files and configure EDM to use the Help files.

Expand a folder by selecting the directional arrow next to the folder name. Some folders have sub-folders such as the Edit folder, which has the Port, NTP, and other sub-folders.

Within each folder and sub-folder, there are numerous options, which provide access to tabs. To open an option, select it. The selected tab displays in the menu bar and opens in the content pane. The following table describes the top-level folders in the navigation pane.

Table 34: Navigation Pane Folders

Menu	Description
Device	Use the Device menu to refresh and update device information or enable polling. <ul style="list-style-type: none"> Preference Setting — Enable polling or hot swap detection. Configure the frequency to poll the device. Refresh Status — Use this option to refresh the device view. Rediscover Device — Use this to trigger a rediscovery to update all of the device information.
VRF Context view	Use the VRF Context view to switch to another VRF context when you use the embedded EDM. GlobalRouter is the default view at log in. You can configure both Global Router (GRT) and Virtual Routing and Forwarding (VRF) instances when you launch a VRF context view. You can open only five tabs for each EDM session.
Edit	Use the Edit menu to view and configure parameters for the chassis hardware or for the currently selected hardware component, including one or more ports. You can also use the Edit menu to perform the following tasks: <ul style="list-style-type: none"> check and configure ports, including the internal Extreme Integrated Application Hosting ports, on the device change the configuration of many features, including but not limited to, the file system, NTP, OVSDB, SMTP, Link-state tracking, VTEP, Management Instance, Endpoint Tracking, and SNMPv3
Graph	Use the Graph menu to view and configure EDM statistics and to produce graphs of the chassis or port statistics.
Power Management	Use the Power Management menu to view and configure Energy Saver.
VLAN	Use the VLAN menu to view and configure VLANs, spanning tree groups (STG), MultiLink Trunks/LACP, SMLT, and SLPP.
Fabric	Use the Fabric menu to view and configure IS-IS, Shortest Path Bridging MAC (SPBM), I-SIDs, Fabric Attach, DvR, Multi-area SPB, and statistics.

Table 34: Navigation Pane Folders (continued)

Menu	Description
VRF	Use the VRF menu to view and create VRFs.
IP	<p>Use the IP menu to view and configure IP routing functions for the system, including the following:</p> <ul style="list-style-type: none"> • IP-VPN • IP-MVPN • IP • TCP/UDP • OSPF • RIP • VRRP • RSMLT • BGP • Multicast • MSDP • IGMP • IPFIX • PIM • SPB-PIM-GW • DHCP Relay • DHCP Snooping • ARP Inspection • Source Guard • UDP Forwarding • IS-IS • Policies • BFD
IPv6	<p>Use the IPv6 menu to view and configure IPv6 routing functions, including the following:</p> <ul style="list-style-type: none"> • IPv6 • IPv6 - VPN • TCP/UDP • Tunnel • OSPFv3 • VRRP • BGP+ • RSMLT • DHCP Relay • Policy • FHS • IS-IS • RIPng • IPv6 PIM • IPv6 MLD • IPv6 Mroute • IPv6 BFD

Table 34: Navigation Pane Folders (continued)

Menu	Description
Security	Use the Security menu to view and configure access policies, ACL filters, certificates, and features such as RADIUS, RADIUS CoA, SSH, IPSec, TACACS+, and EAPoL.
QOS	Use the QOS menu to view and configure mapping tables, QoS port states, CoS Queue Stats, and Queue Profiles.
Serviceability	Use the Serviceability menu to run diagnostics, and to enable, configure, or view the following: <ul style="list-style-type: none"> • RMON • sFlow • Application Telemetry • SLA Monitor • RESTCONF • Virtual services • ExtremeCloud IQ Agent

Menu Bar

The menu bar is above the content pane and consists of two rows of tabs.

- The top row displays the tabs you can open through the navigation pane. The system displays these primary tabs in the sequence in which you open them.
- After you click a primary tab, the secondary tabs associated with it display in the bottom row. Click a secondary tab to display it in the content pane.

In both the top and bottom rows of the menu bar, if the number of tabs exceeds the viewable space, the system displays left- and right-pointing arrows. Click an arrow to scroll to the required tab.

To reduce the number of tabs on the top row, you can click the X on the right corner of a tab to remove it from the row. The following figure shows a sample menu bar.

**Figure 12: Menu bar**

Toolbar

The toolbar buttons provide quick access to commonly used operational commands. The system displays the buttons that vary depending on the tab you select. However, the Apply, Refresh, and Help

buttons are on almost every screen. Other common buttons are Insert and Delete. The following list detail the common toolbar buttons.

- Apply—Use this button to execute all edits that you make.
- Refresh—Use this button to refresh all data on the screen.
- Help—Use this button to display online help that is context sensitive to the current dialog box.
- Insert—Use this button to display a secondary dialog box related to the selected tab. After you edit the configurable parameters, click the Insert button in the dialog box. This causes a new entry to display in the dialog box of the selected tab.
- Delete—Use this button to delete a selected entry.

The following figure shows a sample toolbar.

Figure 13: Toolbar

Content Pane

The content pane is the main area on the right side of the window that displays the configuration tabs and dialog boxes. Use the content pane to view or configure parameters on the switch.

Note

You can view valid ranges for all configurable parameters on EDM tabs.

The following figure is a sample that shows the content pane for the Port 1/3 General, Interface tab. If you want to compare the information in two tabs, you can undock one, then open another tab. For more information about undocking a tab, see [Undocking and docking tabs](#) on page 275.

Figure 14: Content pane

EDM user session extension

If the EDM user session remains unused for a duration of ten minutes, the system displays the following message:

Your session will expire in about 5 minute(s). Would you like to extend the session?

If you do not respond, EDM automatically ends the session with the following message: `Your session has expired.`

You can log on again if you want to continue to use EDM.

EDM interface procedures

This section contains procedures for starting and using Enterprise Device Manager (EDM). The software is built-in to the switch, and you do not need to install additional software.

Connect to EDM

Before You Begin

- Ensure that the switch is running.
- Note the IP address of the switch.
- Ensure that you use a supported browser version.
- Ensure that you enable the web server using CLI.

About This Task

Perform this procedure to connect to EDM to configure and maintain your network through a graphical user interface.

Procedure

1. In the address field, enter the IP address of the system using the following formats: **https://<IP_address>** (default) or **http://<IP_address>**.

Note

By default the web server is configured with the secure-only option, which requires you to use HTTPS to access EDM. To access EDM using HTTP, you must disable the secure-only option.

2. In the **User Name** field, type the user name.
The default is admin.
3. In the **Password** field, type a password.
The default is password.
4. Select **Log On**.

Configure the Web Management Interface

Note

DEMO FEATURE - Read Only User for EDM is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

Before You Begin

- Enable the web server.
- For VSP 8600 Series, enable the web server RO user in CLI.

About This Task

Configure the web management interface to change the user names and passwords for management access to the switch using a web browser.

HTTP, FTP, and TFTP server supports both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

You can also use the CLI interface for creating users.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **General**.
3. Select the **Web** tab.
4. Complete the **WebRWAUserName** and **WebRWAUserPassword** fields to specify the user name and password for access to the web interface.
This user will have full permission.
5. To enable the RO user for the web server, select **WebROEnable**.

**Note**

This step does not apply to VSP 8600 Series.

6. Complete the **WebROUserName** and **WebROUserPassword** fields to specify the user name and password for access to the web interface.
This user will have read only permission.
7. Select **Apply**.

Web Field Descriptions

Use the data in the following table to use the **Web** tab.

Name	Description
WebRWAUserName	Specifies the RWA username from 1-20 characters. The default is admin.
WebRWAUserPassword	Specifies the password from 1-32 characters. The default is 12345678.
WebROEnable Note: Exception: not supported on VSP 8600 Series.	Enables the web server read-only (RO) user, which is disabled by default after a software upgrade.
WebEncryptionType	Specifies the ciphers for preset version of TLS for the web server.

Name	Description
WebCertSubjectName	Specifies the digital certificate subject Name used as identity certificate in the web server.
WebCertCAName	Specifies the digital certificate CA trustpoint name used for the certificate in the web server.
WebROUserName	Specifies the RO username. The default is user. Note: Product Notice: For VSP 8600 Series the web server RO username must be enabled in CLI.
WebROUserPassword	Specifies the password from 1–32 characters. The default is password.
MinimumPasswordLength	Configures the minimum password length. By default, the minimum password length is 8 characters.
HttpPort	Specifies the HTTP port for web access. The default value is 80.
HttpsPort	Specifies the HTTPS port for web access. The default value is 443.
SecureOnly	Controls whether the secure-only option is enabled. The default is enabled.
InactivityTimeout	Specifies the idle time (in seconds) to wait before the EDM login session expires. The default value is 900 seconds (15 minutes).
TlsMinimumVersion	Configures the minimum version of the TLS protocol supported by the web-server. You can select from the following options: <ul style="list-style-type: none"> • <code>tlsv10</code> – Configures the version to TLS 1.0. • <code>tlsv11</code> – Configures the version to TLS 1.1. • <code>tlsv12</code> – Configures the version to TLS 1.2 The default is <code>tlsv12</code> .
InUseCertType Note: Exception: not supported on VSP 8600 Series.	Shows if the certificate is self-signed or user-installed. Note: Product Notice: For VSP 8600 Series use the show web-server command in CLI to view this information.
HelpTftp/Ftp_SourceDir	Configures the TFTP or FTP directory for Help files, in one of the following formats: <code>a.b.c.d:/peer;/ [<dir>]</code> . The path can use 0–256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> • <code>192.0.2.1:/Help</code> • <code>192.0.2.1:/</code>

Name	Description
DefaultDisplayRows	Configures the web server display row width between 10-100. The default is 30.
LastChange	Shows the last web-browser initiated configuration change.
NumHits	Shows the number of hits to the web server.
NumAccessChecks	Shows the number of access checks performed by the web server.
NumAccessBlocks	Shows the number of access attempts blocked by the web server.
LastHostAccessBlockedAddressType	Shows the address type, either IPv4 or IPv6, of the last host access blocked by the web server.
LastHostAccessBlockedAddress	Shows the IP address of the last host access blocked by the web server.
NumRxErrors	Shows the number of receive errors the web server encounters.
NumTxErrors	Shows the number of transmit errors the web server encounters.
NumSetRequest	Shows the number of set-requests sent to the web server.

Using the chassis shortcut menu

About This Task

Perform the following procedure to display the chassis shortcut menu.

Procedure

1. In the Device Physical View, select the chassis.
2. Right-click the chassis.

Chassis shortcut menu field descriptions

Use the data in the following table to use the **Chassis** shortcut menu.

Name	Description
Edit	Edits chassis parameters.
Graph	Graphs chassis statistics.
Refresh Status	Refreshes the status of the chassis and MDAs.
Refresh Port Tooltips	Refreshes the port tooltip data of the system. The port tooltip data contains the following variables: Slot/Port, PortName, and PortOperSpeed.

Using the port shortcut menu

About This Task

Perform this procedure to display the port shortcut menu.

Procedure

1. In the Device Physical View, select a port.
2. Right-click the selected port.

Port shortcut menu field descriptions

Use the data in the following table to use the port shortcut menu.

Name	Description
Edit General	Configures the general options for the port.
Edit IP	Configures the IP options for the port.
Edit IPv6	Configures the IPv6 options for the port.
Channelization Enable	Enables channelization for the port.
Channelization Disable	Disables channelization for the port.
Graph	Displays the statistics for the port.
Enable	Enables the port.
Disable	Disables the port.

Using a table-based tab

About This Task

Change an existing configuration using a table-based tab. You cannot edit grey-shaded fields in the table. The following procedure is an illustration on how to use a table-based tab.

Note

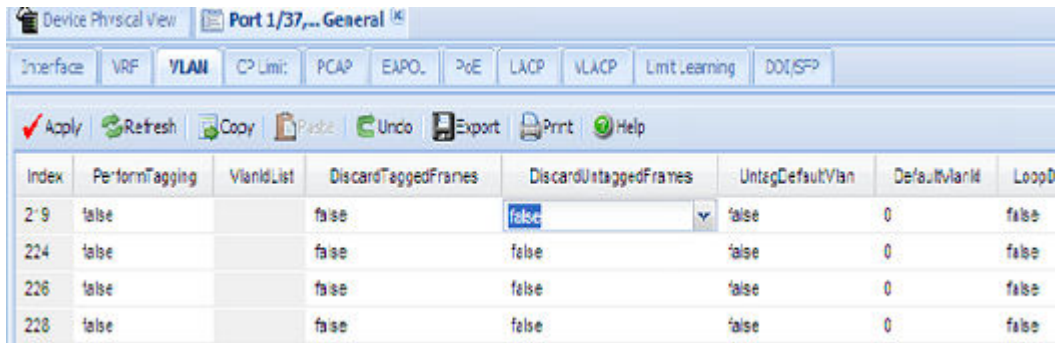

You can expand the appropriate folders for any feature you configure and select a table-based tab.

Procedure

1. In the Device Physical View, select multiple ports.
2. In the navigation pane, expand the **Configuration > Edit > Port > General** folders.
3. Click the **VLAN** tab.

The system displays a table-based tab with the VLAN information.
4. Select a table-based tab.
5. Double-click a white-shaded field to edit the value.

- Click the arrow in the list field to view the options, and then select the appropriate value.

- In a text-entry field, double-click, and then edit the value.

- Click **Apply** to save the configuration changes.

Monitor Multiple Ports and Configuration Support

About This Task

You can monitor or apply the same configuration changes to more than one port by using the multiple port selection function. You can use the standard menu or the shortcut menu to edit the configuration settings for multiple ports.

Tip

A selected port shows a yellow outline around the port.

Procedure

- Select the **Device Physical View** tab.
- To select multiple ports, press **Ctrl** (Control), and then select the required ports.

Open Folders and Tabs

About This Task

Perform this procedure to navigate in EDM.

Procedure

1. In the navigation pane, expand the **Configuration** folder.
2. Click a subfolder to expand the subfolder and see the list of menu options, for example, the **VLAN** folder.
3. In a folder or subfolder menu, click an option to open the related tabs.

Undocking and docking tabs

About This Task

Perform this procedure to undock a tab. You can undock tabs to have more than one tab visible at a time.

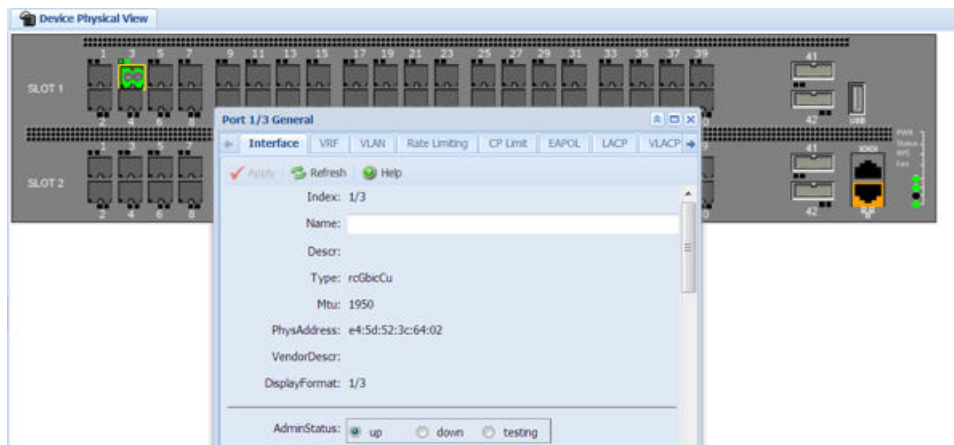

Procedure

1. In the navigation pane, click a tab.
2. In the menu bar, click and drag a tab to undock it.
3. In the top right corner of the tab, click **pages** to dock the tab.

Example of undocking and docking tabs

Procedure

1. Click the **Device Physical View** tab.
2. In the Device Physical View, select a port. In this example, right-click port 3.
3. In the **Port** shortcut menu, click **Edit General**.
4. Click and drag the **Port 1/3 General** tab wherever you want on the screen as shown in the following figure.

5. To reposition the tab anywhere on the screen, click and drag the title bar.
6. To manipulate the tab, click on the buttons in the top-right of the dialog box.

- Click the up arrowhead to minimize the tab as shown in the following figure.

- Click the down arrowhead to restore the tab to its original size.
- Click the pages to dock the tab back into the menu bar.
- Click the X to close the tab.

Installing EDM help files

While the EDM GUI is bundled with the switch software, the associated EDM help files are not. To access the help files from the EDM GUI, you must install the EDM help files on a TFTP or FTP server in your network.

Use the following procedure to install the EDM help files on a TFTP or FTP server, and configure EDM to use the help files

Before You Begin

If you use an FTP server to store the help files, ensure that you configure the switch with the host user name and password.

Procedure

- Download the EDM help file.
- On a TFTP or FTP server reachable from the switch, create a directory called **Help**.

Tip

You can name the directory anything that will help you remember its purpose.

- Unzip the EDM help zip file into the directory created in the preceding step.
- In the EDM navigation pane, expand the **Configuration > Security > Control Path** folders.
- Click **General**.
- Click **Web**.
- In the **HelpTftp/Ftp_SourceDir** field, enter the IP address of the file server and the path to the help files, for example, 192.0.2.15:/home/Help/.

File Management in EDM

This section contains procedures for managing files with Enterprise Device Manager (EDM).

Use the File System tab to perform the following tasks:

- Copy a file.
- Check the amount of memory used and the number of files stored in the internal flash memory.
- Verify the name, size, and storage date of each file present in the internal flash memory.
- Display USB file information.

Copy a File

About This Task

Copy files on the internal flash.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **File System**.
3. Select the **Copy File** tab.
4. Edit the fields as required.
5. Select **Apply**.

Copy File Field Descriptions

Use the data in the following table to use the **Copy File** tab.

Name	Description
Source	<p>Identifies the device and file name to copy. You must specify the full path and filename, for example, <deviceip-ftp server>:/<filename></p> <p>Note: For certain switches in enhanced secure mode, sensitive files and paths are protected.</p>
Destination	<p>Identifies the location to which to copy the source file with the filename, for example, /intflash/<filename>.</p> <p>Note: For certain switches in enhanced secure mode, sensitive files and paths are protected.</p>

Name	Description
Action	Starts or stops the copy process.
Result	Specifies the result of the copy process: <ul style="list-style-type: none"> • none • inProgress • success • fail • invalidSource • invalidDestination • outOfMemory • outOfSpace • fileNotFound

Display Storage Use

About This Task

Display the amount of memory used, memory available, and the number of files for internal flash memory.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **File System**.
3. Select the **Storage usage** tab.

Storage Usage Field Descriptions

Use the data in the following table to use the **Storage Usage** tab.

Name	Description
IntflashBytesUsed	Specifies the number of bytes used in internal flash memory.
IntflashBytesFree	Specifies the number of bytes available for use in internal flash memory.
IntflashNumFiles	Specifies the number of files in internal flash memory.
UsbBytesUsed	Specifies the number of bytes used in USB device.
UsbBytesFree	Specifies the number of bytes available for use in USB device.
UsbNumFiles	Specifies the number of files in USB device.

Display Internal Flash File Information

About This Task

Display information about the files in internal flash memory on this device.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **File System**.
3. Click the **Flash Files** tab.

Flash Files field descriptions

Use the data in the following table to use the **Flash Files** tab.

Name	Description
Slot	Specifies the slot number.
Name	Specifies the directory name of the file.
Date	Specifies the creation or modification date of the file.
Size	Specifies the size of the file.

Display USB File Information

About This Task

Display information about the files on a USB device to view general file information.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **File System**.
3. Click the **USB Files** tab.

USB Files field descriptions

Use the data in the following table to use the **USB Files** tab.

Name	Description
Slot	Specifies the slot number of the device.
Name	Specifies the directory name of the file.
Date	Specifies the creation or modification date of the file.
Size	Specifies the size of the file.

Image Management

[Image Upgrades](#) on page 280

[Image Naming Conventions](#) on page 281

[Interfaces](#) on page 281

[File Storage Options](#) on page 282

[Before You Upgrade](#) on page 282

[Saving the Configuration](#) on page 285

[Upgrade the Software](#) on page 286

[Verifying the upgrade](#) on page 289

[Commit an upgrade](#) on page 290

[Downgrade the Software](#) on page 291

[Remove a Software Build](#) on page 292

[Update the Complex Programmable Logic Device \(CPLD\) Image](#) on page 292

[Upgrade the Boot Loader Image](#) on page 295

This section details what you must know to manage the software image on the switch.

Image Upgrades

Install new software upgrades to add functionality to the switch. Major and minor upgrades are released depending on how many features the upgrade adds or modifies.

Upgrade time requirements

Image upgrades take less than 30 minutes to complete. The switch continues to operate during the image download process. A service interruption occurs during the installation and subsequent reset of the device. The system returns to an operational state after a successful installation of the new software and device reset.

Before you upgrade the software image

Before you upgrade the switch, ensure that you read the entire upgrading procedure.

You must keep a copy of the previous configuration file (config.cfg), in case you need to return to the previous version. The upgrade process automatically converts, but does not save, the existing configuration file to a format that is compatible with the new software release. The new configuration file may not be backward compatible.

Image Naming Conventions

The switch software use a standardized dot notation format.

Software Images

Software image names use the following number format to identify release and maintenance values:

```
Product Name.Major Release.Minor Release.Maintenance Release.Maintenance
Release Update.tgz
```

For example, the image file name `VOSS4K.4.2.1.0.tgz` denotes a software image for the VSP 4450 Series product with a major release version of 4, a minor release version of 2, a maintenance release version of 1 and a maintenance release update version of 0. Similarly, the image file name `VSP4K.3.0.1.0.tgz` denotes a software image for the VSP 4450 Series product with a major release version of 3, a minor release version of 0, a maintenance release version of 1 and a maintenance release update version of 0. TGZ is the file extension.

Firmware Update And Verification With Digital Signed Certificate

VOSS software images are cryptographic signed. Code signing is the process of digitally signing executables and scripts to confirm the software author and guarantee that the code has not been altered or corrupted since it was signed. This process employs the use of a cryptographic hash to validate authenticity and integrity.

The **show software** command displays information about the software image:

```
Switch:1#show software
=====
=====
                        software releases in /intflash/release/
=====
=====
4900_mux_64 (Backup Release) (Signed Release)
VOSS4900.8.5.0.int020 (Primary Release) (Signed Release)
```

Operational Considerations

The following section describes operational considerations:

- You not required to provide additional input.
- You can use unsigned images; however, this is not recommended. To use an unsigned image, downgrade to a pre-VOSS 8.5 software image then load a debug image.
- You cannot enter Enhanced Secure Mode with an unsigned image. Enhanced Secure Mode requires a signed image.

Interfaces

You can apply upgrades to the switch using the Command Line Interface (CLI).

For more information about CLI, see [Command Line Interface](#) on page 240.

File Storage Options

This section details what you must know about the internal boot and system flash memory and Universal Serial Bus (USB) mass-storage device, which you can use to store the files that start and operate the switch.

The switch file system uses long file names.

Internal flash

The switch has two internal flash memory devices: the boot flash memory and the system flash memory. The system flash memory size is 2 gigabytes (GB).

Boot flash memory is split into two banks that each contain a different copy of the boot image files. Only the Image Management feature can make changes to the boot flash.

The system flash memory stores configuration files, runtime images, the system log, and other files. You can access files on the internal flash through the `/intflash/` folder.

USB device

The switch can use a USB device for additional storage or configuration files, release images, and other files. The USB device provides a convenient, removable mechanical to copy files between a computer and a switch, or between switches. In cases where network connectivity has not yet been established, or network file transfer is not feasible, you can use a USB device to upgrade the configuration and image files on the switch.

File Transfer Protocol

You can use File Transfer Protocol (FTP) to load the software directly to the switch, or to download the software to the internal flash memory or to an installed USB device.

The switch can act as an FTP server or client. If you enable the FTP daemon (ftpd), you can use a standards-based FTP client to connect to the switch by using the CLI log on parameters. Copy the files from the client to either the internal flash memory or USB device.

Before You Upgrade

This section provides important feature impacts you need to understand before you upgrade the switch software.

Important Upgrade Note for Systems using IPv6 Static Neighbors

Due to an issue in VOSS 4.2.1 and later releases, the port number for an IPv6 static neighbor is saved with the wrong value in the configuration file if the port is part of an MLT or SMLT. You can view the incorrect port number by using the **show running-config** command.

If performing a named boot (e.g. **boot config.cfg**), the configuration loading fails and the switch remains in a default configuration. You can manually source the configuration file (e.g. **source**

`config.cfg`) to retrieve/reapply the configuration (minus the IPv6 neighbor configuration with the invalid port value).

If you boot the switch without a specified configuration (e.g. `reset -y`), the primary configuration fails to load and the backup configuration file is loaded instead.

Caution

You should never configure an IPv6 static neighbor on a port belonging to an MLT or SMLT.

Pre-upgrade Instructions for IS-IS Metric Type

The command used to redistribute routes into IS-IS supports a parameter called `metric-type`, which can take one of two values: **internal** or **external**. In releases that do not support the external metric type, the routes are always advertised into IS-IS as internal, irrespective of whether you configure the metric-type to internal or external. The saved configuration itself correctly shows the value that you selected.

If the configuration file has redistribution commands that set the metric-type to external, after you upgrade to a release that supports the external metric type, the routes will be advertised into IS-IS as external routes. This constitutes a change in how the routes are advertised into IS-IS after the upgrade as compared to before the upgrade. This configuration can cause unintended traffic issues if the other switches in the network are not yet upgraded to a release that recognizes external routes in IS-IS.

To know which release supports the external metric type on your platform, see [VOSS Release Notes](#) for interoperability considerations.

To avoid unintentionally impacting traffic immediately following an upgrade, as a best practice, check the existing IS-IS redistribution configuration of a switch to determine if the metric-type is set to external in the redistribution commands. If metric-type external is not used in the redistribution, the switch can be upgraded using the normal upgrade procedures. If the metric-type external is used with any redistribution command, change it to internal, and then save the configuration. After this the switch can be upgraded using the normal upgrade procedures.

Commands to check metric-type in redistribution configuration:

```
Switch:1(config-isis)#show ip isis redistribute [vrf WORD<1-16>]
=====
  ISIS Redistribute List - GlobalRouter
=====
SOURCE MET MTYPE      SUBNET  ENABLE LEVEL  RPOLICY
-----
RIP      0   internal  allow   TRUE  11
OSPF     0   external  allow   TRUE  11
LOC      0   external  allow   TRUE  11
```

Commands to change metric-type to internal for GRT:

```
router isis
isis redistribute <protocol> metric-type internal
save config
```

The protocol above could be one of the following: direct, ospf, static, rip or bgp.

Commands to change metric-type to internal for VRF:

```
router vrf WORD<1-16>
isis redistribute <protocol> metric-type internal
save config
```

The protocol above could be one of the following: direct, ospf, static, rip or bgp.

VLAN and MLT Upgrade Considerations

VLAN or MLT Name Uses all Numbers

Representational State Transfer Configuration Protocol (RESTCONF) does not allow VLAN or MLT names that contain all numbers. Beginning with VOSS 8.0, the VLAN or MLT name cannot use all numbers. If, in a release prior to 8.0, you configured a name that was all numbers, see the following table to understand the impact of upgrading to a newer release.

Table 35: Upgrade impact on interface names with all numbers

Target upgrade release	Impact after upgrade
VOSS 8.0.5.x, 8.0.6.x, or 8.0.7.x	The system prepends VLAN- or MLT- , and appends -01, to the name during the upgrade. For example, the VLAN name 222 becomes VLAN-222-01.
VOSS 8.0.8 and later	If you plan to enable RESTCONF, you must check interface names for invalid special characters or conflicts, and make necessary modifications manually. For information about how to check interface names, see the RESTCONF content in Representational State Transfer Configuration Protocol (RESTCONF) on page 2791.
VOSS 8.1 or 8.1.1.x	The system prepends VLAN- or MLT- , and appends -01, to the name during the upgrade. For example, the VLAN name 222 becomes VLAN-222-01.
VOSS 8.1.2 and later	If you plan to enable RESTCONF, you must check interface names for invalid special characters or conflicts, and make necessary modifications manually. For information about how to check interface names, see the RESTCONF content in Representational State Transfer Configuration Protocol (RESTCONF) on page 2791.

Digital Certificate Upgrade Considerations

Public Key Length

To support SNMP walk for rcDigitalCertTable where the public key length exceeds 2,048 characters, VOSS 8.1 and later configures MAX_KEY_LEN to 2,048 to extend PublicKey to hold a maximum of 4,096-bit key. After this key length is updated, the format for /intflash/.cert/cert_info.cfg

changes based on the new public key maximum length and you will be unable to restore the CertInfoTable from this file.

If you upgrade to VOSS 8.1 or later from an earlier release, you must reconfigure the certificates because you cannot restore the old certificate configuration after reboot.

The switch displays the following log message after you upgrade to VOSS 8.1, or later, and reboot:

```
GlobalRouter DIGITALCERT ERROR Unable to restore info from /
intflash/.cert/cert_info.cfg due to different/wrong format
```

Fast PoE and Perpetual PoE Upgrade Considerations

When you upgrade from VOSS 8.1.X to VOSS 8.1.5, the POE Controller undergoes a firmware update, which reverts previously configured Fast PoE and Perpetual PoE settings back to the default values. The system displays a message to inform you about this change.

Saving the Configuration

Save the configuration

- When you make a change to the configuration.
- To create a backup configuration file before you upgrade the software on the switch.

After you change the configuration, you must save the changes on the device. Save the configuration to a file to retain the configuration settings.

Note that not all CLI commands are included in configuration files. Typical examples include, but are not limited to some operational and security-related commands.

Note

When loading large configuration files or large sections of a configuration file, avoid copying and pasting of the files into the console or terminal window as it can lead to the loss of configuration. You must either source the file or boot to the intended configuration file. Sourcing and booting allow for the debug and verification of the configuration file using the boot config flags. For more information about booting, sourcing, and debugging or verification using boot flags, see [VOSS CLI Commands Reference](#).

About This Task

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support IPv4 and IPv6 addresses.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Save the running configuration:
`save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]`

Example

```
Switch:1> enable
```

Save the configuration to the default location:

```
Switch:1# save config
```

Identify the file as a backup file and designate a location to save the file:

```
Switch:1# save config backup /usb/PreUpgradeBackup.cfg
```

Variable Definitions

The following table defines parameters for the **save config** command.

Variable	Value
<i>backup</i> <i>WORD</i> <1-99>	Saves the specified file name and identifies the file as a backup file. <i>WORD</i> <1-99> uses one of the following format: <ul style="list-style-type: none"> • a.b.c.d:<file> • /intflash/<file> • /usb/<file> The file name, including the directory structure, can include up to 99 characters.
<i>file</i> <i>WORD</i> <1-99>	Specifies the file name in one of the following format: <ul style="list-style-type: none"> • a.b.c.d:<file> • /intflash/<file> • /usb/<file> The file name, including the directory structure, can include up to 99 characters.
<i>verbose</i>	Saves the default and current configuration. If you omit this parameter, the command saves only parameters you change.

Upgrade the Software

**Important**

Upgrades from some releases require release-specific steps. For more information, see [VOSS Release Notes](#).

Perform this procedure to upgrade the software on the switch. This procedure shows how to upgrade the software using the internal flash memory as the file storage location.

Use one of the following options to upload the file with the new software to the switch:

- Use FTP or SFTP to transfer the file.

- Download the image file to your computer. Copy the file to a USB device and insert the USB device into the USB port on the switch.

You can store up to six software releases on the switch. If you have six releases already stored on the switch, you are prompted to remove one release before you can proceed to add and activate a new software release.

For information about how to remove a software release, see [Remove a Software Build](#) on page 188.

Before You Begin

- To obtain the new software, go to the Extreme Networks support site: <http://www.extremenetworks.com/support>. You need a valid user or site ID and password.
- Back up the configuration files.
- Use an FTP or SFTP application or USB device to transfer the file with the new software release to the switch.
- Ensure that you have not configured a VLAN above 4059. If you have, you must port all configuration on this VLAN to another VLAN, before you begin the upgrade.

Caution

Only VLAN range 2 to 4059 is supported. All configuration on a higher numbered VLAN from earlier releases will be lost after the upgrade.

Note

Software upgrade configurations are case-sensitive.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. If you are using the USB port to transfer files, go to the next step. If you are using FTP or SFTP to download the files, start the FTP daemon on the switch and enable the `ftpd` flag for FTP or `sshd` flag for SFTP:

Note

Start an FTP session from your computer to the switch using the same username and password used to Telnet or SSH to the switch. Upload or copy the image to the switch.

```
boot config flag <ftpd | sshd>
```

```
end
```

3. Download the files to the switch through FTP or SFTP, or transfer them to the switch through the USB port.
4. Enter Privileged EXEC configuration mode by exiting the Global Configuration mode.

```
exit
```
5. Extract the release distribution files to the `/intflash/release/` directory:

```
software add WORD<1-99>
```

6. Install the image:

```
software activate WORD<1-99>
```

7. Restart the switch:

```
reset
```

Important

After you restart the system, you have the amount of time configured for the commit timer to verify the upgrade and commit the software to gold. If you do not commit the software to gold and auto-commit is not enabled, the system restarts with the last known working version after the commit timer has expired. This feature ensures you can regain control of the system if an upgrade fails. By default, auto-commit is enabled.

8. After you restart the switch, enter Privileged EXEC configuration mode:

```
rwa
```

```
enable
```

9. Confirm the software is upgraded:

```
show software
```

10. Commit the software:

```
software commit
```

Important

If you disable the auto-commit feature, you must run the **software commit** command manually before the commit timer expires to commit the new software version, otherwise the system restarts automatically to the previous (committed) version. By default, auto-commit is enabled.

Example

Note

The image file name is switch dependent. See [VOSS Release Notes](#) for information about file names.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags ftpd
Switch:1#end
Switch:1#copy /usb/VOSS8200.8.5.0.0.tgz /intflash/VOSS8200.8.5.0.0.tgz
Switch:1#software add VOSS8200.8.5.0.0.tgz
Switch:1#software activate VOSS8200.8.5.0.0.GA
Switch:1#reset -y
Switch:1#show software
=====
                        software releases in /intflash/release/
=====
VOSS8200.8.5.0.0.GA (Primary Release) (Signed Release)
VOSS8200.8.4.2.0.GA (Backup Release) (Unsigned Release)
-----
Auto Commit      : enabled
Commit Timeout   : 10 minutes
```

```

Remaining time until software auto-commit is 8 minutes 59 seconds

Switch:1#show software detail
=====
                        software releases in /intflash/release/
=====

VOSS8200.8.5.0.0.GA(Primary Release) (Signed Release)
  SSIO
    UBOOT                18081615
    KERNEL                4.9
    ROOTFS               4.9

  AVAILABLE ENCRYPTION MODULES
    No Modules Added
-----
Auto Commit      : enabled
Commit Timeout  : 10 minutes

Remaining time until software auto-commit is 8 minutes 41 seconds

Switch:1#software commit
Executing software commit for version VOSS8200.8.5.0.0.GA.
Software commit successful

```

Variable Definitions

The following table defines parameters for the **software** command.

Variable	Value
<i>activate</i> WORD<1-99>	Copies the software version to the boot flash file. When you use the software activate command, the system checks for hardware dependencies and prevents a downgrade if it detects a dependency. For example, if a hardware component has a minimum software version dependency, you cannot downgrade to an incompatible software version or install the hardware component in a chassis that runs an incompatible software version.
<i>add</i> WORD<1-99>	Unpacks a software release <version>.

Verifying the upgrade

Verify your upgrade to ensure proper switch operation.

Procedure

1. Check for alarms or unexpected errors:
`show logging file tail`
2. Verify all modules and slots are online:
`show sys-info`

Commit an upgrade

Perform the following procedure to commit an upgrade.

About This Task

The software commit functionality for software upgrades allows maximum time set by the commit timer (the default is 10 minutes) to ensure that the upgrade is successful. If you enable the auto-commit option, the system automatically commits to the new software version after the commit timer expires.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. (Optional) Configure the timer to activate the software:
`sys software commit-time <10-60>`

The default is 10 minutes.

**Note**

VSP 8600 Series default is 15 minutes.

3. **(Optional)** Extend or reduce the time to commit the software:
`software reset-commit-time [<1-60>]`
4. Commit the upgrade:
`software commit`

**Important**

If you disable the auto-commit feature, you must run the **software commit** command manually before the commit timer expires to commit the new software version, otherwise the system restarts automatically to the previous (committed) version. By default, auto-commit is enabled.

Downgrade the Software

Perform this procedure to downgrade the switch from the current trusted version to a previous release.

Important

MACsec connectivity association (CA) configurations fail during downgrade. If you plan to downgrade MACsec to an earlier version, delete the MACsec CA entries, perform the downgrade, and then reconfigure the MACsec CA entries. This applies to both 2AN and 4AN modes.

Before You Begin

Ensure that you have a previous version installed.

About This Task

Note

The image file name is switch dependent. See [VOSS Release Notes](#) for information about file names.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Extract the release distribution files to the `/intflash/release/` directory:
`software add WORD<1-99>`
3. Activate a prior version of the software:
`software activate WORD<1-99>`
4. Restart the switch:
`reset`

Important

After you restart the system, you have the amount of time configured for the commit timer to verify the software change and commit the software to gold. If you do not commit the software to gold and auto-commit is not enabled, the system restarts with the last known working version after the commit timer expires. This feature ensures you can regain control of the system if an upgrade fails. By default, auto-commit is enabled.

5. Commit the software change:
`software commit`

Important

If you disable the auto-commit feature, you must run the `software commit` command manually before the commit timer expires to commit the new software version, otherwise the system restarts automatically to the previous (committed) version. By default, auto-commit is enabled.

6. Verify the downgrade:
 - Check for alarms or unexpected errors using the `show logging file tail` command.
 - Verify all modules and slots are online using the `show sys-info` command.
7. (Optional) Remove unused software:

```
software remove WORD<1-99>
```

Variable Definitions

The following table defines parameters for the `software` command.

Variable	Value
activate WORD<1-99>	Specifies the name of the software release image.
add WORD<1-99>	Specifies the path and version of the compressed software release archive file.
remove WORD<1-99>	Specifies the path and version of the compressed software release archive file.

Remove a Software Build

Use the following procedure to remove a software build for the switch.

Note

A maximum of 6 software releases can be installed on the switch. When the limit is reached, you are prompted to remove one release before you can proceed with adding and activating a new software release.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Remove the software build:

```
software remove WORD<1-99>
```

Example

Remove the software build:

```
Switch:1>enable
Switch:1#software remove w.x.y.z
```

Update the Complex Programmable Logic Device (CPLD) Image

Note

This procedure only applies to VSP 4900 Series.

During the device bootup, if an older version of a CPLD module is detected, the system displays a log message to upgrade the CPLD module image.

The following is an example of the log message:

```
1 2020-01-17T13:08:16.630Z VSP-4900-12MXU-12XE CP1 - 0x0026050d -
00000000 GlobalRouter SW INFO cpu CPLD/FPGA module is running older
version. Recommended to upgrade using command cpld-install.
```

You can also use **show sys-info cpld** command to check the current version of the CPLD module on the device.

Before You Begin

Upgrade the software on the switch to the latest build.

About This Task

The **cpld-install** command compares the image version of the modules with the current version on the device:

- If the versions are the same, the command exits.
- If the current version is an earlier version, you must update the image version of the specific module.

The device automatically restarts after successful installation of the specific module.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Update one of the following CPLDs:
 - CPU:

```
cpld-install cpu [WORD<1-99>]
```
 - Field-Programmable Gate Array (FPGA):

```
cpld-install fgpa [WORD<1-99>]
```
 - Port:

```
cpld-install port [WORD<1-99>]
```
 - VIM (Versatile Interface Module):

```
cpld-install vim [WORD<1-99>]
```
3. When prompted, type **y** to continue with the CPLD update.

Example

Update the CPLD for port module.

```
Switch:1>cpld-install port /intflash/1.1.8_sd_portpld.tgz
image file md5 checksum passed
Current port CPLD version is 0x1108, 1.1.08

Do you want to continue with cpld update? (y/n) ? y

WARNING: Upgrading FPGA requires writing to a device

WARNING: It will take about a minute or so to complete.
```

```

WARNING: DO NOT TURN POWER OFF OR MAKE ANY HARDWARE CHANGES ONCE YOU START THIS OPERATION.

FPGA upgrade completed successfully

System is going for powercycle now...

```

Variable Definitions

The following table defines parameters for the **cpld-install** command.

Variable	Value
<i>cpu</i>	Updates the CPU module.
<i>fpga</i>	Updates the FPGA module.
<i>port</i>	Updates the Port module.

Variable	Value
<code>vim</code>	Updates the VIM module.
<code>WORD<1-99></code>	Specifies the image filename. Note: This parameter is optional. If you do not specify the filename, the command checks the .tgz file for the image from the running VOSS filesystem.

Upgrade the Boot Loader Image

Note

This procedure does not apply to VSP 4900 Series, VSP 7400 Series, and XA1400 Series.

Warning

This command is an advanced-level command that upgrades the device uboot image. Only use this command if specifically advised to do so by Technical Support. Improper use of this command can result in permanent damage to the device and render it unusable.

If the need to use this command arises, instructions on usage will be provided by technical support.

Before You Begin

- Transfer the image to the `/intflash/` directory on the switch.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. View the current uboot version:
`show sys-info uboot`
3. Upgrade the boot loader image:
`uboot-install WORD<1-99>`
4. Restart the system.

Example

```
Switch:1#>show sys-info uboot

U-Boot Info :
-----
Default Version      : 2.3.2.1
Alternate Version    : 2.3.2.1
Boot Version Used    : Default
Trusted Delivery Status : Boot Image Verified
```

Variable Definitions

The following table defines parameters for the **uboot-install** command.

Variable	Value
<i>WORD<1-99></i>	Specifies the full path and filename that contains the uboot image.

Address Resolution Protocol

Network stations using the IP protocol need both a physical address and an IP address to transmit a packet. In situations where the station knows only the network host IP address, the network station uses Address Resolution Protocol (ARP) to determine the physical address for a network host by binding a 32-bit IP address to a 48-bit MAC address. A network station can use ARP across a single network only, and the network hardware must support physical broadcasts.

The network station uses ARP to determine the host physical address as follows:

- The network station broadcasts a special packet, called an ARP request, that asks the host at the specified IP address to respond with its physical address.
- All network hosts receive the broadcast request.
- Only the specified host responds with its hardware address.
- The network station then maps the host IP address to its physical address and saves the results in an address-resolution cache for future use.
- The network station ARP table displays the associations of the known MAC address to IP address.

You can create ARP entries, and you can delete individual ARP entries.

Enable ARP traffic

The switch accepts and processes ARP traffic, spanning tree bridge packet data units (BPDU), and Topology Discovery Protocol packets on port-based VLANs with the default port action of drop. If a filter port action is drop for a packet, ARP packets are also dropped. As a result, ARP entries on that port are cleared and are not relearned when the ARP aging timer expires.

To prevent dropped ARP packets, configure the following options:

- A user-defined protocol-based VLAN for ARP EtherType (byprotocol usrDefined 0x0806).
- Ports as static members to this VLAN with the default port action of drop.
- The port default VLAN ID to the correct port-based VLAN where the ARPs are processed.

You do not need to make configuration changes for the BPDU and Topology Discovery Protocol packets.

Only one user-defined protocol-based VLAN for ARP is allowed for each Spanning Tree Group (STG). If the ports with the default port action of drop are in different STGs, you must create additional user-defined protocol-based VLANs.

Proxy ARP

A network station uses proxy ARP to respond to an ARP request from a locally attached host or end station for a remote destination. The network station sends an ARP response back to the local host with its own MAC address of the network station interface for the subnet on which the ARP request was received. The reply is generated only if the device has an active route to the destination network.

The following figure shows an example of proxy ARP operation. In this example, the system displays host C with mask 24 to be locally attached to host B with mask 16, so host B sends an ARP request for host C. However, the switch is between the two hosts. To enable communication between the two hosts, the switch responds to the ARP request with the IP address of host C but with its own MAC address.

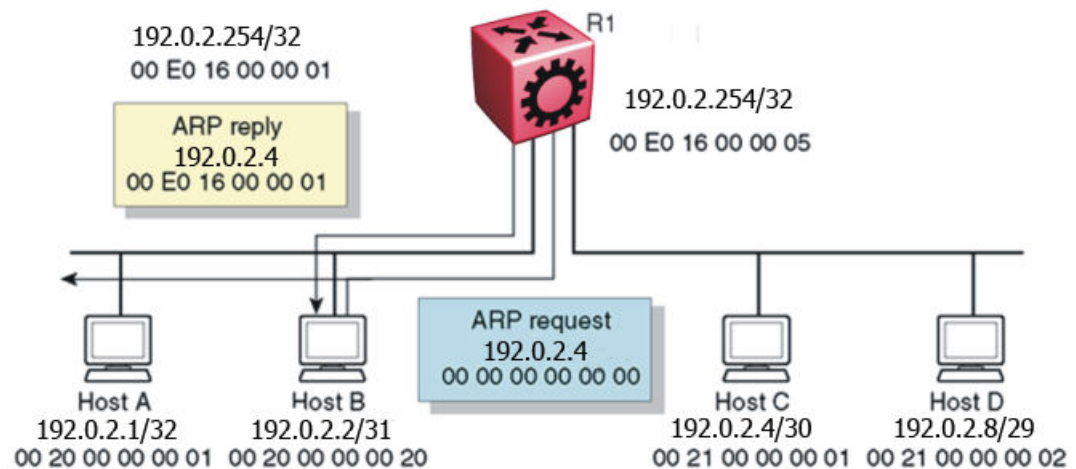

Figure 15: Proxy ARP operation

Loop detection

To prevent cases of ARP looping, configure the ARP loop detection flag to detect this situation. When a loop is detected, the port is shut down.

Flushing router tables

For administrative or troubleshooting purposes, sometimes you must flush the routing tables. Flush routing tables either by VLAN or by port. In a VLAN context, all entries associated with the VLAN are flushed. In a port context, all entries associated with the port are flushed.

Reverse Address Resolution Protocol

Certain devices use the Reverse Address Resolution Protocol (RARP) to obtain an IP address from a RARP server. MAC address information for the port is broadcast on all ports associated with an IP protocol-based or port-based VLAN. To enable a device to request an IP address from a RARP server outside its IP VLAN, you must create a RARP protocol-based VLAN.

RARP has the format of an ARP frame but its own Ethernet type (8035). You can remove RARP from the IP protocol-based VLAN definition and treat it as a separate protocol, thus creating a RARP protocol-based VLAN.

A typical network topology provides desktop switches in wiring closets with one or more trunk ports that extend to one or more data center switches where attached servers provide file, print, and other services. Use RARP functionality to define all ports in a network that require access to a RARP server as potential members of a RARP protocol-based VLAN. You must define all tagged ports and data center RARP servers as static or permanent members of the RARP VLAN. Therefore, a desktop host broadcasts an RARP request to all other members of the RARP VLAN. In normal operation, these members include only the requesting port, tagged ports, and data center RARP server ports. Because all other ports are potential members of this VLAN and RARP is only transmitted at startup, all other

port VLAN memberships expire. With this feature, one or more centrally located RARP servers extend RARP services across traditional VLAN boundaries to reach desktops globally.

ARP configuration using the CLI

Network stations that use IP protocol require both a physical address and an IP address to transmit packets. In situations where the station knows only the network host IP address, the Address Resolution Protocol (ARP) lets you use the network station to determine a network host physical address by binding a 32-bit IP address to a 48-bit MAC address.

A network station can use ARP across a single network only, and the network hardware must support physical broadcasts. If a network station wants to send a packet to a host but knows only the host IP address, the network station uses ARP to determine the host physical address.

ARP response is enabled by default.

Enabling ARP on a port or a VLAN

Enable ARP on the device so that it answers local ARP requests.

About This Task

You can enable or disable ARP responses on the device. You can also enable ARP proxy, which lets a router answer a local ARP request for a remote destination.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable ARP on the device:

```
ip arp-response
```

Example

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface vlan 200  
Switch:1(config-if)#ip arp-response
```

Enabling ARP proxy

About This Task

Configure an ARP proxy to allow the platform to answer a local ARP request for a remote destination. ARP proxy is disabled by default.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable ARP proxy on the device:

```
ip arp-proxy enable
```

Use the no operator to disable ARP proxy: `no ip arp-proxy [enable]`

Example

Enable ARP proxy on VLAN 200:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 200
Switch:1(config-if)#ip arp-proxy enable
```

View ARP Information

The **show ip arp** command displays all of the configured and dynamically learned ARP entries in the ARP table.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display ARP information for a specified port or for all ports:

```
show ip arp interface gigabitethernet [slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]]
```
3. Display ARP information for a VLAN:

```
show ip arp interface vlan <1-4059>
```

Example

```
Switch:1>show ip arp interface
```

```
=====
```

```

```

Variable definitions

Use the data in the following table to use the **show ip arp** command.

Variable	Value
<i>A.B.C.D</i>	Specifies the IP address of a network.
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>interface</i>	Displays ARP interface configuration information.
<i>spbm-tunnel-as-mac</i>	Displays the remote host name in the TUNNEL column for the SPBM ARP entry.
<i>-s</i>	Specifies a subnet. You must indicate the IP address followed by the subnet mask expressed as <A.B.C.D> <A.B.C.D>.
<i>vlan <1-4059></i>	Displays ARP entries for a particular VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies a VRF name expressed as text from 1 to 16 characters in length. The total number of ARPs listed in the summary line of the show ip arp output represents the total number of ARPs on the chassis, including all VRFs (which includes the Management Router VRF).
<code>vrfids WORD<0-512></code>	Specifies a range of VRFIDs as text from 0 to 512 characters in length. The total number of ARPs listed in the summary line of the show ip arp output represents the total number of ARPs on the chassis, including all VRFs (which includes the Management Router VRF).

Use the data in the following table to help you understand the **show ip arp interface** command output.

Variable	Value
PORT_NUM	Indicates the port number.
DOPROXY	Indicates if ARP proxy responses are enabled or disabled on the specified interface.
DORESP	Indicates if the sending of ARP responses is enabled or disabled on the specified interface.

Use the data in the following table to help you understand the **show ip arp interface vlan** command output.

Variable	Value
VLAN_ID	Indicates the VLAN ID.
DOPROXY	Indicates if ARP proxy responses are enabled or disabled on the specified interface.
DORESP	Indicates if the sending of ARP responses is enabled or disabled on the specified interface.

Configuring IP ARP static entries

About This Task

Configure ARP static entries to modify the ARP parameters on the device. The only way to change a static ARP is to delete the static ARP entry and create a new entry with new information.

Note

Static multicast ARP entries are not supported for NLB Unicast or NLB Multicast operations.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Configure ARP static entries on the device:

```
ip arp <A.B.C.D> 0x00:0x00:0x00:0x00:0x00:0x00 {slot/port [-slot/port]
[, ...]}
```

Example

Configure ARP static entries:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip arp 192.0.2.10 00-16-76-7D-80-C2 2/1
```

Variable Definitions

Use the data in the following table to use the **ip arp** command.

Variable	Value
<i>request-threshold</i> <50-1000>	Configures the maximum number of outstanding ARP requests that a device can generate. The range is 50-1000. The default value is 500. To configure this option to the default value, use the default operator with this command.
<i>timeout</i> <1-32767>	Configures the length of time in seconds an entry remains in the ARP table before timeout. The range is 1-32767. To configure this option to the default value, use the default operator with this command. Note: The aging of ARP records is tied to the aging of MAC records. The ARP record for a given IP address is not removed unless the associated MAC record ages out and the router stops receiving a response to ARP requests for that IP address. In cases where the ARP aging time is set to less than the MAC aging time, the switch waits until the MAC ages out before deleting the ARP for an inactive host.
<A.B.C.D>	Adds ARP entries.

Clearing ARP entries

Use this procedure to clear dynamic ARP table entries associated with the interface or VLAN.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear ARP entries:

```
clear ip arp interface <gigabitethernet|vlan> <slot/port[/sub-port] [-slot/port[/sub-port]][, ...] <1-4059>>
```

Example

Clear ARP entries:

```
Switch:1> enable
Switch:1# clear ip arp interface gigabitethernet 1/16
```

Variable definitions

Use the data in the following table to use the **clear ip arp interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<i>gigabitethernet vlan</i>	Specifies the interface type.
{ <i>slot/port[/sub-port] [-slot/port[/sub-port]][, ...]</i> }	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Showing ARP table information

Show ARP information to view the configuration information in the ARP table.

About This Task

When you use the *interface* parameter with the **show ip arp** command you can display ARP configuration information only for a specific switch.

The **show ip arp** command displays all of the configured and dynamically learned ARP entries in the ARP table.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display the ARP table:
show ip arp [<A.B.C.D>] [-s <A.B.C.D>] [gigabitEthernet <slot/port[/sub-port]>] [interface <gigabitEthernet|vlan>] [nlb] [spbm-tunnel-as-mac] [vlan <1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>]

Example

```
Switch:1#show ip arp

ARPs on TX-NNI: Current = 0, re-ARP count = 0
```

Variable definitions

Use the data in the following table to help you use the **show ip arp** command.

Variable	Value
-s	Specifies the subnet for the table.
<i>gigabitEthernet</i>	Displays the entries for a particular brouter port.

Variable	Value
<i>interface</i>	Displays ARP interface configuration information. Use the following parameters to display ARP table information specifically for: <ul style="list-style-type: none"> gigabitethernet {slot/port[-slot/port][,...]} displays IP ARP gigabitethernet interface information VLAN <1-4059> displays IP ARP VLAN interface information Example: <code>show ip arp interface vlan 1</code>
<i>nlb</i>	Displays the Network Load Balancing (NLB) ARP entries on the switch.
<i>spbm-tunnel-as-mac</i>	Displays the remote host name in the TUNNEL column for the SPBM ARP entry.
<i>vlan</i>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. Use these parameters to display ARP table information specifically for: <ul style="list-style-type: none"> vrf WORD<1-16>—the VLAN VRF name in a range from 1 to 16 characters vrfids WORD<0-512>—the VLAN VRF ID in a range from 0 to 512 Example: <code>show ip arp vlan 1 vrf 1</code>
<i>vrf WORD <1-16></i>	Specifies the name of the VRF. The total number of ARPs listed in the summary line of the "show ip arp" display represents the total number of ARPs on the chassis including all VRFs.
<i>vrfids WORD <0-512></i>	Specifies the VRF ID. The total number of ARPs listed in the summary line of the "show ip arp" display represents the total number of ARPs on the chassis including all VRFs.
<i><A.B.C.D></i>	Specifies the network IP address for the table.

Use the data in the following table to help you understand the output of the **show ip arp** command.

Parameter	Description
IP_ADDRESS	Indicates the IP address where ARP is configured.
MAC_ADDRESS	Indicates the MAC address where ARP is configured.

Parameter	Description
VLAN	Indicates the VLAN address where ARP is configured.
PORT	Indicates the port where ARP is configured.
TYPE	Indicates the type of learning (dynamic or local) where ARP is configured.
TTL<10 secs>	Indicates the time to live as tenths of a second where ARP is configured.
TUNNEL	Displays the remote host name in the TUNNEL column for the SPBM ARP entry.
MULTICAST-MAC-FLOODING	Displays whether IP ARP multicast MAC flooding is enabled or disabled. When enabled, the ARP entries for multicast MAC addresses are associated with the VLAN or port interface on which they were learned.
AGING (Minutes)	Displays when the ARP aging timer expires.
ARP-THRESHOLD	Displays the maximum number of outstanding ARP requests that a device can generate.

Configuring Gratuitous ARP

Use the following procedure to configure Gratuitous Address Resolution Protocol (ARP). When Gratuitous ARP is enabled the switch allows all Gratuitous ARP request packets. The default is enabled.

If you disable Gratuitous ARP, the switch only allows Gratuitous ARP packets associated with Routed Split Multi-Link Trunking (RSMLT) or Virtual Router Redundancy Protocol (VRRP), and the switch discards all other Gratuitous ARP request packets.

About This Task

ARP translates network layer (layer 3) IP addresses into link layer (layer 2) MAC addresses. A host sends a Gratuitous ARP request packet to inform other hosts of the existence of an interface on the network, so other local hosts can update their ARP tables. If the IP or MAC address changes, or in the event of a failover, a host sends a Gratuitous ARP request packet to inform other hosts to update their ARP tables.

VRRP and RSMLT use gratuitous ARP to update the MAC address tables on switches.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable Gratuitous ARP:

```
ip gratuitous-arp
```
3. (Optional) Disable Gratuitous ARP:

```
no ip gratuitous-arp
```
4. (Optional) Configure Gratuitous ARP to the default value:

```
default ip gratuitous-arp
```
5. Save the changed configuration.

```
save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]
```

ARP configuration using Enterprise Device Manager

Network stations using the IP protocol need both a physical address and an IP address to transmit a packet. In situations where the station knows only the network host IP address, the network station can use Address Resolution Protocol (ARP) to determine a network host physical address by binding a 32-bit IP address to a 48-bit MAC address. A network station can use ARP across a single network only, and the network hardware must support physical broadcasts. If a network station wants to send a packet to a host but knows only the host IP address, the network station uses ARP to determine the host physical address.

Enabling or disabling ARP on the router port or a VRF instance

About This Task

After you assign the IP address, you can configure ARP. By default, ARP Response is enabled and Proxy ARP is disabled.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **ARP** tab.
5. In the **DoProxy** check box, select **enable** to enable the Proxy ARP function.
6. In the **DoResp** check box, select **enable** to configure the system to respond to an ARP. The default is enable.
7. Click **Apply**.

The ARP function is available only when the port or VLAN is routed; that is, it is assigned an IP address.

ARP field descriptions

Use the data in the following table to use the **ARP** tab fields.

Name	Description
DoProxy	Configures the system to respond to an ARP request from a locally attached host or end station for a remote destination. The default value is disable.
DoResp	Configures the system to send ARP responses for this IP interface address. The default value is enable.

Enabling or disabling ARP on a VLAN or a VRF instance

About This Task

Use the following procedure to enable ARP on VLAN level.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.

2. Click **VLANs > Basic**.
3. Select a VLAN.
4. Click **IP**.
5. Click the **ARP** tab.
6. In the **DoProxy** field, click **enable** to enable the Proxy ARP function.
7. In the **DoResp** field, click **enable** to configure the system to respond to an ARP. The default is enable.
8. Click **Apply**.

The ARP dialog box is available only if the port or VLAN is routed; that is, it is assigned an IP address.

ARP field descriptions

Use the data in the following table to use the **ARP** tab.

Name	Description
DoProxy	Configures the system to respond to an ARP request from a locally attached host or end station for a remote destination. The default value is disable.
DoResp	Configures the system to send ARP responses for this IP interface address. The default value is enable.

Viewing and managing ARP

About This Task

You can view and manage known MAC address to IP address associations. In addition, you can create or delete individual ARP entries.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **ARP** tab.

ARP field descriptions

Use the data in the following table to use the **ARP** tab.

Name	Description
NetAddress	Specifies the IP address corresponding to the media-dependent physical address.
IfIndex	Identifies the router interface for this ARP entry: <ul style="list-style-type: none"> • Brouter interfaces are identified by the slot/port number of the brouter port. • VLAN interfaces are identified by the vlan name.
PhysAddress	Specifies the media-dependent physical address (that is, the Ethernet address).
Type	Specifies the type of ARP entry: <ul style="list-style-type: none"> • local—a locally configured ARP entry • static—a statically configured ARP entry • dynamic—a learned ARP entry

Name	Description
TimeToLive	Indicates the time to live where the ARP is configured.
DestIfIndex	Indicates the slot/port on which the ARP entry was learned. For brouter interfaces this is the same value as IfIndex, but for VLAN interfaces, it designates the particular port in the VLAN on which the ARP was learned.
DestVlanId	VLAN ID where the ARP is configured.
BMac	Identifies the backbone MAC address if the entry is learned from an SPBM network.
DestCvid	Identifies the customer VLAN ID for a Switched UNI port.

Creating static ARP entries

About This Task

Use the following procedure to create a static ARP entry.

Note

Static multicast ARP entries are not supported for NLB Unicast or NLB Multicast operations.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **ARP** tab.
4. Click **Insert**.
5. In the **NetAddress** field, type the IP address.
6. Click **Port**.
OR
Click **Port in VLAN**
7. In the dialog box, select the interface.
8. Click **OK**.
9. In the **PhysAddress** field, type the MAC address.
10. Click **Insert**.

Configuring ARP proxy

About This Task

With an ARP proxy, the switch can respond to an ARP request from a locally attached host or end station for a remote destination. Proxy ARP does so by sending an ARP response back to the local host with its own MAC address of the router interface for the subnet on which the ARP request was received. The reply is generated only if the system has an active route to the destination network.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.

2. Click **VLANs > Basic**.
3. Choose a VLAN.
4. Click **IP**.
5. Click **ARP** tab.
6. Select **DoProxy enable**.
7. Click **Apply**.

To avoid traffic interruption, you can globally enable the alternative routes feature so the router can use the next-best route, also known as an alternative route, if the best route becomes unavailable.

Routers learn routes to a destination through routing protocols. Routers maintain a routing table of the learned alternative routes sorted in order by route preference, route costs, and route sources. The first route on the list is the best route and the route that the router prefers to use.

The alternative route concept also applies between routing protocols. For example, if an OSPFv3 route becomes unavailable and an alternative RIPng route is available, the system activates the RIPng route without waiting for the update interval to expire.

Route Preference

On the switch, all standard routing protocols have default preference values that determine the routing priority of the protocol. The router uses default preferences to select the best route when a clash exists in preference between the protocols.

You can modify the global preference for a protocol to give the protocol a higher or lower priority than other protocols. If you change the global preference for a static route and all best routes remain best routes, only the local route tables change. However, if the protocol preference change causes best routes to no longer be best routes, the change affects neighboring route tables.

Important

Changing route preferences is a process-intensive operation that can affect system performance and network reach while you perform route preference procedures. As a best practice, if you want to change preferences for static routes or routing protocols, do so when you configure routes or during a maintenance window.

If a router learns a route with the same network mask and cost values from multiple sources, the router uses the route preferences to select the best route to add to the forwarding database.

Note

To modify the preference for a route, you do *not* need to disable a route before you edit the configuration.

Preferences for Static Routes

When you configure a static route on the switch, you can specify a global preference for the route. You can also specify an individual route preference that overrides the global static route preference. The preference value can be between 0 and 255, with 0 reserved for local routes and 255 representing an unreachable route.

Preferences for Dynamic Routes

You can modify the preference value for dynamic routes through route filtering and IP policies, and this value overrides the global preference for the protocol.

The following table shows the default preferences for routing protocols and route types. Use this table to help you modify the global preference value.

Table 38: Routing protocol default preferences

Protocol	Default preference
Local	0
Static	5

Table 38: Routing protocol default preferences (continued)

Protocol	Default preference
SPBM_L1	7
OSPF intra-area	20

OSPFv3 inter-area	25
OSPFv3 external type 1	120
OSPFv3 external type 2	125

Alternative Route Configuration using CLI

Enable IPv4 Alternative Routes

About This Task

The default value is enabled. If you disable the alternative-route parameter, all existing alternative routes are removed. After you enable the parameter, all alternative routes are readded.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```
2. Activate the alternative route feature globally:

```
ip alternative-route
```

Enable IPv6 Alternative Routes

Use this procedure to enable IPv6 alternative routes and view the configuration on the switch.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
enable

configure terminal

Optional: router vrf WORD<1-16>

2. Enable IPv6 alternative routes:
ipv6 alternative-route

Note

IPv6 alternative routes are enabled by default.

3. Verify the configuration of the IPv6 alternative route:

show ipv6 global [vrf WORD<1-16> | vrfids WORD<0-512>]

show ipv6 route alternative [vrf WORD<1-16> | vrfids WORD<0-512>]

Example:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf globalRouter
Switch:1(router-vrf)#ipv6 alternative-route
```

```
Switch:1#show ipv6 global
```

```

Alternative Route Configuration using EDM

Enable IPv4 Alternative Routes Globally

Before You Begin

- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 3853.

About This Task

Globally enable alternative routes so that you can subsequently enable it on interfaces.

Procedure

1. In the navigation tree, expand **Configuration > IP**.
2. Select **IP**.
3. Select the **Globals** tab.
4. Select **AlternativeEnable**.

If the **AlternativeEnable** parameter is disabled, all existing alternative routes are removed. After you enable the parameter, all alternative routes are re-added.

5. Select **Apply**.

Enable IPv6 Alternative Routes Globally

Global configuration includes the following:

- IPv6 alternative routes: To avoid traffic interruption, enable alternative routes globally on the switch, to replace the best route with the next-best route if the best route becomes unavailable. By default, this feature is enabled.

Before You Begin

Change the VRF instance as required to configure IPv6 globally on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation tree, expand **Configuration > IPv6**.
2. Select **IPv6**.
3. Select the **Globals** tab.
4. To enable IPv6 alternative routes, click **AlternativeRouteEnable**.
5. Select **Apply**.

IPv6 Alternative Routes Configuration Example

To avoid traffic interruption, you can enable alternative routes globally to replace the best route with the next-best route, if the best route becomes unavailable.

The concept of alternative route applies between routing protocols. For example, if an OSPFv3 route becomes unavailable and an alternative RIPng route is available, the system activates the RIPng route immediately without waiting for an update interval to expire.

By default, the alternative routes feature is globally enabled on the switch.

The following example demonstrates this behavior.

In this example, you configure OSPFv3 and RIPng routes on two switches Switch-1 and Switch-2, as shown in the following figure.

Configuration on Switch-1

VLAN configuration:

On Switch-1, configure VLAN 2 and the IPv6 interface address 2000:0:0:0:0:0:0:1/64.

```
Switch1:1:1>enable
Switch1:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch1:1(config)#vlan create 2 type port-mstprstp 0
Switch1:1(config)#vlan members 2 4/5
Switch1:1(config)#interface vlan 2
Switch1:1(config-if)#ipv6 interface address 2000:0:0:0:0:0:0:1/64
Switch1:1(config-if)#ipv6 interface enable
Switch1:1(config-if)#exit

Switch1:1(config)#show vlan basic
```

```

Viewing route and alternative route configuration on the switches

On Switch-1 and Switch-2, the route 3000:0:0:0:0:0:0:2/64 is learned using the protocols RIPng and OSPFv3. The OSPFv3 route is learned as the best route because of its route preference value of 20. The RIPng route is added as alternative route as it has the route preference 100, which is greater than the OSPFv3 route preference of 20. On Switch-2, the route 3000:0:0:0:0:0:0:2/64 is a local route.

Viewing route and alternative route configuration on Switch-1:

```
Switch1:1(config)#show ipv6 route alternative

Changing the route preference on Switch-1

On the switch, default preferences are assigned to all standard routing protocols. You can modify the global preference for a protocol to give it a higher or lower priority than other protocols. When you change the preference for a static route, if all best routes remain best routes, only the local route tables change. However, if changing the protocol preference causes best routes to no longer be best routes, neighboring route tables can be affected.

In the following example scenario, you configure a different routing preference for the RIPng protocol on Switch-1 and observe the learning of best and alternative routes. The existing route preference for RIPng is 100.

```

Switch1:1#show ipv6 route alternative
=====
IPv6 Routing Table Information - GlobalRouter
=====
Destination Address/PrefixLen  NEXT HOP          VID/BID/TID  PROTO  COST  AGE  TYPE  PREF

```

Configure a different route preference for the RIPng protocol, for example, 19:

```
Switch1:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch1:1(config)#ipv6 route preference protocol ripng 19
Switch1:1(config)#exit
```

Verify the route preference configuration:

```
Switch1:1#show ipv6 route preference
```

```
=====
                        IPv6 Route Preference - GlobalRouter
=====
PROTOCOL          DEFAULT    CONFIG

Extreme Networks offers two Analytics solutions that monitor traffic on your network:

- sFlow

- Application Telemetry

**Important**

You can use either sFlow, or sFlow with Application Telemetry or both at the same time as they can coexist on a switch. Note that to enable Application Telemetry, you must enable sFlow first.

In both solutions, the switch collects flow information and sends it to a central server that processes the information and provides statistical data in the form of reports. Then you can use Extreme Management Center or ExtremeCloud IQ - Site Engine to analyze the reports to give you a full understanding of the applications on your network and learn who is using those applications. Extreme Management Center or ExtremeCloud IQ - Site Engine also provides information such as DoS tracking, security monitoring, and statistics for protocols, ports, and applications.

This section describes how Application Telemetry works and how to configure it. Because there is some commonality between the two features, this section also describes some sFlow features.

For further information about sFlow, see [sFlow Fundamentals](#) on page 3087.

For more information about Extreme Management Center or ExtremeCloud IQ - Site Engine, see the documentation on the Extreme Networks Documentation portal (www.extremenetworks.com/documentation/) with special attention to the *Application Analytics User Guide*.

How Application Telemetry Works

Both sFlow and Application Telemetry mirror packets to a server for deep packet inspection, but they collect streams in different ways:

- sFlow samples 1 out of n packets to create flow streams. This methodology achieves scalability and applies to high speed networks, but it provides limited application visibility.
- Application Telemetry does not sample some packets like sFlow; it monitors all traffic and uses policy rules to filter packets for analysis. This pattern matching methodology enables Application Telemetry to monitor all application-level traffic flows at wire speed on all interfaces simultaneously.

The policy rules that Application Telemetry uses are ACL and ACE filters that are pre-configured in a policy configuration file called `sflow.pol`. This policy file is not user configurable. These rules enable the switch to recognize several signatures that represent a combination of the following:

- IP protocol type (TCP/UDP)
- TCP flags
- Layer 4 port numbers
- data patterns (defined as offset/data/mask triplets)

Pattern matching enables Application Telemetry to target very specific, well-defined packets in each flow and not full streams of traffic. Thus, the switch mirrors only a relatively few packets to the Analytics

Engine. It is the Analytics Engine that performs deep packet inspection to create reports of statistical data.

Important

When you enable Application Telemetry, the switch loads the filter rules based on the logic below:

- Application Telemetry uses the `apptelemetry.pol` or the `sflow.pol` file because the filter rules can exist in either file. The `sflow.pol` file is the default file and is included with the image that is loaded on the switch. This file contains the default filter rules. The `apptelemetry.pol` file is the user-defined file, which can be updated by the Extreme Management Center or ExtremeCloud IQ - Site Engine. To use this file, configure Application Telemetry using the Extreme Management Center or ExtremeCloud IQ - Site Engine. When you run the Application Telemetry LiveUpdate script from Extreme Management Center or ExtremeCloud IQ - Site Engine, the updated `apptelemetry.pol` file is placed in `/intflash/`.
- When you enable Application Telemetry, the feature uses the files in the following order:
 - If the user-defined file (`apptelemetry.pol`) exists, then the switch loads the rules from this file.
 - If the `apptelemetry.pol` file does not exist or if there is a problem reading this file, then the switch uses the default `sflow.pol` file.

Common Elements Between sFlow and Application Telemetry

sFlow and Application Telemetry send mirrored packets from a common source to a common destination. sFlow sends samples directly to the destination, while Application Telemetry sends mirrored packets through a GRE tunnel, to the same destination.

The tunnel source is the switch that you want to monitor:

- sFlow sends sampled flows.
- Application Telemetry sends packets that match its policy rules.

Both sFlow and Application Telemetry use an agent to package either the sFlow streams or the Application Telemetry packets. To configure the agent, they both use the `sflow agent-ip` command.

Note

The switch sends only one mirrored copy, even if the packet matches two or more policies. For information on which mirrored copies take precedence, see [Configuration considerations](#).

The tunnel destination for the mirrored traffic is a server where software performs a deep packet inspection of the mirrored traffic.

- sFlow sends flow and counter samples as datagrams to the sFlow Collector.
- Application Telemetry sends packets that match the policy rules over a GRE tunnel to the Analytics Engine.

To configure the tunnel destination, they both use the **sflow collector <1-2>** command.

Important

You can configure two Collectors, but Application Telemetry uses Collector 1 only. You must configure Collector 1 before you enable Application Telemetry.

Operational Considerations and Restrictions

The following section describes operational considerations for deploying Application Telemetry, including general considerations, followed by a summary of platform-specific considerations.

General Considerations

The following list describes general Application Telemetry operational considerations:

- When you enable Application Telemetry, it is globally enabled on all ports. You cannot disable the feature on a per-port basis.
- Application Telemetry supports IPv4 and IPv6 packets, although host monitoring is available for IPv4 hosts only.
- Application Telemetry filter rules are not user configurable. However, an updated `app-telemetry.pol` file can be installed through the Extreme Management Center or ExtremeCloud IQ - Site Engine.
- If a user-created filter rule (ACL) conflicts with an Application Telemetry defined filter, the user-created rule always takes precedence.
- There are two configurable sFlow collectors (Collector 1 and Collector 2). However, Application Telemetry uses Collector 1 only and you must configure it before enabling Application Telemetry.
- In a Fabric Extend deployment on VSP 4450 Series, VSP 7200 Series, VSP 8200 Series, VSP 8400 Series, or VSP 8400 Series, Application Telemetry does not mirror ingress NNI to UNI IP Shortcut traffic.

Platform-Specific Considerations

This section provides a summary of operational considerations for different switches.

Table 40: Supported flow types

Attribute	VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series	VSP 8600 Series
Flows that ingress standard VLAN ports	Supported	Supported
Flows that ingress UNI ports	Supported	Supported
Flows that ingress NNI ports and egress UNI ports (Layer 2 VSN)	Supported	Not supported

Configuration Overview

After the optional step of uploading the `app telemetry.pol` file to flash memory using Extreme Management Center or ExtremeCloud IQ - Site Engine, activate Application Telemetry by configuring the following:

1. Configure the IP address of the egress interface for the GRE tunnel with the **sFlow agent-ip** command.
2. Enable sFlow with the **sflow enable** command.
3. Configure the IP address of the Analytics Engine with the **sFlow collector 1** command.
4. Enable Application Telemetry with the **app-telemetry enable** command.

The following figure shows the Application Telemetry agent on various routers and switches with packets being sent to the Analytics Engine.

Figure 16: Application Telemetry Overview

Table 49: Application Telemetry Legend

Number	Description
1	Analytics Engine
2	GRE tunnels
3	Application Telemetry agents

Host Monitoring

You can use Application Telemetry to get better visibility for a selected host by performing a timed packet capture for both incoming and outgoing traffic specific to that host. Initiate the packet capture (PCAP) from Extreme Management Center or ExtremeCloud IQ - Site Engine and specify a source or destination IP address to match. Extreme Management Center or ExtremeCloud IQ - Site Engine pushes an additional rule to the Application Telemetry agent on the switch, which captures packets that match this rule and uses the existing ERSPAN GRE session to mirror these packets to Analytics Engine for analysis.

To use this feature, all configuration occurs in Extreme Management Center or ExtremeCloud IQ - Site Engine. The following prerequisites for configuration must be met:

- Application Telemetry is active.

- The Analytics Engine records application flows.
- You can see the flows in Extreme Management Center or ExtremeCloud IQ - Site Engine.

In Extreme Management Center or ExtremeCloud IQ - Site Engine, select a flow and configure packet capture. You can specify the host, either the originating or destination host for the flow, and a monitoring interval. For more information about how to configure packet capture in Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation.

The following list identifies restrictions specific to host monitoring:

- You cannot configure monitoring of the same host twice.
- Host monitoring shares resources with the filter ACL application. The maximum number of hosts that can be monitored depends on the number of ACEs you configure. If no resources are available, the Resource Manager generates an error for both applications.
- You cannot configure monitoring of the sFlow agent IP address or collector IP address.

Although you use Extreme Management Center or ExtremeCloud IQ - Site Engine to configure the packet capture, the switch logs a message when this feature is activated or deactivated. Configuration of host monitoring is not saved; the monitoring is time-based.

Note

Host monitoring is supported beginning with Extreme Management Center or ExtremeCloud IQ - Site Engine version 8.2.4.

Application Telemetry Configuration Using CLI

Use Application Telemetry to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure this feature using CLI.

Configuring the Agent IP Address

Use this procedure to configure the source of the Application Telemetry packets.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable the agent IPv4 address:
`sflow agent-ip {A.B.C.D}`

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow agent-ip 192.0.2.27
```

Variable Definitions

Use the data in the following table to use the **sflow agent-ip** command.

Variable	Definition
{A.B.C.D. }	Specifies the agent-ip address (IPv4).

Configuring an Analytics Engine and Enabling Application Telemetry Globally

Use this procedure to enable Application Telemetry and configure the device used as either an sFlow Collector or an Application Telemetry Analytics Engine. This device is where the agent sends sFlow datagrams and Application Telemetry packets for analysis.

sFlow supports up to two collectors for each interface slot in the chassis. However, Application Telemetry supports Collector 1 only.

Note

- You can configure two Collectors, but Application Telemetry uses Collector 1 only. You must configure Collector 1 before you enable Application Telemetry.
- Before you change or remove Collector 1, you must disable Application Telemetry.
- By default, Application Telemetry is globally disabled.

Before You Begin

- You must configure the sFlow agent IP address.
- You must enable sFlow before you can enable Application Telemetry.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the Analytics Engine information using Collector 1:

```
sflow collector 1 address {A.B.C.D} [owner WORD<1-20>] [vrf  
WORD<1-16>]
```

3. Verify the Analytics Engine configuration:

```
show sflow collector 1
```

4. Enable Application Telemetry:

```
app-telemetry enable
```

5. Verify the global configuration:

```
show app-telemetry status
```

Note

The output of this command shows whether Application Telemetry is enabled or not and if the collector is reachable.

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow collector 1 address 192.0.2.26 owner sflow1 port 6343 timeout 497
Switch:1(config)#show sflow collector 1

=====
                          sFlow Collector Configuration Info

Switch:1(config)#app-telemetry enable
Switch:1(config)#show app-telemetry status
Application Telemetry is enabled
Collector is reachable via 192.0.2.26
```

Variable Definitions

Use the data in the following table to use the **sflow collector** command.

Variable	Value
<1-2>	Specifies the ID of the collector where you want to send packets for analysis. Application Telemetry uses Collector 1 only.
owner WORD<1-20>	Specifies the name of the collector.
Collector-IP {A.B.C.D.}	Specifies the IP address of the collector.
port <1-65535>	Specifies the destination port. The default port is 6343. Note: Application Telemetry does not use this parameter.
timeout <1-65535>	Specifies the time remaining (in seconds) before the collector is released. The default timeout is 0, which means the timeout is not used and the switch sends data forever. Note: Application Telemetry does not use this parameter.
vrf WORD<1-16>	Specifies the name of the VRF used to reach the collector. Note: This parameter is not supported on all hardware platforms.

View Application Telemetry Counters

Use the following procedure to view the Application Telemetry status counters. The switch assigns an ID to each counter and displays information about each filter rule by name. The information includes how many packets were transmitted to the Analytics Engine that matched the specified pattern in the rule and the total number of bytes in the packets.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View Application Telemetry counters:

```
show app-telemetry counter [name <WORD<1-32> | id <1-2000>]
```

Example

```
Switch:1>show app-telemetry counter
```

```
=====
Application Telemetry Counters

EntryId      Name      Packets    Bytes
-----
1            ssh       1258       72145
2            sslclient 457         27000
-----
```

```
All 2 out of 2 Total Num of Application Telemetry counters entries displayed
```

Clearing Application Telemetry Counters

Use this procedure to clear the Application Telemetry status counters. You can clear all of the counters or specify just the counters you want to clear by name or ID.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Clear Application Telemetry counters:

```
clear app-telemetry counter [name <WORD<1-32> | id <1-2000>]
```

3. Verify that the counters were cleared:

```
show app-telemetry counter [name <WORD<1-32> | id <1-2000>]
```

Example

Clear the counters.

```
Switch:1>enable
Switch:1#clear app-telemetry counter
Switch:1>show app-telemetry counter
```

```

Application Telemetry Configuration Using EDM

Use Application Telemetry to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure this feature using EDM.

sFlow and Application Telemetry send mirrored packets from a common source to a common destination. sFlow sends samples directly to the destination, while Application Telemetry sends mirrored packets through a GRE tunnel, to the same destination.

Both sFlow and Application Telemetry use an agent to package either the sFlow streams or the Application Telemetry packets. To configure the agent, they both use the **Serviceability > Sflow > Globals** and **Serviceability > Sflow > Collector** tabs. For more information, see [sFlow Configuration Using EDM](#) on page 3098.

Enabling Application Telemetry Globally

Use this procedure to globally enable Application Telemetry so it can send packets to an Analytics Engine. By default, Application Telemetry is globally disabled.

Before You Begin

You must complete the following:

- Configure an agent IP address.
- Enable sFlow.
- Configure Collector 1.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Application Telemetry**.
3. Click the **Globals** tab.
4. Select the **AdminEnable** check box.
5. Click **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AdminEnable	Shows whether Application Telemetry is enabled. By default, the check box is not enabled.
ClearCounterStats	Clears the Application Telemetry status counters.

Viewing Application Telemetry Counters

Use the following procedure to view the Application Telemetry status counters. The switch assigns an ID to each counter and displays information about each filter rule by name. The information includes how many packets were transmitted to the Analytics Engine that matched the specified pattern in the rule and the total number of bytes in the packets.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Application Telemetry**.
3. Click the **Counter** tab.

Counter field descriptions

Use the data in the following table to use the **Counter** tab.

Name	Description
CounterId	Shows the Application Telemetry rule ID.
CounterName	Shows the rule name.
CounterPkts	Shows the number of packets transmitted to the Analytics Engine that matched the specified pattern in the rule.
CounterBytes	Shows the total number of bytes in the packets.

Clearing Application Telemetry Counters

Use this procedure to clear the Application Telemetry status counters. You can clear all of the counters or specify just the counters you want to clear by name or ID.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Application Telemetry**.
3. Perform one of the following actions:
 - To clear all the counters, click the **Globals** tab, and then select **ClearCounterStats**.
 - To clear specific counters, click the **Counter** tab, select the counter ID you want to clear, and then click **ClearStats**.
4. Click **Apply**.

Viewing Application Telemetry Status

About This Task

Use this procedure to view the status of the Application Telemetry collector.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.

2. Click **Application Telemetry**.
3. Click the **Status** tab.

Status field descriptions

Use the data in the following table to use the **Status** tab.

Name	Description
Collector IP Address	Shows the address of the Application Telemetry collector.
IsReachable	Shows whether the Application Telemetry collector is reachable.
NextHop	If the collector is reachable, shows the name or address of the next hop through which the collector is reachable.

Use Bidirectional Forwarding Detection (BFD) to provide a failure detection mechanism between two systems.

The following sections provide information and procedures for BFD.

BFD Fundamentals

The following sections provide fundamentals information about Bidirectional Forwarding Detection (BFD).

BFD Overview

Bidirectional Forwarding Detection (BFD) is a simple Hello protocol used between two peers. In BFD, peer systems periodically transmit BFD packets to each other. If one of the systems does not receive a BFD packet after a certain period of time, the system assumes that the link or other system is not operating.

A path is considered operational when bidirectional communication is established between systems. However, this does not preclude the use of unidirectional links.

BFD provides low-overhead, short-duration failure detection between two systems. BFD also provides a single mechanism for connectivity detection over any media, at any protocol layer.

Because BFD sends rapid failure-detection notifications to the routing protocols that run on the local system, which initiates routing table recalculations, BFD helps reduce network convergence time.

BFD supports IPv4/IPv6 single hop detection for static routes, OSPFv2, OSPFv3, iBGP, iBGPv6. Forwarding path failure detection for Fabric Extend tunnels is supported over an IPv4 network only.

Note

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

Note

iBGPv6 is not supported in VRF.

BFD Operation

The switch uses one BFD session for all protocols with the same destination. For example, if a network runs OSPFv2 and BGP across the same link with the same peer, only one BFD session is established, and BFD shares session information with both routing protocols.

You can enable BFD over data paths with specified OSPFv2 and OSPFv3 neighbors, BGP neighbors, static routing next-hop addresses, and Fabric Extend tunnels.

The switch supports BFD asynchronous mode, which sends BFD control packets between two systems to activate and maintain BFD neighbor sessions. To reach an agreement with its neighbor about how rapidly failure detection occurs, each system estimates how quickly it can send and receive BFD packets.

A session begins with the periodic, slow transmission of BFD control packets. When bidirectional communication is achieved, the BFD session comes up.

After the session is up, the transmission rate of Control packets can increase to achieve detection time requirements. If Control packets are not received within the calculated detection time, the session is declared down. After a session is down, Control packet transmission returns to the slow rate.

If a session is declared down, it cannot come back up until the remote end signals that it is down (three-way handshake). A session can be kept administratively down by configuring the state of AdminDown.

In asynchronous mode, detection time is equal to the value of DetectMult received from the remote system multiplied by the agreed transmit interval of the remote system (the greater of RequiredMinRxInterval and DesiredMinTxInterval.) DetectMult is approximately equal to the number of sequential packets that must be missed to declare a session down.

BFD States

A session normally proceeds through three states; two states are used to establish a session (Init and Up) and one state is used to tear down a session (Down). This allows a three-way handshake for both session establishment and session teardown, assuring that both systems are aware of all session state changes. There is a fourth state (AdminDown) that you can use to administratively put a session down indefinitely.

- Down state: Indicates the session is down or has just been created. The session will remain in Down state until the remote system sends a BFD control packet indicating anything other than Up state. If the control packet signals Down state, the session advances to Init state. If the control packet signals Init state, the session advances to Up state.
- Init state: In this state, the host system establishes communications with the remote system and sends a request to move the session to the Up state, but the remote system has not yet recognized the request. A session remains in Init state until it receives a BFD control packet signaling Init or Up state, or until the connectivity timer expires, indicating communication with the remote system is lost.
- Up state: Indicates the BFD session is established and connectivity is working. A session remains in Up state until connectivity fails or until the session is taken down administratively.
- AdminDown state: Indicates the BFD session is being held down administratively. This causes the remote system to enter Down state and remain there until the local system exits AdminDown state.

BFD Configuration

The following sections provide conceptual information about BFD configuration. For detailed procedural information about BFD configuration, see [BFD Configuration using CLI](#) on page 351 and [BFD Configuration using EDM](#) on page 365.

Enable BFD

To enable Bidirectional Forwarding Detection (BFD) between 2 peers:

- Configure BFD globally.
- Configure BFD on the required interfaces of both peer systems.

- Enable BFD on the required routing protocols.
- Specify the next-hop device with which the switch initiates the BFD session.

Delete a BFD Session

To delete a BFD session, disassociate all applications with the BFD session, then administratively bring down the BFD session.

Note

To successfully delete a BFD session, you must execute the commands in the following order:

1. Disassociate all applications from the BFD session.
2. Disable BFD at the global level or interface level, which transitions the BFD session to AdminDown state.

If you change the above order of operations, the BFD session is not deleted.

BFD Considerations

The following considerations apply to Bidirectional Forwarding Detection (BFD):

- BFD is supported only in asynchronous mode. Demand mode and echo functionalities are not supported.
- You configure BFD parameters on a per session basis, not on a per next-hop basis.
- BFD creates multiple sessions even though a neighbor shares an IP address.
- The granularity of the fault detection interval in BFD is 100 ms, and the minimum multiplier is 2.

The minimum value for the transmit interval or the receive interval is 100 ms. If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

You can configure a total of 16 BFD sessions. Of the 16 possible BFD sessions, you can configure a maximum of 4 BFD sessions with the minimum value for transmit interval or receive interval. You can configure the remaining BFD sessions with a transmit interval or a receive interval that is greater than or equal to the 200 ms default value.

- BFD is not supported over RSMLT links. This applies to BFD sessions over IPv4 interfaces and IPv6 interfaces.
- Inter-tunnel routing with 6in4 tunnels is not supported. This means that incoming IPv6 packets over a tunnel cannot be forwarded over another tunnel configured on the same switch.
- BFD for Interior Border Gateway Protocol (iBGP) and BGPv6 in VRF is not supported.
- Session dampening is not supported for BFD.
- BFD for eBGPv6 in VRF is not supported.
- The switch supports BFD multihop only at the eBGP application level. For other applications, the switch does not support BFD multihop, as defined by RFC 5883. However, there is no requirement for source and destination IP addresses to be in the same subnet.
- BFD over IPv6 Fabric Extend (FE) tunnels is not supported.
- The minimum value for the transmit interval or the receive interval is 1 second with a fault detection time of 3 seconds for BFD over IPv4 FE tunnels.

- BFD does not support a static route flag.
- BFD is not supported on a Virtual Router Redundancy Protocol (VRRP) interface.
- High Availability for BFD is not supported.
- You can configure a total of 256 BFD and Virtual Link Aggregation Control Protocol (VLACP) sessions.
- BFD packets cannot be mirrored when BFD is configured on the switch.

BFD Configuration using CLI

Use the following procedures to configure Bidirectional Forwarding Detection (BFD) using CLI. BFD provides low-overhead, short-duration failure-detection between two systems.

Enable BFD Globally

Note

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD globally.

Note

Enabling BFD globally does not establish a BFD session. To establish a BFD session, you must also configure BFD at the interface level and at the application level.

Procedure

1. Enter BFD Router Configuration mode:

```
enable

configure terminal

router bfd
```

2. Enable BFD:

```
router bfd enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bfd
Switch:1(router-bfd)#router bfd enable
```

Configure BFD on an IPv4 Interface

About This Task

Use the following procedure to enable and to configure Bidirectional Forwarding Detection (BFD) on an IPv4 interface. All interface configuration is performed at the VLAN, GigabitEthernet, or Loopback level.

Note

Enabling BFD on an interface does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the application level.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

followed by one of the following:

- `interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`
- `interface loopback <1-256>`
- `interface vlan <1-4059>`

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable BFD on an interface:

```
ip bfd enable
```

3. (Optional) Configure the transmit interval:

```
ip bfd interval <100-65335>
```

4. (Optional) Configure the minimum receive interval:

```
ip bfd min-rx <100-65335>
```

5. (Optional) Configure the multiplier:

```
ip bfd multiplier <1-20>
```

6. (Optional) In GigabitEthernet Interface Configuration mode, you can configure a value for port:

```
ip bfd port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. (Optional) In VLAN Interface Configuration mode, you can configure a value for VLAN:

```
ip bfd vlan <1-4094>
```

8. (Optional) In Loopback Interface Configuration mode, you can configure a value for loopback:

```
ip bfd loopback <1-256>
```

Variable Definitions

The following table defines parameters for the **ip bfd** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
enable	Enable BFD on a port, VLAN, or loopback.
interval <100-65335>	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: For XA1400 Series, the default is 1000 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
min-rx <100-65335>	Specifies the receive interval in milliseconds. The default is 200 ms. Note: For XA1400 Series, the default is 1000 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.
multiplier <1-20>	Specifies the multiplier used to calculate the amount of time BFD waits before declaring a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan <1-4094>	Specifies the VLAN ID.
loopback <1-256>	Specifies the Loopback ID.

Configure BFD on an IPv6 Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

Use the following procedure to enable and to configure BFD on an IPv6 interface. All interface configuration is performed at the VLAN or GigabitEthernet level.

Note

Enabling BFD on an interface does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the application level.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable BFD on an interface:

```
ipv6 bfd enable
```

3. (Optional) Configure the transmit interval:

```
ipv6 bfd interval <100-65335>
```

4. (Optional) Configure the minimum receive interval:

```
ipv6 bfd min-rx <100-65335>
```

5. (Optional) Configure the multiplier:

```
ipv6 bfd multiplier <1-20>
```

6. (Optional) In GigabitEthernet Interface Configuration mode, you can configure a value for port:

```
ipv6 bfd port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. (Optional) In VLAN Interface Configuration mode, you can configure a value for VLAN:

```
ipv6 bfd vlan <1-4094>
```

Variable Definitions

The following table defines parameters for the **ip bfd** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
enable	Enable BFD on a port, VLAN, or loopback.
interval <100-65335>	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: For XA1400 Series, the default is 1000 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
min-rx <100-65335>	Specifies the receive interval in milliseconds. The default is 200 ms. Note: For XA1400 Series, the default is 1000 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.
multiplier <1-20>	Specifies the multiplier used to calculate the amount of time BFD waits before declaring a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan <1-4094>	Specifies the VLAN ID.
loopback <1-256>	Specifies the Loopback ID.

Enable BFD at the BGP Application Level

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

BFD supports internal Border Gateway Protocol (iBGP) and external Border Gateway Protocol (eBGP) on IPv4 interfaces. You configure BFD on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. BFD does not support BGPv6 for VRF on IPv6 interfaces.

Note

Enabling BFD at the BGP application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. Enter BGP Router Configuration mode:

```
enable

configure terminal

router bgp
```
2. Enable BFD for the BGP protocol:

```
neighbor WORD<0-1536> fall-over bfd
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bgp
Switch:1(router-bgp)#neighbor 192.0.2.15 fall-over bfd
```

Variable Definitions

The following table defines parameters for the **neighbor** command.

Variable	Value
WORD<0-1536>	Specifies the peer IP address or the peer group name.

Enable BFD at the OSPF Application Level

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

BFD supports Open Shortest Path First (OSPF) for IPv4 interfaces and OSPFv3 for IPv6 interfaces.

Use the following procedure to enable BFD at the OSPF application level.

Note

Enabling BFD at the OSPF application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. (Optional) Enable BFD on an IPv4 interface under the OSPF protocol:

```
ip ospf bfd
```

3. Enable BFD on an IPv6 interface under the OSPF protocol:

```
ipv6 ospf bfd
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/3
Switch:1(config-if)#ip ospf bfd
```

Variable Definitions

The following table defines parameters for the **ip ospf bfd** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code><1-4059></code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Configure BFD on an IPv4 Static Route

About This Task

Use the following procedure to configure BFD on an IPv4 static route.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure BFD on an IPv4 static route:

```
ip route bfd {A.B.C.D}
```

Variable Definitions

The following table defines parameters for the **ip route bfd** command.

Variable	Value
{A.B.C.D}	Specifies the BFD static route IPv4 address.

Configure BFD on an IPv6 Static Route

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

Use the following procedure to configure BFD on an IPv6 static route.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure BFD on an IPv6 static route:

```
ipv6 route bfd WORD<0-128>
```
3. (Optional) Configure an IPv6 static route for a port:

```
ipv6 route bfd WORD<0-128> port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
4. (Optional) Configure an IPv6 static route for a VLAN:

```
ipv6 route bfd WORD<0-128> vlan <1-4094>
```

Variable Definitions

The following table defines parameters for the **ipv6 route bfd** command.

Variable	Value
WORD<0-128>	Specifies the BFD static route IPv6 address.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies the port number for the BFD IPv6 static route.
vlan <1-4094>	Specifies the VLAN ID for the BFD IPv6 static route.

Clear BFD Session Statistics

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

Use the following procedure to clear local and remote Bidirectional Forwarding Detection (BFD) session statistics for IPv4 or IPv6 interfaces.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. (Optional) Clear BFD session statistics for an IPv4 interface:
`clear ip bfd stats`
3. Clear BFD session statistics for an IPv6 interface:
`clear ipv6 bfd stats`

Variable Definitions

The following table defines parameters for the **clear ip bfd stats** command.

Variable	Value
vrf WORD<1-16>	Specifies a VRF instance by VRF name.
vrfids WORD<0-512>	Specifies a VRF or range of VRFs by ID.

Display BFD Global Configuration

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

Use this procedure to display global configuration information for BFD.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display global BFD configuration information:

```
show ip bfd [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

The following example displays global configuration information for BFD on an IPv4 interface.

```
Switch:1>show ip bfd
=====
                        BFD information - GlobalRouter
=====
                        BFD Version : 1
                        Admin Status : TRUE
                        Trap Enable  : FALSE
-----
Total session number : 1

UP: 1, DOWN: 0, AdminDown: 0, Init: 0
-----
```

Variable Definitions

The following table defines parameters for the **show ip bfd** command.

Variable	Value
<i>vrf</i> WORD<1-16>	Specifies a VRF instance by VRF name.
<i>vrfids</i> WORD<0-512>	Specifies a VRF or range of VRFs by ID.

Display BFD Configuration for an IPv4 Interface

About This Task

Use the following procedure to display BFD configuration on an interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD on a Gigabit Ethernet interface:

```
show ip bfd interfaces GigabitEthernet [{slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

3. Display BFD on a VLAN interface:

```
show ip bfd interfaces vlan [<1-4059>] [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

Examples

The following example displays VLAN interface configuration information for BFD.

```
Switch:1>show ip bfd interfaces vlan 11
=====
                        Vlan Bfd
=====
```

VLAN	STATUS	MIN_RX	INTERVAL	MULTIPLIER	VRF-ID
11	enable	200	200	3	0

The following example displays Loopback interface configuration information for BFD:

```
Switch:1>enable
Switch:1#show ip bfd interfaces loopback
```

Circuitless IP Interface Bfd					
INTF ID	STATUS	MIN_RX	INTERVAL	MULTIPLIER	VRF-ID
1	enable	200	200	3	0
2	enable	200	200	3	2

Variable Definitions

The following table defines parameters for the **show ip bfd interfaces** command.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
vrf WORD<1-16>	Specifies a VRF instance by VRF name.
vrfids WORD<0-512>	Specifies a VRF or range of VRFs by ID.

Display BFD Configuration for an IPv6 Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

Use the following procedure to display BFD configuration on an IPv6 interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD on a Gigabit Ethernet interface:

```
show ipv6 bfd interfaces GigabitEthernet [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

3. Display BFD on a VLAN interface:

```
show ipv6 bfd interfaces vlan <1-4059>
```

Example

The following example displays port configuration information for BFD.

```
Switch:1>show ipv6 bfd interfaces gigabitethernet 1/3

=====
                                     Port Bfd
=====
PORT          STATUS    MIN_RX  INTERVAL  MULTIPLIER  VRF-ID
-----
1/3           enable   200     200       3           0
```

Variable Definitions

The following table defines parameters for the **show ip bfd interfaces** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
vrf WORD<1-16>	Specifies a VRF instance by VRF name.
vrfids WORD<0-512>	Specifies a VRF or range of VRFs by ID.

Display BFD IPv4 Neighbor Information

About This Task

Use this procedure to display BFD session information for IPv4 neighbors.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD neighbor information:

```
show ip bfd neighbors
```
3. (Optional) Display BFD neighbor next-hop information:

```
show ip bfd neighbors next-hop {A.B.C.D}
```
4. (Optional) Display BFD neighbor information for a particular VRF:

```
show ip bfd neighbors vrf WORD<1-16>
```

5. (Optional) Display BFD neighbor information for a VRF ID or a range of VRF IDs:

```
show ip bfd neighbors vrfids WORD<0-512>
```

Example

The following example displays BFD session information for an IPv4 neighbor.

```
Switch:1>show ip bfd neighbors
=====
                        BFD Session - GlobalRouter
=====
MY_DISC   YOUR_DISC  NEXT_HOP      STATE      MULTI  MIN_TX  MIN_RX  ACT_TX  DETECT_TIME  REMOTE_STATE  APP   RUN
-----
1         0         192.0.2.11    Down       3      200    200    1000   600          Down         O
-----

=====
APP and RUN Legend:
    B=BGP, O=OSPF, S=Static Route
=====
```

Variable Definitions

The following table defines parameters for the **show ip bfd neighbors** command.

Variable	Value
{A.B.C.D}	Specifies the next-hop IP address in the format a.b.c.d.
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
vrfids WORD<0-512>	Specifies a range of VRFs by ID number (the ID ranges from 0-512).

Display BFD IPv6 Neighbor Information

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

Use this procedure to display information about BFD IPv6 neighbors.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD neighbor information:

```
show ipv6 bfd neighbors
```
3. (Optional) Display BFD neighbor next-hop information:

```
show ipv6 bfd neighbors next-hop WORD<0-128>
```
4. (Optional) Display BFD neighbor information for a particular VRF:

```
show ipv6 bfd neighbors vrf WORD<1-16>
```
5. (Optional) Display BFD neighbor information for a range of VRFs:

```
show ipv6 bfd neighbors vrfids WORD<0-512>
```

Example

The following example displays BFD session information for an IPv6 neighbor.

```
Switch:1>show ipv6 bfd neighbors
=====
                        BFD Session - GlobalRouter
=====
MY_DISC  YOUR_DISC  NEXT_HOP                STATE    MULTI  MIN_TX  MIN_RX  ACT_TX  DETECT_TIME  REMOTE_STATE  APP  RUN
-----  -
1         0          2001:DB8:0:0:25AB:0:0:1  Down    3      200    200    1000   0           Down         O    O
-----  -
1 out of 1 BFD session displayed
-----
APP and RUN Legend:
  B=BGP_IPv6, O=OSPFv3, S=IPv6 Static Route
-----
```

Variable Definitions

The following table defines parameters for the **show ipv6 bfd neighbors** command.

Variable	Value
WORD<0-128>	Specifies the next-hop IPv6 address in the format a:b:c:d:e:f:g:h.
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
vrfids WORD<0-512>	Specifies a range of VRFs by ID number (the ID ranges from 0-512).

Display BFD Statistics

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

Use the following procedure to display BFD statistics for IPv4 or IPv6 interfaces.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD IPv4 statistics:
`show ip bfd stats [vrf] [vrfids]`
3. Display BFD IPv6 statistics:
`show ipv6 bfd stats [vrf] [vrfids]`

Example

The following example displays BFD statistics for IPv4 interfaces.

```
Switch:1>show ip bfd stats
=====
                        BFD statistics - GlobalRouter
=====
MY_DISC  YOUR_DISC  NEXT_HOP  PACKET_IN  PACKET_OUT  LAST_UP                LAST_DOWN
-----  -
1         0          192.0.2.10  4661750    4620630     Mon Sep  6 15:31:15 2021  Mon Sep  6 15:28:08 2021
-----  -
```

The following example displays BFD statistics for IPv6 interfaces.

```
Switch:1>show ipv6 bfd stats
-----
BFD statistics - GlobalRouter
-----
MY_DISC  YOUR_DISC  NEXT_HOP          PACKET_IN  PACKET_OUT  LAST_UP          LAST_DOWN
-----
1         0         2001:DB8:0:0:0:0:ffff 4661750    4620630     Mon Sep  6 15:31:15 2021  Mon Sep  6 15:28:08 2021
-----
```

Variable Definitions

The following table defines parameters for the **show ip bfd stats** command.

Variable	Value
vrf	Specifies a VRF instance by VRF name.
vrfids	Specifies a VRF or range of VRFs by ID.

BFD Configuration using EDM

Use the following procedures to configure Bidirectional Forwarding Detection (BFD) using EDM. BFD provides low-overhead, short-duration failure-detection between two systems.

Enable BFD Globally

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD globally.

Note

Enabling BFD globally does not establish a BFD session. To establish a BFD session, you must enable BFD at the interface level and at the application level.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **BFD**.
3. Select the **Globals** tab.
4. In the **AdminStatus** field, select **enabled**.
5. (Optional) Select **TrapEnabled** to send BFD traps.

BFD Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AdminStatus	Specifies whether BFD is enabled.
VersionNumber	Specifies the current version number of the BFD protocol.
TrapEnabled	Specifies whether BFD traps are sent.

Display BFD Sessions

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to display information about BFD sessions. You can optionally display BFD session information for IPv4 or IPv6 interfaces.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **BFD**.
3. Select the **Sessions** tab.
4. (Optional) Select **Filter**.
5. (Optional) Select **AddrType**.
6. (Optional) In the **AddrType** field, specify a value for address type.

BFD Sessions Field Descriptions

Use the data in the following table to use the **Sessions** tab.

Name	Description
Discriminator	Specifies the local discriminator that uniquely identifies the BFD session.
RemoteDiscr	Specifies the discriminator of the remote system in the BFD session.
UdpPort	Specifies the UDP Port for the BFD session. The default value is the well-known value for the port.
State	Specifies the state of the BFD session. Possible values are Down, Up, Init, and AdminDown.
Addr	Specifies the IP address of the interface associated with the BFD session. A value of unknown (0) indicates the BFD session is not associated with a specific interface.
DesiredMinTxInterval	Specifies the preferred minimum interval for transmitting BFD control packets by the local system.
ReqMinTxInterval	Specifies the minimum interval for transmitting BFD control packets that the local system can support.

Name	Description
DestAddr	Specifies the destination IP address of the interface associated with the BFD session.
OldState	Specifies the old state of the BFD session.
App	Specifies the applications configured on the BFD session.
AppRun	Specifies the applications running on the BFD session.
AddrType	Specifies the IP address type of the interface associated with this BFD session. Possible values are ipv4 and ipv6.

Configure BFD for an IPv4 Interface on a Port

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv4 interface on a port.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Port**.
2. Select **IP**.
3. Select the **BFD** tab.
4. Select **Enable**.
5. (Optional) In the **MinRxInterval** field, specify the minimum receive interval..
6. (Optional) In the **TxInterval** field, specify the transmit interval.
7. (Optional) In the **Multiplier** field, specify a value for the multiplier used to calculate a receive timeout.

BFD Field Descriptions

Use the data in the following table to use the **BFD** tab.

Name	Description
Enable	Enable BFD on the port.
MinRxInterval	Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.

Name	Description
TxInterval	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
Multiplier	Specifies a value for the multiplier used to calculate a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

Configure BFD for an IPv6 Interface on a Port

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv6 interface on a port.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Port**.
2. Select **IPv6**.
3. Select the **IPv6 BFD Interface** tab.
4. (Optional) In the **MinRxInterval** column, double-click the field and type a value for **MinRxInterval**.
5. (Optional) In the **TxInterval** column, double-click the field and type a value for **TxInterval**.
6. (Optional) In the **Multiplier** column, double-click the field and type a value for **Multiplier**.

BFD Field Descriptions

Use the data in the following table to use the **BFD** tab.

Name	Description
Interface	Specifies the BFD interface.
MinRxInterval	Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.

Name	Description
TxInterval	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
Multiplier	Specifies a value for the multiplier used to calculate a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

Configure BFD for an IPv4 Interface on a VLAN

About This Task

BFD provides a failure detection-mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv4 interface on a VLAN.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANS**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to configure BFD.
5. Select **IP**.
6. Select **BFD**.
7. Select **Enable**.
8. (Optional) In the **MinRxInterval** field, specify the minimum receive interval..
9. (Optional) In the **TxInterval** field, specify the transmit interval.
10. (Optional) In the **Multiplier** field, specify a value for the multiplier used to calculate a receive timeout.

IP BFD field descriptions

Use the data in the following table to use the **BFD** tab.

Name	Description
Enable	Enable BFD on the VLAN.
MinRxInterval	Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.
TxInterval	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
Multiplier	Specifies a value for the multiplier used to calculate a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

Configure BFD for an IPv6 Interface on a VLAN

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv6 interface on a VLAN.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to configure BFD.
5. Select **IPV6**.
6. Select **IPv6 BFD Interface**.
7. (Optional) In the **MinRxInterval** column, double-click the field and type a value for **MinRxInterval**.
8. (Optional) In the **TxInterval** column, double-click the field and type a value for **TxInterval**.

9. (Optional) In the **Multiplier** column, double-click the field and type a value for **Multiplier**.

IPv6 BFD Interface field descriptions

Use the data in the following table to use the **IPv6 BFD Interface** tab.

Name	Description
Interface	Specifies an index value that uniquely identifies the interface.
Enable	Enable BFD on the VLAN.
MinRxInterval	Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.
TxInterval	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
Multiplier	Specifies a value for the multiplier used to calculate a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

Enable BFD for BGP Peers

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for Border Gateway Protocol (BGP) peers.

Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Peers** tab.
4. Select **Insert**.

5. Select **BfdEnable**.

Peers Field Descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
Instance	Specifies the BGP peer instance.
LocalAddrType	Specifies the local IP address type of the entered BGP peer.
LocalAddr	Specifies the local IP address of the entered BGP peer.
RemoteAddrType	Specifies the remote IP address type of the entered BGP peer.
RemoteAddr	Specifies the remote IP address of the entered BGP peer.
AdminStatus	Specifies the administrative status of the BGP peer.
GroupName	Specifies the peer group name to which the peer belongs (optional).
PeerState	Specifies the BGP peer connection state.
RemoteAs	Configures a remote AS number for the peer or peer-group in the range 0–65535.
Enable	Controls whether the peer connection is enabled or disabled. The default is disabled.
EbgpMultiHop	Enables or disables a connection to a BGP peer that is more than one hop away from the local router. The default value is disable.
RoutePolicyIn	Specifies the policy (by name) that applies to all network routes learned from this peer.
RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing route updates.
RemovePrivateAs	Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.
UpdateSourceInterface	Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.
ConnectRetryInterval	Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.
HoldTimeConfigured	Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.

Name	Description
KeepAliveConfigured	Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.
MD5Authentication	Enables and disables MD5 authentication.
AdvertisementInterval	Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGP neighbor. The default value is 30 seconds and the range is 5–120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained.
DefaultOriginate	When enabled, specifies that the current route originated from the BGP peer. This parameter enables or disables sending the default route information to the specified neighbor or peer. The default value is false.
DefaultOriginateIpv6	When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.
Weight	Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0–65535.
MaxPrefix	Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0–2147483647. A value of 0 means no limit exists.
NextHopSelf	Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.
RouteReflectorClient	Specifies that this peer is a route reflector client. Note: This parameter only applies to VRF 0.

Name	Description
SoftReconfigurationIn	When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).
DebugMask	Displays the specified debug information for the BGP peer. The default value is none. <ul style="list-style-type: none"> • None disables all debug messages. • Event enables the display of debug event messages. • State enables display of debug state transition messages. • Update enables display of debug messages related to updates transmission and reception. • Error enables the display of debug error messages. • Trace enables the display of debug trace messages. • Init enables the display of debug initialization messages. • All enables all debug messages. • Packet enables the display of debug packet messages. • Warning enables the display of debug warning messages. • Filter enables the display of debug messages related to filtering.
SendCommunity	Enables or disables sending the community attribute of the update message to the specified peer. The default value is disable.
Vpnv4Address	Specifies the vpnv4 routes.
IppvnLiteCap	Enable or disable IP VPN-lite capability on the BGP neighbor peer.
Ipv6Cap	Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.
SooAddress	Specifies the site-of-origin (SoO) address of the BGP peer.
SooAsNumber	Specifies the site-of-origin (SoO) Autonomous System (AS) number of the BGP peer.
SooAssignedNum	Specifies the site-of-origin (SoO) assigned number of the BGP peer.
SooType	Specifies the site-of-origin (SoO) type of the BGP peer.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.
AsOverride Note: This field does not apply on all hardware platforms.	Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.

Name	Description
AllowAsIn Note: This field does not apply on all hardware platforms.	Specifies the number of AS-in allowed for the BGP peer. The range is 1-10.
Ipv6RoutePolicyIn	Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.
Ipv6RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing IPv6 route updates.
Ipv6MaxPrefix	Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for this BGP peer.

Enable BFD for BGP Peer Groups

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for Border Gateway Protocol (BGP) peer groups.

Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Peer Groups** tab.
4. Select **Insert**.
5. Select **BfdEnable**.

Peer Groups field descriptions

Use the data in the following table to use the **Peer Groups** tab.

Name	Description
Index	Specifies the index of this peer group.
GroupName	Specifies the peer group to which this neighbor belongs (optional).
Enable	Enables or disables the peer group.

Name	Description
RemoteAs	Configures a remote AS number for the peer-group in the range 0-65535.
DefaultOriginate	When enabled, the BGP speaker (the local router) sends the default route 0.0.0.0 to a group of neighbors for use as a default route. The default is disabled.
DefaultOriginateIpv6	When enabled, the BGP speaker (the local router) sends the default route to a group of neighbors for use as a default route. The default is disabled.
EbgpMultiHop	When enabled, the switch accepts and attempts BGP connections to external peers that reside on networks that do not directly connect. The default is disabled.
AdvertisementInterval	Specifies the time interval, in seconds, that elapses between BGP routing updates. The default value is 30 seconds.
KeepAlive	Specifies the time interval, in seconds, between sent BGP keep alive messages to remote peers. The default value is 60.
HoldTime	Configures the hold time for the group of peers in seconds. Use a value that is three times the value of the KeepAlive time. The default value is 180.
Weight	Assigns an absolute weight to a BGP network. The default value is 100.
MaxPrefix	Limits the number of routes accepted from this group of neighbors. A value of zero indicates no limit. The default value is 12,000 routes.
NextHopSelf	Specifies that the switch must set the NextHop attribute to the local router address before sending updates to remote peers.
RoutePolicyIn	Specifies the route policy that applies to all networks learned from this group of peers.
RoutePolicyOut	Specifies the route policy that applies to all outgoing updates to this group of peers.
RouteReflectorClient	Specifies that this peer group is a route reflector client. Note: This parameter only applies to VRF 0.
SoftReconfigurationIn	When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is enable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).
MD5Authentication	Enables and disables MD5 authentication. The default is disable.
RemovePrivateAs	Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.
SendCommunity	Enables or disables sending the community attribute of the update message to the specified peer group. The default value is disable.

Name	Description
AfUpdateSourceInterfaceType	Specifies the interface type.
AfUpdateSourceInterface	Specifies the IP address used for circuitless IP (CLIP) for this peer group.
Vpvn4Address	Enables BGP address families for IPv4 (BGP) and Layer 3 VPN (MP-BGP) support. Enable this parameter for VPN/VRF Lite routes.
IppvnLiteCap	Specifies (when enabled) that IP VPN Lite capability can be enabled or disabled on the BGP neighbor peer. The default is disable.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.
AsOverride	Specifies that the AS Override parameter can be enabled or disabled for the BGP peer group. The default is disable.
AllowedAsIn	Specifies the number of AS-in allowed for the BGP peer group. The range is 1-10.
IPv6Cap	Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.
Ipv6RoutePolicyIn	Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.
Ipv6RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing IPv6 route updates.
Ipv6MaxPrefix	Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for the BGP peer group.

Enable BFD for BGPv6 Peers

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for BGPv6 peers.

Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Note

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **BGP+**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Select **BfdEnable**.

Peers Field Descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddr	Specifies the remote IPv6 address of the entered BGP+ peer.
GroupName	Specifies the peer group name to which the peer belongs (optional).
PeerState	Specifies the BGPv6 peer connection state.
RemoteAs	Configures a remote AS number for the peer or peer-group in the range 0 to 65535.
Enable	Controls whether the peer connection is enabled or disabled. The default is disabled.
EbgpMultiHop	Enables or disables a connection to a BGPv6 peer that is more than one hop away from the local router. The default value is disable.
RoutePolicyIn	Specifies the policy (by name) that applies to all network routes learned from this peer.
RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing route updates.
RemovePrivateAs	Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.
UpdateSourceInterface	Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.
ConnectRetryInterval	Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.
HoldTimeConfigured	Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.

Name	Description
KeepAliveConfigured	Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.
MD5Authentication	Enables and disables MD5 authentication.
AdvertisementInterval	Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGPv6 neighbor. The default value is 30 seconds and the range is 5 to 120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained.
DefaultOriginatelpv6	When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.
Weight	Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0 to 65535.
MaxPrefix	Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0 to 2147483647. A value of 0 means no limit exists.
NextHopSelf	Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.
RouteReflectorClient	Specifies that this peer is a route reflector client. Note: This parameter only applies to VRF 0.
SoftReconfigurationIn	When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).

Name	Description
DebugMask	Displays the specified debug information for the BGP peer. The default value is none. <ul style="list-style-type: none"> • None disables all debug messages. • Event enables the display of debug event messages. • State enables display of debug state transition messages. • Update enables display of debug messages related to updates transmission and reception. • Error enables the display of debug error messages. • Trace enables the display of debug trace messages. • Init enables the display of debug initialization messages. • All enables all debug messages. • Packet enables the display of debug packet messages. • Warning enables the display of debug warning messages. • Filter enables the display of debug messages related to filtering.
SendCommunity	Enables or disables sending the community attribute of the update message to the specified peer. The default value is disable.
IvpnLiteCap	Enable or disable IP VPN-lite capability on the BGP neighbor peer.
Ipv6Cap	Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.
AsOverride Note: This field does not apply on all hardware platforms.	Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.
AllowAsIn Note: This field does not apply on all hardware platforms.	Specifies the number of AS-in allowed for the BGP peer. The range is 1-10.
Ipv6RoutePolicyIn	Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.
Ipv6RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing IPv6 route updates.
Ipv6MaxPrefix	Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for this peer.

Enable BFD for OSPF on an IPv4 Port Interface

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for the OSPF protocol on an IPv4 port interface.

Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **IP**.
4. Select the **OSPF** tab.
5. Select **BfdEnable**.

OSPF Field Descriptions

Use the data in the following table to use the **OSPF** tab.

Name	Description
Enable	Enables or disables OSPF routing on the specified port. The default is false.
HelloInterval	Specifies the length of time, in seconds, between the transmission of hello packets. This value must be the same for all routers attached to a common network. The default is 10 seconds. After you change the hello interval values, you must save the configuration file, and then restart the switch. After the switch restarts, it restores the values and checks for consistency.
RtrDeadInterval	Specifies the interval used by adjacent routers to determine if the router was removed from the network. This interval must be identical on all routers on the subnet, and a minimum of four times the hello interval. To avoid interoperability issues, the RtrDeadInterval value for the OSPF interface needs to match with the RtrDeadInterval value for the OSPF virtual interface. The default is 40 seconds.
DesigRtrPriority	Specifies the priority of this port in multiaccess networks to use in the designated router election algorithm. The value 0 indicates the router is not eligible to become the designated router on this particular network. If a tie occurs, routers use their router ID as a tie breaker. The default is 1.
Metric	Specifies the metric for the type of service (TOS) on this port. The value of the TOS metric is $(10^9 / \text{interface speed})$. The default is 1. <ul style="list-style-type: none"> • FFFF—No route exists for this TOS. • IPCP links—Defaults to 0. • 0—Use the interface speed as the metric value when the state of the interface is up.

Name	Description
AuthType	<p>Specifies the type of authentication required for the interface.</p> <ul style="list-style-type: none"> • none—Specifies that no authentication required. • simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter. • MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key. • sha1—Specifies secure hash algorithm (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long. You can only access and enable the SHA-1 authentication type after you enable enhanced secure mode. • sha-2—Specifies SHA-2, which offers the hash function SHA-256. <p>Note: sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.</p>
AuthKey	Specifies the key (up to 8 characters) when you specify simple password authentication in the port AuthType variable.
AreaId	Specifies the OSPF area name in dotted-decimal format. The area name is not related to an IP address. You can use a suitable value for the OSPF area name (for example, 1.1.1.1 or 200.200.200.200).
AdvertiseWhenDown	<p>Advertises the network on this port as up, even if the port is down. The default is false.</p> <p>After you configure a port with no link and enable AdvertiseWhenDown, it does not advertise the route until the port is active. Then, OSPF advertises the route even if the link is down. To disable advertising based on link-states, disable AdvertiseWhenDown.</p>
IfType	<p>Specifies the type of OSPF interface (broadcast, NBMA, or passive).</p> <p>Before you change an OSPF interface type, you must first disable the interface. If the interface is an NBMA interface, you must also delete all configured neighbors.</p>
PollInterval	Specifies the length of time, in seconds, between hello packets sent to an inactive OSPF router. Neighbors must have the same poll interval.
IfMtuIgnore	Specifies whether the interface ignores the global maximum transmission unit (MTU) configuration. To allow the switch to accept OSPF database description (DD) packets with a different MTU size, enable MtuIgnore. The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes.
BfdEnable	Enable Bidirectional Forwarding Detection (BFD) for OSPF.

Enable BFD for OSPF on an IPv4 VLAN Interface

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable OSPF BFD on an IPv4 VLAN interface.

Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to enable BFD for OSPF.
5. Select **IP**.
6. Select **OSPF**.
7. Select **BfdEnable**.

OSPF Field Descriptions

Use the data in the following table to use the **OSPF** tab.

Name	Description
Enable	Enables or disables OSPF routing on the specified VLAN. The default is false.
HelloInterval	Specifies the length of time, in seconds, between the transmission of hello packets. This value must be the same for all routers attached to a common network. The default is 10 seconds. After you change the hello interval values, you must save the configuration file, and then restart the switch. After the switch restarts, it restores the values and checks for consistency.
RtrDeadInterval	Specifies the interval used by adjacent routers to determine if the router was removed from the network. This interval must be identical on all routers on the subnet and a minimum of four times the hello interval. To avoid interoperability issues, the RtrDeadInterval value for the OSPF interface needs to match with the RtrDeadInterval value for the OSPF virtual interface. The default is 40 seconds.
DesigRtrPriority	Specifies the priority of this VLAN in multiaccess networks to use in the designated router election algorithm. The value 0 indicates the router is not eligible to become the designated router on this particular network. If a tie occurs, routers use their router ID as a tie breaker. The default is 1.

Name	Description
Metric	<p>Specifies the metric for this TOS on this VLAN. The value of the TOS metric is $(10^9 / \text{interface speed})$. The default is 1.</p> <ul style="list-style-type: none"> • FFFF—No route exists for this TOS. • IPCP links—Defaults to 0. • 0—Use the interface speed as the metric value when the state of the interface is up.
AuthType	<p>Specifies the type of authentication required for the interface.</p> <ul style="list-style-type: none"> • none—Specifies that no authentication required. • simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter. • MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key. • sha1—Specifies secure hash algorithm 1 (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long. You can only access and enable the SHA-1 authentication type after you enable enhanced secure mode. • sha-2—Specifies SHA-2, which offers the hash function SHA-256. <p>Note: sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.</p>
AuthKey	<p>Specifies the key (up to eight characters) when you specify simple password authentication in the VLAN AuthType variable.</p>
AreaId	<p>Specifies the OSPF area name in dotted-decimal format. The area name is not related to an IP address. You can use a suitable value for the OSPF area name (for example, 1.1.1.1 or 200.200.200.200).</p>
AdvertiseWhenDown	<p>Advertises the network even if the port is down. If true, OSPF advertises the network on this VLAN as up, even if the port is down. The default is false.</p> <p>After you configure a port without a link and enable AdvertiseWhenDown, it does not advertise the route until the port is active. Then, OSPF advertises the route even when the link is down. To disable advertising based on link states, disable AdvertiseWhenDown.</p>
IfType	<p>Specifies the type of OSPF interface (broadcast, NBMA, or passive).</p> <p>Before you change an OSPF interface type, you must first disable the interface. If the interface is an NBMA interface, you must also delete all configured neighbors.</p>
PollInterval	<p>Specifies the length of time, in seconds, between hello packets sent to an inactive OSPF router. Neighbors must use the same poll interval.</p>

Name	Description
IfMtuIgnore	Specifies whether the VLAN ignores the MTU configuration. To allow the switch to accept OSPF DD packets with a different MTU size, enable MtuIgnore. The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for OSPF.

Enable BFD for OSPF on an IPv6 Port Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for the OSPF protocol on an IPv6 port interface.

Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **IPv6**.
4. Select the **IPv6 OSPF Interface** tab.
5. Select **Insert**.
6. Select **BfdEnable**.

IPv6 OSPFv3 Interface Field Descriptions

Use the data in the following table to use the **IPv6 OSPFv3 Interface** tab.

Name	Description
Index	Specifies the interface index for the IPv6 interface on which OSPFv3 is configured.
Areald	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
Type Note: Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> • broadcast • NBMA • point-to-point • point-to-multipoint • passive

Name	Description
AdminStat	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.
RtrPriority Note: Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
TransitDelay Note: Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
RetransInterval Note: Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.
HelloInterval Note: Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.
RtrDeadInterval Note: Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
PollInterval Note: Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.

Name	Description
State	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> • down • loopback • waiting • pointToPoint • designatedRouter • backupDesginatedRouter • otherDesignatedRouter
DesignatedRouter	Shows the router ID for the designated router.
BackupDesignatedRouter	Shows the router ID for the backup designated router.
MetricValue Note: Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100. Note: If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
LinkLsaSuppression Note: Value is not configurable for OSPFv3 CLIP interfaces.	Specifies whether Link LSA suppression is enabled.

Enable BFD for OSPF on an IPv6 VLAN Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable OSPF BFD on an IPv6 VLAN interface.

Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Select **VLANs**.
3. Select the **Basic** tab.

4. Select the VLAN on which you want to enable BFD for OSPF.
5. Select **IPv6**.
6. Select **IPv6 OSPF Interface**.
7. Select **Insert**.
8. Select **BfdEnable**.

IPv6 OSPF Interface Field Descriptions

Use the data in the following table to use the **IPv6 OSPF Interface** tab.

Name	Description
Index	Shows the interface index for the IPv6 interface on which OSPFv3 is configured.
AreaId	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
Type	Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> • broadcast • NBMA • point-to-point • point-to-multipoint • passive
AdminStat	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.
RtrPriority	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
TransitDelay	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
RetransInterval	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.
HelloInterval	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.

Name	Description
RtrDeadInterval	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
PollInterval	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
State	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> • down • loopback • waiting • pointToPoint • designatedRouter • backupDesignatedRouter • otherDesignatedRouter
DesignatedRouter	Shows the router ID for the designated router.
BackupDesignatedRouter	Shows the router ID for the backup designated router.
MetricValue	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100. Note: If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
LinkLsaSuppression	Specifies whether Link LSA suppression is enabled.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for OSPF.

Configure BFD on an IPv4 Static Route

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BFD**.
3. Select **Insert**.
4. In the **NextHop** field, type the IPv4 address of the next hop of the BFD session.
5. (Optional) In the **VrfId** field, type the ID of the VRF associated with the BFD session.

BFD Static Route Field Descriptions

Use the data in the following table to use the **Static Route** tab.

Name	Description
NextHop	Specifies the IPv4 address of the next hop of the BFD session.
VrfId	Specifies the ID of the VRF associated with the BFD session.
VrfName	Specifies the name of the VRF associated with the BFD session.

Configure BFD on an IPv6 Static Route

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **IPv6 BFD**.
3. Select **Insert**.
4. In the **Interface** field, select either **Port** or **Vlan** and select an interface.
5. In the **NextHop** field, type the IPv6 address of the next hop of the BFD session.
6. (Optional) In the **VrfId** field, type the ID of the VRF associated with the BFD session.

IPv6 BFD Static Route Field Descriptions

Use the data in the following table to use the **Static Route** tab.

Name	Description
Interface	Specifies either a port or VLAN interface.
NextHop	Specifies the IPv4 address of the next hop of the BFD session.
VrfId	Specifies the ID of the VRF associated with the BFD session.
VrfName	Specifies the name of the VRF associated with the BFD session.

Display BFD Performance Counters

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **BFD**.
3. Select the **Performance counters** tab.

BFDPerformance Counters Field Descriptions

Use the data in the following table to use the **Performance counters** tab.

Name	Description
PktIn	Specifies the total number of BFD messages received for this BFD session.
PktOut	Specifies the total number of BFD messages sent for this BFD session.

The following sections provide conceptual information and procedures that you can use to configure Border Gateway Protocol (BGP) services. The following operations are supported by BGP:

- IPv4
- 4-byte AS
- Peer groups
- Redistribution

Examples and network illustrations in these sections illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

Border Gateway Protocol (BGP) is an inter-domain routing protocol that provides loop-free routing between autonomous systems (AS) or within an AS. This section describes the major BGP features.

Autonomous Systems

An Autonomous system (AS) is a group of routers and hosts run by a single technical administrator that has a single, clearly defined routing policy. Each AS uses a unique AS number assigned by the appropriate Internet Registry entity. LANs and WANs that interconnect by IP routers form a group of networks called an internetwork. For administrative purposes, internetworks divide into boundaries known as autonomous systems.

The following figure shows a sample internetwork segmented into three autonomous systems.

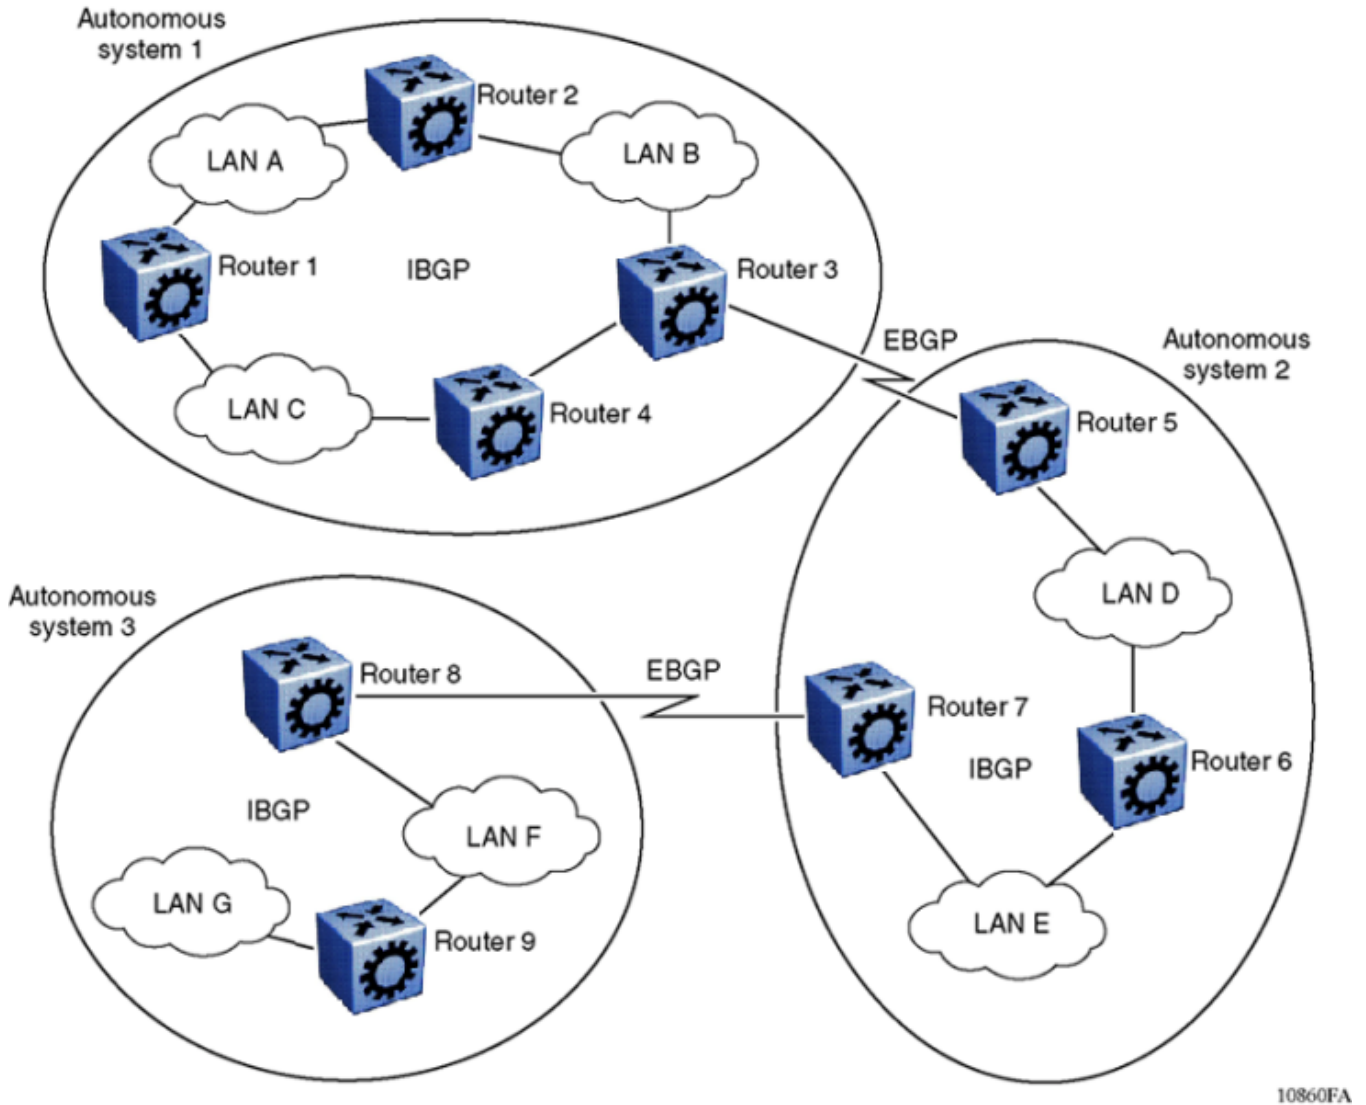

Figure 17: Internetwork segmented into three autonomous systems

BGP exchanges information between autonomous systems as well as between routers within the same AS. As shown in the preceding figure, routers that are members of the same AS and exchange BGP updates run internal BGP (iBGP), and routers that are members of different autonomous systems and exchange BGP updates run external BGP (eBGP).

Internal and external BGP routing

The switch supports both iBGP intra-AS routing and eBGP external-AS routing. With iBGP, each router within an AS runs an interior gateway protocol (IGP), such as Routing Information Protocol (RIP) or Open Shortest Path First (OSPF). The iBGP information, along with the IGP route to the originating BGP border router, determines the next hop to use to exchange information with an external AS. Each router uses iBGP exclusively to determine reachability to external autonomous systems. After a router receives an iBGP update destined for an external AS, it passes the update to IP for inclusion in the routing table only if a viable IGP route to the correct border gateway is available.

BGP speakers in different autonomous systems use eBGP to communicate routing information.

BGP speaker

BGP routers employ an entity within the router, referred to as a BGP speaker, which transmits and receives BGP messages and acts upon them. BGP speakers establish a peer-to-peer session with other BGP speakers to communicate.

All BGP speakers within an AS must be fully meshed. The following figure shows a BGP network with fully-meshed BGP speakers.

10861FA

Figure 18: BGP networks

Transit AS

An AS with more than one BGP speaker can use iBGP to provide a transit service for networks located outside the AS. An AS that provides this service is a transit AS. As shown in the preceding figure, [BGP networks](#), AS 40 is the transit AS. AS 40 provides information about the internal networks, as well as transit networks, to the remaining autonomous systems. The iBGP connections between routers D, E, and F provide consistent routing information to the autonomous systems.

Stub and multihomed autonomous systems

As shown in the preceding figure, [BGP networks](#), an AS can include one or more BGP speakers that establish peer-to-peer sessions with BGP speakers in other autonomous systems to provide external route information for the networks within the AS.

A stub AS has a single BGP speaker that establishes a peer-to-peer session with one external BGP speaker. In this case, the BGP speaker provides external route information only for the networks within its own AS.

A multihomed AS has multiple BGP speakers.

Peers

BGP uses Transmission Control Protocol (TCP) as a transport protocol. When two routers open a TCP connection to each other for the purpose of exchanging routing information, they form a peer-to-peer relationship. In the preceding figure, [BGP networks](#), Routers A and D are BGP peers, as are Routers B and E, C and E, F and G, and Routers D, E, and F.

Although Routers A and D run eBGP, Routers D, E, and F within AS 40 run iBGP. The eBGP peers directly connect to each other, while the iBGP peers do not. As long as an IGP operates and allows two neighbors to logically communicate, the iBGP peers do not require a direct connection.

Note

You cannot create the same iBGP peers on two different VRFs, or the same eBGP peers on two different chassis. Only one local autonomous system (AS) can exist for each chassis or VRF.

Because all BGP speakers within an AS must be fully meshed logically, the iBGP mesh can grow to large proportions and become difficult to manage. You can reduce the number of peers within an AS by creating confederations and route reflectors.

BGP peers exchange complete routing information only after the peers establish a connection. Thereafter, BGP peers exchange routing updates. An update message consists of a network number, a list of autonomous systems that the routing information passed through (the AS path), and other path attributes that describe the route to a set of destination networks. When multiple paths exist, BGP compares the path attributes to choose the preferred path. Even if you disable BGP, the system logs all BGP peer connection requests. For more information about update messages, see [BGP Updates](#) on page 412.

Supernet advertisements

BGP has no concept of address classes. Each network listed in the network layer reachability information (NLRI) portion of an update message contains a prefix length field, which describes the length of the mask associated with the network. The prefix length field allows for both supernet and

subnet advertisement. The supernet advertisement is what makes classless interdomain routing (CIDR) possible (see [CIDR and aggregate addresses](#) on page 401).

Bandwidth and maintenance reduction

BGP provides two features that reduce the high bandwidth and maintenance costs associated with a large full-mesh topology:

- confederations
- route reflectors

Note

Confederations and route reflectors are not supported on iBGP for non-default VRFs.

For information on confederations and route reflectors, see [Routing information consolidation](#) on page 401.

BGP 4 Byte AS Support

Each Autonomous System (AS) must have its own unique number. Because the 2-byte AS numbering scheme is unable to meet the increasing demand, the switch supports 4-byte AS numbers. This feature is enabled by supporting RFC 4893, BGP Support for 4-octet AS Number Space.

The switch supports the following three types of peer relationships as a result of 4 byte AS support:

- Old peer to old peer
- Old peer to new peer
- New peer to new peer

An old peer is the one that supports 2-byte AS numbers only and new peer is the one that supports both 2-byte AS numbers and 4-byte AS numbers.

RFC4893 supports two new path attributes:

- AS4_PATH contains the AS path encoded with a 4-octet AS number.
- AS4-AGGR is a new aggregator attribute that carries a 4-octet AS number.

Figure 19: 2-byte and 4-byte Mixed Environment

The preceding figure shows an example of how the switch uses the AS4_PATH attribute in a mixed environment. The figure illustrates how a 2-byte BGP speaker interoperates with a 4-byte BGP speaker.

Router B is a 2-byte BGP speaker. Router A substitutes AS_PATH with the AS_TRANS, a 2-octet AS number defined by RFC4893 for backward compatibility, and encodes the 4-byte AS into AS4_PATH in BGP updates it sends to router B.

Router B does not understand the AS4_PATH but does preserve the information and sends it to router C.

Router C is a 4-byte BGP speaker. Router C merges the information received in AS_PATH and AS4_PATH, and encodes the 4-byte AS when it sends the AS_PATH information to router D.

Old Peer to Old Peer

When the peer relationship between an old peer and another old peer is established, 4 byte AS numbers contained in the AS4_PATH and AS4_AGGREGATOR are transited to other peers.

Important

Do not assign 23456 as an AS number. The Internet Assigned Numbers Authority (IANA) reserved this number for the AS_TRANS attribute and BGP uses it to facilitate communication between peer modes. AS_TRANS uses a 2-byte AS format to represent a 4-byte AS number. The switch interprets the AS_TRANS attribute and propagates it to other peers.

New Peer to New Peer

The new BGP speaker establishes its 4 byte AS support through BGP capability advertisement. A BGP speaker that announces such capability and receives it from its peer, uses 4 byte AS numbers in

AS_PATH and AGGREGATOR attributes and assumes these attributes received from its peer are encoded in 4 byte AS numbers.

The new BGP attributes AS4_PATH and AS4_AGGREGATOR received from the new BGP speaker between the new BGP peers in the update message is discarded.

Old Peer to New Peer

An old BGP speaker and a new BGP speaker can form peering relationship only if the new BGP speaker is assigned a 2 byte AS number. This 2 byte number can be any global unique AS number or AS_TRANS.

New BGP speaker sends AS path information to the old BGP speaker in AS_PATH attribute as well as AS4_PATH attribute. If the entire AS_PATH consists of only 2 byte AS numbers then the new BGP speaker does not send AS4_PATH information.

The 4-byte AS number feature does not in any way restrict the use or change the way you configure 2-byte AS numbers. You can also configure 2-byte AS or 4 byte AS numbers in AS path lists, community lists, and route policies.

BGP 4-byte AS Number Notation

BGP 4-byte AS numbers are represented in two ways: AS Plain and AS dot. The default form of representing the AS numbers is AS Plain while you have an option to configure AS dot. AS Plain form of representation is preferred over AS dot representation as a large amount of network providers find the AS dot notation incompatible with the regular expressions used by them. In case of any issues, troubleshooting and analyzing also gets difficult with AS dot notation.

BGP AS Number Format - AS Plain

Table 52: Default Asplain 4-Byte Autonomous System Number Format

Format	Configuration Format	Show Command Output and Regular Expression Match Format
asplain	2-byte: 1 to 65535 4-byte: 65536 to 4294967295	2-byte: 1 to 65535 4-byte: 65536 to 4294967295
asdot	2-byte: 1 to 65535 4-byte: 1.0 to 65535.65535	2-byte: 1 to 65535 4-byte: 65536 to 4294967295

BGP AS Number Format - ASdot

Table 53: Asdot 4-Byte Autonomous System Number Format

Format	Configuration Format	Show command output and Regular Expression Match Format
asplain	2-byte: 1 to 65535 4-byte: 65536 to 4294967295	2-byte: 1 to 65535 4-byte: 1.0 to 65535.65535
asdot	2-byte: 1 to 65535 4-byte: 1.0 to 65535.65535	2-byte: 1 to 65535 4-byte: 1.0 to 65535.65535

For more information on configuring 4 byte AS numbers, see [Configure 4-byte AS numbers](#) on page 433.

Routing information consolidation

Use the information in this section to understand how to reduce the size of routing tables.

CIDR and aggregate addresses

Classless interdomain routing (CIDR) is an addressing scheme (also known as supernetting) that eliminates the concept of classifying networks into class types. Earlier addressing schemes identified five classes of networks: Class A, Class B, Class C, Class D, and Class E. This document does not discuss Classes D (used for multicast) and E (reserved and currently not used).

Network 195.215.0.0, an illegal Class C network number, becomes a legal supernet when represented in CIDR notation as 195.215.0.0/16. The /16 is the prefix length and expresses the explicit mask that CIDR requires. In this case, the addition of the prefix /16 indicates that the subnet mask consists of 16 bits (counting from the left).

Using this method, supernet 195.215.0.0/16 represents 195.215.0.0 255.255.0.0. The following table shows the conversion of prefix length to subnet mask.

Table 54: CIDR conversion

Prefix	Dotted-decimal	Binary	Network class
/1	128.0.0.0	1000 0000 0000 0000 0000 0000 0000 0000	128 Class A
/2	192.0.0.0	1100 0000 0000 0000 0000 0000 0000 0000	64 Class A
/3	224.0.0.0	1110 0000 0000 0000 0000 0000 0000 0000	32 Class A
/4	240.0.0.0	1111 0000 0000 0000 0000 0000 0000 0000	16 Class A
/5	248.0.0.0	1111 1000 0000 0000 0000 0000 0000 0000	8 Class A
/6	252.0.0.0	1111 1100 0000 0000 0000 0000 0000 0000	4 Class A
/7	254.0.0.0	1111 1110 0000 0000 0000 0000 0000 0000	2 Class A
/8	255.0.0.0	1111 1111 0000 0000 0000 0000 0000 0000	1 Class A or 256 Class B
/9	255.128.0.0	1111 1111 1000 0000 0000 0000 0000 0000	128 Class B
/10	255.192.0.0	1111 1111 1100 0000 0000 0000 0000 0000	64 Class B
/11	255.224.0.0	1111 1111 1110 0000 0000 0000 0000 0000	32 Class B
/12	255.240.0.0	1111 1111 1111 0000 0000 0000 0000 0000	16 Class B
/13	255.248.0.0	1111 1111 1111 1000 0000 0000 0000 0000	8 Class B
/14	255.252.0.0	1111 1111 1111 1100 0000 0000 0000 0000	4 Class B
/15	255.254.0.0	1111 1111 1111 1110 0000 0000 0000 0000	2 Class B
/16	255.255.0.0	1111 1111 1111 1111 0000 0000 0000 0000	1 Class B or 256 Class C
/17	255.255.128.0	1111 1111 1111 1111 1000 0000 0000 0000	128 Class C

Table 54: CIDR conversion (continued)

Prefix	Dotted-decimal	Binary	Network class
/18	255.255.192.0	1111 1111 1111 1111 1100 0000 0000 0000	64 Class C
/19	255.255.224.0	1111 1111 1111 1111 1110 0000 0000 0000	32 Class C
/20	255.255.240.0	1111 1111 1111 1111 1111 0000 0000 0000	16 Class C
/21	255.255.248.0	1111 1111 1111 1111 1111 1000 0000 0000	8 Class C
/22	255.255.252.0	1111 1111 1111 1111 1111 1100 0000 0000	4 Class C
/23	255.255.254.0	1111 1111 1111 1111 1111 1110 0000 0000	2 Class C
/24	255.255.255.0	1111 1111 1111 1111 1111 1111 0000 0000	1 Class C

Use CIDR to assign network prefixes of arbitrary lengths, as opposed to the obsolete class system, which assigned prefixes as even multiples of an octet.

For example, you can assign a single routing table supernet entry of 195.215.16/21 to represent 8 separate Class C network numbers: 195.215.16.0 through 195.215.23.0.

Supernet addressing

You can create a supernet address that covers an address range.

For example, to create a supernet address that covers an address range of 192.32.0.0 to 192.32.9.255, perform the following steps:

1. Convert the starting and ending address range from dotted-decimal notation to binary notation (see the following figure).

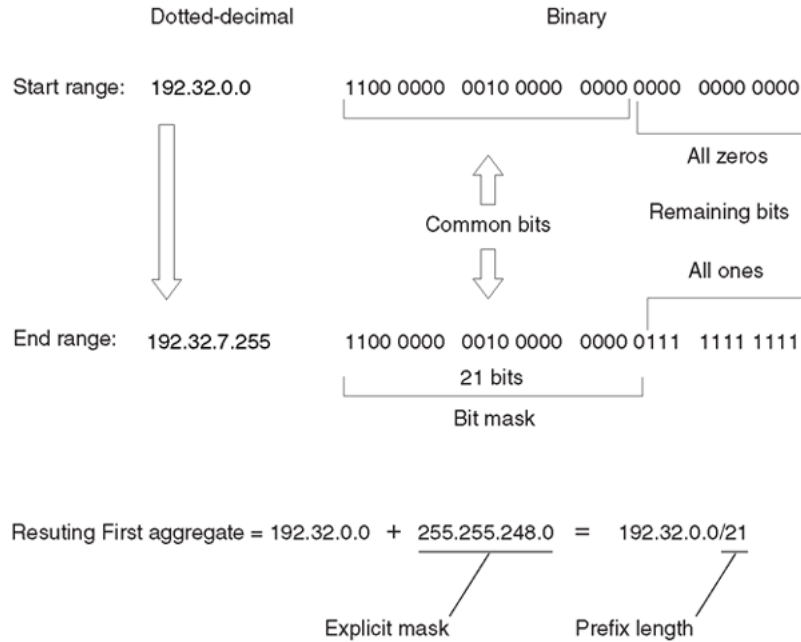

Figure 20: Binary notation conversion

2. Locate the common bits in both ranges. Ensure that the remaining bits in the start range are zeros, and the remaining bits in the end range are all ones. In this example, the remaining bits in the end range are not all ones.
3. If the remaining bits in the end range are not all ones, you must recalculate to find the IP prefix that has only ones in the remaining bits in the end range.
4. Recalculate to find a network prefix that has all ones in the remaining end range bits (see the following figure). In this example, 192.32.7.255 is the closest IP prefix that matches the common bits for the start range.

10863EA

Figure 21: First aggregate and prefix length

5. The 21 bits that match the common bits form the prefix length. The prefix length is the number of binary bits that form the explicit mask (in dotted-decimal notation) for this IP prefix.
6. The remaining aggregate is formed from 192.32.8.0 to the end range, 192.32.9.255.

As shown in [Figure 21](#), the resulting first aggregate 192.32.0.0/21 represents all of the IP prefixes from 192.32.0.0 to 192.32.7.255.

The following figure shows the results after forming the remaining aggregate from 192.32.8.0 to the end range, 192.32.9.255.

The resulting aggregate 192.32.8.0/23 represents all of the IP prefixes from 192.32.8.0 to 192.32.9.255.

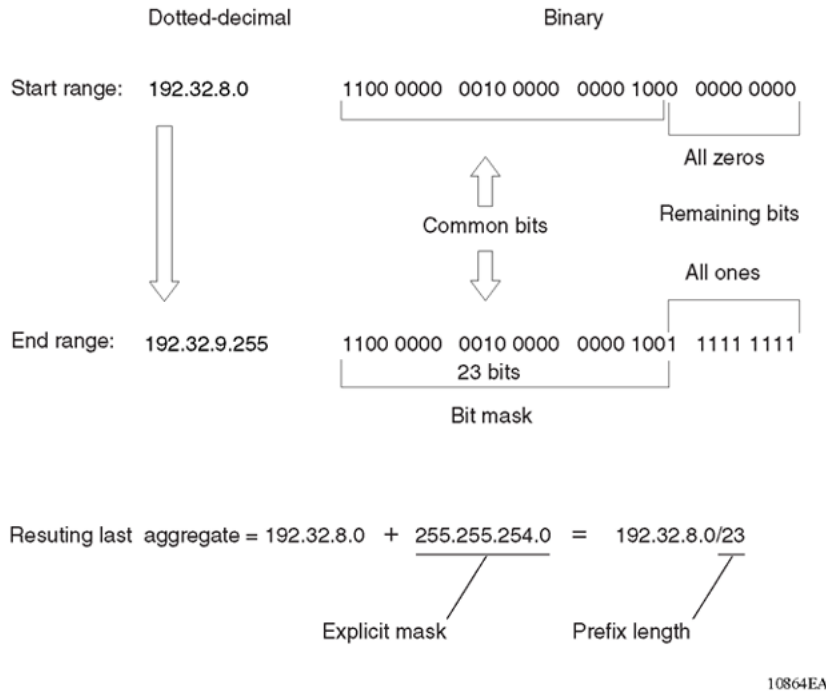

Figure 22: Last aggregate and prefix length

The final result of calculating the supernet address that ranges from 192.32.0.0 to 192.32.9.255 is as follows:

192.32.0.0 (with mask) 255.255.248.0 = 192.32.0.0/21

192.32.8.0 (with mask) 255.255.254.0 = 192.32.8.0/23

Aggregate routes

Eliminating the idea of network classes provides an easy method to aggregate routes. Rather than advertise a separate route for each destination network in a supernet, BGP uses a supernet address to advertise a single route (called an aggregate route) that represents all the destinations. CIDR also reduces the size of the routing tables used to store advertised IP routes.

The following figure shows an example of route aggregation using CIDR. In this example, a single supernet address 195.215.0.0/16 advertises 256 separate Class C network numbers 195.215.0.0 through 195.215.255.0.

Figure 23: Aggregating routes with CIDR

Confederations

A BGP router configured for iBGP establishes a peer-to-peer session with every other iBGP speaker in the AS. In an AS with a large number of iBGP speakers, this full-mesh topology can result in high bandwidth and maintenance costs.

Note

Confederations are not supported on iBGP for non-default VRFs.

As shown in the following example, a full-mesh topology for an AS with 50 iBGP speakers requires 1225 internal peer-to-peer connections:

Example:

$$n \times (n-1)/2 = n \text{ iBGP sessions}$$

where:

$$50 \times (50-1)/2 = 1225 \text{ number of unique iBGP sessions}$$

You can reduce the high bandwidth and maintenance costs associated with a large full-mesh topology by dividing the AS into multiple smaller autonomous systems (sub-autonomous systems), and then group them into a single confederation (see the following figure).

Figure 24: Confederations

As shown in the preceding figure, each sub-AS is fully meshed within itself and has eBGP sessions with other sub-autonomous systems in the same confederation.

Although the peers in different autonomous systems have eBGP sessions with the various sub-AS peers, they preserve the next-hop, Multi-Exit Discriminator (MED), and local preference information and exchange routing updates as if they were iBGP peers. All of the autonomous systems retain a single interior gateway protocol (IGP). When the confederation uses its own confederation identifier, the system displays the group of sub-autonomous systems as a single AS (with the confederation identifier as the AS number).

Route reflectors

Another way to reduce the iBGP mesh inherent in an AS with a large number of iBGP speakers is to configure a route reflector. Using this method, when an iBGP speaker needs to communicate with other

BGP speakers in the AS, the speaker establishes a single peer-to-peer route reflector client session with the iBGP route reflector.

Note

Route reflectors are not supported on iBGP for non-default VRFs.

In an AS, more than one route reflector cluster can exist and more than one route reflector in a cluster. When more than one reflector exists in a cluster, take care to prevent route loops.

The following figure shows a simple iBGP configuration with three iBGP speakers (routers A, B, and C). Without route reflectors, after Router A receives an advertised route from an external neighbor, it must advertise the route to Routers B and C.

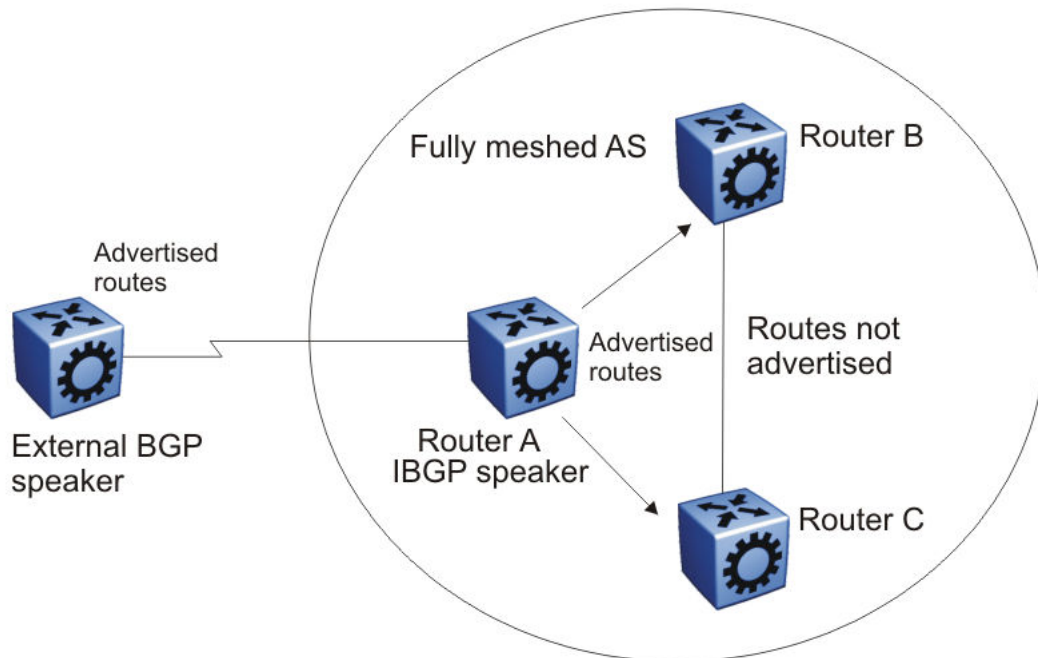

Figure 25: Fully meshed AS with iBGP speakers

Routers B and C do not readvertise the iBGP learned routes to other iBGP speakers. BGP does not allow routers to pass routes learned from internal neighbors on to other internal neighbors, which avoids routing information loops.

As shown in the following figure, when you configure an internal BGP peer (Router B) as a route reflector, all of the iBGP speakers do not need to be fully meshed. In this case, the assigned route reflector passes iBGP learned routes to a set of iBGP neighbors.

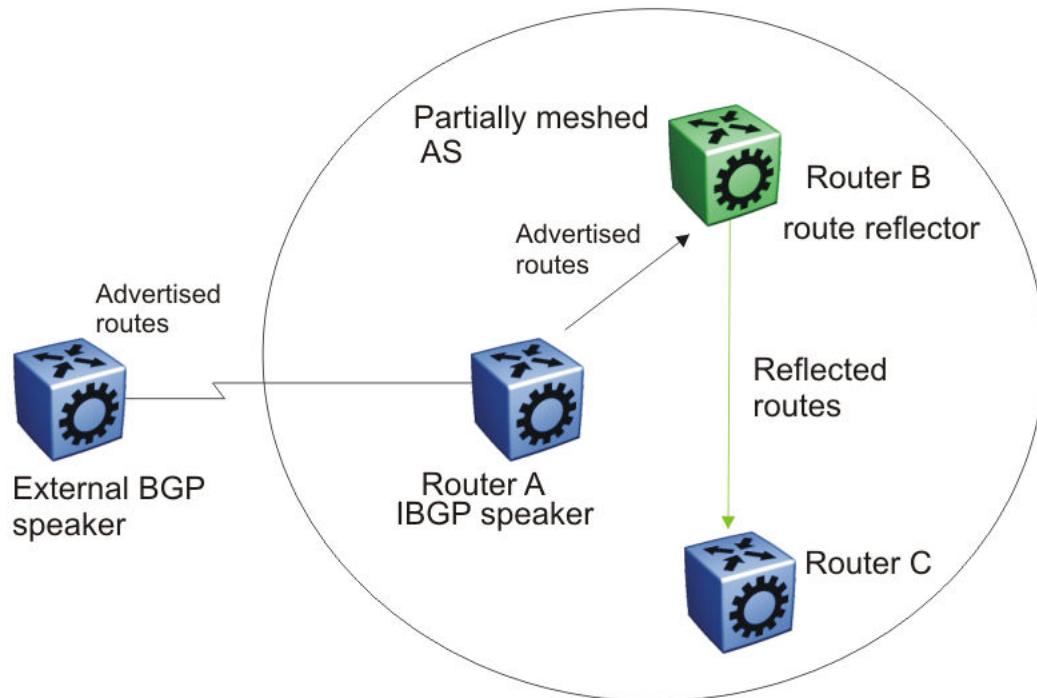

Figure 26: AS with route reflector

After Router B, the route reflector, receives routes from Router A (the iBGP speaker), it advertises them to router C. Conversely, after the route reflector receives routes from internal peers, it advertises those routes to Router A. Routers A and C do not need an iBGP session.

Route reflectors separate internal peers into two groups: client peers and nonclient peers. The route reflector and its clients form a cluster. The client peers in the cluster do not need to be fully meshed, and do not communicate with iBGP speakers outside their cluster. Nonclient peers must be fully meshed with each other.

The following figure shows a cluster, where Router A is the route reflector in a cluster with client routers B, C, and D. Routers E, F, and G are fully meshed, nonclient routers.

Figure 27: Route reflector with client and nonclient peers

BGP Communities

You can group destinations into communities to simplify policy administration. A community is a group of destinations that share a common administrative property.

Use community control routing policies with respect to destinations. Create communities when you have more than one destination and want to share a common attribute.

The following list identifies specific community types:

- Internet—advertise this route to the Internet community
- no advertise—do not advertise to BGP peers including iBGP peers

You can use a community to control which routing information to accept, prefer, or distribute to other BGP neighbors. If you specify the append option in the route policy, the router adds the specified community value to the existing value of the community attribute. Otherwise, the specified community value replaces a previous community value.

BGP path attributes

You can create policies that control routes, work with default routing, control specific and aggregated routes, and manipulate BGP path attributes.

Four categories of BGP path attributes exist:

- Well-known mandatory attributes must be in every BGP update message.
- Well-known discretionary attributes can be in a BGP update message.
- Optional transitive attributes are accepted and passed to other BGP peers.
- Optional non-transitive attributes can be either accepted or ignored, but must not pass along to other BGP peers.

Border routers that utilize built-in algorithms or manually configured policies to select paths use path attributes. BGP uses the following path attributes to control the path a BGP router chooses:

- origin (well-known mandatory)
- AS_path (well-known mandatory)
- next hop (well-known mandatory)
- MED attribute (optional non-transitive)
- local preference (well-known discretionary)
- atomic aggregate (well-known discretionary)
- aggregator (optional transitive)
- community (optional transitive)

For more information about path attributes in BGP updates, see [Path Attributes](#) on page 413.

BGP Route Selection

A BGP router determines the best path to a destination network. This path is then eligible for use in the IP forwarding table and the router also advertises the path to its eBGP peers. To choose the best of multiple BGP routes to a destination, the router executes a best path algorithm.

The algorithm chooses a route in the following order:

- highest weight

Weight is a locally significant parameter associated with each BGP peer. You can use the weight to influence which peer paths the router uses.

- highest local preference

The local preference has global significance within an AS. You can manipulate the preference using route policies to influence path selection.

- prefer locally originated paths

The router prefers a path locally originated using the network, redistribution, or aggregate command over a path learned through a BGP update. The router prefers local paths sourced by network or redistribute commands over local aggregates sourced by the aggregate address command.

- shortest AS path

The AS path parameter specifies the autonomous systems that the network prefix traversed. The AS path commonly determines the best path. For example, a router can choose a path based on whether the network passed through a specific AS. You can configure a route policy to match the AS, and then modify the local preference. Also, you can pad the AS path before the AS advertises it to a peer AS, so that downstream routers are less likely to prefer the advertised network path.

The AS_CONFED_SEQUENCE length will also be considered while picking the best path inside the confederation.

- lowest origin type

The order of preference is IGP, EGP, INC (incomplete).

- lowest MED

The MED parameter influences the preferred path from a remote AS to the advertising AS. This parameter applies when there are multiple exit points from the remote AS to the advertising AS. A lower MED value indicates a stronger path preference than a higher MED value. By default, the MED attribute is ignored as specified by the BGP global parameter Always Compare MED except when the routes come from the same AS. This parameter must be enabled for MEDs to be compared (and for this step of the best path algorithm to execute).

The router compares MEDs regardless of what the first (neighboring) AS specified in the AS_PATH. Deterministic MED, when enabled, means that the first AS of the multiple paths must be the same. Paths received with no MED are assigned a MED of 0, unless the global BGP parameter Missing Is Worst is enabled. If so, received paths are assigned a MED of 4 294 967 294. Missing is Worst is enabled by default. The "no-med-path-is-worst" flag has an impact only when the "First AS" or the "Most Left AS" is the same for multiple routes received. The router changes paths received with a MED of 4 294 967 295 to 4 294 967 294 before insertion into the BGP table.

Note

You cannot enable or disable the MED selection process. BGP aggregation does not occur when routes have different MEDs or next hops.

When MED value is set in route-map configuration, the configured MED value is not applicable if it is already set in the associated Path Attribute.

1. When router A sets MED value of 100 by route-map, it will send Path Attribute with MED=100 to EBGP peer B.
2. Router B sends Path Attribute with MED=100 to IBGP peer C.
3. If the route-map is configured with "set MED 200", then router C does not apply MED=200 to the Path Attribute as it is already set to 100 when it is received from router B.
4. Router D will get Path Attribute with MED=100 so that router C does not influence router D when it selects the best route.

Example: If Prefix: X is set as MED=100 from router A, it will be received at B with MED=100, and will carry same MED=100 value to router C, as it is an IBGP peer. Router C will not propagate MED=100 value to D as MED is a non-transitive attribute, so MED can travel maximum of 1 AS.

- lowest IGP metric to the BGP next-hop

If multiple paths exist whose BGP next-hop is reachable through an IGP, the path with the lowest IGP metric to the BGP next-hop is chosen.

- prefer external paths (learned by eBGP) over internal paths (iBGP)

The system prefers external paths over internal paths.

- if Equal Cost Multipath (ECMP) is enabled, insert up to four paths in the routing table

If you enable ECMP, multiple BGP learned routes that use the same metric to different IP next-hops are installed in the IP forwarding table for traffic load-balancing purposes.

- lowest router ID

The lowest router ID, or Circuitless IP (CLIP) address, is preferred.

BGP and dampened routes

The switch supports route dampening (route suppression). When you use route dampening, a route accumulates penalties each time the route fails. After the accumulated penalties exceed a threshold, the router no longer advertises the route. The router enters the suppressed routes into the routing table only after the accumulated penalty falls below the reuse threshold.

Route flap dampening suppresses the advertisement of the unstable route until the route becomes stable. For information about how to enable flap-dampening, see [Configure BGP](#) on page 428. For information about viewing flap dampening configurations, see [Viewing global flap-dampening configurations](#) on page 459.

Dampening applies only to routes that are learned through an eBGP. Route flap dampening prevents routing loops and protects iBGP peers from having higher penalties for routes external to the AS.

The following paragraph describes the algorithm that controls route flaps.

After the route flaps the first time

- the router creates a route history entry
- a timer starts (180 seconds)

If the route does not flap again, the router uses this timer to delete the history entry after the 180 seconds expires.

After the route flaps a second time

- The penalty is recalculated based on the decay function.

If the penalty is greater than the cut-off value (1536), the route is suppressed and the reuse time is calculated based on the reuse time function.

- The reuse timer starts.

After the reuse time expires, the suppressed route is announced again (the reuse time is recalculated if the route flaps again). The penalty decays slower for withdrawn routes than for update routes. The route history entry is kept longer if the route is withdrawn. For update history, the delete time is 90 seconds and the withdrawn history delete time is 180 seconds.

BGP Updates

BGP uses update messages to communicate information between two BGP speakers. The update message can advertise a single feasible route to a peer, or withdraw multiple unfeasible routes from service.

The following figure shows the format of an update message.

Figure 28: Update Message Format

This section describes how BGP uses the update message fields to communicate information between BGP speakers.

Withdrawn Routes Length

The withdrawn routes length parameter (referred to in RFC1771 as the Unfeasible Routes Length field) indicates the total length of the withdrawn routes field in octets. The withdrawn routes length field calculates the length of the NLRI field. For example, a value of 0 indicates that no routes are withdrawn from service, and that the withdrawn routes field is not present in this update message.

Withdrawn Routes

The withdrawn routes parameter is a variable-length parameter that contains a list of IP prefixes for routes that are withdrawn from service. The following figure shows the format of an IP prefix.

Figure 29: IP Prefix Format

The length indicates the number of bits in the prefix (also called the network mask).

For example, 192.0.2.0/24 is equivalent to 192.0.2.0 255.255.255.0 (the /24 indicates the number of bits in the length parameter to represent the network mask 255.255.255.0).

The prefix parameter contains the IP address prefix itself, followed by enough trailing bits to make the length of the whole field an integer multiple of 8 bits (1 octet).

Total Path Attributes Length

The total path attributes length parameter indicates the total length of the path attributes parameter in octets.

The total path attributes length calculates the length of the NLRI parameter. For example, a value of 0 indicates that no NLRI field is present in this update message.

Path Attributes

The path attributes parameter is a variable-length sequence of path attributes that exists in every BGP update. The path attributes contain BGP attributes associated with the prefixes in the NLRI parameter.

For example, the attribute values allow you to specify the prefixes that the BGP session can exchange, or which of the multiple paths of a specified prefix to use.

The attributes carry the following information about the associated prefixes:

- the path origin
- the AS paths through which the prefix is advertised
- the metrics that display degrees of preference for this prefix

The following figure shows the encoding used with the path attribute parameter.

Figure 30: Path Attribute Encoding

Attribute Type

As shown in the following figure, the attribute type is a two-octet field that comprises two sub-fields: attribute flags and attribute type code.

Figure 31: Attribute Type Fields

The attribute flags parameter is a bit string that contains four binary values that describe the attribute, and four unused bits. The following list provides bit descriptions (from the high-order bit to the low-order bit):

- The high-order bit (bit 0) is the optional bit. When this bit is set (the value is 1), the attribute is optional. When this bit is clear (the value is 0), the attribute is well-known. Well-known attributes must be recognized by all BGP implementations and, when appropriate, passed on to BGP peers. Optional attributes are not required in all BGP implementations.
- The second high-order bit (bit 1) is the transitive bit. For well-known attributes, this bit must be set to 1. For optional attributes, it defines whether the attribute is transitive (when set to 1) or non-transitive (when set to 0).
- The third high-order bit (bit 2) is the partial bit. The partial bit defines whether the information in the optional transitive attribute is partial (when set to 1) or complete (when set to 0). For well-known attributes and for optional non-transitive attributes the partial bit must be set to 0.
- The fourth high-order bit (bit 3) is the extended length bit. The extended length bit defines whether the attribute length is one octet (when set to 0) or two octets (when set to 1). The attribute flag can use the extended length only if the length of the attribute value is greater than 255 octets.
 - If the extended length bit of the attribute flags octet is set to 0, the third octet of the path attribute contains the length of the attribute data in octets.
 - If the extended length bit of the attribute flags octet is set to 1, then the third and the fourth octets of the path attribute contain the length of the attribute data in octets.
- The lower-order four bits of the attribute flags octet are unused. The lower-order four bits must be zero (and must be ignored when received).

The attribute type code parameter contains the attribute type code, as defined by the Internet Assigned Numbers Authority (IANA). The attribute type code uniquely identifies the attribute from all others. The remaining octets of the path attribute represent the attribute value and are interpreted according to the attribute flags and the attribute type code parameters.

The following table shows the supported attribute type codes.

Table 55: BGP Mandatory Path Attributes

Attribute	Type code	Description
Origin	1	Defines the origin of the path information: <ul style="list-style-type: none"> Value = 0 --- IGP (the path is valid all the way to the IGP of the originating AS) Value = 1--- EGP (the last AS in the AS path uses an EGP to advertise the path) Value = 2--- Incomplete (the path is valid only to the last AS in the AS path)
AS path	2	Contains a list of the autonomous systems that packets must traverse to reach the destinations. This code represents each AS path segment as follows: <ul style="list-style-type: none"> path segment type path segment length path segment value
Next hop	3	Specifies the IP address of the border router to use as a next hop for the advertised destinations (destinations listed in the NLRI field of the update message).
Multixit discriminator	4	Discriminates among multiple exit or entry points to the same neighboring AS on external (internal-AS) links.
Local preference	5	Indicates the preference that AS border routers assign to a chosen route when they advertise it to iBGP peers
Atomic aggregate	6	Ensures that certain NLRI is not deaggregated
Aggregator	7	Identifies which AS performed the most recent route aggregation. This attribute contains the last AS number that formed the aggregate route followed by the IP address of the BGP speaker that formed the aggregate route.

Attribute Length

The attribute length can be one or two octets in length, depending on the value of the extended length parameter in the attributes flag field.

This parameter indicates the length of the attribute value field.

Attribute Value

The attribute value contains the actual value of the specific attribute. The system implements the attribute value according to the values in the attribute flags and the attribute type code parameters.

NLRI

The NLRI parameter is a variable length field that contains a list of prefixes. The packet size that BGP speakers can exchange limits the number of prefixes in the list.

Equal Cost Multipath

Equal Cost Multipath (ECMP) support allows a BGP speaker to perform route or traffic balancing within an AS by using multiple equal-cost routes submitted to the routing table by OSPF, RIP, or static routes.

For more information about ECMP, see [Equal Cost Multipath](#) on page 1843.

MD5 message authentication

Authenticate BGP messages by using Message Digest 5 (MD5) signatures. After you enable BGP authentication, the BGP speaker verifies that the BGP messages it receives from its peers are actually from a peer and not from a third party masquerading as a peer.

BGPv4 TCP MD5 message authentication provides the following features:

- A TCP MD5 signature can exist for BGP peers. You can configure authentication and secret keys for each peer. Peers configured with common secret keys can authenticate each other and exchange routing information.
- The switch can concurrently have BGP peers with authentication enabled and other BGP peers with authentication disabled.
- The switch always encrypts the secret keys.

After you enable BGPv4 TCP MD5 authentication, the router computes an MD5 signature for each TCP packet based on the TCP packet and an individual peer secret key. The router adds this MD5 signature to the TCP packet that contains a BGP message and sends it with the packet, but it does not send the secret key.

The receiver of the TCP packet also knows the secret key and can verify the MD5 signature. A third party that tries to masquerade as the sender, however, cannot generate an authentic signature because it does not know the secret key.

In commands, the term *password* refers to the secret key. The secret keys provide security. If the keys are compromised, then the authentication itself is compromised. To prevent this, the switch stores the secret keys in encrypted form.

MD5 signature generation

BGP peers calculate MD5 signatures in BGP messages based on the following elements:

- TCP pseudo-header
- TCP header, excluding options
- TCP segment data
- TCP MD5 authentication key

If TCP receives an MD5 authentication key, it reduces its maximum segment size by 18 octets, which is the length of the TCP MD5 option. TCP adds an MD5 signature to each transmitted packet. The peer inserts the resulting 16-byte MD5 signature into the following TCP options: *kind*=19, *length*=18.

MD5 signature verification

After the switch receives a packet, it performs three tests. The following table lists the tests and the event message that TCP logs if a test fails.

Table 56: MD5 signature verification rules on BGP TCP packets

Condition tested	Action on success	Failure event message
Is the connection configured for MD5 authentication?	Verify that the packet contains a kind=19 option.	TCP MD5 No Signature
Is MD5 authentication enabled for this TCP connection?	TCP computes the expected MD5 signature.	TCP MD5 Authentication Disabled
Does the computed MD5 signature match the received MD5 signature?	TCP sends the packet to BGP.	TCP MD5 Invalid Signature

If a packet passes a test, it proceeds to the next test. After a packet passes all three tests, TCP accepts the packet and sends it to BGP.

If a packet fails a test, the switch logs an event, increments the count of TCP connection errors (wfTcpConnMd5Errors), and discards the packet. The TCP connection remains open.

BGP and route redistribution

Redistribution imports routes from one protocol to another. Redistribution sends route updates for a protocol-based route through another protocol. For example, if OSPF routes exist in a router and they must travel through a BGP network, then configure redistribution of OSPF routes through BGP. This sends OSPF routes to a router that uses BGP.

The switch can redistribute routes:

- on an interface basis.
- on a global basis between protocols on a single VRF instance (intraVRF).
- between the same or different protocols on different VRF instances (interVRF).

Configure interface-based redistribution by configuring a route policy and apply it to the interface. Configure the match parameter to the protocol from which to learn the routes.

You can redistribute routes on a global basis, rather than on an interface basis. Use the **ip bgp redistribute** command to accomplish the (intraVRF) redistribution of routes through BGP, so that BGP redistribution occurs globally on all BGP-enabled interfaces. This redistribution does not require a route policy, but you can use one for more control.

If you configure redistribution globally and on an interface, redistribution through the route policy takes precedence.

You can redistribute routes from a protocol in one VRF to BGP in another VRF. You can use a route policy for redistribution control. If you enable route redistribution between VRF instances, ensure that IP addresses do not overlap.

Use caution when you configure redistribution. An improperly configured parameter can cause the router to advertise learned eBGP routes out of your local AS. If this happens, the local AS can route other networks.

Do not use redistribution if you peer to an Internet Service Provider (ISP) and do not want traffic to transit your local AS.

When you redistribute OSPF routes into BGP, route priorities can create routing loops. Because BGP has a higher route preference than OSPF external type 1 and 2 routes, if you redistribute OSPF external type 1 and 2 routes into BGP, the router uses the BGP routes, which can cause a routing loop.

Route-maps and BGP neighbors

BGP Routing Information Base (BGP RIB) stores routing information received from different peers. BGP RIB has two types of BGP routes, External and Internal (Local). The routes learned from BGP neighbors are External routes and all imported routes are considered as Internal (Local) routes.

In BGP RIB, the OSPF routes redistributed into BGP are considered as Internal (Local) and are matched by route-type only when the keyword is set to **local**. When match route-type is set to **external**, the route-maps applied on BGP neighbors are ignored and the set operation is not performed.

Note

This is applied only on the route-maps applied to BGP neighbors in BGP RIB, and not considered when applying a route-map to the redistribute command.

BGP route redistribution and DvR

DvR Controllers redistribute routes (direct routes, static routes and the default route) into the DvR domain. You can configure redistribution of DvR host routes into BGP.

For information on DvR, see [Distributed Virtual Routing](#) on page 681.

BGP+

The switch extends the BGPv4 process to support the exchange of IPv6 routes using BGPv4 peering. BGP+ is an extension of BGPv4 for IPv6, which is indicated using the Address Family Identifier (AFI) in the BGP header.

The switch supports capabilities for AFI with the following values: 1 (IPv4) and 2 (IPv6). If the switch receives an OPEN message advertising an AFI with a different value, the connection is closed and a BGP notification message is sent to the peer mentioning unsupported capability.

BGP+ is only supported on the global VRF instance.

Note

Ensure you configure IPv6 forwarding for BGP+ to work.

Note that the BGP+ support on the switch is not an implementation of BGPv6. Native BGPv6 peering uses the IPv6 Transport layer (TCPv6) for establishing the BGPv6 peering, route exchanges, and data traffic.

The switch supports the exchange of IPv6 reachability information over IPv4 transport. To support BGP+, the switch supports two BGP protocol extensions, standards RFC 4760 (multi-protocol extensions to BGP) and RFC 2545 (MP-BGP for IPv6). These extensions allow BGPv4 peering to be enabled with IPv6 address family capabilities.

The implementation of BGP+ on the switch uses an existing TCPv4 stack to establish a BGPv4 connection. Optionally, nontransitive BGP properties are used to transfer IPv6 routes over the BGPv4 connection. Any BGP+ speaker has to maintain at least one IPv4 address to establish a BGPv4 connection.

Different from IPv4, IPv6 introduces scoped unicast addresses, identifying whether the address is global or link-local. When BGP+ is used to convey IPv6 reachability information for interdomain routing, it is sometimes necessary to announce a next hop attribute that consists of a global address and a link-local address. For BGP+, no distinction is made between global and site-local addresses.

The BGP+ implementation includes support for BGPv6 policies, including redistributing BGPv6 into OSPFv3, ISIS, RIPng, and advertising OSPFv3, ISIS, RIPng, IPv6 static and local routes into BGPv6 (through BGP+). It also supports the aggregation of global unicast IPv6 addresses.

When configuring BGP+ on the router that is enabled only for IPv6 (the router does not have an IPv4 address), then BGP router ID must be manually configured for the router.

BGP+ does not support confederations. You can configure confederations for IPv4 routes only.

The basic configuration of BGP+ is the same as BGPv4 with one additional parameter added and some existing commands altered to support IPv6 capabilities. You can enable and disable IPv6 route exchange by specifying the address family attribute as IPv6. Note that an IPv6 tunnel is required for the flow of IPv6 data traffic.

BGP+ tunnel

When you use BGP+ you must configure an IPv6 tunnel and static routes at BGP+ peers.

When BGP+ peers advertise route information, they use Update messages to advertise route information.

These RTM routes contain next-hop addresses from the BGP peer that the route was learned from.

The static routes correlate the next-hop addresses represented by the IPv4-mapped IPv6 address to a specific outgoing interface.

Following is one way to express a static route in an IPv6-configured tunnel for BGP+:

```
ipv6 route 2001:DB8:0:0:0:ffff:192.0.2.0/24 cost 1 tunnel 10 where  
2001:DB8:0:0:0:ffff:192.0.2.0 is the IPv4-mapped IPv6 address of the BGP peer at 192.0.2.0
```

ECMP with BGP+

The ECMP feature supports and complements BGP+ protocol.

The number of equal-cost-paths supported can differ by hardware platform. For more information, see [VOSS Release Notes](#).

You can use multiple paths for load sharing of traffic. These multiple paths allow faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use your links between routers more efficiently when sending IP and IPv6 traffic. Equal Cost Multipath is formed using routes from the same protocol.

Note

To add BGP+ equal cost paths in the routing table, you must enable the following:

- IPv6 ECMP feature globally
- BGP multiple-paths attribute

BGPv6

BGP peering over IPv6 transport uses a BGPv6 peer to exchange IPv6 routes over an IPv6 transport layer. This is different than BGP+, which enables exchange of IPv6 routes over a BGPv4 peer. Also with BGP+, you must use an IPv6 tunnel to install and configure IPv6 routes in an IPv6 Routing Table Manager (RTM). BGP+ uses an IPv4 mapped IPv6 address for the next hop address and requires you to configure IPv6 static routes and install IPv6 routes in an IPv6 RTM where the next hop for the static route is an IPv6 tunnel interface.

BGPv6 supports the following:

- Input/Output policies.
- Redistribution of OSPFv3, IS-IS, IPv6 static route, and IPv6 direct routes into BGPv6.
- Aggregation of global unicast IPv6 addresses.

Note

BGP+ also supports the preceding features.

RFC

The switch supports the BGP multiprotocol extension, as described in RFC 4760. Also supports RFC 2545 (MP-BGP for IPv6).

The BGP protocol extensions ensure peering can be enabled with IPv6 address family capabilities.

Route exchange

BGPv6 does not exchange any IPv4 routes. BGPv6 advertises or learns only IPv6 routes.

The following table shows the differences between BGPv4 and BGPv6 for route exchange.

	GRT/VRF	IPv4 Routes Exchange	IPv6 Routes Exchange
BGPv4	GRT	Supported	Supported (BGP+)
	VRF	Supported	Not supported Note: IPv6 over IPv4 tunnels is not yet virtualized.

	GRT/VRF	IPv4 Routes Exchange	IPv6 Routes Exchange
BGPv6	GRT	Not supported	Supported
	VRF	Not supported	Supported

Specify the address family attribute as IPv6 to enable IPv6 route exchange.

You can enable IPv6 route exchange by specifying the address family attribute as IPv6. Optionally, you can use non-transitive BGP properties to exchange IPv6 routes between the BGPv6 peering. Any BGPv6 speaker must maintain at least one IPv6 address to establish a BGPv6 connection. The IPv6 scoped unicast addresses can identify the address as global or link-local. If you use BGPv6 to convey IPv6 reachability information for interdomain routing, you can also announce a next hop attribute that consists of a global address and a link-local address.

Note

BGPv6 does not support adjacency on link-local.

Authentication

BGPv6 uses IPsec for security. MD-5 authentication is supported for BGPv4 and is not supported for BGPv6.

The following table shows the differences between BGPv4 and BGPv6 for authentication.

	MD5	IPsec	SHA1/SHA2
BGPv4	Supported	Not supported	Not supported
BGPv6	Not supported	Supported Note: IP Sec is not virtualized, hence BGPv6 is supported only in Global Router mode, and not supported in VRF mode.	Not supported

MD5 authentication

MD5 authentication is not supported in BGPv6 so it is not necessary to enable MD5 authentication.

IPsec

Only IPsec is supported. Therefore, MD5 authentication cannot be configured.

Consistency checking

Includes consistency checking for MD5 authentication. BGP peer and BGP peer group configuration for IPv6 addresses include a rule to block MD5 authentication. If you attempt to configure MD5 authentication, you will receive an error message.

IPv6 tunneling

With BGPv6, IPv6 tunneling is not required for IPv6 data traffic flow. An IPv6 tunnel is required for BGP +.

Circuitless IP

Circuitless IP (CLIP) is a virtual (or loopback) interface that you do not associate with a physical port. You can use a CLIP interface to provide uninterrupted connectivity to your switch as long as an actual path exists to reach the device. For example, as shown in the following figure, a physical point-to-point link exists between R1 and R2 along with the associated addresses (195.39.1.1/30 and 195.39.1.2/30). Note also that an iBGP session exists between two additional addresses 195.39.128.1/32 (CLIP 1) and 195.39.128.2/32 (CLIP 2).

Figure 32: Routers with iBGP connections

The system treats the CLIP interface like an IP interface and treats the network associated with the CLIP as a local network attached to the device. This route always exists and the circuit is always up because no physical attachment exists.

The router advertises routes to other routers in the domain either as external routes using the route-redistribution process or after you enable OSPF in a passive mode to advertise an OSPF internal route. You can configure only the OSPF protocol on the CLIP interface. After you create a CLIP interface, the system software programs a local route with the CPU as the destination ID. The CPU processes all packets destined to the CLIP interface address. The system treats other packets with destination addresses associated with this network (but not to the interface address) as if they are from an unknown host.

A circuitless IP or CLIP address is a logical IP address for network management, as well as other purposes. The CLIP is typically a host address (with a 32 bit subnet mask). Configure the OSPF router ID to the configured CLIP address. By default, the BGP router ID is automatically equivalent to the OSPF router ID.

For information about how to configure CLIP interfaces, see [Configure a CLIP Interface](#) on page 1871 and [Configure a Circuitless IPv4 Interface](#) on page 1896.

BGP Configuration Considerations and Limitations

Use the information in this section to help you configure BGP on your switch, which supports BGPv4 as described in RFC 1771.

BGP Implementation Guidelines

The following list provides guidelines to successfully implement BGP:

- BGP does not operate with an IP router in nonforwarding (host-only) mode. Make sure that the routers you want BGP to operate with are in forwarding mode.
- If you use BGP for a multihomed AS (one that contains more than a single exit point), use OSPF for your IGP and BGP for your sole exterior gateway protocol, or use intra-AS iBGP routing.
- If OSPF is the IGP, use the default OSPF tag construction. Using EGP or modifying the OSPF tags makes network administration and proper configuration of BGP path attributes difficult.
- For routers that support both BGP and OSPF, the OSPF router ID and the BGP identifier must be the same IP address. The BGP router ID automatically uses the OSPF router ID.
- In configurations where BGP speakers reside on routers that have multiple network connections over multiple IP interfaces (the typical case for iBGP speakers), consider using the address of the circuitless (virtual) IP interface as the local peer address. In this configuration, you ensure that BGP is reachable as long as an active circuit exists on the router.
- By default, BGP speakers do not advertise or inject routes into the IGP. You must configure route policies to enable route advertisement.
- Coordinate routing policies among all BGP speakers within an AS so that every BGP border router within an AS constructs the same path attributes for an external path.
- Configure accept and announce policies on all iBGP connections to accept and propagate all routes. Make consistent routing policy decisions on external BGP connections.

Minimum Requirements

You must configure the following minimum parameters:

- router ID
- local AS number
- enable BGP globally
- BGP neighbor peer session: remote IP addresses
- enable BGP peers
- When you use both BGP and OSPF, the OSPF and BGP router ID must be the same.

The router ID must be a valid IP address of an IP interface on the router or a CLIP address. BGP update messages use this IP address. By default, the BGP router ID automatically uses the OSPF router ID.

You cannot configure the BGP router ID if you configure BGP before you configured the OSPF router ID. You must first disable BGP, configure the OSPF route ID, and then enable BGP globally.

You can add BGP policies to the BGP peer configuration to influence route decisions. BGP policies apply to the peer through the soft-reconfiguration commands.

After you configure the switch for BGP, some parameter changes can require you to enable or disable the BGP global state or the neighbor admin-state.

You can dynamically modify BGP policies. On the global level, the BGP redistribution command has an apply parameter that causes the policy to take effect after you issue the command.

BGP Neighbor Maximum Prefix Configuration

By default, the maximum prefix parameter limits 12 000 NLRI messages for each neighbor. The maximum prefix parameter limits the number of routes that the switch can accept.

The maximum prefix parameter prevents large numbers of BGP routes from flooding the network if you implement an incorrect configuration. You can assign a value to the maximum prefix limit, including 0 (0 means unlimited routes). When you configure the maximum prefix value, consider the maximum number of active routes that your equipment configuration can support.

BGP and OSPF Interaction

RFC1745 defines the interaction between BGP and OSPF when OSPF is the IGP within an autonomous system. For routers that use both protocols, the OSPF router ID and the BGP ID must be the same IP address. You must configure a BGP route policy to allow BGP advertisement of OSPF routes.

Interaction between BGPv4 and OSPF can advertise supernets to support CIDR. BGPv4 supports interdomain supernet advertisements; OSPF can carry supernet advertisements within a routing domain.

BGP and Internet Peering

By using BGP, you can perform Internet peering directly between the switch and another edge router. In such a scenario, you can use each switch for aggregation and link it with a Layer 3 edge router, as shown in the following figure.

Figure 33: BGP and Internet peering

In cases where the Internet connection is single-homed, to reduce the size of the routing table, as a best practice, advertise Internet routes as the default route to the IGP.

For route scaling information, see [VOSS Release Notes](#).

Routing Domain Interconnection with BGP

You can implement BGP so that autonomous routing domains, such as OSPF routing domains, connect. This connection allows the two different networks to begin communicating quickly over a common

infrastructure, thus providing additional time to plan the IGP merger. Such a scenario is particularly effective when you need to merge two OSPF area 0.0.0.0s, as shown in the following figure.

Figure 34: Routing Domain Interconnection with BGP

BGP and Edge Aggregation

You can perform edge aggregation with multiple point of presence or edge concentrations. The switch supports 12 pairs (peering services). You can use BGP to inject dynamic routes rather than using static routes or RIP (see the following figure).

Figure 35: BGP and Edge Aggregation

BGP and ISP Segmentation

You can use the platform as a peering point between different regions or autonomous systems (AS) that belong to the same ISP. In such cases, you can define a region as an OSPF area, an AS, or a part of an AS.

You can divide the AS into multiple regions that each run different IGPs. Interconnect regions logically by using a full iBGP mesh. Each region then injects its IGP routes into iBGP and also injects a default route inside the region. For destinations that do not belong to the region, each region defaults to the BGP border router.

Use the community parameter to differentiate between regions. To provide Internet connectivity, this scenario requires you to make your Internet connections part of the central iBGP mesh (see the following figure).

Figure 36: Multiple Regions Separated by iBGP

In the preceding figure, consider the following:

- The AS is divided into three regions that each run different and independent IGPs.
- Regions logically interconnect by using a full-mesh iBGP, which also provides Internet connectivity.
- Internal non-BGP routers in each region default to the BGP border router, which contains all routes.
- If the destination belongs to another region, the traffic is directed to that region; otherwise, the traffic is sent to the Internet connections according to BGP policies.

To configure multiple policies between regions, represent each region as a separate AS. Implement eBGP between autonomous systems, and implement iBGP within each AS. In such instances, each AS injects its IGP routes into BGP, where they are propagated to all other regions and the Internet.

The following figure shows the use of eBGP to join several autonomous systems.

Figure 37: Multiple regions Separated by eBGP

You can obtain AS numbers from the Inter-Network Information Center (NIC) or use private AS numbers. If you use private AS numbers, be sure to design your Internet connectivity carefully. For example, you can introduce a central, well-known AS to provide interconnections between all private autonomous systems and the Internet. Before it propagates the BGP updates, this central AS strips the private AS numbers to prevent them from leaking to providers.

The following figure illustrates a design scenario in which you use multiple OSPF regions to enable peering with the Internet.

Figure 38: Multiple OSPF Regions Peering with the Internet

BGP Peers

The following list provides rules related to BGP peers:

- Only metric (=MED) attribute is applied to the output policy if its BGP peer is IBGP
- metric (=MED) and community attributes are applied to output policy if its BGP peer is EBGP

- To influence EBGP and IBGP peers with all applicable BGP attributes, configure **route-map** as an option to **neighbor** command, for example, `neighbor 192.0.2.2 out-route-map policy1`

BGP and Route Aggregation

When you configure the attribute-map with the aggregate command, community, metric, AS Path, and next-hop attributes are set, while the origin attribute is not set.

BGP Session Flapping when IPv6 Forwarding is Enabled or Disabled

In a BGP session that is established with IPv4 and IPv6 capability, disabling or enabling IPv6 forwarding results in BGP session flapping due to capability negotiation. The flapping session in turn affects the IPv4 routing through BGP and the BGP session gets terminated. Ultimately, a capability negotiation takes place to re-establish the IPv4 and IPv6 capable session.

BGP configuration using CLI

Configure the Border Gateway Protocol (BGP) to create and maintain an interdomain routing system that guarantees loop-free routing information between autonomous systems (AS).

For information about how to configure route policies for BGP, see [Configure IP Route Policies](#) on page 2911.

Configure BGP

Configure BGP globally to enable BGP on the switch and determine how BGP operates.

Before You Begin

- To configure the suppress-map, advertise-map, or attribute-map options, the route policy for those options must exist.
- For initial BGP configuration, you must know the AS number.
- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

Note

Route refresh is not currently supported on non-default VRFs.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Specify the AS number and enable BGP:

```
router bgp [WORD <0-11>] [enable]
```

Note

- This command applies only on VRF 0. To enable BGP globally on other VRFs, use the **ip bgp enable** command. You must configure BGP locally before you configure it globally.
- You can also configure AS number on non-default VRFs. For more information, see [Configure an AS Number for a Non-default VRF](#) on page 454.

- Access Router BGP Configuration mode:

```
router bgp
```

- Configure BGP variables or accept the default values.

Example

Specify the AS number and enable BGP:

```
Switch(config)#router bgp 3 enable
```

Access Router BGP Configuration mode:

```
Switch(config)#router bgp
```

```
Switch(router-bgp)#
```

Variable Definitions

The following table defines parameters for the **router bgp** command.

Variable	Value
<i>WORD</i> <0-11>	Specifies the AS number. You cannot enable BGP until you change the local AS to a value other than 0.
<i>enable</i>	Enables BGP on the router.

Use the data in the following table to use the BGP variables in BGP and VRF Router Configuration mode.

Variable	Value
<i>aggregate-address</i> <i>WORD</i> <1-256>	Specifies an IP address and its length in the form {a.b.c.d/len}, or an IPv6 address and its length in the form {ipv6addr/len}.
<i>auto-peer-restart enable</i>	Enables the process that automatically restarts a connection to a BGP neighbor. The default value is enable.
<i>auto-summary</i>	When enabled, BGP summarizes networks based on class limits, for example, Class A, B, and C networks. The default value is enable.

Variable	Value
<code>bgp always-compare-med</code>	Enables the comparison of the multi-exit discriminator (MED) parameter for paths from neighbors in different autonomous systems. The system prefers a path with a lower MED over a path with a higher MED. The default value is disable.
<code>bgp aggregation</code>	Enables the aggregation feature on the interface.
<code>bgp client-to-client reflection</code>	Enables or disables route reflection between two route reflector clients. This variable applies only if the route reflection value is enable. The default value is disable. You can enable route reflection even when clients are fully meshed. This variable only applies to VRF 0. Example: <code>Switch(router-bgp) # bgp client-to-client reflection</code> System Response: Restart or soft-restart BGP for the change to take effect.
<code>bgp cluster-id {A.B.C.D}</code>	Configures a cluster ID. This variable applies only if the route reflection value is enable, and if multiple route reflectors are in a cluster. {A.B.C.D} is the IP address of the reflector router. This variable only applies to VRF 0. Example: <code>Switch(router-bgp) # bgp cluster-id 0.0.0.0</code>
<code>bgp confederation identifier <0-4294967295> [peers WORD<0-255>]</code>	Configures a BGP confederation. <code>identifier<0-4294967295></code> specifies the confederation identifier. Use 0-65535 for 2-byte AS and <0-4294967295> for 4-byte AS. <code>peers WORD<0-255></code> lists adjoining autonomous systems that are part of the confederation in the format (5500,65535,0,10,.....). Use quotation marks (") around the list of autonomous systems. Note: Use this command only on VRF 0. Example: <code>Switch(router-bgp) # bgp confederation identifier 1 peers "20 30 40"</code>
<code>bgp default local-preference <0-2147483647></code>	Specifies the default value of the local preference attribute. The default value is 0. You must disable BGP before you can change the default value. Example: <code>Switch(router-bgp) # bgp default local-preference 2-12</code>
<code>bgp deterministic-med enable</code>	Enables deterministic MED. Example: <code>Switch(router-bgp) # bgp deterministic-med enable</code>

Variable	Value
<code>bgp multiple-paths <1-8></code>	<p>Configures the maximum number of equal-cost-paths that are available to a BGP router by limiting the number of equal-cost-paths the routing table can store. The default value is 1.</p> <p>Example: <code>Switch(router-bgp) # bgp multiple-paths 4</code></p> <p>Note: Configuring the <code>bgp multiple-paths</code> variable does not affect existing routes. The routing table does not show ECMP routes; instead only one route is shown in the routing table.</p> <p>To view Equal-Cost Multipath (ECMP) routes, receive the routes after executing the <code>bgp multiple-paths</code> variable, or toggle the BGP state.</p> <p>The number of equal-cost-paths supported can differ by hardware platform. For more information, see VOSS Release Notes.</p>
<code>comp-bestpath-med-confed enable</code>	<p>When enabled, compares MED attributes within a confederation. The default value is disable.</p> <p>This variable only applies to VRF 0.</p> <p>Example: <code>Switch(router-bgp) # comp-bestpath-med-confed enable Restart or soft-restart BGP for the change to take effect</code></p>
<code>debug-screen <off on></code>	<p>Displays debug messages on the console, or saves them in a log file. Disable BGP screen logging (off) or enable BGP screen logging (on).</p> <p>Example: <code>Switch(router-bgp) # debug-screen on</code> System Response: BGP Screen Logging is On</p>
<code>default-information originate</code>	<p>Enables the advertisement of a default route to peers, if the route exists in the routing table. The default value is disable.</p>
<code>default-information ipv6-originate</code>	<p>Enables the advertisement of an IPv6 default route to peers, if the route exists in the routing table. The default value is disable.</p>
<code>default-metric <-1-2147483647></code>	<p>Configures a value to send to a BGP neighbor to determine the cost of a route a neighbor uses. A default metric value solves the problems associated with redistributing routes that use incompatible metrics. For example, whenever metrics do not convert, using a default metric provides a reasonable substitute and redistribution proceeds. Use this option in conjunction with the redistribute commands so the current routing protocol uses the same metric for all redistributed routes. The default value is 0.</p>
<code>flap-dampening enable</code>	<p>Enables route suppression for routes that flap on and off. The default value is disable.</p>

Variable	Value
<i>global-debug mask</i> <i>WORD<1-100></i>	<p>Displays specified debug information for BGP global configurations. The default value is none.</p> <ul style="list-style-type: none"> <i><WORD 1-100></i> is a list of mask choices separated by commas with no space between choices. <p>Mask choices are:</p> <ul style="list-style-type: none"> <i>none</i> disables all debug messages. <i>all</i> enables all debug messages. <i>error</i> enables display of debug error messages. <i>packet</i> enables display of debug packet messages. <i>event</i> enables display of debug event messages. <i>trace</i> enables display of debug trace messages. <i>warning</i> enables display of debug warning messages. <i>state</i> enables display of debug state transition messages. <i>init</i> enables display of debug initialization messages. <i>filter</i> enables display of debug messages related to filtering. <i>update</i> enables display of debug messages related to sending and receiving updates. <p>Example: Switch(router-bgp) # global-debug mask event, trace, warning, state</p>
<i>ibgp-report-import-rt enable</i>	Configures BGP to advertise imported routes to an interior BGP (iBGP) peer. This variable enables or disables advertisement of nonBGP imported routes to other iBGP neighbors. The default value is enable.
<i>ignore-illegal-rtrid enable</i>	When enabled, BGP overlooks an illegal router ID. For example, you can configure this variable to enable or disable the acceptance of a connection from a peer that sends an open message using a router ID of 0 (zero). The default value is enable.
<i>neighbor-debug-all mask</i> <i>WORD<1-100></i>	<p>Displays specified debug information for BGP neighbors. The default value is none. For mask options, see the <i>global-debug mask WORD<1-100></i> variable.</p> <p>Example: Switch(router-bgp) # neighbor-debug-all mask error, packet, event.trace, state, filter</p>
<i>no-med-path-is-worst enable</i>	Enables BGP to treat an update without a MED attribute as the worst path. The default value is disable.
<i>quick-start enable</i>	Enables the quick-start flag for exponential backoff.
<i>route-reflector enable</i>	Enables the reflection of routes from iBGP neighbors. The default value is disable. This variable only applies to VRF 0.
<i>route-refresh</i>	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request. This variable only applies to VRF 0.

Variable	Value
<code>router-id {A.B.C.D}</code>	Specifies the BGP router ID in IP address format. This variable only applies to VRF 0.
<code>synchronization</code>	Enables the router to accept routes from BGP peers without waiting for an update from the IGP. The default value is enable.
<code>traps enable</code>	Enables BGP traps.
<code>vrf-as WORD<0-11></code>	Configures an AS number on a specific VRF instance. Use 0-65535 for a 2-byte AS and <0-4294967295> for a 4-byte AS. The default value of 0, or configuring the local-as in the VRF to 0, is equivalent to deleting the local-as configured on user-defined VRFs, and in both cases the local-as on the VRF becomes the local-as on the GlobalRouter.

Job Aid

Use debug command values to control debug messages for global BGP message types, and for message types associated with a specified BGP peer or peer group.

Tip

The following tips can help you use the debug commands:

- Display debug commands for multiple mask choices by entering the mask choices separated by commas, with no space between choices.
- To end (disable) the display of debug messages, use the mask choice of none.
- You can save debug messages in a log file, or you can display the messages on your console using the debug-screen command.

For more information about the logged debug messages, see [VOSS Alarms and Logs Reference](#).

Configure 4-byte AS numbers

Configure Autonomous System (AS) numbers using the 4-byte format and represent the numbers in octets.

Before You Begin

- You cannot modify the global BGP configuration unless BGP is disabled.
- Configure the local AS number at Global Router (VRF0) only.
- Make sure that you define AS numbers in policies the same way that you configure them for the router. The AS list for the route policies accepts AS number only in the **asplain** format. If you create policies using **asplain** and configure the switch with **asdot**, the match will not occur.

About This Task

Use BGP 4-byte AS numbers to ensure the continuity of loop-free inter-domain routing information between autonomous systems and to control the flow of BGP updates as 2-byte AS numbers will deplete soon. AS Plain notation format is the default and the preferred form of representing 4-byte AS numbers over the AS dot notation format.

You have an option to configure AS dot notation format as well. With AS dot notation, analyzing and troubleshooting any issues encountered becomes difficult as it is incompatible with the regular expressions used by most of the network providers.

If you enable 4-byte AS numbers, or the dotted octet notation, for the Global Router (VRF0), the configuration is inherited by user-defined VRFs. You cannot enable 4-byte AS numbers on individual user-defined VRFs.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Disable BGP to change the AS number format.
`no router bgp enable`
3. Enable the 4-byte AS numbering format.
`router bgp as-4-byte enable`
4. To use the dotted octet notation, enable as-dot.
`router bgp as-dot enable`
5. Configure the 4-byte AS number and enable BGP. If you have enabled as-dot, enter the AS number in octet.
`router bgp WORD<0-11> enable`
6. Access Router BGP Configuration mode:
`router bgp`
7. (Optional) Configure BGP confederation identifier.
`bgp confederation identifier <0-4294967295>`
8. (Optional) Configure BGP confederation peers.
`bgp confederation peers WORD<0-255>`

Example

Disable BGP to change the AS number format.

```
Switch(config)# no router bgp enable
```

Enable the 4-byte AS numbering format.

```
Switch(config)# router bgp as-4-byte enable
```

To use the dotted octet notation, enable as-dot.

```
Switch(config)# router bgp as-dot enable
```

Configure the 4-byte AS number and enable BGP.

```
Switch(config)# router bgp 65536 enable
```

Variable Definitions

The following table defines parameters for the **router bgp** command.

Variable	Value
<i>as-4-byte</i> <i><enable></i>	Enables the switch for using 4 byte numbers for an autonomous system (AS). The default value is disable.
<i>as-dot</i> <i><enable></i>	Enables or disables representing AS numbers in octets. The default is disable so the switch uses the plain notation format. If you enable the 4-byte-as and as-dot parameters, enter numbers in the range of 1.0 to 65535.65535. The default value is disable. Note: This parameter is not supported with BGP+.
<i>WORD</i> <i><0-11></i> <i>enable</i>	Sets the local autonomous system (AS) number. You cannot change local-as when BGP is set to enable. <ul style="list-style-type: none"> To set a 2-byte local AS number, enter a local-as number in the range of 0 to 65535. To set a 4-byte local-as number, enable the 4-byte as variable and enter a number in the range of 0 to 4294967295. Note: If as-4-byte is set to false, the range for AS number is 0-65535 and if as-4-byte is set to true, the range is 0-4294967295. If you enable as-dot, enter the AS number in octets in the range of 1.0 to 65535.65535. Note: This parameter is not supported with BGP+.

Configure Aggregate Routes

Configure aggregate routes so that the router advertises a single route (aggregate route) that represents all destinations. Aggregate routes also reduce the size of routing tables.

Before You Begin

- Disable BGP before you enable aggregation.
- You need the appropriate aggregate address and mask.
- If required, policies exist.
- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

Note

Route refresh is not currently supported on non-default VRFs.

Procedure

1. Enter BGP Router Configuration mode:

```
enable

configure terminal

router bgp
```
2. Enable BGP aggregation:

```
bgp aggregation enable
```
3. Add an aggregate route to the routing table:

```
aggregate-address WORD<1-256> {advertise-map WORD<0-1536>} [as-set]
[attribute-map WORD<0-1536>] [summary-only] [suppress-map WORD<0-
1536>]
```
4. Exit to Global Configuration mode:

```
exit
```
5. Enable BGP:

```
router bgp [<0-65535>] [enable]
```

Example

Add an aggregate route to the routing table:

```
Switch(router-bgp)# aggregate-address 2001:DB8::/32 advertise-map map1
attribute-map map2
```

Enable BGP:

```
Switch(router-bgp)# router bgp 4 enable
```

Variable Definitions

The following table defines parameters for the **aggregate-address** command.

Variable	Value
<i>advertise-map</i> WORD<0-1536>	Specifies the route map name for route advertisements.
<i>as-set</i>	Enables autonomous system information. The default value is disable.
<i>attribute-map</i> WORD<0-1536>	Specifies the route map name.
WORD <1-256>	Specifies an IP address and its length in the appropriate form. The value must be entered in the format a.b.c.d/len or ipv6addr/len.

Variable	Value
<i>summary-only</i>	Enables the summarization of routes not included in routing updates. This variable creates the aggregate route and suppresses advertisements of more specific routes to all neighbors. The default value is disable.
<i>suppress-map WORD<0-1536></i>	Specifies the route map name for the suppressed route list.

The following table defines parameters for the **router bgp** command.

Variable	Value
<0-65535>	Specifies the AS number. You cannot enable BGP until you change the local AS to a value other than 0.
<i>enable</i>	Enables BGP on the router.

Configure Allowed Networks

Configure network addresses to determine the network addresses that BGP advertises. The allowed addresses determine the BGP networks that originate from the switch.

Before You Begin

- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

Procedure

- Enter BGP Router Configuration mode:

```
enable

configure terminal

router bgp
```
- Specify IGP network prefixes for BGP to advertise:

```
network <WORD 1-256> [metric <0-65535>]
```

Example

Specify IGP network prefixes for BGP to advertise:

```
Switch(router-bgp)# network 2001:DB8::/32 metric 32
```

Variable Definitions

The following table defines parameters for the **network** command.

Variable	Value
<i>WORD</i> <1-256>	Specifies an IP address and its length in the appropriate form.
<i>metric</i> <0-65535>	Specifies the metric to use when the system sends an update for the routes in the network table. The metric configures the MED for the routes advertised to eBGP peers. The range is 0-65535.

Configure BGP Peers or Peer Groups

Configure peers and peer groups to simplify BGP configuration and make updates more efficient.

BGP speakers can have many neighbors configured with similar update policies. For example, many neighbors use the same distribute lists, filter lists, outbound route maps, and update source. Group the neighbors that use the same update policies into peer groups and peer associations.

Note

- If required, route policies exist.
- You configure BGPv4 on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.
- Route refresh is not currently supported on non-default VRFs.
- Not all parameters are supported on non-default VRFs.

About This Task

Many of the command variables in this procedure use default values. You can accept the default values or change them to customize the configuration.

Procedure

1. Enter BGP Router Configuration mode:

```
enable

configure terminal

router bgp
```
2. Create a peer or peer group:

```
neighbor WORD<0-1536>
```
3. Apply a route policy to all incoming routes:

```
For BGPv4: neighbor WORD<0-1536> in-route-map WORD<0-256>

For BGPv6: neighbor WORD<0-1536> ipv6-in-route-map WORD<0-256>
```

4. Apply a route policy to all outgoing routes:
For BGPv4: `neighbor WORD<0-1536> out-route-map WORD<0-256>`
For BGPv6: `neighbor WORD<0-1536> ipv6-out-route-map WORD<0-256>`
5. (Optional) Configure the source IP address:
`neighbor WORD<0-1536> update-source WORD<1-256>`
6. Enable MD5 authentication (for BGPv4):
`neighbor WORD<0-1536> MD5-authentication enable`
7. Specify an MD5 authentication password (for BGPv4):
`neighbor password <nbr_ipaddr|peer-group-name> WORD<0-1536>`
8. Change the default values for other command variables as required.
9. Enable the configuration:
`neighbor WORD<0-1536> enable`

Example

Create a peer or a peer group:

```
Switch(router-bgp)# neighbor peergroupa
```

Apply a route policy (in-route-map or out-route-map) to all incoming or outgoing routes:

```
Switch(router-bgp)# neighbor peergroupa in-route-map map1 out-route-map map2
```

Configure the source IP address:

```
Switch(router-bgp)# neighbor peergroupa update-source 192.0.2.1
```

Enable MD5 authentication:

```
Switch(router-bgp)# neighbor peergroupa MD5-authentication enable
```

Specify an MD5 authentication password:

```
Switch(router-bgp)# neighbor password peergroupa password
```

Enable the configuration:

```
Switch(router-bgp)# neighbor peergroupa enable
```

Variable Definitions

The following table defines parameters for the **neighbor** command.

Variable	Value
<i>address-family</i> <ipv6>	Enables the IPv6 address family on BGP neighbor. Switch(router-bgp)# neighbor peergroupa address-family ipv6
<i>advertisement-interval</i> <5-120>	Specifies the time interval, in seconds, that transpires between each transmission of an advertisement from a BGP neighbor. The default value is 5 seconds. Switch(router-bgp)# neighbor peergroupa advertisement-interval 26 enable The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or it should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained.
<i>allow-as-in</i>	Allows BGP to inject updates.
<i>default-ipv6-originate</i>	Enables IPv6 BGP neighbor default originate. Switch(router-bgp)# neighbor peergroupa default-ipv6-originate
<i>default-originate</i>	Enables the switch to send a default route advertisement to the specified neighbor. A default route does not need to be in the routing table. The default value is disable. Do not use this command if default-information originate is globally enabled. Switch(router-bgp)# neighbor peergroupa default-originate enable peer-group test
<i>ebgp-multihop</i>	Enables a connection to a BGP peer that is more than one hop away from the local router. The default value is disable. Switch(router-bgp)# neighbor peergroupa ebgp-multihop retry-interval 3 timers 4 5
<i>enable</i>	Enables the BGP neighbor.
<i>fall-over bfd</i>	Enable fall-over Bidirectional Forwarding Detection (BFD).
<i>in-route-map</i> WORD<0-256>	Applies a route policy rule to all incoming routes that are learned from, or sent to, the peers or peer groups of the local router. The local BGP router is the BGP router that allows or disallows routes and configures attributes in incoming or outgoing updates. WORD<0-256> is an alphanumeric string length (0-256 characters) that indicates the name of the route map or policy. Switch(router-bgp)# neighbor peergroupa in-route-map map1 address-family ipv6

Variable	Value
<i>ipv6-in-route-map</i> <i>WORD</i> <0-256>	Creates IPv6 in route map. <i>WORD</i> <0-256> specifies the route map name in the range of 0 to 256 characters. Switch(router-bgp)# neighbor peergroupa ipv6- in-route-map map1
<i>ipv6-max-prefix</i> <0-2147483647>	Configures a limit on the number of routes that the router can accept from a neighbor. The default value is 12000 routes. A value of 0 (zero) indicates that no limit exists.
<i>ipv6-out-route-map</i> <i>WORD</i> <0-256>	Creates IPv6 out route map. <i>WORD</i> <0-256> specifies the route map name in the range of 0 to 256 characters. Switch(router-bgp)# neighbor peergroupa ipv6-out-route-map map2
<i>max-prefix</i> <0-2147483647>	Configures a limit on the number of routes that the router can accept from a neighbor. The default value is 12000 routes. A value of 0 (zero) indicates that no limit exists. Switch(router-bgp)# neighbor peergroupa max-prefix 158 in-route-map map1 out-route-map map2
<i>MD5-authentication enable</i>	Enables TCP MD5 authentication between two peers. The default value is disable.
<i>neighbor-debug mask</i> <i>WORD</i> <1-100>	Displays specified debug information for a BGP peer. The default value is none. < <i>WORD</i> 1-100> is a list of mask choices separated by commas with no space between choices. For example: {<mask>, <mask>, <mask>... }. Mask choices are: <ul style="list-style-type: none"> • <i>none</i> disables all debug messages. • <i>all</i> enables all debug messages. • <i>error</i> enables display of debug error messages. • <i>packet</i> enables display of debug packet messages. • <i>event</i> enables display of debug event messages. • <i>trace</i> enables display of debug trace messages. • <i>warning</i> enables display of debug warning messages. • <i>state</i> enables display of debug state transition messages. • <i>init</i> enables display of debug initialization messages. • <i>filter</i> enables display of debug messages related to filtering. • <i>update</i> enables display of debug messages related to sending and receiving updates. Switch(router-bgp)# neighbor peergroupa neighbor-debug-mask event, trace, warning, state
<i>next-hop-self</i>	When enabled, specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default value is disable. You can only configure this variable if the neighbor is disabled. Switch(router-bgp)# neighbor peergroupa next-hop-self out-route-map map2 peer-group peergroupb

Variable	Value
<code>out-route-map WORD<0-256></code>	Applies a route policy rule to all outgoing routes that are learned from, or sent to, the peers or peer groups of the local router. The local BGP router is the BGP router that allows or disallows routes and configures attributes in incoming or outgoing updates. <code>WORD<0-256></code> is an alphanumeric string length (0-256 characters) that indicates the name of the route map or policy.
<code>peer-group <WORD 0-1536></code>	Adds a BGP peer to the specified subscriber group. You must create the specified subscriber group before you use this command.
<code>remote-as <WORD 0-11></code>	Configures the remote AS number of a BGP peer or a peer-group. You must disable the admin-state before you can configure this variable. <code>Switch(router-bgp) # neighbor peergroupa remote-as As-number <WORD 0-11></code> is an alphanumeric string length (0-11 characters) that indicates the AS number.
<code>remove-private-as enable</code>	Strips private AS numbers when an update is sent. The default value is enable.
<code>retry-interval <1-65535></code>	Configures the time interval, in seconds, for the ConnectRetry timer. The default value is 120 seconds. <code>Switch(router-bgp) # neighbor 198.51.100.2 retry-interval 34</code> You can configure the retry interval for BGP neighbors only; you cannot configure the retry interval for BGP peer groups.
<code>route-reflector-client</code>	Configures the specified neighbor or group of neighbors as a route reflector client. The default value is disable. All configured neighbors become members of the client group and the remaining iBGP peers become members of the nonclient group for the local route reflector. Note: This variable only applies to VRF 0. <code>Switch(router-bgp) # neighbor</code>
<code>route-refresh</code>	Enables route refresh for the BGP peer. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request. Note: This variable only applies to VRF 0.
<code>send-community</code>	Enables the switch to send the update message community attribute to the specified peer. The default value is disable.
<code>site-of-origin</code>	Specifies a site of origin that is added to the extended communities list in each route from a specific peer.

Variable	Value
<code>soft-reconfiguration-in enable</code>	Enables the router to relearn routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable.
<code>timers <0-21845> <0-65535></code>	Configures timers, in seconds, for the BGP speaker for this peer. <0-21845> is the keepalive time. The default is 60. As a best practice, configure a value of 30 seconds. <0-65535> is the hold time. The default is 180. Switch(router-bgp)# neighbor peergroupa timers 4 6
<code>update-source WORD<1-256></code>	Specifies the source IPv4 address {A.B.C.D.} or IPv6 address to use when the system sends BGP packets to this peer or peer group. You must disable the admin-state before you can configure this variable. Switch(router-bgp)# neighbor peergroupa update-source 192.0.2.2 weight 560
<code>weight <0-65535></code>	Specifies the weight of a BGP peer or peer group, or the priority of updates the router can receive from that BGP peer. The default value is 0. If you have particular neighbors that you want to use for most of your traffic, you can assign a higher weight to all routes learned from that neighbor.
<code>WORD<0-1536></code>	Specifies the peer IP address or the peer group name.

Configure a BGP Peer or Peer Group Password

Use this procedure to configure a BGP peer or peer group password for Transmission Control Protocol (TCP) MD5 authentication between two peers.

Note

You configure BGP peer on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix `ip bgp`. The VRF must have an RP Trigger of BGP. Route refresh is not currently supported on non-default VRFs.

Procedure

- Enter BGP Router Configuration mode:

```
enable

configure terminal

router bgp
```
- Assign a BGP peer or peer group password:

```
neighbor password <nbr_ipaddr|peer-group=name> WORD <0-1536>
```

Example

Assign a BGP peer or peer group password:

```
Switch(router-bgp)# neighbor password peergroupa password1
```

Variable Definitions

The following table defines parameters for the **neighbor password <nbr_ipaddr|peer-group-name>** command.

Variable	Value
<code>password <nbr_ipaddr peer-group-name> WORD <0-1536></code>	Specifies a password for TCP MD5 authentication between two peers. WORD <0-1536> is an alphanumeric string length from 0 to 1536 characters. To disable this option, use no operator with the command. To configure this option to the default value, use default operator with the command.

Configure Redistribution to BGP

Configure a redistribution entry to announce routes of a certain source protocol type into the BGP domain such as: DvR routes, static routes, Routing Information Protocol (RIP) routes, or direct routes. Use a route policy to control the redistribution of routes.

Note

When a route map with attributes set to `origin` and `local-pref` is applied to the BGP redistribute command, the attributes are not applied to the redistributed routes.

Before You Begin

- If required, a route policy exists.
- You can configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

Note

Route refresh is not currently supported on non-default VRFs.

- Before you redistribute DvR host routes to BGP, you must disable BGP aggregation and BGP auto-summarization of networks, using the commands **no ip bgp aggregation enable** and **no ip bgp auto-summary** respectively.

Disabling these settings ensures that all the DvR host routes are correctly advertised into BGP and are not summarized.

Note

When applying a route map to an inter-vrf redistribution, the route map and any associated IP prefix lists must be configured first on the source VRF before configuring the redistribute policy on the destination VRF.

Inter-vrf redistribution is not supported on IPv6 routes.

Procedure

1. Enter BGP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router bgp
```

2. Create a redistribution instance:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static>
```

Note

Redistribution of ripng routes into BGP is supported only on VRF 0.

3. If required, specify a route policy to govern redistribution:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> route-map WORD<0-64> [vrf-src WORD<1-16>]
```

4. If required, configure the route metric:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> metric <0-65535> [vrf-src WORD<1-16>]
```

5. If required, configure the route metric-type:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> metric-type live-metric [vrf-src WORD<1-16>]
```

6. Enable the instance:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> enable [vrf-src WORD<1-16>]
```

7. Exit BGP Router Configuration mode:

```
exit
```

8. Apply the redistribution instance configuration:

```
For IPv4: ip bgp apply redistribute <direct|dvr|isis|ospf|rip|static> [vrf WORD<1-16>] [vrf-src <WORD 1-16>]
```

```
For IPv6: ipv6 bgp apply redistribute <direct|dvr|isis|ospf|rip|static> [vrf <WORD 1-16>]
```

9. Apply BGP redistribution to a specific VRF:

```
ip bgp apply redistribute vrf WORD<1-16>
```

Changes do not take effect until you apply them.

10. View all routes (including DvR host routes) that are redistributed into BGP:

View routes redistributed from GRT to BGP:

For IPv4: `show ip bgp imported-routes`

For IPv6: `show bgp ipv6 imported-routes`

View routes redistributed to BGP for a specific VRF instance:

For IPv4: `show ip bgp imported-routes [vrf WORD<1-64>] [vrfids WORD<0-512>]`

For IPv6: `show bgp ipv6 imported-routes [WORD<1-256>] [vrf WORD<1-16>] [vrfids WORD<0-255>]`

Examples

Redistribute direct routes from the VRF instance `source1` into BGP, in the GRT context.

Create a redistribution instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bgp
Switch(router-bgp)#redistribute direct vrf-src source1
```

If required, specify a route policy to govern redistribution:

```
Switch(router-bgp)# redistribute direct route-map policy1 vrf-src source1
```

If required, configure the route metric:

```
Switch:1(router-bgp)# redistribute direct metric 4 vrf-src source1
```

Enable the instance:

```
Switch:1(router-bgp)# redistribute direct enable vrf-src source1
```

Exit BGP Router Configuration mode:

```
Switch:1(router-bgp)# exit
```

Apply the redistribution instance configuration:

```
Switch:1(config)# ip bgp apply redistribute direct vrf-src source1
```

Redistribute DvR routes from the GRT to BGP:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bgp
Switch:1(router-bgp)#redistribute dvr
Switch:1(router-bgp)#redistribute dvr enable
Switch:1(router-bgp)#exit
Switch:1(config)#ip bgp apply redistribute dvr
```

View the host routes (including DvR host routes) that are redistributed from the GRT to BGP:

```
Switch:1(config)#show ip bgp imported-routes vrf vrf1

=====
                        BGP Imported Routes - VRF vrf1

```

Redistribute DvR routes to BGP for the specific VRF instance vrf1:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router vrf vrf1
Switch:1(router-vrf)#ip bgp redistribute dvr
Switch:1(router-vrf)#ip bgp redistribute dvr enable
Switch:1(router-vrf)#exit
Switch:1(config)#ip bgp apply redistribute dvr vrf vrf1
```

View the DvR host routes that are redistributed to BGP for vrf vrf1:

```
Switch:1(config)#show ip bgp imported-routes vrf vrf1

```

This example demonstrates redistribution of inter-VRF routes (both direct and DvR routes) to BGP, with a route policy configured.

Redistribute inter-VRF DvR routes between VRFs (with VRF IDs 10 and 30), to BGP.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf 10
Switch:1(router-vrf)#ip prefix-list "test10" 192.0.2.0/24 ge 25 le 32
Switch:1(router-vrf)#route-map "test10" 1
Switch:1(router-vrf)#permit
Switch:1(router-vrf)#enable
Switch:1(router-vrf)#match network "test10"
Switch:1(router-vrf)#set metric 99
Switch:1(router-vrf)#exit
```

```

Switch:1(config)#router vrf 30
Switch:1(router-vrf)#ip bgp redistribute direct vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute direct enable vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute dvr vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute dvr route-map "test10" vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute dvr enable vrf-src 10
Switch:1(router-vrf)#exit

Switch:1(config)#ip bgp apply redistribute direct vrf 30 vrf-src 10
Switch:1(config)#ip bgp apply redistribute dvr vrf 30 vrf-src 10

```

Variable Definitions

The following table defines parameters for the **redistribute** and **ip bgp apply redistribute** commands.

Variable	Value
<code><direct dvr ipv6-direct ipv6-isis ipv6-static isis ospf ospfv3 rip ripng static ></code>	Specifies the type of routes to redistribute (the protocol source).
<code>enable</code>	Enables the BGP route redistribution instance.
<code>metric <0-65535></code>	Configures the metric to apply to redistributed routes.
<code>metric-type live-metric</code>	Configures the metric type to apply to redistributed routes. When you enable the live-metric option, when BGP redistributes static, RIP, OSPF, IS-IS, or DvR routes, the metric value is taken from the routing table and is set to the Path attributes as a MED value. By default, this option is disabled, which means the BGP MED value is not derived from the metric in the routing table.
<code>route-map WORD<0-64></code>	Configures the route policy to apply to redistributed routes.
<code>vrf WORD<1-16></code>	Specifies the name of a VRF instance.
<code>vrf-src WORD<1-16></code>	Specifies the source VRF instance by name for route redistribution.

Configure redistribution to BGP+ for VRF 0

Configure an IPv6 redistribute entry to announce IPv6 routes of a certain source protocol type into the BGP domain, for example, static, OSPF, IS-IS, RIPng, or direct routes. Use a route policy to control the redistribution of routes.

Note

When a route map with attributes set to `origin` and `local-pref` is applied to the BGP redistribute command, the attributes are not applied to the redistributed routes.

Before You Begin

- If required, a route policy exists.

Procedure

1. Enter BGP Router Configuration mode:

```
enable

configure terminal

router bgp
```

2. Create a redistribution instance:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static>
```

3. If required, specify a route policy to govern redistribution:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> route-map WORD <0-64>
```

4. If required, configure a route metric:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> metric <0-65535>
```

5. Enable the instance:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> enable
```

Unlike IPv4 redistribution, you do not need to manually apply the IPv6 redistribution instance. Once you enable the IPv6 redistribution instance, it is automatically applied.

Example

Specify a route policy to govern redistribution by using the following command:

```
Switch:1(router-bgp)#redistribute ipv6-direct route-map policy2
```

Variable Definitions

The following table defines parameters for the **redistribute <ipv6-direct|ipv6-static|ospfv3|ipv6-isis|ripng>** command.

Variable	Value
<i>enable</i>	Enables the BGP route redistribution instance. The default value is none. To configure this option to the default value, use default operator with the command. To disable this option, use no operator with the command.
<i>metric<0-65535></i>	Configures the metric to apply to redistributed routes. The default value is 0. To configure this option to the default value, use default operator with the command.
<i>route-map <Word 0-64></i>	Configures the route policy to apply to redistributed routes. The default value is none. To configure this option to the default value, use default operator with the command.

Job Aid

Use the data in the following table to know how route policies are used for BGP from IPv6 perspective.

Table 57: BGP for IPv6 Route Policy Support

	REDISTRIBUTE					ACCEPT	ANNOUNCE
	IPv6 Direct	IPv6 Static	OSPFv3	IPv6 IS-IS	RIPng	BGP	BGP
MATCH							
as-path						Yes	Yes
community	Yes	Yes	Yes	Yes	Yes	Yes	Yes

SET							
as-path						Yes	Yes
as-path-mode						Yes	Yes
automatic-tag							
community						Yes	Yes
community-mode						Yes	Yes
injectlist	Yes	Yes	Yes	Yes	Yes		
ip-preference							
local-preference						Yes	Yes
mask							
metric	Yes	Yes	Yes	Yes	Yes	Yes	Yes
metric-type							

Table 57: BGP for IPv6 Route Policy Support (continued)

	REDISTRIBUTE					ACCEPT	ANNOUNCE
	IPv6 Direct	IPv6 Static	OSPFv3	IPv6 IS-IS	RIPng	BGP	BGP
metric-type-internal							
next-hop						Yes	Yes
nssa-pbit							
origin							Yes
origin-egp-as							
tag							
weight						Yes	

Configure AS Path Lists

Configure an AS path list to restrict the routing information a router learns or advertises to and from a neighbor. The AS path list acts as a filter that matches AS paths.

Before You Begin

- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

Note

Route refresh is not currently supported on non-default VRFs.

Procedure

- Enter BGP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router bgp
```

- Create the path list:

```
ip as-list <1-1024> memberid <0-65535> <permit|deny> as-path WORD<0-1536>
```

Use this command for each member by specifying different member IDs.

Example

Create the path list:

```
Switch(config)# ip as-list 234 memberid 3456 permit as-path "5"
```

Variable Definitions

The following table defines parameters for the **ip as-list** command.

Variable	Value
<0-65535>	Specifies an integer value between 0-65535 that represents the regular expression entry in the AS path list.
<1-1024>	Specifies an integer value from 1-1024 that represents the AS-path list ID you want to create or modify.
<permit deny>	Permits or denies access for matching conditions.
WORD<0-1536>	Specifies the AS number as an integer value between 0-1536. Place multiple AS numbers within quotation marks (").

Configure Community Lists

Configure community lists to specify permitted routes by using their BGP community. This list acts as a filter that matches communities or AS numbers.

Before You Begin

- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

Note

Route refresh is not currently supported on non-default VRFs.

Procedure

- Enter BGP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router bgp
```

- Create a community list:

```
ip community-list <1-1024> memberid <0-65535> <permit|deny> community-string WORD<0-256>
```

Example

Create a community list:

```
Switch(config)# ip community-list 1 memberid 4551 permit community-string internet
```

Variable Definitions

The following table defines parameters for the **ip community-list** command.

Variable	Value
<0-65535>	Specifies an integer value from 0-65535 that represents the member ID in the community list.
<1-1024>	Specifies an integer value from 1-1024 that represents the community list ID.
<permit deny>	Configures the access mode, which permits or denies access for matching conditions.
WORD<0-256>	Specifies the community as an alphanumeric string value with a string length from 0-256 characters. Enter this value in one of the following formats: <ul style="list-style-type: none"> (AS num:community-value) (well-known community string) <p>Well known communities include: internet, no-export, no-advertise, local-as (known as NO_EXPORT_SUBCONFED).</p>

Configure Extended Community Lists

Configure community lists to specify permitted routes by BGP extended community attributes, including route targets and sites of origin (SOO). This list acts as a filter that matches route targets and SOO.

Before You Begin

- Configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

Note

Route refresh is not currently supported on non-default VRFs.

Procedure

- Enter BGP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router bgp
```

- Create an extended community list based on the route target attribute:

```
ip extcommunity-list <1-1024> memberId <0-65535> rt {<0-65535>
<0-2147483647>|<A.B.C.D> <0-65535>} [soo {<0-65535> <0-2147483647>|
<A.B.C.D> <0-65535>}]
```

You can optionally configure the SOO attributes at the end of the same command or you can configure the SOO separately using the syntax in the following step.

3. Create an extended community list based on the SOO attribute:

```
ip extcommunity-list <1-1024> memberId <0-65535> soo {<0-65535>
<0-2147483647>|<A.B.C.D> <0-65535>}
```

Example

Create an extended community list based on the route target attribute:

```
Switch(config)# ip extcommunity-list 1 memberid 234 rt 192.0.2.1 5 soo
32 45
```

Variable Definitions

The following table defines parameters for the **ip extcommunity-list** command.

Variable	Value
<1-1024>	Specifies an integer value from 1-1024 that represents the community list ID you want to create or modify.
<i>memberId</i> <0-65535>	Specifies an integer value from 0-65535 that represents the member ID in the community list.
<i>rt</i> <0-65536> <0-2147483647> <i>rt</i> <A.B.C.D> <0-65535>	Specifies the route target in the format {AS number:assigned number} (that is, {0-65535}:{0-2147483647}) or {ipaddress:assigned number} (that is, {a.b.c.d}:{0-65535}).
<i>soo</i> <0-65535> <0-2147483647> <i>soo</i> <A.B.C.D> <0-65535>	Specifies the site of origin in the format {AS number:assigned number} (that is, {0-65535}:{0-2147483647}) or {ipaddress:assigned number} (that is, {a.b.c.d}:{0-65535}).

Configure an AS Number for a Non-default VRF

The Autonomous System (AS) number configured on the global Virtual Routing Forwarding (VRF) instance, called the GlobalRouter (GRT), is inherited by all user-created VRFs by default, however, you can override the AS number for the specific VRF instance using the following procedure.

Before You Begin

- Disable BGP synchronization.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Set the AS number:

```
ip bgp vrf-as WORD<0-11>
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
Switch:1(config)#router vrf vrfred
Switch:1(router-vrf)#ip bgp vrf-as 3
```

Variable Definitions

The following table defines parameters for the **ip bgp vrf-as** command.

Variable	Value
<code>WORD<0-11></code>	<p>Configures the local autonomous system (AS) number for the specific VRF instance. You cannot change local-as when BGP is set to enable.</p> <ul style="list-style-type: none"> To configure a 2-byte local AS number, enter a local-as number in the range of 0 to 65535. To configure a 4-byte local-as number, enable the 4-byte as variable and enter a number in the range of 0 to 4294967295. <p>Note: If as-4-byte is configured to false, the range for AS number is 0-65535 and if as-4-byte is configured to true, the range is 0-4294967295.</p> <p>If you enable as-dot, enter the AS number in octets in the range of 1.0 to 65535.65535. The AS number in a specific VRF instance inherits the AS number in the GlobalRouter in the following instances:</p> <ul style="list-style-type: none"> Configuring the AS number in a specific VRF instance to 0 (ip bgp vrf-as 0). Deleting the AS number in a specific VRF instance (no ip bgp vrf-as or default ip bgp vrf-as).

BGP Verification Using CLI

Use **show** commands to verify Border Gateway Protocol (BGP) configuration and to monitor or troubleshoot BGP operation.

Note

If the next hop of a BGP route is resolved using an IS-IS route, show commands can display the IS-IS internal next hop from the 127.1.x.y class rather than the IS-IS sys name.

Viewing BGP aggregate information

Display information about current aggregate addresses.

Procedure

- To enter User EXEC mode, log on to the switch.
- Display information about current aggregates:

```
show ip bgp aggregates [<prefix/len>] [vrf WORD <1-16>] [vrfids
WORD<0-255>]
```

Variable Definitions

The following table defines parameters for the **show ip bgp aggregates** command.

Variable	Value
<code><prefix/len></code>	Specifies the IP address and the mask length.
<code>vrf WORD<1-16></code>	Specifies a VRF instance by name.
<code>vrfids WORD<0-255></code>	Specifies a range of VRFs by ID number.

Viewing IPv6 BGP+ aggregate information

Display information about current IPv6 aggregate addresses.

About This Task

Use BGP 4 byte AS numbers to ensure the continuity of loop-free inter-domain routing information between ASs and to control the flow of BGP updates as 2 byte AS numbers will deplete soon.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about current IPv6 aggregates:

```
show bgp ipv6 aggregates [<WORD 1-256>] [vrf <WORD 1-16>] [vrfids
<0-255>]
```

Variable Definitions

The following table defines parameters for the **show bgp ipv6 aggregates** command.

Variable	Value
<code>WORD <1-256></code>	Specifies the IPv6 prefix and the prefix length (the length can be 0 to 128).
<code>vrf WORD <1-16></code>	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
<code>vrfids <0-255></code>	Specifies a range of VRFs by ID number (the ID ranges from 0-255).

Viewing CIDR routes

Display information about classless interdomain routing (CIDR) routes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about CIDR routes:

```
show ip bgp cidr-only [<prefix/len>] [vrf WORD<1-16>] [vrfids WORD<0-
512>]
```

Variable Definitions

The following table defines parameters for the **show ip bgp cidr-only** command.

Variable	Value
<prefix/len>	Specifies an exact match of the prefix. This variable is an IP address and an integer value from 0-32 in the format a.b.c.d/xx.
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
vrfids WORD<0-512>	Specifies a range of VRFs by ID number (the ID ranges from 0-512).

View BGP Configuration

View information about the BGP configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about the current BGP configuration:

```
show ip bgp conf [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

```

=====
                        BGP Configuration - VRF vrf1
=====

                          quick-start - disable
                          synchronization - enable

--More-- (q = quit)

```

Variable Definitions

The following table defines parameters for the **show ip bgp conf** command.

Variable	Value
<i>vrf WORD<1-16></i>	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
<i>vrfids WORD<0-512></i>	Specifies a range of VRFs by ID number (the ID ranges from 0-512).

Viewing BGP confederation

Display information about BGP confederations.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about current BGP confederations:

```
show ip bgp confederation
```

Example

```
Switch(config)#show ip bgp confederation
confederation identifier 0
confederation peer as
```

Viewing flap-dampened routes

Display information about flap-dampened routes to determine unreliable routes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about flap-dampened routes:

```
show ip bgp dampened-paths {A.B.C.D} [<prefix/len>] [longer-prefixes]
[vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Variable Definitions

The following table defines parameters for the **show ip bgp dampened-paths** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the source IP address in the format a.b.c.d.
<i>longer-prefixes</i>	Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32).
<i><prefix/len></i>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32).

Variable	Value
<code>vrf WORD<1-16></code>	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
<code>vrfids WORD<0-512></code>	Specifies a range of VRFs by ID number (the ID ranges from 0-512).

Viewing global flap-dampening configurations

Display global information about flap-dampening.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display global information about flap-dampening:

```
show ip bgp flap-damp-config [prefix/len] [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

Example

```
Switch(config)# show ip bgp flap-damp-config vrf vrf1
```

```
=====
                        BGP Flap Dampening - VRF vrf1
=====
                                Status - enable
                                PolicyName - N/A
                                CutoffThreshold - 1536
                                ReuseThreshold - 512
                                Decay - 2
                                MaxHoldDown - 180
```

Variable Definitions

The following table defines parameters for the **show ip bgp flap-damp-config** command.

Variable	Value
<code><prefix/len></code>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32).
<code>vrf WORD<1-16></code>	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
<code>vrfids WORD<0-512></code>	Specifies a range of VRFs by ID number (the ID ranges from 0-512).

Viewing imported routes

Display information about BGP imported routes.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display information about BGP imported routes:

```
show ip bgp imported-routes [<prefix/len>] [longer-prefixes] [vrf
WORD<1-16>] [vrfids WORD<0-512>]
```

Variable Definitions

The following table defines parameters for the **show ip bgp imported-routes** command.

Variable	Value
<i>longer-prefixes</i>	Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32).
<prefix/len>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0-512>	Specifies a range of VRFs by ID number (the ID ranges from 0–512).

Viewing BGPv6 imported routes

Display information about BGPv6 imported routes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGPv6 imported routes:

```
show bgp ipv6 imported-routes [<prefix/len>] [longer-prefixes] [vrf
WORD<1-16>] [vrfids WORD<0-255>]
```

Variable Definitions

The following table defines parameters for the **show bgp ipv6 imported-routes** command.

Variable	Value
<i>longer-prefixes</i>	Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32).
<prefix/len>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0-255>	Specifies a range of VRFs by ID number (the ID ranges from 0–255).

View BGP Neighbors Information

Display information about BGP neighbors.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP neighbors:

```
show ip bgp neighbors [{A.B.C.D}] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
3. Display information about BGP peer advertised routes:

```
show ip bgp neighbors {A.B.C.D} advertised-routes [<prefix/len>] [longer-prefixes] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
4. Display information about BGP peer routes:

```
show ip bgp neighbors {A.B.C.D} routes [<prefix/len>] [community <enable|disable>] [longer-prefixes] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
5. Display statistics for BGP peers:

```
show ip bgp neighbors {A.B.C.D} stats [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

```
Switch:#show ip bgp neighbors vrf vrf1

=====

BGP Neighbor Info - VRF vrf1

Variable Definitions

The following table defines parameters for the **show bgp ipv6 neighbors** command.

Variable	Value
<i>WORD</i> <1-256>	Specifies the IPv6 address.
<i>advertised-routes</i>	Specifies an IPv6 neighbors advertised routes.
<i>routes</i>	Specifies an IPv6 neighbors routes.
<i>WORD</i> <1-256>	Specifies an IPv6 address/length.
<i>longer-prefixes</i>	Shows long prefixes. The longer-prefixes indicate the mask length from any specified prefix to 128. For example, show from prefix :X::X:X/len to X:X::X/X/ 128.

Variable	Value
<code>community <enable disable></code>	Enables or disables the display of community attributes.
<code>vrf</code>	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
<code>vrfids</code>	Specifies a range of VRFs by ID number (the ID ranges from 0-255).

Viewing BGP network configurations

Display information about BGP network configurations.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP network configurations:

```
show ip bgp networks [<prefix/len>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Variable Definitions

The following table defines parameters for the **show ip bgp networks** command.

Variable	Value
<code><prefix/len></code>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32).
<code>vrf WORD<1-16></code>	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
<code>vrfids WORD<0-512></code>	Specifies a range of VRFs by ID number (the ID ranges from 0-512).

Viewing IPv6 BGP+ network configurations

Display information about BGP+ network configurations.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP+ network configurations:

```
show bgp ipv6 networks <WORD 1-256> [vrf <WORD 1-16>] [vrfids <0-255>]
```

Variable Definitions

The following table defines parameters for the **show bgp ipv6 networks** command.

Variable	Value
<WORD 1-256>	Specifies the IPv6 prefix and the prefix length (must be an integer value between 0 and 128).
vrf	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
vrfids	Specifies a range of VRFs by ID number (the ID ranges from 0-255).

Viewing BGP peer group information

Display information about BGP peer groups.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP peer groups:

```
show ip bgp peer-group [WORD<0-1536>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Variable Definitions

The following table defines parameters for the **show ip bgp peer-group** command.

Variable	Value
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
vrfids WORD<0-512>	Specifies a range of VRFs by ID number (the ID ranges from 0-512).
WORD<0-1536>	Specifies the name of the peer group (the string length ranges from 0-1536 characters).

Viewing BGP redistributed routes

Display information about BGP redistributed routes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP redistributed routes:

```
show ip bgp redistributed-routes [<prefix/len>] [vrf WORD<1-16>]
[vrfids WORD<0-512>]
```

Variable Definitions

The following table defines parameters for the **show ip bgp redistributed-routes** command.

Variable	Value
<code><prefix/len></code>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).
<code>vrf WORD<1-16></code>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
<code>vrfids WORD<0-255></code>	Specifies a range of VRFs by ID number (the ID ranges from 0–255).

Viewing BGPv6 redistributed routes

Display information about BGPv6 redistributed routes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGPv6 redistributed routes:

```
show bgp ipv6 redistributed-routes [vrf <WORD 1-16>] [vrfids <0-255>]
```

Variable Definitions

The following table defines parameters for the **show bgp ipv6 redistributed-routes** command.

Variable	Value
<code>vrf</code>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
<code>vrfids</code>	Specifies a range of VRFs by ID number (the ID ranges from 0–255).

View a Summary of BGP Configurations

Display summarized information about BGP.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display summarized information about BGP:

```
show ip bgp summary [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

The following example shows partial output for the **show ip bgp summary** command.

```
Switch:1>show ip bgp summary vrf vrf1
```

```

=====
)

```

Variable Definitions

The following table defines parameters for the **show bgp ipv6 summary** command.

Variable	Value
vrf	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
vrfids	Specifies a range of VRFs by ID number (the ID ranges from 0-255).

Viewing BGP routes

Display information about BGP routes.

Note

BGP stores route information on the AVL tree and this command retrieves that information. Information in the AVL tree is not sorted. The information returned by this command will not be displayed in any particular order.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP routes:

```

show ip bgp route [<prefix/len>] [community <enable|disable>] [ip
{A.B.C.D}] [longer-prefixes] [vrf WORD<1-16>] [vrfids WORD<0-512>]

```

Variable Definitions

The following table defines parameters for the **show ip bgp route** command.

Variable	Value
<i>community</i> <enable disable>	Enables or disables the display of community attributes.
<i>ip</i> {A.B.C.D}	Specifies an IP address.
<i>longer-prefixes</i>	Shows long prefixes. Longer-prefixes indicates the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32).
<prefix/len>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32).
<i>vrf</i> WORD<1-16>	Specifies a VRF instance by name.
<i>vrfids</i> WORD<0-512>	Specifies a range of VRFs by ID number.

Viewing BGPv6 routes

Display information about BGPv6 routes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Enter Privileged EXEC mode:
enable
3. Display information about BGP routes:

```
show bgp ipv6 route [<WORD 1-256> [longer-prefixes]] [community
<enable|disable>] [ipv6 <WORD 1-256>] [vrf <WORD 1-16>] [vrfids
<0-255>]
```

Variable Definitions

The following table defines parameters for the **show bgp ipv6 route** command.

Variable	Value
[<WORD 1-256>]	Specifies the IPv6 prefix and the prefix length (must be an integer value between 0 and 128).
<i>community</i> <enable disable>	Enables or disables the display of community attributes.
<i>ipv6</i> <WORD 1-256>]	Specifies an IPv6 address.
<i>longer-prefixes</i>	Shows long prefixes. The longer-prefixes indicate the mask length from any specified prefix to 128 (for example, show from prefix X:X::X:X/len to X:X::X/X/128).
<i>vrf</i>	Specifies a VRF instance by name (the string length ranges from 1-16 characters).
<i>vrfids</i>	Specifies a range of VRFs by ID number (the ID ranges from 0-255).

BGP configuration using EDM

Configure Border Gateway Protocol (BGP) to create an inter-domain routing system that guarantees loop-free routing information between autonomous systems.

For information about how to configure route policies, see [Configure a Route Policy](#) on page 2923.

Configure BGP

Enable BGP so that BGP runs on the router. Configure general BGP parameters to define how BGP operates on the system.

Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Generals** tab.
4. In AdminStatus, select **enable**.
5. Configure the local autonomous system (AS) ID.
6. In the **Aggregate** area, enable or disable route aggregation as required.
7. Configure the BGP options as required.
8. In the **DebugMask** area, select the check box for the type of information to show for BGP debugging purposes.
9. Configure BGP confederations as required.
10. Configure BGP route reflectors as required.
11. Click **Apply**.

Generals Field Descriptions

Use the data in the following table to use the **Generals** tab.

Name	Description
bgpVersion	Specifies the version of BGP that operates on the router. Note: This parameter only applies to VRF 0.
Identifier	Specifies the BGP router ID number.
AdminStatus	Enables or disables BGP on the router. The default is disable. You cannot enable AdminStatus until you change the LocalAS value to a nonzero value.

Name	Description
4ByteAs	<p>Enables or disables 4-byte AS numbers. The default is disable.</p> <p>Note: This parameter only applies to VRF 0.</p>
LocalAs	<p>Configures the local AS number in the range of 0–65535. You cannot change the LocalAs value if AdminStatus is enable.</p> <p>Note: If the inserted LocalAs is 0, then the LocalAs in that VRFcontext loses its significance and it becomes the LocalAs configured in GlobalRouter (the equivalence to CLI commands ip bgp vrf-as 0 and no ip bgp vrf-as or default ip bgp vrf-as).</p>
AsDot	<p>Enables or disable the AS dot notation format for the 4-byte AS number. The default is disable.</p> <p>The AS dot notation is easier to read and remember than the AS plain notation, but it can be difficult to convert from AS plain to AS dot. The IETF prefers the AS plain notation.</p> <p>Note: This parameter only applies to VRF 0.</p>
Aggregate	Enables or disables aggregation. The default is enable.
DefaultMetric	<p>Configures the metric sent to BGP neighbors. The default metric determines the cost of a route a neighbor uses. Use this parameter in conjunction with the redistribute parameters so that BGP uses the same metric for all redistributed routes.</p> <p>The default is -1. The range is -1-2147483647.</p>
DefaultLocalPreference	<p>Specifies the default local preference. The local preference indicates the preference that AS border routers assign to a chosen route when they advertise it to iBGP peers. The default is 100. The range is 0–2147483647.</p>
AlwaysCompareMed	<p>Enables or disables the comparison of the multi-exit discriminator (MED) parameter for paths from neighbors in different autonomous systems. The system prefers a path with a lower MED over a path with a higher MED. The default is disable.</p>
DeterministicMed	<p>Enables or disables deterministic MED. Deterministic MED compares the MEDs after routes advertised by different peers in the same AS are chosen. The default is disable.</p>
AutoPeerRestart	<p>Enables or disables the process that automatically restarts a connection to a BGP neighbor. The default is enable.</p>
AutoSummary	<p>Enables or disables automatic summarization. If you enable this variable, BGP summarizes networks based on class limits (for example, Class A, B, or C networks). The default is enable.</p>

Name	Description
NoMedPathsWorst	Enables or disables NoMedPathsWorst. If you enable this variable, BGP treats an update without a MED attribute as the worst path. The default is enabled.
BestPathMedConfed	Enables or disables the comparison of MED attributes within a confederation. The default is disable.
DebugMask	Displays the specified debug information for BGP global configurations. The default value is none. Other options are <ul style="list-style-type: none"> • none disables all debug messages. • event enables the display of debug event messages. • state enables display of debug state transition messages. • update enables display of debug messages related to updates transmission and reception. • error enables the display of debug error messages. • trace enables the display of debug trace messages. • init enables the display of debug initialization messages. • all enables all debug messages. • packet enables the display of debug packet messages. • warning enables the display of debug warning messages. • filter enables the display of debug messages related to filtering.
IgnoreIllegalRouterId	Enables BGP to overlook an illegal router ID. For example, this variable enables the acceptance of a connection from a peer that sends an open message using a router ID of 0. The default is enable.
Synchronization	Enables or disables the router to accept routes from BGP peers without waiting for an update from the IGP. The default is enable.
MaxEqualcostRoutes	Configures the maximum number of equal-cost-paths that are available to a BGP router by limiting the number of equal-cost-paths the routing table can store. The default value is 1; the range is 1-8.
IbgpReportImportRoute	Configures BGP to report imported routes to an interior BGP (iBGP) peer. This variable also enables or disables reporting of non-BGP imported routes to other iBGP neighbors. The default is enable.
FlapDampEnable	Enables or disables route suppression for routes that go up and down (flap). The default is disable.
QuickStart	Enables or disables the Quick Start feature, which forces the BGP speaker to begin establishing peers immediately, instead of waiting for the auto-restart timer to expire. The default is disable.
TrapEnable	Enables or disables the BGP traps. The default is disable.

Name	Description
ConfederationASIdentifier	Specifies a BGP confederation identifier in the range of 0-65535. Note: This parameter applies only to VRF 0.
ConfederationPeers	Lists adjoining autonomous systems that are part of the confederation in the format (5500,65535,0,10,...).. This value can use 0-255 characters. Note: This parameter applies only to VRF 0.
RouteReflectionEnable	Enables or disables the reflection of routes from iBGP neighbors. The default is enable. Note: This parameter applies only to VRF 0.
RouteReflectorClusterId	Configures a reflector cluster ID IP address. This variable applies only if you enable RouteReflectionEnable, and if multiple route reflectors are in a cluster. Note: This parameter applies only to VRF 0.
ReflectorClientToClientReflection	Enables or disables route reflection between two route reflector clients. This variable applies only if RouteReflectionEnable is enable. The default is enable. Note: This parameter applies only to VRF 0.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request. Note: This parameter only applies to VRF 0.

Configure 4-byte AS numbers

Configure AS numbers using the 4-byte format and represent the numbers in octets.

Before You Begin

- You cannot modify the global BGP configuration unless BGP is disabled.
- Make sure that you define AS numbers in policies the same way that you configure them for the router. The choices are asplain (regular expression) or asdot (dot notation). If you create policies using asplain and configure the switch with asdot, the match will not occur.

About This Task

Use BGP 4-byte AS numbers to ensure the continuity of loop-free inter-domain routing information between autonomous systems and to control the flow of BGP updates as 2 byte AS numbers will deplete soon. AS Plain notation format is the default and the preferred form of representing 4-byte AS numbers over the AS dot notation format.

You have an option to configure AS dot notation format as well. With AS dot notation, analyzing and troubleshooting any issues encountered becomes difficult as it is incompatible with the regular expressions used by most of the network providers.

If you enable 4-byte AS numbers, or the dotted octet notation, for the Global Router (VRF0), the configuration is inherited by user-defined VRFs. You cannot enable 4-byte AS numbers on individual user-defined VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Generals** tab.
4. To change the AS number format, select **disable** for **AdminStatus**.
5. Select **Apply**.
6. In **4-byteAs**, select **enable**.
7. In **AsDot**, select **enable**.
8. In **LocalAs**, type the 4-byte AS number in octets.
9. In **AdminStatus**, select **enable**.
10. Select **Apply**.

4-byte AS Field Descriptions

Use the data in the following table to use the 4-byte AS related fields on the **Generals** tab.

Name	Description
LocalAs	Configures the local autonomous system (AS) number. You cannot change this field when AdminStatus is set to enable. This field sets a 2-byte local AS number in the range from 0 to 65535. To set a 4-byte local AS number, click enable in the 4ByteAs field and enter a number in the LocalAs field. Attention: The switch does not support this parameter with BGP +.
4byteAs	Enables or disables the switch from using 4 byte numbers for autonomous systems.
AsDot	Enables or disables representing AS numbers in octets. The default is disable so the switch uses the plain notation format. If you enable this field and the 4ByteAs field, enter the AS number in the LocalAs field. Attention: The switch does not support this parameter with BGP +.

Viewing BGP Global Stats

View BGP global stats.

Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **BGP**.
3. Click the **Global Stats** tab.

Global Stats Field Descriptions

Use the data in the following table to use the BGP Global Stats tab.

Name	Description
AbsoluteValue	Displays the counter value.
Cumulative	Displays the total value since you opened the Stats tab.
Average/sec	Displays the average value for each second.
Minimum/sec	Displays the minimum value for each second.
Maximum/sec	Displays the maximum value for each second.
LastVal/sec	Displays the last value for each second.
Starts	Displays the number of times the BGP connection started.
Stops	Displays the number of times the BGP connection stopped.
Opens	Displays the number of times BGP opens TCP.
Closes	Displays the number of times BGP closes TCP.
Fails	Displays the number of times TCP attempts failed.
Fatals	Displays the number of times TCP crashes due to fatal error.
ConnExps	Displays the number of times the TCP retry timer expired.
HoldExps	Displays the number of times the hold timer expired.
KeepExps	Displays the number of times the keepalive timer expired.
RxOpens	Displays the number of open instances BGP receives.
RxKeeps	Displays the number of keepalive instances BGP receives.
RxUpdates	Displays the number of update instances BGP receives.
RxNotifys	Displays the number of notification instances BGP receives.
TxOpens	Displays the number of open instances BGP transmitted.
TxKeeps	Displays the number of keepalive instances BGP transmitted.
TxUpdates	Displays the number of updates instances BGP transmits.
TxNotifys	Displays the number of notification instances BGP transmits.
BadEvents	Displays the number of invalid events FSM received.
SyncFails	Displays the number of times FDB sync failed.
TrEvent	Displays the trace event.

Name	Description
RxECodeHeader	Displays the total header errors received.
RxECodeOpen	Displays the total open errors received.
RxECodeUpdate	Displays the total update errors received.
RxECodeHoldtimer	Displays the total hold timer errors received.
RxECodeFSM	Displays the total FSM errors received.
RxECodeCease	Displays the total cease errors received.
RxHdrCodeNoSync	Displays the header not synchronized errors received.
RxHdrCodeInvalidMsgLen	Displays the header invalid message length errors received.
RxHdrCodeInvalidMsgType	Displays the header invalid message type errors received.
RxOpCodeBadVer	Displays the open errors received for Bad Version.
RxOpCodeBadAs	Displays the open errors received for le Bad AS Number.
RxOpCodeBadRtID	Displays the open errors received for Bad BGP Rtr ID.
RxOpCodeUnsuppOption	Displays the open errors received for Unsupported Option.
RxOpCodeAuthFail	Displays the open errors received for Auth Failures.
RxOpCodeBadHold	Displays the open errors received for Bad Hold Value.
RxUpdCodeMalformedAttrList	Displays the update errors received for Malformed Attr List.
RxUpdCodeWelKnownAttrUnrecog	Displays the update errors received for Welknown Attr Unrecog.
RxUpdCodeWelknownAttrMiss	Displays the update errors received for Welknown Attr Missing.
RxUpdCodeAttrFlagError	Displays the update errors received for Attr Flag Error.
RxUpdCodeAttrLenError	Displays the update errors received for Attr Len Error.
RxUpdCodeBadORIGINAttr	Displays the update errors received for Bad ORIGIN Attr.
RxUpdCodeASRoutingLoop	Displays the update errors received for AS Routing Loop.
RxUpdCodeBadNHAttr	Displays the update errors received for Bad NEXT-HOP Attr.
RxUpdCodeOptionalAttrError	Displays the update errors received for Optional Attr Error.
RxUpdCodeBadNetworkField	Displays the update errors received for Bad Network Field.
RxUpdCodeMalformedASPath	Displays the update errors received for Malformed AS Path.
TxECodeHeader	Displays the total Header errors transmitted.
TxECodeOpen	Displays the total Open errors transmitted.
TxECodeUpdate	Displays the total Update errors transmitted.
TxECodeHoldtimer	Displays the total Hold timer errors transmitted.
TxECodeFSM	Displays the total FSM errors transmitted.
TxECodeCease	Displays the total Cease errors transmitted.
TxHdrCodeNoSync	Displays the header Not Synchronized errors transmitted.
TxHdrCodeInvalidMsgLen	Displays the header Invalid msg len errors transmitted.
TxHdrCodeInvalidMsgType	Displays the header Invalid msg type errors transmitted.

Name	Description
TxOpCodeBadVer	Displays the open errors transmitted for Bad Version.
TxOpCodeBadAs	Displays the open errors transmitted for Bad AS Number.
TxOpCodeBadRtrID	Displays the open errors transmitted for Bad BGP Rtr ID.
TxOpCodeUnsuppOption	Displays the open errors transmitted for Unsupported Option.
TxOpCodeAuthFail	Displays the open errors transmitted for Auth Failures.
TxOpCodeBadHold	Displays the open errors transmitted for Bad Hold Value.
TxUpdCodeMalformedAttrList	Displays the update errors transmitted for Malformed Attr List.
TxUpdCodeWelknownAttrUnrecog	Displays the update errors transmitted for Welknown Attr Unrecog.
TxUpdCodeWelknownAttrMiss	Displays the update errors transmitted for Welknown Attr Missing.
TxUpdCodeAttrFlagError	Displays the update errors transmitted for Attr Flag Error.
TxUpdCodeAttrLenError	Displays the update errors transmitted for Attr Len Error.
TxUpdCodeBadORIGINAttr	Displays the update errors transmitted for Bad ORIGIN Attr.
TxUpdCodeASRoutingLoop	Displays the update errors transmitted for AS Routing Loop
TxUpdCodeBadNHAttr	Displays the update errors transmitted for Bad NEXT-HOP Attr
TxUpdCodeOptionalAttrError	Displays the update errors transmitted for Optional Attr Error.
TxUpdCodeBadNetworkField	Displays the update errors transmitted for Bad Network Field.
TxUpdCodeMalformedASPath	Displays the update errors transmitted for Malformed AS Path.

Configure Aggregate Routes

Configure aggregate routes so that the router advertises a single route (aggregate route) that represents all destinations. Aggregate routes also reduce the size of routing tables.

Before You Begin

- Enable aggregate routes globally.
- You need the appropriate aggregate address and mask.
- If required, policies exist.
- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Aggregates** tab.
4. Click **Insert**.
5. Configure the aggregate **Address** and **PrefixLen**.
6. Select **AsSetGenerate** or **SummaryOnly** as required.
7. Configure policies for the aggregate route.

8. Click **Insert**.

Aggregates field descriptions

Use the data in the following table to use the **Aggregates** tab.

Name	Description
Address	Specifies the aggregate IP address.
PrefixLen	Specifies the aggregate PrefixLen.
AsSetGenerate	Enables or disables AS-set path information generation. The default is disable.
SummaryOnly	Enables or disables the summarization of routes in routing updates. Enable this parameter to create the aggregate route and suppress advertisements of more-specific routes to all neighbors. The default is disable.
SuppressPolicy	Specifies the route policy (by name) used for the suppressed route list. Enable this parameter to create the aggregate route and suppress advertisements of the specified routes.
AdvertisePolicy	Specifies the route policy (by name) used for route advertisements. The route policy selects the routes that create AS-set origin communities.
AttributePolicy	Specifies the route policy (by name) used to determine aggregate route attributes.

Configuring Aggregate IPv6 Routes

Configure IPv6 aggregate routes so that the router advertises a single route (aggregate route) that represents all destinations. Aggregate routes also reduce the size of routing tables.

To configure aggregate routes for IPv4, see [Configure Aggregate Routes](#) on page 477.

Before You Begin

- Aggregate routes are enabled.
- You have determined the appropriate aggregate prefix and length.
- If required, policies exist.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **BGP+**.
3. Click the **Aggregates** tab.
4. Click **Insert**.
5. Specify the **aggregate Address** and **PrefixLen**
6. Configure **AsSetGenerate** and **SummaryOnly** as required.
7. Configure policies for the aggregate route.
8. Click **Insert**.

Aggregates field descriptions

Use the data in the following table to use the **Aggregates** tab.

Name	Description
Address	Specifies the aggregate address. The default is none.
PrefixLen	Specifies the length of the prefix (in bits).
AsSetGenerate	Enables or disables AS-set path information generation. The default is disable.
SummaryOnly	Enables or disables the summarization of routes in routing updates. Enable this parameter to create the aggregate route and suppress advertisements of more-specific routes to all neighbors. The default is disable.
SuppressPolicy	Specifies the route policy (by name) used for the suppressed route list. Enable this parameter to create the aggregate route and suppress advertisements of the specified routes.
AdvertisePolicy	Specifies the route policy (by name) used for route advertisements. The route policy selects the routes that create AS-set origin communities.
AttributePolicy	Specifies the route policy (by name) used to determine aggregate route attributes.

Configure Allowed Networks

Configure network addresses to determine the network addresses that BGP advertises. The allowed addresses determine the BGP networks that originate from the switch.

Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Network** tab.
4. Click **Insert**.
5. Configure the network address, mask, and metric.
6. Click **Insert**.

Network field descriptions

Use the data in the following table to use the **Network** tab.

Name	Description
NetworkAfAddr	Specifies the network prefix that BGP advertises.
NetworkAfPrefixLen	Specifies the prefix length of the network address.
NetworkAfMetric	Specifies the metric to use when the system sends an update for the routes in the network table. The metric configures the MED for the routes advertised to eBGP peers. The range is 0–65535.

Configuring Allowed IPv6 Networks

Configure IPv6 network addresses to determine the network addresses that BGP advertises. The allowed addresses determine the BGP networks that originate from the switch.

To configure allowed IPv4 networks, see [Configure Allowed Networks](#) on page 479.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **BGP+**.
3. Click the **Network** tab.
4. Click **Insert**.
5. Configure the **network address, prefix length** and **metric**.
6. Click **Insert**.

Network field descriptions

Use the data in the following table to use the **Network** tab.

Name	Description
NetworkAfAddr	Specifies the network prefix that BGP advertises. The default is none.
NetworkAfPrefixLen	Specifies the network prefix length. The default is none.
NetworkAfMetric	Specifies the metric used when an update is sent for the routes in the network table. The metric configures the MED for the routes advertised to EBGP peers. The range is 0 to 65535. The default is 0.

Configure BGP Peers

Configure BGP peers to connect two routers to each other for the purpose of exchanging routing information. BGP peers exchange complete routing information only after they establish the peer connection.

Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Configure the peer as required.
6. Select **Insert**.
7. In the **Enable** column, double-click the value, and then select **true**.
By default, new peer configuration parameters are disabled.
8. Select **Apply**.
9. To modify a peer configuration, double-click the value, and then select a new value.

Peers Field Descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
Instance	Specifies the BGP peer instance.
LocalAddrType	Specifies the local IP address type of the entered BGP peer.
LocalAddr	Specifies the local IP address of the entered BGP peer.
RemoteAddrType	Specifies the remote IP address type of the entered BGP peer.
RemoteAddr	Specifies the remote IP address of the entered BGP peer.
AdminStatus	Specifies the administrative status of the BGP peer.
GroupName	Specifies the peer group name to which the peer belongs (optional).
PeerState	Specifies the BGP peer connection state.
RemoteAs	Configures a remote AS number for the peer or peer-group in the range 0–65535.
Enable	Controls whether the peer connection is enabled or disabled. The default is disabled.
EbgpMultiHop	Enables or disables a connection to a BGP peer that is more than one hop away from the local router. The default value is disable.
RoutePolicyIn	Specifies the policy (by name) that applies to all network routes learned from this peer.
RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing route updates.
RemovePrivateAs	Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.
UpdateSourceInterface	Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.

Name	Description
ConnectRetryInterval	Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.
HoldTimeConfigured	Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.
KeepAliveConfigured	Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.
MD5Authentication	Enables and disables MD5 authentication.
AdvertisementInterval	Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGP neighbor. The default value is 30 seconds and the range is 5–120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained.
DefaultOriginate	When enabled, specifies that the current route originated from the BGP peer. This parameter enables or disables sending the default route information to the specified neighbor or peer. The default value is false.
DefaultOriginateIpv6	When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.
Weight	Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0–65535.
MaxPrefix	Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0–2147483647. A value of 0 means no limit exists.

Name	Description
NextHopSelf	Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.
RouteReflectorClient	Specifies that this peer is a route reflector client. Note: This parameter only applies to VRF 0.
SoftReconfigurationIn	When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).
DebugMask	Displays the specified debug information for the BGP peer. The default value is none. <ul style="list-style-type: none"> • None disables all debug messages. • Event enables the display of debug event messages. • State enables display of debug state transition messages. • Update enables display of debug messages related to updates transmission and reception. • Error enables the display of debug error messages. • Trace enables the display of debug trace messages. • Init enables the display of debug initialization messages. • All enables all debug messages. • Packet enables the display of debug packet messages. • Warning enables the display of debug warning messages. • Filter enables the display of debug messages related to filtering.
SendCommunity	Enables or disables sending the community attribute of the update message to the specified peer. The default value is disable.
Vpnv4Address	Specifies the vpnv4 routes.
IpvpnLiteCap	Enable or disable IP VPN-lite capability on the BGP neighbor peer.
Ipv6Cap	Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.
SooAddress	Specifies the site-of-origin (SoO) address of the BGP peer.
SooAsNumber	Specifies the site-of-origin (SoO) Autonomous System (AS) number of the BGP peer.
SooAssignedNum	Specifies the site-of-origin (SoO) assigned number of the BGP peer.
SooType	Specifies the site-of-origin (SoO) type of the BGP peer.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.

Name	Description
AsOverride Note: This field does not apply on all hardware platforms.	Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.
AllowAsIn Note: This field does not apply on all hardware platforms.	Specifies the number of AS-in allowed for the BGP peer. The range is 1-10.
Ipv6RoutePolicyIn	Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.
Ipv6RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing IPv6 route updates.
Ipv6MaxPrefix	Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for this BGP peer.

Configure BGPv6 Peers

Configure BGPv6 peers to connect two routers to each other for the purpose of exchanging routing information. BGPv6 peers exchange complete routing information only after they establish the peer connection.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **BGP+**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Configure the peer, as required.
6. Select **Insert**.
7. In the **Enable** column, double-click the value, and then select **enable**.
By default, new peer configuration parameters are disabled.
8. Select **Apply**.
9. To modify a peer configuration, double-click the value, and then select a new value.

Peers Field Descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddr	Specifies the remote IPv6 address of the entered BGP+ peer.
GroupName	Specifies the peer group name to which the peer belongs (optional).
PeerState	Specifies the BGPv6 peer connection state.
RemoteAs	Configures a remote AS number for the peer or peer-group in the range 0 to 65535.
Enable	Controls whether the peer connection is enabled or disabled. The default is disabled.
EbgpMultiHop	Enables or disables a connection to a BGPv6 peer that is more than one hop away from the local router. The default value is disable.
RoutePolicyIn	Specifies the policy (by name) that applies to all network routes learned from this peer.
RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing route updates.
RemovePrivateAs	Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.
UpdateSourceInterface	Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.
ConnectRetryInterval	Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.
HoldTimeConfigured	Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.
KeepAliveConfigured	Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.
MD5Authentication	Enables and disables MD5 authentication.

Name	Description
AdvertisementInterval	Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGPv6 neighbor. The default value is 30 seconds and the range is 5 to 120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained.
DefaultOriginatelpv6	When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.
Weight	Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0 to 65535.
MaxPrefix	Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0 to 2147483647. A value of 0 means no limit exists.
NextHopSelf	Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.
RouteReflectorClient	Specifies that this peer is a route reflector client. Note: This parameter only applies to VRF 0.
SoftReconfigurationIn	When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).

Name	Description
DebugMask	<p>Displays the specified debug information for the BGP peer. The default value is none.</p> <ul style="list-style-type: none"> • None disables all debug messages. • Event enables the display of debug event messages. • State enables display of debug state transition messages. • Update enables display of debug messages related to updates transmission and reception. • Error enables the display of debug error messages. • Trace enables the display of debug trace messages. • Init enables the display of debug initialization messages. • All enables all debug messages. • Packet enables the display of debug packet messages. • Warning enables the display of debug warning messages. • Filter enables the display of debug messages related to filtering.
SendCommunity	Enables or disables sending the community attribute of the update message to the specified peer. The default value is disable.
IpvpnLiteCap	Enable or disable IP VPN-lite capability on the BGP neighbor peer.
Ipv6Cap	Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.
AsOverride Note: This field does not apply on all hardware platforms.	Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.
AllowAsIn Note: This field does not apply on all hardware platforms.	Specifies the number of AS-in allowed for the BGP peer. The range is 1-10.
Ipv6RoutePolicyIn	Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.
Ipv6RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing IPv6 route updates.
Ipv6MaxPrefix	Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for this peer.

Configure Peer Groups

Configure or edit peer groups to create update policies for neighbors in the same group.

Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Peer Groups** tab.

You can modify an existing parameter by double-clicking the value.

4. Select **Insert**.
5. Configure the peer group as required.
6. Select **Insert**.

Peer Groups field descriptions

Use the data in the following table to use the **Peer Groups** tab.

Name	Description
Index	Specifies the index of this peer group.
GroupName	Specifies the peer group to which this neighbor belongs (optional).
Enable	Enables or disables the peer group.
RemoteAs	Configures a remote AS number for the peer-group in the range 0-65535.
DefaultOriginate	When enabled, the BGP speaker (the local router) sends the default route 0.0.0.0 to a group of neighbors for use as a default route. The default is disabled.
DefaultOriginateIpv6	When enabled, the BGP speaker (the local router) sends the default route to a group of neighbors for use as a default route. The default is disabled.
EbgpMultiHop	When enabled, the switch accepts and attempts BGP connections to external peers that reside on networks that do not directly connect. The default is disabled.
AdvertisementInterval	Specifies the time interval, in seconds, that elapses between BGP routing updates. The default value is 30 seconds.
KeepAlive	Specifies the time interval, in seconds, between sent BGP keep alive messages to remote peers. The default value is 60.
HoldTime	Configures the hold time for the group of peers in seconds. Use a value that is three times the value of the KeepAlive time. The default value is 180.
Weight	Assigns an absolute weight to a BGP network. The default value is 100.

Name	Description
MaxPrefix	Limits the number of routes accepted from this group of neighbors. A value of zero indicates no limit. The default value is 12,000 routes.
NextHopSelf	Specifies that the switch must set the NextHop attribute to the local router address before sending updates to remote peers.
RoutePolicyIn	Specifies the route policy that applies to all networks learned from this group of peers.
RoutePolicyOut	Specifies the route policy that applies to all outgoing updates to this group of peers.
RouteReflectorClient	Specifies that this peer group is a route reflector client. Note: This parameter only applies to VRF 0.
SoftReconfigurationIn	When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is enable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).
MD5Authentication	Enables and disables MD5 authentication. The default is disable.
RemovePrivateAs	Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.
SendCommunity	Enables or disables sending the community attribute of the update message to the specified peer group. The default value is disable.
AfUpdateSourceInterfaceType	Specifies the interface type.
AfUpdateSourceInterface	Specifies the IP address used for circuitless IP (CLIP) for this peer group.
Vpvn4Address	Enables BGP address families for IPv4 (BGP) and Layer 3 VPN (MP-BGP) support. Enable this parameter for VPN/VRF Lite routes.
IpvpnLiteCap	Specifies (when enabled) that IP VPN Lite capability can be enabled or disabled on the BGP neighbor peer. The default is disable.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.
AsOverride	Specifies that the AS Override parameter can be enabled or disabled for the BGP peer group. The default is disable.
AllowedAsIn	Specifies the number of AS-in allowed for the BGP peer group. The range is 1-10.
IPv6Cap	Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.

Name	Description
Ipv6RoutePolicyIn	Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.
Ipv6RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing IPv6 route updates.
Ipv6MaxPrefix	Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for the BGP peer group.

View IPv6 Community Attributes

View IPv6 community attributes for specific routes to utilize the update message fields to communicate information between BGP speakers. Use the Path Attribute values to specify the prefixes that the BGP session can exchanged, or which of the multiple paths of a specified prefix to use.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **BGP+**.
3. Select the **Bgp Route Summary** tab.
4. Select a route for which you want to view the route summary information.
5. Select the **Route Comm Attr** option on the menu.

The **BGP Path Attributes** tab opens with the BGP IPv6 community attribute information.

BGP Path Attributes field descriptions

Use the data in the following table to use the **Community List** tab.

Name	Description
Origin	Specifies the ultimate origin of the path information.
NextHopAddr	Specifies the address of the border router that is used to access the destination network. This address is the nexthop address received in the UPDATE packet associated with this prefix.
Med	This metric is used to discriminate between multiple exit points to an adjacent autonomous system. When the MED value is absent but has a calculated default value, this object will contain the calculated value.
LocalPref	Specifies the value used during route decision process in the BGP protocol. Applicable to BGP only.
AggregatorAS	Specifies the AS number of the last BGP4 speaker that performed route aggregation. If the AGGREGATOR path attribute is absent, this object will not be present in the conceptual row.

Name	Description
AggregatorAddr	Specifies the IP address of the last BGP4 speaker that performed route aggregation. If the AGGREGATOR path attribute is absent, this object will not be present in the conceptual row.
String	This is a string representing the autonomous system path to the network which was received from the peer which advertised it. The format of the string is implementation-dependent, and is designed for operator readability. Note: SnmpAdminString is only capable of representing a maximum of 255 characters. This may lead to the string being truncated in the presence of a large AS Path.

Display Dampened Routes Information

Display dampened path information to see which routes are suppressed.

Before You Begin

- Change the VRF instance as required to view BGP information about a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.
- Enable dampened routes.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Dampened Routes** tab.

Dampened Routes field descriptions

Use the data in the following table to use the **Dampened Routes** tab.

Name	Description
IpAddrPrefix	Specifies the IP address prefix in the NLRI field. This variable is an IP address that contains the prefix with a length specified by IpAddrPrefixLen. Bits beyond the length specified by IpAddrPrefixLen are set to zero.
IpAddrPrefixLen	Specifies the length, in bits, of the IP address prefix in the NLRI field.
Peer	Specifies the IP address of the peer from which the router learns the path information.
FlapPenalty	Specifies the penalty based on number of route flaps.
FlapCount	Specifies the number of times a route flapped (went down and up) since the last time the penalty was reset to zero.
RouteDampened	Indicates whether this route is suppressed or announced.
ReuseTime	Specifies the system-configured time for route reuse.

Configure Redistribution to BGP

Configure redistribute entries for BGP to announce routes of a certain source type to BGP, for example, DvR, direct, static, Routing Information Protocol (RIP), and Open Shortest Path First (OSPF). If you do not configure a route policy, then the switch uses the default action based on metric, metric type, and subnet. Use a route policy to perform detailed redistribution.

Before You Begin

- If required, configure a route policy.
- When you configure BGP on a specific VRF instance, the VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.
- Before you redistribute DvR host routes to BGP, ensure that you disable BGP aggregation and BGP auto-summarization of networks. Disabling these settings ensures that all the DvR host routes are advertised into BGP correctly, and are not summarized.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Configure the source protocol.
6. If required, choose a route policy.
7. Configure the metric to apply to redistributed routes.
8. Enable the redistribution instance.
9. Click **Insert**.

Redistribute field descriptions

Use the data in the following table to use the **Redistribute** tab.

Name	Description
DstVrflid	Specifies the destination VRF instance (read-only).
Protocol	Specifies the protocols that receive the redistributed routes.
SrcVrflid	Specifies the source VRF instance (read-only).
RouteSource	Specifies the source protocol for the route redistribution entry.
Enable	Enables (or disables) a BGP redistribute entry for a specified source type.
RoutePolicy	Configures the route policy to use for the detailed redistribution of external routes from a specified source into the BGP domain.
Metric	Configures the metric for the redistributed route. The value can be a range between 0–65535. The default value is 0. Use a value that is consistent with the destination protocol.

Configure Redistribution to BGPv6

Configure redistribute entries for BGPv6 to announce routes of a certain source type to BGPv6, for example, DvR, direct, static, Routing Information Protocol (RIP), and Open Shortest Path First (OSPF). If

you do not configure a route policy, then the switch uses the default action based on metric, metric type, and subnet. Use a route policy to perform detailed redistribution.

Before You Begin

- If required, configure a route policy.
- Before you redistribute DvR host routes to BGPv6, ensure that you disable BGPv6 aggregation and BGPv6 autosummarization of networks. Disabling these settings ensures that all the DvR host routes are advertised into BGPv6 correctly, and are not summarized.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **BGP+**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Configure the source protocol.
6. If required, choose a route policy.
7. Configure the metric to apply to redistributed routes.
8. Enable the redistribution instance.
9. Click **Insert**.

Redistribute field descriptions

Use the data in the following table to use the **Redistribute** tab.

Name	Description
DstVrfId	Specifies the destination VRF instance (read-only).
Protocol Note: This field does not apply on all hardware platforms.	Specifies the protocols that receive the redistributed routes.
SrcVrfId	Specifies the source VRF instance (read-only).
RouteSource	Specifies the source protocol for the route redistribution entry.
Enable	Enables (or disables) a BGPv6 redistribute entry for a specified source type.
RoutePolicy	Configures the route policy to use for the detailed redistribution of external routes from a specified source into the BGPv6 domain.
Metric	Configures the metric for the redistributed route. The default value is 0. Use a value that is consistent with the destination protocol.
MetricType	Specifies the metric type. Specifies a type1 or a type2 metric. For metric type1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type2, the cost of the external routes is equal to the external cost alone. The default is type2.

View BGP+ or BGPv6 Route Summary Information

You can display current IPv6 BGP+ route information.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
Use the **IP** folder in the navigation pane to view the IPv4 route summary.
2. Click **BGP+**.
3. Click the **Bgp Route Summary** tab to view the BGP route summary information

Bgp Route Summary field descriptions

Use the data in the following table to use the **Bgp Route Summary** tab.

Name	Description
Prefix	Specifies the IP address prefix in the Network Layer Reachability Information (NLRI) field. This is an IP address that contains the prefix with a length specified by IpAddrPrefixLen. Any bits beyond the length specified by IpAddrPrefixLen are set to zero.
PrefixLen	Specifies the length, in bits, of the IP address prefix in the NLRI field.
LocalAddr	The local address of this entry's BGP connection.
RemoteAddr	Specifies the IP address of the peer from which path information was learned.

Viewing BGP Route Summary

Display BGP route summary.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Bgp Route Summary** tab.

Bgp Route Summary field descriptions

Use the data in the following table to use the Bgp Route Summary tab.

Name	Description
Prefix	Configures the IP address of the route.
PrefixLen	Specifies the IP address and the mask length (the length can be 0–32).
LocalAddr	Specifies the local IP address of the entered BGP route.
RemoteAddr	Specifies the remote IP address of the entered BGP route.

Configure an AS Path List

Configure an AS path list to restrict the routing information a router learns or advertises to and from a neighbor. The AS path list acts as a filter that matches AS paths.

Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **Policy**.
3. Click the **As Path List** tab.
4. Click **Insert**.
5. Enter the appropriate information for your configuration.
6. Click **Insert**.

As Path List field descriptions

Use the data in the following table to use the **As Path List** tab.

Name	Description
Id	Specifies the AS path list.
MemberId	Specifies the AS path access list member ID.
Mode	Specifies the action to take if the system selects a policy for a specific route. Select permit (allow the route) or deny (ignore the route).
AsRegularExpression	Specifies the expression to use for the AS path.

Configure a Community Access List

Configure community lists to specify permitted routes by using their BGP community. This list acts as a filter that matches communities or AS numbers.

Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **Policy**.
3. Click the **Community List** tab.
4. Click **Insert**.
5. Configure the list as required.
6. Click **Insert**.

Community List field descriptions

Use the data in the following table to use the **Community List** tab.

Name	Description
Id	Specifies the community list. The range is 0-1024.
MemberId	Specifies the community list member ID. The range is 0-65535.
Mode	Specifies the action to take if the system selects a policy for a specific route. Select permit (allow the route) or deny (ignore the route).
Community	Specifies the community access list community string.

BGP Configuration Examples

IPv6 Tunnel Configurations for BGP+

You must configure an IPv6 tunnel and static routes at BGP+ peers when you use BGP+.

When BGP+ peers advertise route information, they use Update messages to advertise route information. And, when route information is encapsulated in Update messages, BGP+ peers convert their own IPv4 peer addresses to IPv4-mapped IPv6 addresses and insert them into the next-hop field in the Update message.

When the BGP+ software module receives Update messages, it adds route information to the IPv6 Routing Manager (RTM). These RTM routes contain next-hop addresses from the BGP peer that the route was learned from. The next-hop addresses are represented as IPv4-mapped IPv6 addresses.

But, because the IPv6 RTM cannot correlate the IPv4-mapped IPv6 address to a specific outgoing interface, you must create a manually-configured static route to make the link between the BGP peer and the IPv6 tunnel interface so that traffic can reach networks advertised by the peer.

Following is one way to express a static route in an IPv6-configured tunnel for BGP+:

```
ipv6 route 0:0:0:0:0:ffff:192.0.2.0/24 cost 1 tunnel 10
```

Configure the IPv6 tunnel endpoint and the BGP peer to reside on the same switch.

If the IPv6 tunnel endpoint and the BGP peer must reside on different switches you can terminate the tunnel on a different switch, but you must consider the following:

- Because the IPv6 tunnel endpoint does not reside on the same switch as the BGP peer, the BGP device cannot use the tunnel as the outgoing interface. That is, to reach the IPv6-configured tunnel endpoint, if the BGP peer resides on a different switch from the IPv6 tunnel endpoint, the next-hop for the manually-configured IPv4-mapped IPv6 static route is the native IPv6 interface next-hop address.

- The node where the tunnel terminates must contain all of the information needed to route the packets between the remote IPv6 network clouds.

**Note**

In order for the tunnel endpoint switch to be aware of all of the necessary IPv6 routes, you may need to redistribute the BGP routes into OSPFv3.

IPv4-mapped IPv6 address

IPv4-mapped IPv6 addresses are IPv4 addresses that the system has mapped into the IPv6 address space.

The system uses these IPv4-mapped IPv6 addresses for devices that are only IPv4-capable.

These IPv4-mapped address have the first 80 bits set to zeros, followed by the next 16 bits set to ones, and the last 32 bits have IPv4 addresses.

When converted to an IPv4-mapped IPv6 address, an IPv4 device address of 192.0.2.1 would be represented as one of the following:

- 0:0:0:0:FFFF:192.0.2.1
- ::FFFF:192.0.2.1

The following figure illustrates the components in an IPv4-mapped IPv6 address.

Figure 39: IPv4-mapped IPv6 address components

eBGP+ peers between two switches with IPv6 Tunneling

The following figure shows a sample network that contains eBGP+ peers using IPv6 tunneling.

Figure 40: eBGP+ peers with IPv6 tunneling

The configuration in the figure, *eBGP+ peers with IPv6 tunneling*, assumes that the BGP peer IP address is the next hop.

When you configure the static route for the BGP+ tunnel, you must designate the BGP peer IP address as the next hop in most cases.

You can configure multiple static routes, using the same tunnel, but you must ensure reachability when you create the static routes.

R1 configuration

```
interface GigabitEthernet 3/2
brouter port 3/2 vlan 2090 subnet 192.0.2.1/255.255.255.0 mac-offset 2
exit
# BGP CONFIGURATION - GlobalRouter

iBGP+ peership on CLIP between two switches with IPv6 Tunneling

The following figure shows a sample network that contains iBGP+ peers using IPv6 tunneling.

Figure 41: iBGP+ peers on CLIP interfaces with IPv6 tunneling

You must enable OSPF on the interface and globally as well.

If you cannot enable OSPF, you must configure static routes to provide reachability to the BGP+ peer.

The static route must point to the next hop for the routes to be installed in the IPv6 RTM.

The next hop must be the BGP peer IP address.

The IPv4 interfaces do not need to connect directly, but the routing table on each switch must include the IPv4 interface of the other switch.

iBGP between the CLIP interfaces needs to run OSPF as a routing protocol so that the BGP neighbor can remain reachable.

eBGP connections cannot use a CLIP interface as an end point.

R1 configuration

Native IPv6 eBGP peership between two switches on VRF

The following figure shows a sample network that contains native IPv6 eBGP peers on VRFs.

Figure 42: Native IPv6 eBGP peers on VRFs

Configure the local AS first on GRT (and it is inherited by all VRFs), and then enable BGP on GRT/VRF.

You must configure the **address-family ipv6** option for IPv6 peers, otherwise, peer-ship is formed, but no routing updates between them will take place.

You must configure the **ebgp-multihop** option for the given eBGP peer that is not on one of local subnets (remote peers), otherwise, peer-ship will not be formed.

Note

The switch does not accept any configuration command for BGP in router-vrf configuration mode unless a BGP instance associated to the VRF context is created. You can use `ip bgp` command in router-vrf configuration mode to create a BGP instance on VRF.

R1 configuration

```

iBGP over User-created VRFs Configuration Example

This section shows examples of configured internal Border Gateway Protocol (iBGP) IPv4 and IPv6 peers over user-created Virtual Routing and Forwarding (VRF) instances.

Note

The Autonomous System (AS) number configured on the global VRF is inherited by all user-created VRFs, however, you can override the AS number for a specific user-created VRF. For more information, see [Configure an AS Number for a Non-default VRF](#) on page 454.

Chassis Operations

[Chassis operations fundamentals on page 514](#)

[Chassis operations configuration using the CLI on page 538](#)

[Chassis operations configuration using EDM on page 568](#)

The following sections provide information for chassis operations such as hardware and software compatibility.

Chassis operations fundamentals

This section provides conceptual information for chassis operations such as hardware and software compatibility and power management. Read this section before you configure the chassis operations.

Management Port

Note

The Management Router for management port configuration is only supported on VSP 8600 Series. For all other platforms, see [Segmented Management](#) on page 67.

The management port is a 10/100/1000 Mbps Ethernet port that you can use for an Out-of-Band (OOB) management connection to the switch. To remotely access the switch using the management port, you must configure an IP address for the OOB management port.

Management Router VRF

A separate VRF called Management Router (MgmtRouter) is reserved for the OAM (mgmt) port. The configured IP subnet must be globally unique because the management protocols, for example, SNMP, Telnet, and FTP, can go through in-band or out-of-band ports. The VRF ID for the Management Router is 512.

The switch never switches or routes transit packets between the Management Router VRF port and the Global Router VRF, or between the Management Router VRF and other VRF ports.

The switch honors the VRF of the ingress packet; however, in no circumstance does the switch enable routing between the Management VRF and Global Router VRF. The switch does not support the

configuration if you have an out-of-band management network with access to the same networks present in the GRT routing table.

**Note**

IPv6 is not supported on MgmtRouter.

Non-virtualized client management applications

Do not define a default route in the Management Router VRF. A route originating from the switch and used for non-virtualized client management applications, such as Telnet, Secure Shell (SSH), and FTP will always match a default route defined in the Management Router VRF.

If you want out-of-band management, define a specific static route in the Management Router VRF to the IP subnet where your management application resides. When you specify a static route in the Management Router VRF, it enables the client management applications originating from the switch to perform out-of-band management without affecting in-band management. This enables in-band management applications to operate in the Global Router VRF.

Non-virtualized client management applications originating from the switch, such as Telnet, SSH, and FTP, follow the behavior listed below:

1. Look at the Management Router VRF route table
2. If no route is found, the applications will proceed to look in the Global Router VRF table

Non-virtualized client management applications include:

- DNS
- FTP client with the **copy** command
- NTP
- rlogin
- RADIUS authentication and accounting
- SSH
- SNMP clients in the form of traps
- SYSLOG
- TACACS+
- Telnet
- TFTP client

For management applications that originate outside the switch, the initial incoming packets establish a VRF context that limits the return path to the same VRF context.

Virtualized management applications

Virtualized management applications, such as ping and traceroute, operate using the specified VRF context. To operate ping or traceroute you must specify the desired VRF context. If not specified, ping

defaults to the Global Router VRF. For example, if you want to ping a device through the out-of-band management port you must select the Management Router VRF.

Note

IPv6 is not supported on MgmtRouter.

```
Switch:1(config)#ping 192.0.2.1 vrf MgmtRouter
192.0.2.1 is alive
```

Ping test for IPv6:

```
Switch:1(config)#ping 2001:db8::1 vrf vrfRED
2001:db8::1 is alive
```

Traceroute test for IPv4:

```
Switch:1#traceroute 192.0.2.1 vrf MgmtRouter
```

Traceroute test for IPv6:

```
Switch:1#traceroute 2001:db8::1 vrf vrfRED
```

Entity MIB - Physical Table

The Entity MIB – Physical Table assists in the discovery of functional components on the switch. The Entity MIB – Physical Table supports a physical interface table that includes information about the chassis, power supply, fan, I/O cards, console, and management port.

Some hardware platforms support removable interface modules while others offer a fixed configuration. The names used for these modules can vary depending on the hardware platform.

The following table identifies the entity index range for the switch components.

Component	Entity index range
Chassis	1
Power supply slot	3 to 8
Fan tray and fan slot	9 to 16
I/O slot	17 to 30
SF Slot	31 to 36
I/O card or module	37 to 50
SF Card	51 to 56
Console port	57
Console port 2	58
Management port	64
Management port 2	65
Power supply	68 to 73
Fan tray	74 to 81
Fan module	82 to 105
Port	192 to 1023
Pluggable Module and Sensor	19201 to 102314

For more information about Entity MIB – Physical Table, see [View Physical Entities](#) on page 571.

High Availability-CPU (HA-CPU)

Table 59: High-Availability product support

Feature	Product	Release introduced
High Availability-CPU (HA-CPU) for a standalone switch	VSP 4450 Series	Not Applicable
	VSP 4900 Series	Not Applicable
	VSP 7200 Series	Not Applicable
	VSP 7400 Series	Not Applicable
	VSP 8200 Series	Not Applicable
	VSP 8400 Series	Not Applicable
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	Not Applicable
High Availability-CPU (HA-CPU) for Layer 2 with Simplified vIST	VSP 4450 Series	Not Applicable
	VSP 4900 Series	Not Applicable

	VSP 8600 Series	VSP 8600 6.3
	XA1400 Series	Not Applicable

The High Availability-CPU (HA-CPU) framework supports redundancy at the hardware and application levels. The CP software runs on an Input/Output control (IOC) module in both slots 1 and 2, and the HA-CPU feature activates two CPUs simultaneously in primary or standby role. These CPUs exchange topology data so that, if a failure occurs, one of the CPUs can take over the operations of the other. You can configure the CPUs to operate in either HA mode or non-HA mode. In HA mode, the two CPUs synchronize configuration, protocol states, and tables. In non-HA mode, the two CPUs do not synchronize.

The default mode is HA disabled. To activate HA-CPU mode, use the **boot config flags ha-cpu** command. To deactivate HA-CPU mode, use the **no boot config flags ha-cpu** command.

If you switch from one mode to the other, the standby CP restarts in the specified HA mode (hot standby) or non-HA mode (warm standby). This does not impact the Input/Output process and there is no traffic loss on the physical slot of the card.

If a failure occurs and the chassis is configured for either HA mode (hot standby) or non-HA mode (warm standby), the CP software restarts and runs as standby. The system generates a trap to indicate the change from hot-standby mode to warm-standby mode.

Note

- The HA-CPU feature provides node-level redundancy. Hot standby mode is not supported with fabric functionality, which provides network-level redundancy.
- If your switch is in hot standby mode (ha-cpu boot flag is set to true), you must disable boot config flag to configure SPBM or vIST on the switch. When the switch is in warm standby mode (ha-cpu boot flag is set to false), you must disable SPBM and vIST to move to hot standby mode.
- When you try to switch-over from warm standby mode to hot standby mode using EDM, the system displays the following error message when you enable the boot config flag for ha-cpu:

Hot-standby mode cannot be enabled while SPB/VIST features are still configured.

HA mode

In HA mode, also called hot standby, the platform synchronizes the primary CPU information to the standby secondary CPU. The platform adds any configuration changes or application table changes to the primary CPU by using bulk synchronization or incremental synchronization. After synchronization is complete, both the CPUs contain the same configuration and application tables information.

Application in HA mode support either full HA implementation or partial HA implementation. In full HA implementation, both the configuration and runtime application data tables exist on the primary CPU and the standby CPU.

If the primary CPU fails, the standby CPU takes over the primary responsibility quickly and you do not see an impact on your network. Also, the IOC and SF modules as well as the full HA applications continue to operate and the full HA applications run consistency checks to verify the tables.

The following applications support full HA mode:

Feature	Supported
Layer 1	
Port configuration parameters	Yes
Layer 2	
Media Access Control security (MACsec)	Yes
Multiple Spanning Tree Protocol parameters	Yes
Quality of Service (QoS) parameters	Yes
Rapid Spanning Tree Protocol parameters	Yes
VLAN parameters	Yes

Feature	Supported
Layer 3	
ARP entries	Yes
Border Gateway Protocol (BGP)	Partial (configuration only)
Dynamic Host Configuration Protocol (DHCP) Relay	Partial (configuration only)
Internet Group Management Protocol (IGMP)	Yes
IPv6	Partial (configuration only)
Access Control Lists	Yes
Open Shortest Path First (OSPF)	Yes
Protocol Independent Multicast (PIM)	Partial (configuration only)
Prefix lists and route policies	Yes
Routing Information Protocol	Yes
Router Discovery	Yes
Static and default routes	Yes
Virtual IP (VLANs)	Yes
Virtual Router Redundancy Protocol	Yes
Transport Layer	
Network Load Balancing (NLB)	Yes
Remote Access Dial-In User Services (RADIUS)	Yes
Terminal Access Controller Access-Control System plus (TACACS+)	Partial (configuration only)
UDP forwarding	Yes

Partial HA

A few applications in HA mode have partial HA implementation, where the system synchronizes user configuration data (including interfaces, IPv6 addresses and static routes) from the primary CPU to the standby CPU. However, for partial HA implementation, the platform does not synchronize dynamic data learned by protocols. After failure, those applications restart and rebuild their tables, which causes an interruption to traffic that is dependent on a protocol or application with partial HA support.

The following applications support Partial HA:

- Layer 3
 - Border Gateway Protocol (BGP)
 - Dynamic Host Configuration Protocol (DHCP) Relay
 - Factory defaults flag behavior
 - IPv6
 - MACsec Key Agreement
 - Open Shortest Path First Version 3 for Loopback interfaces
 - Protocol Independent Multicast-Sparse Mode (PIM-SM)
 - Protocol Independent Multicast-Source Specific Mode (PIM-SSM)
 - SHA512 secure password hashing

- Transport Layer
 - Terminal Access Controller Access Control System plus (TACACS+)

Non-HA mode

In non-HA mode, also called warm standby, the platform does not synchronize the configuration between the primary CPU and the standby CPU. When failover happens, the standby CPU switches to primary role, and all the IOCs (except the new primary CPU) are restarted. The new primary CPU loads the configuration when all the cards are ready. These operations cause an interruption to traffic on all ports on the chassis.

Note

- When there is a switch-over to warm standby mode, only the RWA access level user can log in to the new primary CPU console screen.

The remaining users can log in to the CPU console screen only after the primary CP module reloads the configuration and displays the new login prompt.

- When the platform switches from standby CPU to primary CPU in warm standby mode, the platform always uses the previously-saved primary configuration file to boot the chassis on the switch.
- The runtime config file must be present on the flash drive during the boot-up of both the primary CPU and the standby CPU. If the config file that is used by the primary CPU for booting is not available on the standby CPU, the standby CPU loads the default config file. You can run the **save config** command to synchronize the configuration settings or copy the boot config file from the primary CPU to the standby CPU. The standby CPU must be rebooted to load the desired config file.

When the primary CPU is physically removed in warm-standby mode, all cards are rebooted and the standby CPU switches to the primary role and loads the saved configuration. If the old primary CPU is physically not plugged in during this time, the respective slot configuration is not loaded to memory even though the configuration exists in the config file. When the old primary CPU is re-inserted later, the system considers this as a first time insertion and loads the default configuration on the inserted CP card. This is expected behavior in warm-standby mode. To load the configuration for the re-inserted standby CPU, ensure that the **savetostandby** boot-flag is set to true after re-inserting the removed CPU, and run the CLI command **source <config-file>** on the active CPU.

HA-CPU support in Simplified vIST

HA-CPU in Simplified vIST configurations enables synchronization of data for Layer 2 and Layer 3 applications between the master CPU and standby CPU, to provide hot standby capability.

Power Manager

Table 60: Power Manager product support

Feature	Product	Release introduced
Power Management	VSP 4450 Series	Not Supported
	VSP 4900 Series	Not Supported
	VSP 7200 Series	Not Supported
	VSP 7400 Series	Not Supported
	VSP 8200 Series	Not Supported
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	Not Supported

Power Manager identifies the available power in the chassis (called the power budget), and determines if enough power is available to operate the installed components. Power Manager also gives you control over which module slots to supply power to and enables you to prioritize the slots that should shut down first if there isn't enough power available.

If the power usage exceeds the power budget, the system powers off the module with the lowest priority. After a power over-usage occurs, the system uses a Simple Network Management Protocol (SNMP) trap to send a message to the network administrator configured to receive the trap.

The system compares the total chassis power consumed against the total chassis power available, and verifies that if one power supply fails, enough power still remains to operate the chassis and components. If enough power is available to keep all modules powered on in the case of a single failed power supply, then the system is considered to have redundant power.

Note

In a redundant power supply configuration, that is, a +1 configuration where the system has one or more power supplies above the actual requirement, the power management logic automatically employs load-sharing across all active power supplies. This load-sharing ensures that the switch draws power equally from all available power supplies to support the system requirements in a fully active model.

If the system does not have redundant power, then the system sends an SNMP trap to the receiver and a message to CLI to inform you that the device no longer operates in redundant power mode.

For information on configuring Power Manager, see the following:

- If using the CLI, see [Configuring power on module slots](#) on page 556 and [Configuring Slot Priority](#) on page 557.
- If using EDM, see [Configure Slot Priority](#) on page 607.

Software Lock-up Detection

The software lock-up detect feature monitors processes on the CPU to limit situations where the device stops functioning because of a software process issue. Monitored issues include

- software that enters a dead-lock state
- a software process that enters an infinite loop

The software lock-up detect feature monitors processes to ensure that the software functions within expected time limit.

The CPU logs detail about suspended tasks in the log file.

Jumbo frames

Jumbo packets and large packets are particularly useful in server and storage over Ethernet applications. If the payload to header relation increases in a packet, the bandwidth can be used more efficiently. For this reason, increasing Ethernet frame size is a logical option. The switch supports Ethernet frames as large as 9600 bytes, compared to the standard 1518 bytes, to transmit large amounts of data efficiently and minimize the task load on a server CPU.

Tagged VLAN support

A port with VLAN tagging activated can send tagged frames. If you plan to use Jumbo frames in a VLAN, ensure that you configure the ports in the VLAN to accept Jumbo frames and that the server or hosts in the VLAN do not send frames that exceed 9600 bytes. For more information about how to configure VLANs, see [VLAN Configuration](#) on page 3749.

Multi-speed Ports

If a port supports multiple speeds, the software configures the speed automatically based on the optic type it detects in the port; you do not need to configure the port speed. For multi-speed copper ports, Auto-Negotiation detects the speed.

Note

Some VIMs must operate with all ports at the same speed, while others can operate with ports at different speeds. For more information, see [VOSS Release Notes](#). The **sys vim-speed** command is supported only on VIMs that must operate with all ports at the same speed. An error message displays if you run the command on an unsupported VIM.

In addition to the documented maximum port speed, and in cases where the hardware supports it:

- SFP ports are for 1 Gbps but can also support 100 Mbps.
- SFP+ ports are for 10 Gbps but can also support 1 Gbps or 100 Mbps.
- SFP28 ports are for 25 Gbps but can also support 10 Gbps or 1 Gbps.

- QSFP+ ports are for 40 Gbps but can also support 4x10 Gbps if channelization is supported and enabled.
- QSFP28 ports are for 100 Gbps but also can support 40 Gbps, or 4x25 Gbps or 4x10 Gbps if channelization is supported and enabled.

**Note**

A 100 Gbps DAC in a 100 Gbps port can negotiate down to 40 Gbps depending on the hardware and peer connection.

SFP28, SFP+ and SFP ports have the same physical size.

QSFP28 and QSFP+ ports have the same physical size.

To know if a port supports multiple speeds or channelization, see the applicable hardware documentation.

Auto-Negotiation

Table 61: Auto-Negotiation product support

Feature	Product	Release introduced
Auto-Negotiation	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1 Switch models: <ul style="list-style-type: none"> • VSP4900-24S and VSP4900-48P - all fixed ports • VSP4900-12MXU-12XE - all fixed ports, with ports 13 to 24 at 1 Gbps only • VSP4900-24XE - all fixed ports at 1 Gbps only VIM5-4XE at 1 Gbps only and VIM5-4YE at 25 Gbps only
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50

The Auto-Negotiation feature enables the devices to switch between the various operational modes in an ordered fashion and enables you to select a specific operational mode. The Auto-Negotiation feature also provides a parallel detection (called autosensing) function to recognize compatible devices, even if they do not support Auto-Negotiation and helps the device sense the link speed only; not the duplex mode.

You can use the **show interfaces gigabitEthernet 11-config** command to see the Auto-Negotiation operational state on a port. The operational state uses the configuration and transceiver type present in the port. If you enable Auto-Negotiation for the port but the transceiver type does not support Auto-Negotiation, the operational state is disabled (false).

Default Auto-Negotiation Behavior

The default Auto-Negotiation behavior depends on the switch model, port type, and transceiver type. The following table provides the default combinations.

Table 62: VSP 4900 Series default behavior

Model	Port type	Transceiver type	Auto-Negotiation	FEC
VSP4900-48P	1GBASE-T		Enabled	
VSP4900-24S	SFP	100BASE-FX	N/A	
		1GBASE-T	Enabled	
		1G SFP	Enabled	
VSP4900-24XE	SFP+	100BASE-FX	N/A	
		1GBASE-T	Enabled The operational state is always enabled regardless of configuration.	
		1G SFP	Disabled	
		10GBASE-T	Enabled The operational state is always enabled regardless of configuration.	
		10G DAC	Disabled	
		10G SFP+	N/A	
VSP4900-12MXU-12XE	100M/1/2.5/5/10Gbps Copper		Enabled	
	SFP+	100BASE-FX	N/A	
		1GBASE-T	Enabled The operational state is always enabled regardless of configuration.	
		1G SFP	Disabled	
		10GBASE-T	Enabled	
		10G DAC	Disabled	
		10G SFP+	N/A	

Table 62: VSP 4900 Series default behavior (continued)

Model	Port type	Transceiver type	Auto-Negotiation	FEC
VIM5-4X	SFP+	1GBASE-T	Not Supported	
		1G SFP	Disabled	
		10GBASE-T	Enabled	
		10G DAC	Disabled	
		10G SFP+	N/A	
VIM5-4XE	SFP+	1GBASE-T	Enabled The operational state is always enabled regardless of configuration.	
		1G SFP	Disabled	
		10GBASE-T	Enabled The operational state is always enabled regardless of configuration.	
		10G DAC	Disabled	
		10G SFP+	N/A	
VIM5-2Y and VIM5-4Y	SFP28	10GBASE-T	Enabled The operational state is always enabled regardless of configuration.	
		10G DAC	Disabled	
		10G SFP+	N/A	
		25G DAC	Disabled	Not Supported
		25G AOC	N/A	Not Supported
		25G SFP28	N/A	Not Supported
VIM5-4YE	SFP28	10GBASE-T	Enabled The operational state is always enabled regardless of configuration.	
		10G DAC	Disabled	
		10G SFP+	N/A	
		25G DAC	Enabled	FEC is negotiated requesting CL108.
		25G AOC	N/A	FEC auto: CL108
		25G SFP28	N/A	FEC auto: CL108

10/100/1000 Mbps Port Considerations

Auto-Negotiation lets devices share a link, and automatically configures both devices so that they take maximum advantage of their abilities. Auto-Negotiation uses a modified 10BASE-T link integrity test pulse sequence to determine device ability.

**Important**

Product-specific considerations for Auto-Negotiation include:

- If Auto-Negotiation is disabled, the following hardware does not support half-duplex:
 - 8424GT ESM
 - 8424XT ESM
 - VSP 7254XTQ

Configure Auto-Negotiation as shown in the following table, where A and B are two Ethernet devices.

Table 63: Auto-Negotiation configuration on 10/100/1000BASE-TX ports

Port on A	Port on B	Remarks	Best practice
Auto-Negotiation enabled	Auto-Negotiation enabled	Ports negotiate on highest supported mode on both sides.	Use this configuration if both ports support Auto-Negotiation mode.
Full-duplex	Full-duplex	Both sides require the same mode.	Use this configuration if you require full-duplex, but the configuration does not support Auto-Negotiation.

Auto-Negotiation cannot detect the identities of neighbors and cannot shut down misconnected ports. Upper-layer protocols perform these functions.

Note

10 GigabitEthernet (GbE) fiber-based I/O module ports can operate at either 1 Gigabit per second (Gbps) or 10 Gbps, depending upon the capabilities of the optical transceiver that you install.

This situation presents an ambiguity with respect to the Auto-Negotiation configuration of the port, while 1 GbE ports require Auto-Negotiation; Auto-Negotiation is not defined and is non-existent for 10 GbE ports.

For a 10-GbE fiber-based I/O module, you can swap between 1 GbE and 10 GbE operation by simply swapping transceivers. To help with the swap, you can configure Auto-Negotiation when you install a 10 GbE transceiver, even though Auto-Negotiation is not defined for 10 GbE.

You can do this in anticipation of a port changeover from 10 GbE to 1 GbE. In this manner, you can pre-configure a port in 1 GbE mode while the 10 GbE transceiver is still installed. The port is ready to go upon the changeover to the 1 GbE transceiver.

You can use a saved configuration file with Auto-Negotiation enabled, to boot a system with either 10 GbE or 1 GbE transceivers installed. If you install a 1 GbE transceiver, the system applies Auto-Negotiation. If you install a 10 GbE transceiver, the system does not remove the Auto-Negotiation settings from the configuration, but the system simply ignores the configuration because Auto-Negotiation settings are irrelevant to a 10 GbE transceiver. The system preserves the saved configuration for Auto-Negotiation when re-saved no matter which speed of transceiver you install.

25 GbE Port Considerations

25 GbE ports typically support 25 Gbps, 10 Gbps, and 1 Gbps operational speeds. Auto-Negotiation support varies depending on the pluggable type and speed.

The following table provides a summary of Auto-Negotiation support for 25 Gbps ports.

Table 64: 25 Gbps Port Auto-Negotiation

Transceiver Type	Auto-Negotiation
25 Gbps DAC	Supported Note: Exception: VIM5-2Y and VIM5-4Y do not support Auto-Negotiation at 25 Gbps.
25 Gbps SR, LR, AOC	Not Supported
10 Gbps	Not Supported
1 Gbps	Note: Not Supported for VSP 7400-48Y.

Forward Error Correction (FEC) is a negotiated port attribute for 25 GbE connections that support Auto-Negotiation. For more information, see [Forward Error Correction](#) on page 532.

40 GbE Port Considerations

Auto-Negotiation must be enabled in 40 GbE ports when using 40GbCR4 (copper Direct Attached Cables - DACs) pluggable modules as Clause 73 of the 40 GbE standard lists it as mandatory. Though the links may come up in 40 GbE ports even without Auto-Negotiation, the best practice is to always enable Auto-Negotiation. Otherwise, there might be link instability or FCS errors.

100 GbE Port Considerations

Ensure that you enable Auto-Negotiation for ports with 100GbCR4 modules plugged in.

Although Auto-Negotiation is mandatory as per the 100GbCR4 standard, and this is the default software configuration, you can disable Auto-Negotiation to connect with older systems that do not support it. The system does not support FEC on 100GbCR4 links with Auto-Negotiation disabled.

For more information about FEC, see [Forward Error Correction](#) on page 532.

Auto-Negotiation Advertisements

Auto-Negotiation advertisements use Custom Auto-Negotiation Advertisement (CANA) to control the speed and duplex settings that the interface modules advertise during Auto-Negotiation sessions between Ethernet devices. Modules can only establish links using these advertised settings, rather than at the highest common supported operating mode and data rate.

Use CANA to provide smooth migration from 10 Mbps to 10000 Mbps on host and server connections. Using Auto-Negotiation only, the switch always uses the fastest possible data rates. In limited-uplink-bandwidth scenarios, CANA provides control over negotiated access speeds, and improves control over traffic load patterns.

Use the **auto-negotiation-advertisements** command to configure CANA.

To use CANA, you must enable Auto-Negotiation.

Important

If a port belongs to a MultiLink Trunking (MLT) group and you configure CANA on the port (that is, you configure an advertisement other than the default), you must apply the same configuration to all other ports of the MLT group if they support CANA.

The following platforms support full duplex and half duplex modes for CANA:

Platform	Full duplex	Half duplex
VSP 4450 Series	Yes	Yes
VSP 4900 Series	Yes	Supported at 100Mbps on VSP4900-48P and first 12 ports of VSP4900-12MXU-12XE.
VSP 7200 Series	Yes	No
VSP 7400 Series	Yes	No
VSP 8200 Series	Yes	No

Platform	Full duplex	Half duplex
VSP 8400 Series (includes 8424XT, 8418XTQ, and 8424GT ESMs)	Yes	No
VSP 8600 Series	Yes	No
XA1400 Series	Yes	Yes Supported on ports 1/1-1/4 only.

SynOptics Network Management Protocol

Table 65: SONMP product support

Feature	Product	Release introduced
SONMP	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50

The switch supports an auto-discovery protocol known as the SynOptics Network Management Protocol (SONMP). SONMP allows a network management station (NMS) to formulate a map that shows the interconnections between Layer 2 devices in a network. SONMP is also called Topology Discovery Protocol (TDP).

All devices in a network that are SONMP-enabled send hello packets to their immediate neighbors, that is, to interconnecting Layer 2 devices. A hello packet advertises the existence of the sending device and provides basic information about the device, such as the IP address and MAC address. The hello packets allow each device to construct a topology table of its immediate neighbors. A network management station periodically polls devices in its network for these topology tables, and then uses the data to formulate a topology map.

If you disable SONMP, the system stops transmitting and acknowledging SONMP hello packets. In addition, the system removes all entries in the topology table except its own entry. If you enable SONMP, the system transmits a hello packet every 12 seconds. The default status is enabled.

SONMP for the Segmented Management Instance

SONMP and LLDP both advertise the same topology IP address for the Segmented Management Instance management interface. SONMP supports IPv4 advertisement only. If all three management interfaces are configured, the advertised default topology IP priority is management CLIP, then management VLAN, then management OOB. You can change the default topology IP using CLI or EDM. If multiple IPv4 addresses are configured on an OOB or VLAN management interface, the advertised IP priority is static IP address, then DHCP IP address, then link-local IP address.

Channelization

Table 66: Channelization product support

Feature	Product	Release introduced
Channelization of 40 Gbps ports	VSP 4450 Series	Not Applicable
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0 VSP 7432CQ only
	VSP 8200 Series	VOSS 4.2
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 6.1
	XA1400 Series	Not Applicable
Channelization of 100 Gbps ports	VSP 4450 Series	Not Applicable
	VSP 4900 Series	Not Applicable
	VSP 7200 Series	Not Applicable
	VSP 7400 Series	VOSS 8.0 VSP 7432CQ only
	VSP 8200 Series	Not Applicable
	VSP 8400 Series	Not Supported
	VSP 8600 Series	VSP 8600 6.2
	XA1400 Series	Not Applicable

Use the channelization feature to configure a single port to operate as four individual ports. Channelization can apply to the following port speeds:

- 40 Gbps (Quad Small Form-factor Pluggable) (QSFP+) — when channelized, operates as four 10 Gbps ports
- 100 Gbps (QSFP28) — when channelized, operates as four 25 Gbps ports

Note

In cases where the hardware supports it, you can insert a 40 Gbps QSFP+ transceiver in a 100 Gbps port, and use the 100 Gbps port as a 40 Gbps port. If you enable channelization on a 100 Gbps port and the switch detects a 40 Gbps QSFP+ transceiver in the port, the port operates as four individual 10 Gbps ports.

If the switch detects a 100 Gbps QSFP28 transceiver and you enable channelization, the port operates as four 25 Gbps ports.

To know if you can use a 100 Gbps port as a 40 Gbps port and support the channelization of that port, see the applicable hardware documentation.

You can use breakout direct attach cables (DAC) or transceivers with fiber breakout cables to connect the channelized ports to other servers, storage, and switches.

By default, the ports are not channelized, which means that the ports operate as one single port at the fully supported speed. You can enable or disable channelization on a port.

For the number of ports on the switch that support channelization, see the applicable hardware documentation.

If the product supports channelization and you enable or disable channelization on a port, the port QoS configuration resets to default values. For information about configuring QoS values, see [Quality of Service](#) on page 2648.

Note

When you use channelized ports in an Split Multi-Link Trunking (SMLT) configuration, the system does not display the channelized ports properly when you show MLT information for the remote port member if the remote switch runs a release that does not support channelization.

When a port is channelized, use only break out cables (copper or active optical DAC) in it. Using other cables in either a channelized port or a non-channelized port results in mismatched link status between link partners, which can lead to network issues.

Feature Interaction with Channelization

Software features operate on channelized ports. When an interface is dechannelized, the interface cleans up all the channels.

If a feature operates on channel 1/1/1 and 1/1/2, and the circuit is dechannelized, the 1/1/1 configuration is saved and the commands are configured on 1/1. The configuration on 1/1/2 is deleted.

Forward Error Correction

Table 67: Forward Error Correction product support

Feature	Product	Release introduced
Forward Error Correction (FEC) (configurable)	VSP 4450 Series	Not Applicable
	VSP 4900 Series	VOSS 8.1 VIM5-4YE at 25 Gbps
	VSP 7200 Series	Not Applicable
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	Not Supported
	VSP 8400 Series	VOSS 8.0
	VSP 8600 Series	VSP 8600 6.2
	XA1400 Series	Not Applicable

Forward Error Correction (FEC) is a method of obtaining error control in data transmission over an unreliable or noisy channel in which the source (transmitter) encodes the data in a redundant way by using an error correcting code (ECC). This redundancy enables a destination (receiver) to detect a limited number of errors and correct them without requiring a re-transmission.

FEC is useful where re-transmitting data is either expensive or impossible, for example, when transmitting to multiple receivers in multicast. However, although FEC provides more error control, it introduces a latency in data transmission.

FEC Configuration Options

You typically configure FEC on a port. The supported options are:

- cl91 (Clause 91 RS-FEC)
- cl108 (Clause 108 RS-FEC):
- cl74 (Clause 74 Firecode R-FEC):
- auto:

FEC is not supported on:

- Out-of-band (OOB) management ports.
- 100 GbE ports that are changed to 40 GbE ports by dynamically swapping 100 Gb modules with 40 Gb modules. FEC does not support the 40 Gbps speed.

Important

- On ports that support FEC configuration, ensure that you configure the same option at both end-points. Otherwise, the link does not come up.
- You must enable FEC to achieve proper functionality when using interconnects such as the 25Gb SR, 25 Gb SR-lite, 25 Gb ESR optics or the 25 Gb AOC and 25 Gb DAC.
- FEC is not required on 100 Gb or 25 Gb long-range optics because these optics do error checking internally.

Clause 91 RS-FEC

This option supports both the 25 Gbps and 100 Gbps speeds. You can configure this option on ports with either the 100GbSR4 or 100GbCR4 modules plugged in, or on 100 GbE channelized ports operating at 25Gbps speed.

Note

Ensure that you enable Auto-Negotiation for ports with the 100GbCR4 modules plugged in; it is mandatory.

Clause 108 RS-FEC

This option also supports both the 25 Gbps and 100 Gbps speeds. It is similar to Clause 91 but provides extra latency.

Clause 74 Firecode R-FEC

This option supports only the 25 Gbps speed and is used in applications that require reduced latency.

Auto

This option automatically configures FEC based on port speed and pluggable module type.

- For 25 Gbps speeds, FEC CL108 is enabled for all transceiver types.

- For 100Gbps speeds:
 - FEC is disabled for 100GbE LR4 and ER4 transceivers.
 - FEC CL91 is enabled for all other transceiver types (for example, 100GbE SR4, CR4, AOC, CWDM4, SWDM4).

FEC and Auto-Negotiation

FEC is a negotiated port attribute for 25 Gb and 100 Gb connections that support Auto-Negotiation. If you enable Auto-Negotiation on a port for a supported transceiver type, the switch uses the configured FEC value in the negotiation advertisement. Peers can advertise different values, which means the resulting FEC operational state can be different than the one advertised.

The following table lists the 25 Gb end-point advertisements and the resulting FEC operational state:

Table 68: 25 Gb end-point advertisements

Peer A	Peer B	Result
CL108	CL108	CL108
CL74	CL74	CL74
No FEC	No FEC	No FEC
No FEC	CL108	CL108
No FEC	CL74	CL74
CL74	CL108	CL108

The following table lists the 100 Gb end-point advertisements and the resulting FEC operational state:

Table 69: 100 Gb end-point advertisements

Peer A	Peer B	Result
CL91	CL91	CL91
No FEC	No FEC	CL91 Note: Even when both peers advertise no FEC, negotiation results in clause 91 FEC per IEEE standard mandatory setting.
No FEC	CL91	CL91

You can use the **show interfaces gigabitEthernet config** command to see the FEC operational state for a port.

For additional details about support, see [Default Auto-Negotiation Behavior](#) on page 525.

IEEE 802.3X Pause Frame Transmit

Table 70: IEEE 802.3X Pause Frame Transmit product support

Feature	Product	Release introduced
IEEE 802.3X Pause frame transmit	VSP 4450 Series	VOSS 6.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 6.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.0
	VSP 8400 Series	VOSS 6.0
	VSP 8600 Series	Not Supported
	XA1400 Series	VOSS 8.1.50

The switch uses MAC pause frames to provide congestion relief on full-duplex interfaces.

Overview

When congestion occurs on a port, the system can send or receive pause frames, also known as flow control, to temporarily pause the packet flow. The system uses flow control if the rate at which one or more ports receives or sends packets is greater than the rate the switch can process or accept the packets.

The switch can generate pause frames to tell the sending device to stop sending additional packets for a specified time period. After the time period expires, the sending device can resume sending packets. During the specified time period, if the switch determines the congestion is reduced, it can send pause frames to the sending device to instruct it to begin sending packets immediately.

Flow control mode and pause frames

If you enable flow control mode, the switch drops packets on ingress when congestion occurs. If the switch is not in flow control mode, it drops packets at egress when congestion occurs.

Configure an interface to send pause frames when congestion occurs to alleviate packet drops due to flow control mode.

Auto-Negotiation

Interfaces that support auto-negotiation advertise and exchange their flow control capability to agree on a pause frame configuration. IEEE 802.3 annex 28b defines the auto-negotiation ability fields and the

pause resolution. The switch advertises only two capabilities. The following table shows the software bit settings based on the flow control configuration.

Note

Not all interfaces support Auto-Negotiation. For more information, see your hardware documentation.

Table 71: Advertised abilities

Interface configuration	Pause	ASM	Capability advertised
Flow control enabled	1	0	Symmetric pause
Flow control disabled	1	1	Both Symmetric pause and asymmetric pause

The following tables identifies the pause resolution.

Table 72: Pause resolution

Local device pause	Local device ASM	Peer device pause	Peer device ASM	Local device resolution	Peer device resolution
0	0	Do not care	Do not care	Disable pause transmit and receive.	Disable pause transmit and receive.
0	1	0	Do not care	Disable pause transmit and receive.	Disable pause transmit and receive.
0	1	1	0	Disable pause transmit and receive.	Disable pause transmit and receive.
0	1	1	1	Enable pause transmit. Disable pause receive.	Disable pause transmit. Enable pause receive.
1	0	0	Do not care	Disable pause transmit and receive.	Disable pause transmit and receive.
1	Do not care	1	Do not care	Enable pause transmit and receive.	Enable pause transmit and receive.
1	1	0	0	Disable pause transmit and receive.	Disable pause transmit and receive.
1	1	0	1	Disable pause transmit. Enable pause receive.	Enable pause transmit. Disable pause receive.

The following list identifies the type of interfaces that support auto-negotiated flow control:

- 10 Mbps/100 Mbps/1 Gbps copper
- 100 Mbps/1 Gbps/10 Gbps copper
- 1 Gbps fiber (in both SFP and SFP+ ports)

Auto MDIX

Automatic medium-dependent interface crossover (Auto-MDIX) automatically detects the need for a straight-through or crossover cable connection and configures the connection appropriately. This removes the need for crossover cables to interconnect switches and ensures either type of cable can be used. The speed and duplex setting of an interface must be set to Auto for Auto-MDIX to operate correctly.

Auto MDIX is supported on all platforms with fixed copper ports. All fixed copper ports are supported.

IOC Module Preconfiguration

Table 73: IOC Module Preconfiguration

Feature	Product	Release introduced
IOC Module Preconfiguration	VSP 4450 Series	Not Applicable
	VSP 4900 Series	Not Applicable
	VSP 7200 Series	Not Applicable
	VSP 7400 Series	Not Applicable
	VSP 8200 Series	Not Applicable
	VSP 8600 Series	VSP 8600 8.0
	XA1400 Series	Not Applicable

Using IOC Module Pre-Configuration, you can configure a slot for an IOC Module before you insert the module in the chassis. By specifying the slot and module type, all configuration at the slot or port level become available for that slot. You can issue configuration commands for a specific slot before you insert an IOC Module in that slot.

When you insert the IOC Module that matches the pre-configured module type in the specified slot, all configuration related to that slot is applied, and pre-configuration loads on the IOC Module automatically. However, if the module type of the inserted IOC Module does not match the module type of the IOC Module Pre-Configuration, then the IOC module functionality depends on the following card lock configurations:

- If the card lock option is enabled, the inserted IOC Module is rejected and does not boot up. Only modules that are of same type as the IOC Module Pre-Configuration type for the slot are able to boot up on that slot. The output of the **show sys-info** command displays the operational status of the inserted module as `down-Mismatch`.
- If the card lock option is disabled, existing configuration is removed on that slot and a new IOC Module is accepted and boots up with default configuration.

When you remove an IOC Module from the chassis, all configuration on that slot is still available because the module was automatically pre-configured on that slot. You can view the configuration for the module by using the **show sys-info** card command. You can also change the configuration for an IOC Module that has been removed from the chassis. When you save the configuration, the configuration for all slots is saved regardless of which modules are plugged into the chassis.

Hotswapping IOC Modules

If a preconfigured IOC Module is replaced with a model that does not match the preconfigured IOC Module type and the card lock is enabled, then the IOC Module does not boot up. Either a module of the same type as the preconfigured IOC Module must be reinserted in the slot or the pre-configured IOC Module type must be removed from the configuration.

**Important**

Removing the preconfigured IOC Module type from the configuration also removes the configuration for the slot.

When a new IOC Module is inserted in the slot, the module boots with default configuration. If a module is inserted into a running system and the module type is not configured for the slot, the system automatically creates a preconfiguration with the module type of the IOC Module that was inserted. Then the module boots with default configuration.

Chassis operations configuration using the CLI

This section provides the details to configure basic hardware and system settings.

Enabling the High Availability-CPU (HA-CPU) mode

About This Task

Enable High Availability-CPU (HA-CPU) mode to enable devices with two CPUs to recover quickly from a failure of the master CPU.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the following boot flag:

```
boot config flags ha-cpu
```

The configuration file is saved on both the CPUs. After you disable HA mode on the master CPU, the secondary CPU software automatically resets and loads the settings from the previously-saved configuration file.

3. Type `y` after displaying the following prompt:

```
Do you want to continue (y/n) ?
```

Responding to the user prompt with a `y` causes the secondary CPU to reset itself automatically, and that secondary CPU restarts with HA mode enabled.

4. Save the configuration.

Example

```
Switch:1>enable  
Switch:1#configure terminal
```

Enable HA mode:

```
Switch:1(config)#boot config flags ha-cpu
The config files on the Master and Slave will be overwritten with the current active
configuration.
-Layer 2/3 features will be enabled in L2/L3 redundancy mode.
Do you want to continue (y/n)?y
Boot configuration is being saved.
CP-1: Save config to file /intflash/config.cfg successful.
CP-2: Save /intflash/config.cfg to standby successful.
Runtime configuration is being saved.
Resetting Slave CPU from Master CPU.
CP1 [01/07/17 15:21:50.605:UTC] 0x000045e3 00000000 GlobalRouter SNMP INFO Save config
successful.
CP2 [01/07/17 15:22:16.890:UTC] 0x000105e3 00000000 GlobalRouter HW INFO HA-CPU: Table
Sync is complete (Standby CPU)
CP1 [01/07/17 15:22:17.407:UTC] 0x000105c8 00000000 GlobalRouter HW INFO HA-CPU: Table
Sync Completed on Secondary CPU
```

Verify the configuration:

```
Switch:1(config)#show ha-state
Current CPU State : Synchronized State.
Last Event : Table synchronization completed.
Mode : Warm Standby

Card Info :
      Slot#      CardType      Oper      Admin      Power
              Status      Status      State
          1      8624XS      up-Master      up      on
          2      8624XS      up-Warmstandby      up      on

Current Boot Config State: master 1
```

Save the configuration:

```
Switch:1(config)#save config
```

What to Do Next

Note

In HA-CPU mode, whenever there is a mismatch of boot config flags between the master CPU and the standby CPU, the standby CPU follows the master CPU. The mismatch could be due to different runtime config files or primary config files at standby CPU. Once the chassis boots up successfully on the switch, ensure that both the CPUs run the same primary config file and the running config file.

Disabling the High Availability-CPU (HA-CPU) Mode

About This Task

Perform this procedure to disable HA mode.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal

2. Enter the following boot flag command:

```
no boot config flags ha-cpu
```

The configuration file is saved on both the CPUs. After you enable HA mode on the master CPU, the secondary CPU software automatically synchronizes the configuration from the master CPU.

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Disable HA mode:

```
Switch:1(config)#no boot config flags ha-cpu
The config files on the Master and Slave will be overwritten with the current active
configuration.
-No longer Layer 2/3 features run in L2/L3 redundancy mode.
Do you want to continue (y/n) ? y
Boot configuration is being saved.
CP-1: Save config to file /intflash/config.cfg successful.
CP-2: Save /intflash/config.cfg to standby successful.
Resetting Slave CPU from Master CPU.
```

Verify the configuration:

```
Switch:1(config)#show ha-state
Current CPU State : Disabled State.
Last Event : No event.
Mode : Warm Standby

Card Info :
      Slot#      CardType      Oper      Admin      Power
                Status      Status      State
          1      8624XS      up-Master      up      on
          2      8624XS      up-Warmstandby      up      on

Current Boot Config State: master 1
```

Removing an IOC Module with HA Mode Activated

About This Task

Perform this procedure to properly remove the IOC module that is in the master CP slot, when the system operates in HA mode.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Use the `sys action cpu-switch-over` command to fail over to another CP.
3. Remove the IOC module.

Important

Do not reinsert an IOC module until at least 15 seconds has elapsed, which is long enough for another CP slot to become master.

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys action cpu-switch-over
```

Enabling jumbo frames

About This Task

Enable jumbo frames to increase the size of Ethernet frames the chassis supports.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Enable jumbo frames:
sys mtu <1522-9600>

Example

```
Switch:1> enable
Switch:1# configure terminal
Enable jumbo frames to 9600 bytes:
Switch:1#(config)# sys mtu 9600
```

Variable Definitions

The following table defines parameters for the **sys mtu** command.

Variable	Value
<1522-9600>	Configures the frame size support for the data path. Possible sizes are 1522, 1950, or 9600 bytes. The default is 1950 bytes.

Configuring port lock

About This Task

Configure port lock to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify a locked port until you unlock the port.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal

2. Enable port lock globally:

```
portlock enable
```
3. Log on to GigabitEthernet Interface Configuration mode:

```
interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```
4. Lock a port:

```
lock port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} enable
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Log on to GigabitEthernet Interface Configuration mode:

```
Switch:1(config)# interface GigabitEthernet 1/1
```

Unlock port 1/14:

```
Switch:1(config-if)# no lock port 1/14 enable
```

Variable Definitions

The following table defines parameters for the **interface gigabitethernet** and **lock port** commands.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. For the <code>lock port</code> command, use the no form of this command to unlock a port: <code>no lock port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>

Configuring SONMP

About This Task

Configure the SynOptics Network Management Protocol (SONMP) to allow a network management station (NMS) formulate a map that shows the interconnections between Layer 2 devices in a network. The default status is enabled.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Disable SONMP:
no autotopology
3. Enable SONMP:
autotopology

Example

```
Switch:1> enable

Switch:1 configure terminal

Disable SONMP:

Switch:1 (config)# no autotopology
```

View the Topology Message Status

About This Task

View topology message status to view the interconnections between Layer 2 devices in a network.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the contents of the topology table:
show autotopology nmm-table

Unless the switch is physically connected to other devices in the network, this topology will be blank.

Example**Note**

In the following example, the column “ChassisType” uses a generic name. When you use the **show autotopology nmm-table**, your switch displays the actual chassis type.

```
Switch:1 (config)#show autotopology nmm-table
```

```
=====
                          Topology Table
=====
```

Local Port	IpAddress	SegmentId	MacAddress	ChassisType	BT	LS	CS	Rem Port
0/0	192.0.2.81	0x000000	0030ab707a00	ChassisType 1	12	Yes	HtBt	0/0
1/1	192.0.2.81	0x000000	0050ea268800	ChassisType 2	12	Yes	HtBt	1/50
1/42	192.0.2.81	0x000000	070ab307aa00	ChassisType 3	12	Yes	HtBt	1/1
2/1	192.0.2.81	0x000000	0030ab57ab00	ChassisType 4	12	Yes	HtBt	1/49
2/2	192.0.2.81	0x000000	0030ab307af0	ChassisType 5	12	Yes	HtBt	1/50

2/41	192.0.2.81	0x000000	00e0ba327c00	ChassisType 6	12	Yes	HtBt	2/1
2/42/1	192.0.2.81	0x000000	0050eb127400	ChassisType 7	12	Yes	HtBt	1/2

**Note**

When a peer switch is running an older software version that does not include support for SONMP hello messages with channelization information, it can only show the slot/port. It cannot show the sub-port.

Associating a port to a VRF instance

Associate a port to a Virtual Router Forwarding (VRF) instance so that the port becomes a member of the VRF instance.

Before You Begin

- The VRF instance must exist. For more information about the creation of VRFs, see [Create a VRF Instance](#) on page 3836.

About This Task

You can assign a VRF instance to a port after you configure the VRF. The system assigns ports to the Global Router, VRF 0, by default.

Procedure

- Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Associate a VRF instance with a port:

```
vrf <WORD 1-16>
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# interface gigabitethernet 1/12
```

```
Switch:1(config-if)# vrf red
```

Configure an IP Address for the Management Port

Note

This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management](#) on page 67.

Configure an IP address for the management port so that you can remotely access the device using the out-of-band (OOB) management port. The management port runs on a dedicated VRF.

The configured IP subnet has to be globally unique because the management protocols can go through in-band (Global Router) or out-of-band ports (Management VRF).

Before You Begin

- Do not configure a default route in the Management VRF.
- If you want out-of-band management, define a specific static route in the Management Router VRF to the IP subnet where your management application resides.
- If you initiate an FTP session from a client device behind a firewall, you should set FTP to passive mode.
- The switch gives priority to out-of-band management when there is reachability from both in-band and out-of-band. To avoid a potential conflict, do not configure an overlap between in-band and out-of-band networks.

Procedure

1. Enter mgmtEthernet Interface Configuration mode:

```
enable  
  
configure terminal  
  
interface mgmtEthernet <mgmt | mgmt2>
```
2. Configure the IP address and mask for the management port:

```
ip address {<A.B.C.D/X> | <A.B.C.D> <A.B.C.D>}
```
3. Configure an IPv6 address and prefix length for the management port:

```
ipv6 interface address WORD<0-255>
```
4. Show the complete network management information:

```
show interface mgmtEthernet
```
5. Show the management interface packet/link errors:

```
show interface mgmtEthernet error
```
6. Show the management interface statistics information:

```
show interface mgmtEthernet statistics
```

Example

Configure the IP address for the management port:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface mgmtethernet mgmt  
Switch:1(config-if)#ip address 192.0.2.24 255.255.255.0
```

Variable Definitions

The following table defines parameters for the **ip address** command.

Variable	Value
{<A.B.C.D/X> <A.B.C.D> <A.B.C.D>}	Specifies the IP address followed by the subnet mask.

The following table defines parameters for the **ipv6 interface address** command.

Variable	Value
WORD<0-255>	Specifies the IPv6 address and prefix length.

Configure Ethernet Ports with Auto-Negotiation

Configure Ethernet ports so they operate optimally for your network conditions.

About This Task

When you use 1 Gigabit Ethernet SFP transceivers, the software disables Auto-Negotiation on the port. If you use 1 Gbps SFP transceivers, the remote end must also have Auto-Negotiation disabled.

All ports that belong to the same MLT or Link Aggregation Control Protocol (LACP) group must use the same port speed. In the case of MLTs, the software does not enforce this.

The software requires the same Auto-Negotiation settings on link partners to avoid incorrect declaration of link status. Mismatched settings can cause the links to stay down. Ensure the Auto-Negotiation settings between local ports and their remote link partners match before you upgrade the software.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Auto-Negotiation:

```
auto-negotiate [port {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]] enable
```

3. Verify the configuration:

```
show interfaces gigabitEthernet ll-config [{slot/port[/sub-port] [-  
slot/port[/sub-port]] [,...]]
```

Example

```
Switch:>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/8
Switch:1(config-if)#auto-negotiate enable
Switch:1(config-if)#show interfaces gigabitEthernet 1/8
=====
Port Config L1
=====
PORT      AUTO  OPERATE  CUSTOM AUTO  NEGOTIATION  CANA   ADMIN      OPERATE  ADMIN      OPERATE
NUM      NEG.  AUTO-NEG  ADVERTISEMENTS  ORIGIN  DPLX  SPD   DPLX  SPD   TX-FLW-CTRL  TX-FLW-CTRL
-----
1/8      true  true     Not Configured  RADIUS  full  10000  0     enable  enable
```

Variable Definitions

The following table defines parameters for the **auto-negotiate** command.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Specifies the port or ports that you want to configure.
<i>enable</i>	Enables auto-negotiation for the port or other ports of the module. The default Auto-Negotiation behavior depends on the switch model and transceiver type.

Configure Auto-Negotiation Advertisements

Configure local port Auto-Negotiation advertisements to specify the speed and duplex mode for traffic between local ports and remote link partners. Supported speeds and duplex modes vary, depending on your hardware.

Before You Begin

You must enable Auto-Negotiation before you perform this procedure.

About This Task

Configure local port Auto-Negotiation advertisements.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure Auto-Negotiation advertisements on one or more ports:

```
auto-negotiation-advertisements {25000-full|10000-full|2500-full|5000-
full|1000-full|100-full|100-half|10-full|10-half}
```

or

```
auto-negotiation-advertisements port {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]} {25000-full|10000-full|2500-full|5000-full|
1000-full|100-full|100-half|10-full|10-half}
```

- Verify the configuration:

```
show interfaces gigabitEthernet 11-config [{slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]}
```

Variable Definitions

The following table defines parameters for the **auto-negotiation-advertisements** command.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Specifies the port or ports that you want to configure.
<i>25000-full</i>	Advertises 25 Gbps full-duplex.
<i>10000-full</i>	Advertises 10 Gbps full-duplex.
<i>5000-full</i>	Advertises 5 Gbps full-duplex.
<i>2500-full</i>	Advertises 2.5 Gbps full-duplex.
<i>1000-full</i>	Advertises 1 Gbps full-duplex.
<i>100-full</i>	Advertises 100 Mbps full-duplex.
<i>100-half</i>	Advertises 100 Mbps half-duplex.
<i>10-full</i>	Advertises 10 Mbps full-duplex.
<i>10-half</i>	Advertises 10 Mbps half-duplex.
<i>none</i>	Configures the Auto-Negotiate value to none.

Configure IEEE 802.3X Pause Frame Transmit

Configure IEEE 802.3X Pause frame transmit to eliminate or minimize packet loss.

About This Task

By default, flow control mode is disabled. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.

By default, an interface does not send pause frames.

Note

If you enable MACsec on an interface and you send small packet size traffic near line rate, the **In FlowCtrl** frame might increment in the output of the **show interface gigabitEthernet statistics** command because of the processing overhead caused by adding the MACsec header of 32 bytes. This is part of the expected over-subscription footprint.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable flow control mode:

```
boot config flags flow-control-mode
```

3. Save the configuration.

4. Exit Privileged EXEC mode:

```
exit
```

5. Reboot the chassis.

```
boot
```

6. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

7. Configure the interface to generate pause frames:

```
tx-flow-control [enable]
```

8. (Optional) Configure other interfaces to generate pause frames:

```
tx-flow-control port {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} enable
```

9. Verify the boot flag configuration:

```
show boot config flags
```

10. Verify the interface configuration:

```
show interfaces gigabitEthernet ll-config {slot/port[/sub-port] [-  
slot/port[/sub-port]] [,...]}
```

11. View the pause-frame packet count:

```
show interfaces gigabitEthernet statistics {slot/port[/sub-port] [-  
slot/port[/sub-port]] [,...]}
```

Example

Enable flow control on the system and configure slot 1, port 10 to send pause frames. Verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags flow-control-mode
Warning: Please save the configuration and reboot the switch
        for this configuration to take effect.
Switch:1<config>#save config
CP-1: Save config to file /intflash/config.cfg successful.
CP-1: Save license to file /intflash/license.xml successful.
Switch:1<config>#exit
Switch:1#boot
Are you sure you want to re-boot the switch (y/n) ?y
```

Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags

Variable Definitions

The following table defines parameters for the **tx-flow-control** command.

Variable	Value
<i>enable</i>	Configures the interface to send pause frames. By default, flow control is disabled. Note: tx-flow-control is enabled by default on XA1400 Series.
<i>port {slot/ port[/sub- port] [-slot/ port[/sub- port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Use the data in the following table to use the **show interfaces gigabitEthernet ll-config** and **show interfaces gigabitEthernet statistics** commands.

Variable	Value
<i>{slot/port[/ sub-port] [- slot/port[/sub- port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Enable Channelization

Enable channelization on a port to configure it to operate as four channels, or ports.

Important

Enabling or disabling channelization resets the port QoS configuration to default values.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable channelization on a port:

```
channelize [port {slot/port[-slot/port] [,...]}] enable
```

3. Display the status of the ports:

```
show interfaces gigabitEthernet channelize [{slot/port[-slot/port]
[,...]}]
```

To display the details of the sub-ports, use:

```
show interfaces gigabitEthernet channelize detail [{slot/port/sub-
port[-slot/port/sub-port] [,...]}]
```

4. (Optional) To disable channelization on a port, enter:

```
no channelize [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}] enable
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitEthernet 2/1
Switch:1(config-if)# channelize enable
Enabling channelization on port 2/1. Subport 2/1/1 will inherit port 2/1 configuration.
Subports 2,3,4 will use default config. QSFP will be reset as removal and re-insert.
NOTE: Modify QOS configurations on all subports as required.
Do you wish to continue (y/n) ? y
```

Display the port status:

```
Switch:1(config)# show interfaces gigabitEthernet channelize 2/2-2/4
```

```
=====
                        Port Channelization
=====
-----
PORT          ADMIN MODE    CHANNEL TYPE
-----
2/2           true          40G
2/3           false         40G
2/4           false         40G
```

The following is an example of how to disable channelization on a port:

```
Switch:1> enable
Switch:1# configure terminal
```

```
Switch:1(config)# interface gigabitethernet 2/2/1
Switch:1(config-if)# no channelize enable
```

Variable Definitions

The following table defines parameters for the **channelization** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configure FEC on a Port

About This Task

Use this procedure to configure Forward Error Correction (FEC) on supported ports.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. (Optional) Specify the port or ports to configure for FEC:

```
fec port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

3. Configure FEC on a port:

```
fec {auto | c1108 | c174 | c191}
```

4. Verify the configuration:

```
show interfaces gigabitEthernet config {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

Examples

Configure Clause 108 FEC on a 25 Gbps port 1/1:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 1/1
Switch:1(config-if)#fec c1108
```

Verify the configuration when a 25 Gbps optic is present:

```
Switch:1(config-if)#show interfaces gigabitEthernet config 1/1
=====
                        Port Config
=====
PORT          DIFF-SERV   QOS   MLT   VENDOR
NUM          TYPE      EN    TYPE  LVL   ID    NAME
-----
1/1          25GbCX    true  core  1     0     Extreme
=====
                        Port Config
=====
PORT  ADMIN  OPERATE AUTO  ACCESS-SERV  RMON  FLEX-UNI  ADMIN  APPLICABLE  OPERATE
NUM   ROUTING ROUTING RECOVER  EN          FLEX-UNI  FEC    FEC          FEC
-----
1/1   Enable  Disable Disable false          Disable  Disable  Auto  CL108      CL108
```

Verify the configuration when a 10 Gb optic is present in a 25 Gb port:

```
Switch:1(config-if)#show interfaces gigabitEthernet config 1/1
=====
                        Port Config
=====
PORT          DIFF-SERV   QOS   MLT   VENDOR
NUM          TYPE      EN    TYPE  LVL   ID    NAME
-----
1/1          10GbSR    true  core  1     0     Extreme
=====
PORT  ADMIN  OPERATE AUTO  ACCESS-SERV  RMON  FLEX-UNI  ADMIN  APPLICABLE  OPERATE
NUM   ROUTING ROUTING RECOVER  EN          FLEX-UNI  FEC    FEC          FEC
-----
1/1   Enable  Disable Disable false          Disable  Disable  Auto  Not Applicable  Off
```

Variable Definitions

The following table defines parameters for the **fec** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>{auto c1108 c174 c191}</code>	<p>Configures one of the following options for FEC on the port:</p> <ul style="list-style-type: none"> • auto • Clause 91 • Clause 108 • Clause 74 <p>Note: On a 100 GbE port, only the Clause 91 and Clause 108 options are supported. On 100 GbE channelized ports (operating at 25 Gbps speed), you can configure Clause 108 for extra latency or Clause 74 for reduced latency. Configuration of FEC is not supported on a management port or on 100 GbE ports operating at 40 Gbps speed.</p> <p>Important: On ports that support FEC, always configure the same option on both end-points. Otherwise, the link does not come up.</p>

Configuring Serial Management Port Dropping

Configure the serial management ports to drop a connection that is interrupted for any reason. If you enable serial port dropping, the serial management ports drop the connection for the following reasons:

- modem power failure
- link disconnection
- loss of the carrier

Serial ports interrupted due to link disconnection, power failure, or other reasons force out the user and end the user session. Ending the user session ensures a maintenance port is not available with an active session that can allow unauthorized use by someone other than the authenticated user, and prevents the physical hijacking of an active session by unplugging the connected cable and plugging in another.

By default, the feature is disabled with enhanced secure mode disabled. If enhanced secure mode is enabled, the default is enabled.

For more information on enhanced secure mode, see [Enabling enhanced secure mode](#) on page 3337.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Configure the serial port to drop if a connection is interrupted:
`sys security-console`

Example

Configure the serial port to drop if a connection is interrupted:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys security-console
```

Configuring power on module slots

About This Task

Use this procedure to control whether or not to supply power to specific slots that contain either switch fabric modules or input/output modules. By default, power is available to all slots.

After enabling power to specific input/output module slots, you can also configure the priority in which they are powered on. For more information, see [Configuring Slot Priority](#) on page 557.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable power to one or more slots:
`sys power slot <1-4 | 1-8 | SF1-SF3>`
3. Disable power to one or more slots:
`no sys power slot <1-4 | 1-8 | SF1-SF3>`

Example

```
Switch:1>enable

Switch:1#configure terminal

Enable power to Slot 1:

Switch:1 (config)#sys power slot 1

Disable power to Slot 1:

Switch:1 (config)#no sys power slot 1
```

Enable power to Slots 3 and 5:

```
Switch:1(config)#sys power slot 3,5
```

Disable power to Slots 3 and 5:

```
Switch:1(config)#no sys power slot 3,5
```

Variable Definitions

The following table defines parameters for the **sys power slot** command.

Variable	Value
<1-4 1-8 SF1-SF3>	Identifies the slot to provide power in one of the following formats: a single slot (1), a range of slots (1-3), or a series of slots (1,2,4). The default is to provide power to all slots. Use the <code>no</code> operator to disable power to a slot. Use the <code>default</code> operator to enable power to a slot. Different hardware platforms support different slot ranges. Use the CLI Help to see the available range.

Configuring Slot Priority

Note

This procedure only applies to VSP 8600 Series.

About This Task

Configure slot priority to specify which slots you want to shut down if there is insufficient power available in the chassis. By default, power is available to all slots, and the slots have the following priority:

- Slots 1, 2, SF1, SF2, and SF3 must always be *Critical* so you cannot configure them.
- Slots 3-8 are *High* by default, but you can configure any of them to *Low*.

Note

Power is always supplied to critical slots first which are the CP modules, SF modules, and fan trays.

The slot with the lowest priority shuts down first. Slots with the same priority shut down in descending order (highest slot number first) and interface slots shut down before CP, SF modules, and fan tray slots.

For example, if slot 3 has a `low` priority and slots 4 and 5 have a `high` priority, the slot shutdown priority is as follows: 4, 5, 3. Slot 3 has the lowest priority because it was configured as `low` so it would be shut down first. Slots 4 and 5 have the same priority, but slot 5 shuts down before slot 4 because slot 4 has a higher slot number.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure slot priority:

```
sys power slot-priority <3-8> {high|low}
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Configure slot priority to determine that slot 3 has a low priority if insufficient power is available for all modules:

```
Switch:1(config)#sys power slot-priority 3 low
```

Variable Definitions

The following table defines parameters for the **sys power slot-priority** command.

Variable	Value
<3-8>	Identifies the module slot.
<i>high</i> <i>low</i>	Specifies whether the module should have a high or low priority setting if there is insufficient power available for all modules. The default is <i>high</i> .

Enable the Locator LED**Note**

This procedure only applies to VSP 4900 Series.

About This Task

Perform this procedure to turn the system Locator LED on to provide a visual identification of a specific switch.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable the system Locator LED:

```
sys locator-led
```
3. Display the system Locator LED status:

```
show sys locator-led
```

Enable or Disable the USB Port

Perform this procedure to control USB access. For security reasons, you may want to disable this port to prevent individuals from using it. By default, the port is automatically mounted when a USB device is inserted.

Before You Begin

- The switch must be in Enhanced Secure mode.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Disable the USB port:

```
sys usb disable
```
- Enable a previously disabled USB port:

```
no sys usb disable
```

Configure Port Speed

About This Task

Manually configure the port speed.

Important

If Auto-Negotiation is disabled and you change the speed on a port that results in a configuration mismatch in speed between two ports, VSP 4450 Series and VSP 4900 Series switches may show an incorrect operational status of "up" for the mismatched ports.

Procedure

- Enter GigabitEthernet Interface Configuration mode:

```
enable

configure terminal

interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure the speed for one or more ports:

```
speed {10|100|1000|10000|2500|25000|5000}
```

or

```
speed port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} {10|
100|1000|10000|2500|25000|5000}
```

Variable Definitions

The following table defines parameters for the **speed** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port or ports that you want to configure.
<code>10</code>	Configures the port speed to 10 Mbps.
<code>100</code>	Configures the port speed to 100 Mbps.
<code>1000</code>	Configures the port speed to 1 Gbps.
<code>10000</code>	Configures the port speed to 10 Gbps.
<code>2500</code>	Configures the port speed to 2.5 Gbps.
<code>25000</code>	Configures the port speed to 25 Gbps.
<code>5000</code>	Configures the port speed to 5 Gbps.

Configure Ports Speeds for All VIM Ports

Note

This procedure only applies to VSP 4900 Series.

Configure all of the ports on an installed Versatile Interface Module (VIM) to operate at the same speed.

Note

Some VIMs must operate with all ports at the same speed, while others can operate with ports at different speeds. For more information, see [VOSS Release Notes](#). The **sys vim-speed** command is supported only on VIMs that must operate with all ports at the same speed. An error message displays if you run the command on an unsupported VIM.

Before You Begin

Install the VIM before performing this procedure.

About This Task

Use this procedure to configure the speed of all ports in a multi-port VIM to operate at either 10 Gbps or 25 Gbps.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the speed for all of the VIM ports:

```
sys vim-speed {10000 | 25000}
```

Variable Definitions

The following table defines parameters for the **sys vim-speed** command.

Variable	Value
10000 25000	Configures all ports in a multi-port VIM to operate at either 10 Gbps or 25 Gbps. The default is 25 Gbps.

Display Ports Speeds for All VIM Ports

Note

This procedure only applies to VSP 4900 Series.

Display the configured speed on all VIM ports.

Note

Some VIMs must operate with all ports at the same speed, while others can operate with ports at different speeds. For more information, see [VOSS Release Notes](#). The **show sys vim-speed** command is supported only on VIMs that must operate with all ports at the same speed. An error message displays if you run the command with an unsupported VIM installed.

Before You Begin

Install the VIM before performing this procedure.

About This Task

Use this procedure to display the configured speed of all ports in a multi-port VIM.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the speed for all of the VIM ports:

```
show sys vim-speed
```

Prepare a slot for IOC Module Preconfiguration using CLI

About This Task

Use this procedure to designate a slot in the switch for IOC module preconfiguration. You can designate a slot for only one module type at a time.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
3. Designate a slot for IOC module preconfiguration:

```
preconfig slot <1-8> WORD<1-20> [lock]
```
4. Verify IOC module preconfiguration:

```
show sys-info card
```

Example

The following examples prepare a slot for IOC module preconfiguration:

Prepare a slot for IOC module preconfiguration, with card lock enabled on the slot.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#preconfig slot 5 8624XT lock
```

Verify the configuration:

```
Switch:1(config)#show sys-info card

Card Info :
  Slot 5 :

      CardType       : 8624XT
      CardDescription : 8624XT
      CardSerial#    : SDNI86XSD282
      CardPart#      : EC8604002-E6
      CardAssemblyDate : 20161125
      CardHWRevision  : D2
      CardHWConfig    : 0
      AdminStatus     : up
      OperStatus      : up
      PowerStatus      : on
      Preconfigured   : yes
      Preconfig CardType: 8624XT
      Preconfig Lock   : yes
```

If card lock is enabled on the slot, and the module type of the inserted IOC module does not match the preconfigured IOC module type (for example, if the inserted module is type 8624XT but the preconfigured module type is 8624XS), then the operational status of the inserted IOC module displays as down-Mismatch.

```
Switch:1(config)show sys-info card

Card Info :
  Slot 5 :

      CardType       : 8624XS
      CardDescription : 8624XS
      CardSerial#    : SDNI86XSD282
      CardPart#      : EC8604002-E6
      CardAssemblyDate : 20161125
```

```

CardHWRevision      : D2
CardHWConfig        : 0
AdminStatus         : down
OperStatus          : down-Mismatch
PowerStatus         : down
Preconfigured       : yes
Preconfig CardType: 8624XT
Preconfig Lock      : yes

```

Prepare another slot for IOC module preconfiguration, with no card lock enabled on the slot.

```

Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.

Switch:1(config)#preconfig slot 6 8624XS

```

Verify the configuration:

```

Switch:1(config)show sys-info card

Card Info :
  Slot 6 :

      CardType           : 8624XS
      CardDescription    : 8624XS
      CardSerial#        : SDNI86XSD282
      CardPart#          : EC8604002-E6
      CardAssemblyDate   : 20161125
      CardHWRevision     : D2
      CardHWConfig       : 0
      AdminStatus        : up
      OperStatus         : up
      PowerStatus        : on
      Preconfigured      : yes
      Preconfig CardType: 8624XS
      Preconfig Lock     : no

```

If card lock is disabled on the slot, and the IOC module type of the inserted card does not match the preconfigured module type, the existing configuration is deleted and the slot is automatically preconfigured with the module type of the inserted IOC module. The inserted module then boots up with default configuration.

In the following example, when the 8624XT module is inserted in a slot preconfigured for the 8624XS, the pre-configuration for the 8624XS is deleted because it is not locked. The slot is then automatically preconfigured for 8624XT when the IOC module is physically inserted in that slot.

```

Switch:1(config)show sys-info card

Card Info :
  Slot 6 :

      CardType           : 8624XT
      CardDescription    : 8624XT
      CardSerial#        : SDNI86XSD282
      CardPart#          : EC8604002-E6
      CardAssemblyDate   : 20161125
      CardHWRevision     : D2
      CardHWConfig       : 0

```

```

AdminStatus      : up
OperStatus       : up
PowerStatus      : on
Preconfigured    : yes
Preconfig CardType: 8624XT
Preconfig Lock   : no

```

Variable Definitions

The following table defines parameters for the **preconfig slot** command.

Variable	Value
<1-8>	Specifies the slot number designated for pre-configuration.
WORD <1-20>	Specifies the card type that can be assigned to the pre-configured slot.
lock	Specifies that the IO card will be locked to the pre-configured slot. Only the IO card that matches the card type assigned to the pre-configured slot will operate.

View the Management Port Statistics

Use this procedure to view the management port statistics.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- View the management port statistics:

```
show interfaces mgmtethernet statistics
```

Example

View management port statistics:

```

Switch:1#show interfaces mgmtethernet statistics
=====
                        Port Stats Interface
=====
PORT  IN      OUT      IN      OUT
NUM  OCTETS  OCTETS   PACKET  PACKET
-----
mgmt  7222116  44282   81789   586

PORT  IN      OUT      IN      OUT      OUTLOSS
NUM  FLOWCTRL FLOWCTRL PFC     PFC     PACKETS
-----
mgmt  0        0        0       0       0

```

View Port Routing Statistics

About This Task

View port routing statistics to manage network performance.

Note

This command is not available on all hardware platforms.

Procedure

View port routing statistics:

```
show routing statistics interface [gigabitethernet] [{slot/port[-slot/
port] [, ...]}
```

Example

```
Switch:1#show routing statistics interface gigabitethernet 1/7-1/9
```

Port Stats Routing					
PORT NUM	IN_FRAME UNICAST	IN_FRAME MULTICAST	IN DISCARD	OUT_FRAME UNICAST	OUT_FRAME MULTICAST
1/7	1386	0	0	1344	0
1/8	1302	0	0	1344	0
1/9	0	0	0	0	0

Variable Definitions

Use the data in the following table to use the **show routing statistics interface** command.

Variable	Value
<i>gigabitethernet</i>	Specifies the interface type.
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Display Bridging Statistics for Specific Ports

About This Task

Display individual bridging statistics for specific ports to manage network performance.

Note

This command is only available on XA1400 Series.

Procedure

1. Enter Privileged EXEC mode:
enable

2. View bridging statistics for a specific port:

```
show interfaces GigabitEthernet statistics bridging [{slot/port[-slot/port] [, ...]}
```

Example

Switch:1#show interfaces gigabitEthernet statistics bridging

```

1/10  0         0          0          0          0         0          0
1/11  0         0          0          0          0         0          0
1/12  0         0          0          0          0         0          0
1/13  179325    0          0          42040     179325    0          0
1/14  187864    0          0          50437     179324    0          0
1/15  0         0          0          0          0         0          0
1/16  0         0          0          0          0         0          0

--More-- (q = quit)
    
```

Variable Definitions

Use the data in the following table to use the **show interfaces GigabitEthernet statistics bridging** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Displaying Detailed Statistics for Ports

Display detailed statistics for specific ports to manage network performance.

Note

Slot and port information can differ depending on hardware platform.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View statistics for specific ports:
show interfaces GigabitEthernet statistics verbose {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}

Example

View statistics for various ports:

```
Switch:1>enable
Switch:1#show interfaces gigabitethernet statistics verbose

Please widen the terminal for optimal viewing of data.

3/9      0           0           0           0           0           0           0           0

--More-- (q = quit)
```

Variable Definitions

Use the data in the following table to use the **show interfaces GigabitEthernet statistics verbose** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Chassis operations configuration using EDM

This section provides the details to configure basic hardware and system settings using Enterprise Device Manager (EDM).

Edit System Information

About This Task

Edit system identification information, configuration file information, and perform system actions.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Chassis**.
3. Click the **System** tab.
4. Enter or edit the information as required.
5. Click **Apply**.

System Field Descriptions

Use the data in the following table to use the **System** tab.

Name	Description
sysDescr	Shows the system assigned name and the software version.
sysUpTime	Shows the elapsed time since the system last started.
sysContact	Configures the contact information.
sysName	Configures the name of this device.
sysLocation	Configures the physical location of this device.
VirtualIpAddr	Configures the virtual IP address that the primary CPU advertises and stores in the switch configuration file.
VirtualNetMask	Configures the net mask of the virtual management IP address.
VirtualIpv6Addr	Specifies the virtual IPv6 address.
VirtualIpv6PrefixLength	Specifies the length of the virtual IPv6 address prefix (in bits).
DnsDomainName	Configures the default domain for querying the DNS server.
LastChange	Displays the time since the last configuration change.
LastVlanChange	Displays the time since the last VLAN change.
LastStatisticsReset	Displays the time since the statistics counters were last reset.

Name	Description
LastRunTimeConfigSave	Displays the last run-time configuration saved.
DefaultRuntimeConfigFileName	Displays the default Run-time configuration file directory name.
ConfigFileName	Specifies the name of a new configuration file.
ActionGroup1	Performs one of the following actions: <ul style="list-style-type: none"> • resetCounters— Resets all statistic counters. • saveRuntimeConfig— Saves the current run-time configuration. • loadLicense— Loads a software license file to enable features.
LicenseFileName Note: Exception: only supported on the VSP 8600 Series and the XA1400 Series.	Specifies the name of the license file in the / <code>intflash</code> directory.
ActionGroup2	Specifies the following action: resetIstStatCounters —Resets the IST statistic counters
ActionGroup3	Can be the following action: <ul style="list-style-type: none"> • flushIpRouteTbl—flushes IP routes from the routing table
ActionGroup4	Can be the following action: <ul style="list-style-type: none"> • softReset—resets the device without running power-on tests • cpuSwitchOver—switches over to the other CPU • softResetCoreDump —reset with coredump
Result	Displays a message after you select Apply .
LocatorLED Note: Exception: only supported on VSP 4900 Series.	Configures the system Locator LED on or off. The default is off.

Edit Chassis Information

About This Task

Edit the chassis information to make changes to chassis-wide settings.

Procedure

1. In the Device Physical View tab, select the device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Chassis**.

4. Select the **Chassis** tab.
5. Edit the necessary options.
6. Select **Apply**.

Chassis Field Descriptions

Use the data in the following table to use the **Chassis** tab.

Name	Description
Type	Specifies the chassis type.
ModelName This parameter does not apply on all platforms.	Specifies the chassis model name.
BrandName This parameter does not apply on all platforms.	Specifies the chassis brand name.
PartNumber	Specifies the device part number.
SerialNumber	Specifies a unique chassis serial number.
HardwareRevision	Specifies the current hardware revision of the device chassis.
NumSlots	Specifies the number of slots available in the chassis.
NumPorts	Specifies the number of ports currently installed in the chassis.
BaseMacAddr	Specifies the starting point of the block of MAC addresses used by the switch for logical and physical interfaces.
MacAddrCapacity	Specifies the number of routable MAC addresses based on the BaseMacAddr.
Temperature This parameter does not apply for all platforms.	Specifies the temperature of the device measured in degrees Celsius.
MacFlapLimitTime This parameter does not apply for all platforms.	Configures the time limit for the loop-detect feature, in milliseconds, for MAC flapping. The value ranges from 10-5000. The default value is 500.
AutoRecoverDelay	Specifies the time interval, in seconds, after which auto-recovery runs on ports to clear actions taken by CP Limit or link flap. The default is 30.
MTUSize	Configures the maximum transmission unit size. The default is 1950 bytes.
MgidUsageVlanCurrent	Number of MGIDs for VLANs currently in use.
MgidUsageVlanRemaining	Number of remaining MGIDs for VLANs.
MgidUsageMulticastCurrent	Number of MGIDs for multicast currently in use.
MgidUsageMulticastRemaining	Number of remaining MGIDs for multicast.
DdmMonitor	Enables or disables the monitoring of the DDM. When enabled, the user gets the internal performance condition (temperature, voltage, bias, Tx power and Rx power) of the SFP/XFP. The default is disable.

Name	Description
DdmMonitorInterval	Configures the DDM monitor interval in the range of 5 to 60 in seconds. If any alarm occurs, the user gets the log message before the specific interval configured by the user. The default value is 5 seconds.
DdmTrapSend	Enables or disables the sending of trap messages. When enabled, the trap message is sent to the Device manager, any time the alarm occurs. The default is enable.
DdmAlarmPortdown	Sets the port down when an alarm occurs. When enabled, the port goes down when any alarm occurs. The default is disable.
PowerUsage This parameter does not apply on all platforms.	Specifies the amount of power the CPU uses.
PowerAvailable This parameter does not apply on all platforms.	Specifies the amount of power available to the CPU.

View Physical Entities

Perform this procedure to view information about the functional components of the switch.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Entity**.

Physical Entities Field Descriptions

The following table defines the use the Physical Entities tab.

Name	Description
Index	Indicates the index of the entry.
Descr	Indicates the name of the manufacturer for the physical entity.
VendorType	Indicates the vendor-specific hardware type for the physical entity. Because there is no vendor-specifier registration for this device, the value is 0.
ContainedIn	Indicates the index value for the physical entity which contains this physical entity. A value of zero indicates that this physical entity is not contained in any other physical entity.
Class	Indicates the general hardware type of the physical entity. The value is configured to the standard enumeration value that indicates the general class of the physical entity.
ParentRelPos	Indicates the relative position of the child component among the sibling components.

Name	Description
Name	Indicates the name of the component, as assigned by the local device, and that is suitable to use in commands you enter on the console of the device. Depending on the physical component naming syntax of the device, the name can be a text name such as console, or a component number such as port or module number. If there is no local name, there is no value.
HardwareRev	Indicates the vendor-specific hardware revision string for the physical entity. If no specific hardware revision string is associated with the physical component, or if this information is unknown, then this object contains a zero-length string, or there is no value. If there is no information available, there is no value.
FirmwareRev	Indicates the vendor-specific firmware revision string for the physical entity. If no specific firmware programs are associated with the physical component, or if this information is unknown, then this object contains a zero-length string, or there is no value. If there is no information available, there is no value.
SoftwareRev	Indicates the vendor-specific software revision string for the physical entity. If no specific software programs are associated with the physical component, or if this information is unknown, then this object contains a zero-length string, or there is no value. If there is no information available, there is no value.
SerialNum	Indicates the vendor-specific serial number string for the physical entity. The value is the serial number string printed on the component, if present. If there is no information available, there is no value.
MfgName	Indicates the name of the manufacturer of the physical component. The value is the manufacturer name string printed on the component, if present. If the manufacturer name string associated with the physical component is unknown, then this object contains a zero-length string. If there is no information available, there is no value.

Name	Description
ModelName	Indicates the vendor-specific model name identifier string associated with the physical component. The value is the part number which is printed on the component. If the model name string associated with the physical component is unknown, then this object contains a zero-length string.
Alias	Indicates an alias name for the physical entity that is specified by a network manager, and provides a nonvolatile handle for the physical entity. The software supports read-only and provides values for the port interface only.
AssetID	Indicates a user-assigned asset tracking identifier for the physical entity. This value is specified by a network manager, and provides nonvolatile storage of this information. Because this object is not supported, there is no value.
IsFRU	Indicates whether or not the physical entity is considered a field replaceable unit. <ul style="list-style-type: none"> • If the value is <code>true (1)</code>, then the component is a field replaceable unit. • If the value is <code>false (2)</code>, then the component is permanently contained within a field replaceable unit.
MfgDate	Indicates the manufacturing date of the managed entity. If the manufacturing date is unknown, then the value is <code>'0000000000000000'</code> .
Uris	Indicates additional identification information about the physical entity. Uris is not supported, therefore there is no value.

View Entity Aliases

About This Task

Perform this procedure to view the entity aliases on the switch.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Entity**.
3. Click the **Alias** tab.

Alias Field Descriptions

Use the data in the following table to use the **Alias** tab.

Name	Description
Index	The index of the entry
LogicalIndexOrZero	The index of the entry. The value of this object identifies the logical entity that defines the naming scope for the associated instance of the Mapping Identifier object. This is always 0.
MappingIdentifier	The value of this object identifies a particular conceptual row associated with the indicated Physical Index and Logical Index pair. Because only physical ports are modeled in this table, only entries that represent interfaces or ports are allowed. If an ifEntry exists on behalf of a particular physical port, then this object should identify the associated ifEntry. This is the OID of ifIndex.Port.

Viewing Entity Child Indexes

About This Task**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Entity**.
3. Click the **Child Index** tab.

Child Index field descriptions

Use the data in the following table to use the **Child Index** tab.

Name	Description
Index	Indicates the index of the entry.
ChildIndex	The index of the entry. The value of Physical Index for the contained physical entity.

Configure System Flags

About This Task

Configure the system flags to enable or disable flags for specific configuration settings.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **System Flags** tab.

4. Select the system flags you want to activate.
5. Clear the system flags you want to deactivate.
6. Select **Apply**.

**Important**

After you change certain configuration parameters, you must save the changes to the configuration file.

System Flags *Field Descriptions*

Use the data in the following table to use the **System Flags** tab.

Name	Description
EnableAccessPolicy	Activates access policies. The default is disabled.
ForceTrapSender	Configures circuitless IP as a trap originator. The default is disabled.
ForceIpHdrSender	If you enable Force IP Header Sender, the system matches the IP header source address with SNMP header sender networks. The default is disabled.
AuthSuccessTrapEnable	Enables the system to send the authentication success trap, rcnAuthenticationSuccess. The default is disabled.
MrouteStrLimit	Enable or disable Mroute stream limit in system. The default is disabled.
DataPathFaultShutdownEnable	Enable or disable data path fault shutdown. The default is enabled.
PingTracerouteContextType	Configures the default context for executing ping commands and traceroute commands. The default is grt.
Note: Exception: not supported on VSP 8600 Series.	
UdpSrcByVirtualIpEnable	Enables or disables virtual IP as the User Datagram Protocol (UDP) source. The default is disabled.
ForceTopologyIpFlagEnable	Activates or disables the flag that configures the CLIP ID as the topology IP. Values are true or false. The default is disabled.
CircuitlessIpId	Uses the CLIP ID as the topology IP. Enter a value from 1–256.
HaCpu	Activates or disables the CPU High Availability feature. If you enable or disable High Availability mode, the secondary CPU resets automatically to load settings from the saved configuration file. The default is enabled.
MasterCPUSlot	Specifies the slot number, either 1 or 2, for the master CPU. The default value is 1.
EnableSavetoStandby	Enables or disables automatic save of the configuration file to the standby CPU. The default value is enabled.

Name	Description
HaCpuState	Indicates the CPU High Availability state. <ul style="list-style-type: none"> • initialization—Indicates the CPU is in this state. • oneWayActive—Specifies modules that need to synchronize register with the framework (either locally or a message received from a remote CPU). • twoWayActive—Specifies modules that need to synchronize register with the framework (either locally or a message received from a remote CPU). • synchronized—Specifies table-based synchronization is complete on the current CPU. • remoteIncompatible—Specifies CPU framework version is incompatible with the remote CPU. • error—Specifies if an invalid event is generated in a specific state the CPU enters Error state. • disabled—Specifies High Availability is not activated. • peerNotConnected—Specifies no established peer connection. • peerConnected—Specifies peer connection is established. • lostPeerConnection—Specifies a lost connection to peer or standby CPU. • notSynchronized—Specifies table-based synchronization is not complete.
HaEvent	Indicates the High Availability event status. <ul style="list-style-type: none"> • restart—Causes the state machine to restart. • systemRegistrationDone—Causes the CPU to transfer to One Way or Two Way Active state. • tableSynchronizationDone—Causes the CPU to transfer to synchronized state. • versionIncompatible—Causes the CPU to go to remote incompatible state • noEvent—Means no event occurred to date.
StandbyCpu	Indicates the state of the standby CPU.

Configure Channelization

Use this procedure to enable or disable channelization on a port. Channelization configures the port to operate as four channels, or ports.

Important

Enabling or disabling channelization resets the port QoS configuration to default values.

Procedure

1. In the Device Physical View tab, select a port that supports channelization.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Channelization** tab.

5. To enable channelization on the port, select **enable** .
6. Select **Apply** . Alternatively, you can right-click the port on the Device Physical View tab, and then select **Channelization Enable**.
7. To disable channelization on a port, select the first sub-port for the corresponding port, slot/port/1.
8. In the navigation pane, expand **Configuration > Edit > Port**.
9. Select **General**.
10. Select the **Channelization** tab.
11. To disable channelization on the port, select **disable**. This action will disable the four sub-ports.
12. Select **Apply** . Alternatively, you can right-click the port on the Device Physical View tab, and then select **Channelization Disable**.

Channelization Field Descriptions

Use the data in the following table to use the **Channelization** tab.

Name	Description
Channelization	This field determines whether channelization is enabled or disabled on the selected port. The two options are enable and disable . The default is disable .

Configure Basic Port Parameters

Configure options for port operations.

About This Task

If you select more than one port, the format of the tab changes to a table-based tab.

When you use 1 Gigabit Ethernet SFP transceivers, the software disables Auto-Negotiation on the port. If you use 1 Gbps SFP transceivers, the remote end must also have Auto-Negotiation disabled.

Procedure

1. In the Device Physical View tab, select one or more ports.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. Configure the fields as required.

10/100BASE-TX ports do not consistently auto-negotiate with older 10/100BASE-TX equipment. You can sometimes upgrade the older devices with new firmware or driver revisions. If an upgrade does not enable auto-negotiation to correctly identify the link speed and duplex settings, you can manually configure the settings for the link in question.

Check the Extreme Networks website for the latest compatibility information.
6. Select **Apply**.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
Index	Displays the index of the port, written in the slot/port[/sub-port] format.
Name	Configures the name of the port.
Descr	Displays the description of the port. A textual string containing information about the interface.
Type	Displays the type of connector plugged in the port.
Mtu	Displays the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.
PhysAddress	Displays the physical address of the port. The address of the interface at the protocol layer immediately `below' the network layer in the protocol stack. For interfaces which do not have such an address, for example, a serial line, this object should contain an octet string of zero length.
VendorDescr	Displays the vendor of the connector plugged in the port.
DisplayFormat	Identifies the slot and port numbers (slot/port). If the port is channelized, the format also includes the sub-port in the format slot/port/sub-port
AdminStatus	Configures the port as enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.
OperStatus	Displays the current status of the port. The status includes enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.
LicenseControlStatus	Shows the port license status.
Note: Exception: only supported on VSP 7200 Series.	
ShutdownReason	Indicates the reason for a port state change.
LastChange	Displays the timestamp of the last change.
LinkTrap	Enable or disable link trapping.
AutoNegotiate	Enables or disables Auto-Negotiation for this port. The default Auto-Negotiation behavior depends on the switch model and transceiver type.

Name	Description
AutoNegAd	<p>Specifies the port speed and duplex abilities to advertise during link negotiation. Supported speeds and duplex modes vary, depending on your hardware.</p> <p>The abilities specified in this object are only used when auto-negotiation is enabled on the port. If all bits in this object are disabled, and auto-negotiation is enabled on the port, then the physical link process on the port will be disabled (if hardware supports this ability).</p> <p>Any change to this configuration restarts the auto-negotiation process, which has the same effect as physically unplugging and reattaching the cable attached to the port.</p> <p>If you select default, all capabilities supported by the hardware are advertised.</p>
AdminDuplex	Configures the administrative duplex setting for the port.
OperDuplex	Indicates the operational duplex setting for the port.
AdminSpeed	<p>Configures the administrative speed for the port.</p> <p>Important: If Auto-Negotiation is disabled and you change the administrative speed on a port that results in a configuration mismatch in speed between two ports, VSP 4450 Series and VSP 4900 Series switches can show an incorrect operational status of "up" for the mismatched ports.</p>
OperSpeed	Indicates the operational speed for the port.
QoSLevel	Selects the Quality of Service (QoS) level for this port. The default is level1.
DiffServ	Enables the Differentiated Service feature for this port. The default is disabled.
Layer3Trust	Configures if the system should trust Layer 3 packets coming from access links or core links only. The default is core.
Layer2Override8021p	Specifies whether Layer 2 802.1p override is enabled (selected) or disabled (cleared) on the port. The default is disabled (clear).
MltId	Shows the MLT ID associated with this port. The default is 0.
Locked	Shows if the port is locked. The default is unlocked.

Name	Description
UnknownMacDiscard	Discards packets that have an unknown source MAC address, and prevents other ports from sending packets with that same MAC address as the destination MAC address. The default is disabled.
DirectBroadcastEnable	Specifies if this interface forwards direct broadcast traffic.
OperRouting	Shows the routing status of the port.
HighSecureEnable	Enables or disables the high secure feature for this port.
RmonEnable	Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.
FlexUniEnable	Enables Flex UNI on the port. The default is disabled.
IngressRateLimit Note: Exception: not supported on VSP 4450 Series, VSP 7400 Series, or VSP 8600 Series.	Limits the traffic rate that the specific ingress port accepts.
IngressRatePeak	Configures the peak rate in Kbps. The default is 0.
IngressRateSvc	Configures the service rate in Kbps. The default is 0.
EgressRateLimitState	Enables or disables egress port-based shaping to bind the maximum rate at which traffic leaves the port. The default is disabled.
EgressRateLimit Note: Exception: not supported on VSP 7400 Series, VSP 8600 Series, or XA1400 Series.	Specifies the egress rate limit in Kbps. Different hardware platforms support different egress rate limits, depending on the port with the highest speed available on the platform. You cannot configure the egress shaper rate to exceed the port capability. If you configure this value to 0, shaping is disabled on the port.
TxFlowControl Note: Exception: not supported on VSP 8600 Series	Configures if the port sends pause frames. By default, an interface does not send pause frames. You must also enable the flow control feature globally before an interface can send pause frames.
TxFlowControlOperState	Shows the operational state of flow control.
BpduGuardTimerCount	Shows the time, starting at 0, since the port became disabled. When the BpduGuardTimerCount reaches the BpduGuardTimeout value, the port is enabled. Displays in 1/100 seconds.

Name	Description
BpduGuardTimeout	Specifies the value to use for port-state recovery. After a BPDU guard disables a port, the port remains in the disabled state until this timer expires. You can configure a value of 0 or to 65535. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.
BpduGuardAdminEnabled	Enables BPDU Guard on the port. The default is disabled.
ForwardErrorCorrection	Configures one of the following options for Forward Error Correction (FEC) on the port: <ul style="list-style-type: none"> • CL 91 • CL 108 • CL 74 • disable • auto The disable option disables this configuration on the port.
ForwardErrorCorrectionApplicability	Displays whether FEC is applicable on the interface.
OperAutoNegotiate	Shows the operational state of Auto-Negotiation.
OperForwardErrorCorrection	Shows the negotiated operational FEC clause. If the value is off, the port supports FEC and is up but not configured for FEC. If the value is notApplicable, the port does not support FEC. If the value is unknown, the port supports FEC but is down.
IsPortShared	Indicates whether the port is combo or not. <ul style="list-style-type: none"> • portShared—Combo port. • portNotShared—Not a combo port.
PortActiveComponent	Specifies whether the copper port is active or fabric port is active if port is a combo port. <ul style="list-style-type: none"> • fixed port—Copper port is active. • gbic port—Fabric port is active.
Action	Performs one of the following actions on the port <ul style="list-style-type: none"> • none - none of the following actions • flushMacFdb - flush the MAC forwarding table • flushArp - flush the ARP table • flushIp - flush the IP route table • flushAll - flush all tables • triggerRipUpdate — manually triggers a RIP update The default is none.
Result	Displays the result of the selected action. The default is none.

Name	Description
<p>AutoSense</p> <p>Note: Exception: not supported on VSP 8600 Series and XA1400 Series.</p>	<p>Enables or disables Auto-sense on the specific port. The default value is disabled for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.</p>
<p>AutoSenseKeepAutoConfig</p> <p>Note: Exception: not supported on VSP 8600 Series and XA1400 Series.</p>	<p>Retains the Auto-sense configuration if you disable Auto-sense on the port. The dynamic configuration becomes a manual configuration and is visible in the show running-config output.</p>
<p>CustomAutoNegAdOrigin</p>	<p>Specifies the origin of Custom Auto Negotiation Advertisements (CANA) configuration on the port. The supported values are:</p> <ul style="list-style-type: none"> • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.
<p>BpduGuardOrigin</p>	<p>Specifies the origin of BPDU Guard configuration on the port. The supported values are:</p> <ul style="list-style-type: none"> • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.
<p>AutoSenseState</p> <p>Note: Exception: not supported on VSP 8600 Series and XA1400 Series.</p>	<p>Displays the Auto-sense port state.</p>
<p>LinkDebounce</p> <p>Note: Exception: not supported on VSP 8600 Series and XA1400 Series.</p>	<p>Specifies the extended debounce timer on the port. The range is 0 to 300000 milliseconds. The value 0 milliseconds disables debounce time. The default value is 1000.</p>
<p>AutoSenseDatalsid</p> <p>Note: Exception: not supported on VSP 8600 Series and XA1400 Series.</p>	<p>Specifies the Auto-sense data I-SID per port. The range is 0 to 16777215.</p>

Configure Basic Parameters on an Extreme Integrated Application Hosting Port

Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series.

About This Task

Perform this procedure to configure basic parameters on Extreme Integrated Application Hosting (IAH) ports, for example, auto negotiation, QoS level, and remote monitoring.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **Interface** tab.
4. In the **Name** field, type a name for the IAH port.
5. Configure the fields as required.
6. Select **Apply**.

Interface Field Descriptions

Use data in the following table to use the **Interface** tab.

Name	Description
Index	Specifies the index of the Extreme Integrated Application Hosting (IAH) port, written in the slot/port[/sub-port] format.
Name	Specifies the name of the IAH port.
Descr	Specifies the information about the interface.
Type	Specifies the type of connector plugged in the IAH port.
Mtu	Specifies the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.
PhysAddress	Specifies the physical address of the IAH port. The address of the interface at the protocol layer immediately below the network layer in the protocol stack. For interfaces which do not have such an address (like a serial line), this object should contain an octet string of zero length.
VendorDescr	Specifies the vendor of the connector plugged in the IAH port.
DisplayFormat	Specifies the slot and port numbers (slot/port).
AdminStatus	Specifies the operational status of the IAH port. The testing state indicates that no operational packets can be passed.
OperStatus	Specifies the current status of the IAH port. The testing state indicates that no operational packets can be passed.
LicenseControlStatus	Specifies the IAH port license status.

Name	Description
ShutdownReason	Specifies the reason for the IAH port state change.
LastChange	Specifies the timestamp of the last change.
LinkTrap	Enables or disables link trapping. The default is enabled.
AutoNegotiate	Enables or disables auto-negotiation for the IAH port. The default is true (enabled).
AutoNegAd	Specifies the port speed and duplex abilities to be advertised during link negotiation. The abilities specified in this object are only used when auto-negotiation is enabled on the IAH port. If all bits in this object are disabled, and auto-negotiation is enabled on the IAH port, then the physical link process on the IAH port will be disabled (if hardware supports this ability). Any change in the value of this bit map will force the switch to restart the auto-negotiation process. The capabilities being advertised are either all the capabilities supported by the hardware or the user-configured capabilities, which is a subset of all the capability supported by hardware. By default, all capabilities supported by the hardware are enabled.
AdminDuplex	Specifies the administrative duplex setting for the IAH port.
OperDuplex	Specifies the operational duplex setting for the IAH port.
AdminSpeed	Specifies the administrative speed for the IAH port.
OperSpeed	Specifies the operational speed for the IAH port.
QoSLevel	Specifies the Quality of Service (QoS) level for the IAH port. The default is level1.
DiffServ	Enables the Differentiated Service feature for the IAH port. The default is enabled.
Layer3Trust	Specifies if the system should trust Layer 3 packets coming from access links or core links only. The default is core.
Layer2Override8021p	Specifies whether Layer 2 802.1p override is enabled or disabled. The default is disabled.
MltId	Specifies the MLT ID associated with the IAH port. The default is 0.
Locked	Specifies if the IAH port is locked. The default is false.
UnknownMacDiscard	Enables the functionality to discard packets with an unknown source MAC address, and prevents the other IAH port from sending packets with the same MAC address as the destination MAC address. The default is disabled.

Name	Description
DirectBroadcastEnable	Specifies if the IAH port forwards direct broadcast traffic.
OperRouting	Specifies the routing status of the IAH port. The default is disabled.
HighSecureEnable	Enables or disables the high secure feature for the IAH port. The default is disabled.
RmonEnable	Enables or disables Remote Monitoring (RMON) on the IAH port. The default is disabled.
FlexUniEnable	Enables or disables Flex UNI on the IAH port. The default is disabled.
EgressRateLimitState	Enables or disables egress port-based shaping to bind the maximum rate at which traffic leaves the IAH port. The default is disabled.
EgressRateLimit	Specifies the egress rate limit in Kbps. Different hardware platforms provide different port speeds. The default is 0.
TxFlowControl	Specifies if the IAH port is sending pause frames. The default is disabled. Note: You must enable the flow control feature globally.
TxFlowControlOperState	Specifies the operational state of flow control.
BpduGuardTimerCount	Specifies the duration since when the IAH port is disabled. When the BpduGuardTimerCount reaches the BpduGuardTimeout value, the IAH port is enabled.
BpduGuardTimeout	Specifies the time (in seconds) for the IAH port-state recovery. After the IAH port is disabled by the BPDU guard, the IAH port remains in the disabled state until this timer expires. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.
BpduGuardAdminEnabled	Enables or disables BPDU Guard on the IAH port. The default is disabled.
ForwardErrorCorrection	Configures one of the following options for Forward Error Correction (FEC) on the IAH port: <ul style="list-style-type: none"> • CL 91 • CL 108 • CL 74 • disable • auto The disable option disables this configuration on the port.
ForwardErrorCorrectionApplicability	Displays whether FEC is applicable on the interface.

Name	Description
OperAutoNegotiate	Shows the operational state of Auto-Negotiation.
OperForwardErrorCorrection	Shows the negotiated operational FEC clause. If the value is off, the port supports FEC and is up but not configured for FEC. If the value is notApplicable, the port does not support FEC. If the value is unknown, the port supports FEC but is down.
Action	Specifies the following actions on the IAH port: <ul style="list-style-type: none"> • none - no action. • flushMacFdb - flush the MAC forwarding table. • flushArp - flush the ARP table. • flushIp - flush the IP route table. • flushAll - flush all tables. • triggerRipUpdate - manually triggers a RIP update. • clearLoopDetectAlarm - clears the loop detection alarm on the IAH port. The default is none.
Result	Specifies the result of the selected action. The default is none.
AutoSense	Enables or disables Auto-sense on the specific port. The default value is disabled for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.
AutoSenseKeepAutoConfig	Retains the Auto-sense configuration if you disable Auto-sense on the port. The dynamic configuration becomes a manual configuration and is visible in the show running-config output.
AutoSenseState	Displays the Auto-sense port state.
CustomAutoNegAdOrigin	Specifies the origin of Custom Auto Negotiation Advertisements (CANA) configuration on the port. The supported values are: <ul style="list-style-type: none"> • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.
BpduGuardOrigin	Specifies the origin of BPDU Guard configuration on the port. The supported values are: <ul style="list-style-type: none"> • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.

Configure IEEE 802.3X Pause Frame Transmit

Configure IEEE 802.3X Pause frame transmit to eliminate or minimize packet loss.

About This Task

By default, flow control mode is disabled. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.

By default, an interface does not send pause frames.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **Boot Config** tab.
4. For EnableFlowControlMode, select **enable**.
5. Select **Apply**.
6. Save the switch configuration.
7. Reboot the chassis, and log in again.
8. In the Device Physical View, select a port or ports.
9. In the navigation pane, expand **Configuration > Edit > Port**.
10. Select **General**.
11. Select the **Interface** tab.
12. For TxFlowControl, select **enable** to enable the interface to generate pause frames.
13. Select **Apply**.

View the Boot Configuration

About This Task

View the boot configuration to determine the software version, as well as view the source from which the switch last started.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **Boot Config** tab.

Boot Config Field Descriptions

Use the data in the following table to use the **Boot Config** tab.

Name	Description
SwVersion	Specifies the software version that currently runs on the chassis.
LastRuntimeConfigSource	Specifies the last source for the run-time image.
PrimaryConfigSource	Specifies the primary configuration source.

Name	Description
PrimaryBackupConfigSource	Specifies the backup configuration source to use if the primary does not exist.
EnableFactoryDefaultsMode	<p>Specifies whether the switch uses the factory default settings at startup.</p> <ul style="list-style-type: none"> • false: The node does not use factory default settings at startup. • fabric: This mode is not supported. • noFabric: The node uses the factory default mode settings at startup. <p>The default value is false. This flag is automatically reset to the default setting after the switch restarts. If you change this parameter, you must restart the switch for the change to take effect.</p> <p>Note: The factorydefaults flag deletes the runtime, primary and backup configuration files, local password files, authentication keys, and certificates. After a factory default, you must change the password on first login.</p>
EnableDebugMode	<p>Enabling the debugmode allows a user to enable TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. It only works on console connection. The default value is disabled.</p> <p>Important: Do not change this parameter.</p>
EnableRebootOnError	<p>Activates or disables automatic reboot on a fatal error. The default value is activated.</p> <p>Important: Do not change this parameter.</p>
EnableTelnetServer	Activates or disables the Telnet server service. The default value is disabled.
EnableRloginServer	<p>Activates or disables the rlogin and rsh server. The default value is disabled.</p> <p>Note: Exception: only supported on VSP 8600 Series.</p>
EnableFtpServer	Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the TFTP flag is disabled.
EnableTftpServer	Activates or disables Trivial File Transfer Protocol server service. The default value is disabled.

Name	Description
EnableSshServer	Activates or disables the SSH server service. The default value is disabled.
EnableSpbmConfigMode	Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. The boot flag is enabled by default.
EnableIpv6Mode Note: Exception: not supported on VSP 4450 Series or XA1400 Series .	Enable this flag to support IPv6 routes with prefix-lengths greater than 64 bits. This flag is disabled by default.
EnableEnhancedSecureMode	Enables or disables the enhanced secure mode. Select either jitc or non-jitc to enable the enhanced secure mode in one of these sub-modes. The default is disabled. Note: As a best practice, enable the enhanced secure mode in the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.
EnableUrpMode	Enables Unicast Reverse Path Forwarding (uRPF) globally. You must enable uRPF globally before you configure it on a port or VLAN. The default is disabled.
EnableVxlanGwFullInterworkingMode Note: Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.	Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vST. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag. In Base Interworking Mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments.
EnableFlowControlMode Note: Exception: not supported on VSP 8600 Series.	Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames. The default is disabled.

Name	Description
<p>AdvancedFeatureBwReservation</p> <p>Note: Exception: only supported on VSP 7400 Series and XA1480.</p>	<p>Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work.</p> <ul style="list-style-type: none"> The high level means that the switch reserves the maximum bandwidth for the advanced features. The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features. <p>The default is enabled with low level. If you change this parameter, you must restart the switch.</p>
<p>EnableDvrLeafMode</p>	<p>Enables the switch to be configured as a DVR Leaf. When enabled, you cannot configure the switch to operate as a DvR Controller.</p>
<p>EnablevrfScaling</p>	<p>Changes the maximum number of VRFs and Layer 3 VSNs that the switch supports. If you select this check box, the maximum number increases. The default is disabled.</p> <p>Important: If you select both this check box and the EnableSpbmConfigMode check box, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see VOSS Release Notes.</p>
<p>EnableSyslogRfc5424Format</p>	<p>Enables or disables the RFC 5424 syslog format. The default is enabled. If the pre-existing configuration file is for a release prior to this enhancement, then the flag is disabled automatically.</p>
<p>NniMstp</p>	<p>Enables MSTP, and allows non SPBM B-VLAN configuration on SPBM NNI ports. The default is disabled.</p> <p>Note: Spanning Tree is disabled on all SPBM NNIs.</p> <p>You cannot add an SPBM NNI port or MLT port to any non SPBM B-VLAN.</p>
<p>EnableIpv6EgressFilterMode</p>	<p>Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch.</p>
<p>MasterCPUSlot</p> <p>Note: Exception: only supported on VSP 8600 Series.</p>	<p>Specifies the slot number, either 1 or 2, for the master CPU. The default value is 1.</p>

Name	Description
EnableHaCpu Note: Exception: only supported on VSP 8600 Series.	Enables or disables the CPU High Availability feature. If you enable or disable HA mode, the secondary CPU automatically resets to load settings from the previously-saved configuration file. The default is enabled.
EnableSavetoStandby Note: Exception: only supported on VSP 8600 Series.	Enables or disables automatic save of the configuration file to the standby CPU. The default value is enabled.
Slot	Specifies the slot number.
TftpHash	Enables TFTP hashing.
TftpRetransmit	Set TFTP retransmit timeout counter.
TftpTimeout	Set TFTP timeout counter.
User	Configure host user.
Password	Configure host password.

Configure Boot Flags

About This Task

Change the boot configuration to determine the services available after the system starts.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Chassis**.
2. Select the **Boot Config** tab.
3. Select the services you want to enable.
4. Select **Apply**.

Boot Config Field Descriptions

Use the data in the following table to use the **Boot Config** tab.

Name	Description
SwVersion	Specifies the software version that currently runs on the chassis.
LastRuntimeConfigSource	Specifies the last source for the run-time image.
PrimaryConfigSource	Specifies the primary configuration source.
PrimaryBackupConfigSource	Specifies the backup configuration source to use if the primary does not exist.

Name	Description
EnableFactoryDefaultsMode	<p>Specifies whether the switch uses the factory default settings at startup.</p> <ul style="list-style-type: none"> • false: The node does not use factory default settings at startup. • fabric: This mode is not supported. • noFabric: The node uses the factory default mode settings at startup. <p>The default value is false. This flag is automatically reset to the default setting after the switch restarts. If you change this parameter, you must restart the switch for the change to take effect.</p> <p>Note: The factorydefaults flag deletes the runtime, primary and backup configuration files, local password files, authentication keys, and certificates. After a factory default, you must change the password on first login.</p>
EnableDebugMode	<p>Enabling the debugmode allows a user to enable TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. It only works on console connection. The default value is disabled.</p> <p>Important: Do not change this parameter.</p>
EnableRebootOnError	<p>Activates or disables automatic reboot on a fatal error. The default value is activated.</p> <p>Important: Do not change this parameter.</p>
EnableTelnetServer	<p>Activates or disables the Telnet server service. The default value is disabled.</p>
EnableRloginServer	<p>Activates or disables the rlogin and rsh server. The default value is disabled.</p> <p>Note: Exception: only supported on VSP 8600 Series.</p>
EnableFtpServer	<p>Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the TFTPD flag is disabled.</p>
EnableTftpServer	<p>Activates or disables Trivial File Transfer Protocol server service. The default value is disabled.</p>
EnableSshServer	<p>Activates or disables the SSH server service. The default value is disabled.</p>

Name	Description
EnableSpbmConfigMode	Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. The boot flag is enabled by default.
EnableIpv6Mode Note: Exception: not supported on VSP 4450 Series or XA1400 Series .	Enable this flag to support IPv6 routes with prefix-lengths greater than 64 bits. This flag is disabled by default.
EnableEnhancedsecureMode	Enables or disables the enhanced secure mode. Select either jitc or non-jitc to enable the enhanced secure mode in one of these sub-modes. The default is disabled. Note: As a best practice, enable the enhanced secure mode in the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.
EnableUrpMode	Enables Unicast Reverse Path Forwarding (uRPF) globally. You must enable uRPF globally before you configure it on a port or VLAN. The default is disabled.
EnableVxlanGwFullInterworkingMode Note: Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.	Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vST. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag. In Base Interworking Mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments.
EnableFlowControlMode Note: Exception: not supported on VSP 8600 Series.	Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames. The default is disabled.

Name	Description
<p>AdvancedFeatureBwReservation</p> <p>Note: Exception: only supported on VSP 7400 Series and XA1480.</p>	<p>Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work.</p> <ul style="list-style-type: none"> The high level means that the switch reserves the maximum bandwidth for the advanced features. The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features. <p>The default is enabled with low level. If you change this parameter, you must restart the switch.</p>
<p>EnableDvrLeafMode</p>	<p>Enables the switch to be configured as a DVR Leaf. When enabled, you cannot configure the switch to operate as a DvR Controller.</p>
<p>EnablevrfScaling</p>	<p>Changes the maximum number of VRFs and Layer 3 VSNs that the switch supports. If you select this check box, the maximum number increases. The default is disabled.</p> <p>Important: If you select both this check box and the EnableSpbmConfigMode check box, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see VOSS Release Notes.</p>
<p>EnableSyslogRfc5424Format</p>	<p>Enables or disables the RFC 5424 syslog format. The default is enabled. If the pre-existing configuration file is for a release prior to this enhancement, then the flag is disabled automatically.</p>
<p>NniMstp</p>	<p>Enables MSTP, and allows non SPBM B-VLAN configuration on SPBM NNI ports. The default is disabled.</p> <p>Note: Spanning Tree is disabled on all SPBM NNIs.</p> <p>You cannot add an SPBM NNI port or MLT port to any non SPBM B-VLAN.</p>
<p>EnableIpv6EgressFilterMode</p>	<p>Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch.</p>
<p>MasterCPUSlot</p> <p>Note: Exception: only supported on VSP 8600 Series.</p>	<p>Specifies the slot number, either 1 or 2, for the master CPU. The default value is 1.</p>

Name	Description
EnableHaCpu Note: Exception: only supported on VSP 8600 Series.	Enables or disables the CPU High Availability feature. If you enable or disable HA mode, the secondary CPU automatically resets to load settings from the previously-saved configuration file. The default is enabled.
EnableSavetoStandby Note: Exception: only supported on VSP 8600 Series.	Enables or disables automatic save of the configuration file to the standby CPU. The default value is enabled.
Slot	Specifies the slot number.
TftpHash	Enables TFTP hashing.
TftpRetransmit	Set TFTP retransmit timeout counter.
TftpTimeout	Set TFTP timeout counter.
User	Configure host user.
Password	Configure host password.

Reserve Bandwidth for Advanced Features

Use this procedure if you want the switch to support advanced features. When you enable the boot flag, you need to save and reboot with the new configuration.

Note

This procedure only applies to VSP 7400 Series and XA1480.

Before You Begin

Product Notice: For VSP 7400 Series, you must ensure your configuration does not include reserved ports before you enable this feature. If the configuration includes reserved ports after you enable this feature and restart the switch, the switch stops loading the configuration.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Chassis**.
2. Select the **Boot Config** tab.
3. In the **AdvancedFeatureBWReservation** field, select **high** or **low** to enable the boot flag.
4. Select **Apply**.

A message displays to remind you that the configuration cannot include reserved ports, and that you must save the configuration and reboot the switch for changes to take effect.

5. Select **Yes** to continue or select **No** to cancel the change because the configuration includes reserved ports.

If you selected No, you can modify your switch configuration to remove the reserved ports and then return to this tab to change the **AdvancedFeatureBWReservation** configuration.

6. Save the configuration, and then reboot the switch.

Enable Jumbo Frames

About This Task

Enable Jumbo frames to increase the size of Ethernet frames supported on the chassis.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **Chassis** tab.
5. In **MTU size**, select either 1950, 9600 or 1522.
6. Click **Apply**.

Configure the Date and Time

Configure the date and time to correctly identify when events occur on the system.

About This Task

Note

According to a bill passed by the government of Russia, from October 2014 Moscow has moved from UTC+4 into UTC+3 time zone with no daylight savings. The software includes this change.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **User Set Time** tab.
5. Type and select the correct details.
6. Click **Apply**.

User Set Time field descriptions

Use the data in the following table to use the **User Set Time** tab.

Name	Description
Year	Configures the year (integer 1998–2097). The default is 1998.
Month	Configures the month. The default is 1.
Date	Configures the day (integer 1–31). The default is 1.
Hour	Configures the hour (12am–11pm). The default is 0.
Minute	Configures the minute (integer 0–59). The default is 0.

Name	Description
Second	Configures the second (integer 0–59). The default is 0.
Time Zone	Configures the time zone.

Configure CP Limit

Configure CP Limit functionality to protect the switch from becoming congested by an excess of data flowing through one or more ports.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **CP Limit** tab.
5. Select the **AutoRecoverPort** check box.
6. Click **Apply**.

CP Limit field descriptions

Use the data in the following table to use the **CP Limit** tab.

Name	Description
AutoRecoverPort	Activates or disables auto recovery of the port from action taken by CP Limit or link flap features. The default value is disabled.

Configure CP Limit on an Extreme Integrated Application Hosting Port

Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series.

About This Task

Perform this procedure to configure CP Limit functionality to protect the switch from becoming congested by excess data flow through Extreme Integrated Application Hosting (IAH) ports.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **CP Limit** tab.
4. Select **AutoRecoverPort**.
5. Select **Apply**.

CP Limit Field Descriptions

Use data in the following table to use the **CP Limit** tab.

Name	Description
AutoRecoverPort	Enables or disables auto recovery of the Extreme Integrated Application Hosting port from action taken by CP Limit or the link flap features. The default is disabled.

Configure an IP Address for the Management Port

**Note**

This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management Instance Configuration for VOSS using EDM](#) on page 114.

Configure an IP address for the management port so that you can remotely access the device using the out-of-band (OOB) management port. The management port runs on a dedicated VRF.

The configured IP subnet must be globally unique because the management protocols can go through in-band (Global Router) or out-of-band ports (Management VRF).

This procedure only applies to hardware with a dedicated, physical management interface.

Before You Begin

- You must make a direct connection through the console port to configure a new IP address. If you connect remotely, you can view or delete the existing IP address configuration. If you delete the IP address remotely, you lose the EDM connection to the device.
- Do not configure a default route in the Management VRF.
- If you want out-of-band management, define a specific static route in the Management Router VRF to the IP subnet where your management application resides.
- If you initiate an FTP session from a client device behind a firewall, you should set FTP to passive mode.
- The switch gives priority to out-of-band management when there is reachability from both in-band and out-of-band. To avoid a potential conflict, do not configure any overlapping between in-band and out-of-band networks.

About This Task

Configure an IP address for the management port so that you can remotely access the device using the out-of-band (OOB) management port. The management port runs on a dedicated VRF. Redirect all commands that are run on the management port to its VRF.

The configured IP subnet has to be globally unique because the management protocols can go through in-band or out-of-band ports.

Note

Do not configure a default route in the Management VRF and instead use a static route. Inbound FTP does not work when a default route is configured at the Management VRF. When you initiate FTP, you should also set FTP to passive mode.

Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Select **Set VRF Context View**.
3. Select **MgmtRouter**, VRF 512.
4. Select **Launch VRF Context View**.

A new EDM webpage displays for the VRF context. Parameters that you cannot configure for this context appear dim.

5. In the Device Physical view, select the management port.
6. In the navigation pane, expand **Configuration > Edit**.
7. Select **Mgmt Port**.
8. Select the **IP Address** tab.
9. Select **Insert**.
10. Configure the IP address and mask.
11. Select **Insert**.
12. Collapse the VRF context view.

IP Address field descriptions

Use the data in the following table to use the **IP Address** tab.

Name	Description
Interface	Specifies the slot and port for the management port.
Ip Address	Specifies the IP address for the management port.
Net Mask	Specifies the subnet mask for the IP address.
BcastAddrFormat	Specifies the broadcast address format for the management port.
ReasmMaxSize	Specifies the size of the largest IP datagram that can be reassembled from IP fragmented datagrams received on the management port.

Name	Description
VlanId	Specifies the VLAN ID to which the management port belongs. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
BrouterPort	Specifies if the management port is a brouter port rather than a routeable VLAN. You cannot change this value after the row is created.
MacOffset	Translates the IP address into a MAC address.

Edit the Management Port Parameters

About This Task

Note

This procedure only applies to hardware with a dedicated physical management interface.

The management port on the switch is a 10/100/1000 Mb/s Ethernet port that you can use for an out-of-band management connection to the switch.

If you use EDM to configure the static routes of the management port, you do not receive a warning if you configure a non-natural mask. After you save the changes, the system deletes those static routes after the next restart, possibly causing the loss of IP connectivity to the management port.

If you are uncertain whether the mask you configure is non-natural, use the CLI to configure static routes.

Procedure

1. In the Device Physical View tab, select the management port.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Mgmt Port**.
4. Select the **General tab**.
5. Modify the appropriate settings.
6. Select **Apply**.

General Field Descriptions

Use the data in the following table to use the **General** tab.

Name	Description
Index	Specifies the slot and port number of the management port.
AdminStatus	Configures the administrative status of the device as up (ready to pass packets) or down. The testing state indicates that no operational packets can be passed.
OperStatus	Specifies the operational status of the device.
LicenseControlStatus	Shows the license status of the port: <ul style="list-style-type: none"> • Locked means the port requires a Port License but one is not present on the switch. • Unlocked means the port requires a Port License and one is present on the switch. • notApplicable means the port does not require a Port License.
Mtu	Shows the configuration for the maximum transmission unit. The size of the largest packet which can be sent/received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.
LinkTrap	Enables or disables traps for the link status.
IpsecEnable	Enables IPsec on the management port. The default is disabled.
PhysAddress	Shows the MAC address.
AutoNegotiate	Enables or disables Auto-Negotiation for the management port. The default varies depending on the platform: <ul style="list-style-type: none"> • VSP 4900 Series - enabled • VSP 7200 Series - disabled • VSP 7400 Series - enabled • VSP 8200 Series - enabled • VSP 8400 Series - enabled • VSP 8600 Series - enabled
AdminDuplex	Specifies the administrative duplex mode for the management port. The default is full.
OperDuplex	Specifies the operational duplex configuration for this port.
AdminSpeed	Specifies the administrative speed for this port. The default is 100 Mb/s.
OperSpeed	Shows the current operating data rate of the port.

Configure the Management Port IPv6 Interface Parameters

**Note**

This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management Instance Configuration for VOSS using EDM](#) on page 114.

About This Task

Configure IPv6 management port parameters to use IPv6 routing on the port.

This procedure only applies to hardware with a dedicated, physical management interface.

Procedure

1. In the Device Physical View tab, select the management port.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Mgmt Port**.
4. Select the **IPv6 Interface** tab.
5. Select **Insert**.
6. Edit the fields as required.
7. Select **Insert**.
8. Select **Apply**.

IPv6 Interface field descriptions

Use the data in the following table to use the **IPv6 Interface** tab.

Name	Description
Interface	Identifies the unique IPv6 interface.
Descr	Specifies a textual string containing information about the interface. The network management system also configures the Descr string.
Type	Specifies the type of interface.
ReasmMaxSize(MTU)	Configures the MTU for this IPv6 interface. This value must be the same for all the IP addresses defined on this interface. The default value is 1500.
PhysAddress	Specifies the physical address for the interface. For example, for an IPv6 interface attached to an 802.x link, this value is a MAC address.
AdminStatus	Configures the indication of whether IPv6 is activated (up) or disabled (down) on this interface. This object does not affect the state of the interface, only the interface connection to an IPv6 stack. The default is false (cleared).
ReachableTime	Configures the time, in milliseconds, that the system considers a neighbor reachable after it receives a reachability confirmation. The value is in a range from 0-3600000. The default value is 30000.

Name	Description
RetransmitTimer	Configures the time between retransmissions of neighbor solicitation messages to a neighbor; during address resolution or neighbor reachability discovery. The value is expressed in milliseconds in a range from 0–3600000. The default value is 1000.
CurHopLimit	Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for the current hop limit. The default is 64.

Configure Management Port IPv6 Addresses

Note

This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management Instance Configuration for VOSS using EDM](#) on page 114.

About This Task

Configure management port IPv6 addresses to add or remove IPv6 addresses from the port.

The switch supports IPv6 addressing with Ping, Telnet, and SNMP.

Procedure

1. In the Device Physical View tab, select the management port.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Mgmt Port**.
4. Select the **IPv6 Addresses** tab.
5. Select **Insert**.
6. In the **Addr** box, type the required IPv6 address for the management port.
7. In the **AddrLen** box, type the number of bits from the IPv6 address you want to advertise.
8. Select **Insert**.
9. Select **Apply**.

IPv6 Addresses field descriptions

Use the data in the following table to use the **IPv6 Addresses** tab.

Name	Description
Interface	Specifies an index value that uniquely identifies the interface.
Addr	Specifies the IPv6 address to which this entry addressing information pertains. If the IPv6 address exceeds 116 octets, the object identifiers (OIDs) of instances of columns in this row is more than 128 subidentifiers and you cannot use SNMPv1, SNMPv2c, or SNMPv3 to access them.

Name	Description
AddrLen	Specifies the prefix length value for this address. You cannot change the address length after creation. You must provide this field to create an entry in this table.
Type	Specifies unicast, the only supported type.
Origin	Specifies the origin of the address. The origin of the address can be one of the following: other, manual, dhcp, linklayer, or random.
Status	Specifies the status of the address, describing if the address can be used for communication. The status can be one of the following: preferred, deprecated, invalid, inaccessible, unknown, tentative, or duplicate.
Created	Specifies the time this entry was created. If this entry was created prior to the last initialization of the local network management subsystem, then this option contains a zero value.
LastChanged	Specifies the time this entry was last updated. If this entry was updated prior to the last initialization of the local network management subsystem, then this option contains a zero value.

Automatically Reactivating the Port of the SLPP Shutdown

About This Task

Use the following procedure to automatically reactivate the port that is shut down by the SLPP.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **CP Limit** tab.
5. Select **AutoRecoverPort** to activate auto recovery of the port from the action taken by SLPP shutdown features. The default value is disabled.
6. Click **Apply**.

Edit Serial Port Parameters

About This Task

Perform this procedure to specify serial port communication settings. The serial port on the device is the console port. Depending on the hardware platform, the console port displays as console or 10101.

Procedure

1. In the Device Physical View tab, select the console port on the device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Serial Port**.
4. Edit the port parameters as required.
5. Click **Apply**.

Serial Port Field Descriptions

Use the data in the following table to use the **Serial Port** tab.

Name	Description
IfIndex	Identifies the port as a serial port.
BaudRate	<p>Specifies the baud rate of this port. Different hardware platforms support different baud rates, which also impacts the default value for each hardware platform:</p> <ul style="list-style-type: none"> • VSP 4450 Series — 9600 • VSP 4900 Series — 115200 • VSP 7200 Series — 9600 • VSP 7400 Series — 115200 • VSP 8200 Series — 9600 • VSP 8400 Series — 9600 • VSP 8600 Series — 115200 • XA1400 Series — 115200
DataBits	Specifies the number of data bits, for each byte of data, this port sends and receives. The default is eight.

Enable Port Lock

About This Task

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Port Lock** tab.
4. To enable port lock, select the **Enable** check box.
5. Click **Apply**.

Port Lock field descriptions

Use the data in the following table to use the **Port Lock** tab.

Name	Description
Enable	Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.
LockedPorts	Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock.

Lock a Port

Before You Begin

- You must enable port lock before you lock or unlock a port.

About This Task

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **General**.
- Click the **Port Lock** tab.
- In the **LockedPorts** box, click the ellipsis (...) button.
- Click the desired port or ports.
- Click **Ok**.
- In the **Port Lock** tab, click **Apply**.

Port Lock field descriptions

Use the data in the following table to use the **Port Lock** tab.

Name	Description
Enable	Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.
LockedPorts	Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock.

Configure Power on Module Slots

Note

This procedure only applies to VSP 8600 Series.

About This Task

Use this procedure to control whether or not to supply power to specific slots that contain either switch fabric modules or input/output modules. By default, power is available to all slots.

After enabling power to specific input/output module slots, you can also configure the priority in which they are powered on. For more information, see [Configure Slot Priority](#) on page 607.

Note

This feature is not available for hardware platforms with fixed configurations. It is only available for platforms where the user can install modules in slots.

Procedure

1. In the Device Physical View tab, select a module.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Card**.
4. Click the **Card** tab.
5. In the **SlotPower** field, select the priority level: *on* or *off*.
6. Click **Apply**.

Configure Slot Priority

Note

This procedure only applies to VSP 8600 Series.

About This Task

Configure slot priority to specify which slots you want to shut down if there is insufficient power available in the chassis. By default, power is available to all slots, and the slots have the following priority:

- Slots 1, 2, SF1, SF2, and SF3 must always be *Critical* so you cannot configure them.
- Slots 3-8 are *High* by default, but you can configure any of them to *Low*.

Note

Power is always supplied to critical slots first which are the CP modules, SF modules, and fan trays.

The slot with the lowest priority shuts down first. Slots with the same priority shut down in descending order (highest slot number first) and interface slots shut down before CP, SF modules, and fan tray slots.

For example, if slot 3 has a *Low* priority and slots 4 and 5 have a *High* priority, the slot shutdown priority is as follows: 4, 5, 3. Slot 3 has the lowest priority because it was configured as *Low* so it would be shut down first. Slots 4 and 5 have the same priority, but slot 5 shuts down before slot 4 because slot 4 has a higher slot number.

Procedure

1. In the Device Physical View tab, select a module.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Card**.
4. Click the **Card** tab.
5. In the **PowerManagementPriority** field, select the priority level: *high* or *low*.
6. Click **Apply**.

View Power Information

About This Task

View power information to see the amount of power available and used by the chassis and all components.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Select **Chassis**.
4. Select the **Power Info** tab.

Power Info field descriptions

Use the data in the following table to use the **Power Info** tab.

Name	Description
TotalPower	Shows the total power for the chassis.
RedundantPower	Shows the redundant power for the chassis.
PowerUsage	Shows the power currently used by the complete chassis.
PowerAvailable	Shows the unused power.

View Power Status

About This Task

Perform the following procedure to view the power consumption of the modules in the chassis.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Click **Chassis**.
3. Click the **Power Consumption** tab.

Power consumption field descriptions

Use the data in the following table to use the **Power Consumption** tab.

Name	Description
Index	Displays an index value that identifies the component.
PowerStatus	Displays the power status: on or off.
BasePower	Displays the base power required for the slot.
ConsumedPower	Displays the actual consumed power for the slot. This value is 0 if the power status is off.
PowerPriority	Displays the priority of the slot for power management.

Name	Description
SlotDescription	Displays the slot number.
CardDescription	Identifies the type of module in the slot.

View Fan Tray Information

View fan tray information to see manufacturing information about the fans.

Note

Not all fields are supported on all hardware platforms.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Chassis**.
4. Select the **Fan Tray Info** tab.

Fan Tray Info field descriptions

Use the data in the following table to use the **Fan Tray Info** tab.

Name	Description
TrayId	Specifies the fan tray ID.
Description	Shows a description of the fan tray.
SerialNumber	Shows the serial number for the fan tray.
PartNumber	Shows the part number for the fan tray.
FlowType	Specifies whether the air flow is front-to-back or back-to-front.

View USB Port Information

About This Task

Perform this procedure to view information about the USB port on the switch.

Note

This information may not apply to your hardware model. For more information about your model features, see your hardware documentation.

Procedure

1. In the Device Physical View, select the USB port.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **USB Port**.
4. Click the **General** tab.

General field descriptions

Use the data in the following table to use the **General** tab.

Name	Description
UsbStatus	Displays the current status of USB storage: either present or notPresent.
UsbDescription	Displays a description of the USB storage.

View USB Device Information

About This Task

Perform this procedure to view information about an inserted USB device.

Note

This information may not apply to your hardware model. For more information about your model features, see your hardware documentation.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **USB** tab.

USB field descriptions

Use the data in the following table to use the USB tab.

Name	Description
SlotDescription	Specifies the slot type information.
VendorId	Specifies the vendor ID for the inserted USB device.
Manufacturer	Specifies the manufacturer of the inserted USB device.
ProductId	Specifies the product ID of the inserted USB device.
ProductName	Specifies the product name of the inserted USB device.
SerialNumber	Specifies the serial number of the inserted USB device.
Revision	Specifies the release number of the inserted USB device.
MaxCurrent	Specifies the maximum power as defined by the specification for the inserted USB device. The units of measurement are milliamps.

View Topology Status Information

About This Task

View topology status information (which includes MIB status information) to view the configuration status of the SynOptics Network Management Protocol (SONMP) on the system.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Topology**.
3. Click the **Topology** tab.

Topology field descriptions

Use the data in the following table to use the **Topology** tab.

Name	Description
IpAddr	Specifies the IP address of the device.
Status	Indicates whether topology (SONMP) is on or off for the device.
NmmLstChg	Specifies the value of sysUpTime, the last time an entry in the network management MIB (NMM) topology table was added, deleted, or modified, if the table did not change since the last cold or warm start of the agent.
NmmMaxNum	Specifies the maximum number of entries in the NMM topology table.
NmmCurNum	Specifies the current number of entries in the NMM topology table.

View the Topology Message Status

About This Task

View topology message status to view the interconnections between Layer 2 devices in a network.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Topology**.
3. Click the **Topology Table** tab.

Topology Table Field Descriptions

Use the data in the following table to use the **Topology Table** tab.

Name	Description
Slot	Specifies the slot number in the chassis that received the topology message.
Port	Specifies the port that received the topology message.
SubPort	Specifies the channel of a channelized 40 Gbps port that received the topology message.

Name	Description
IpAddr	Specifies the IP address of the sender of the topology message.
SegId (RemPort)	Specifies the segment identifier of the segment from which the remote agent sent the topology message. This value is extracted from the message.
MacAddr	Specifies the MAC address of the sender of the topology message.
ChassisType	Specifies the chassis type of the device that sent the topology message.
BkplType	Specifies the backplane type of the device that sent the topology message.
LocalSeg	Indicates if the sender of the topology message is on the same Ethernet segment as the reporting agent.
CurState	Specifies the current state of the sender of the topology message. The choices are <ul style="list-style-type: none"> • topChanged—Topology information recently changed. • heartbeat—Topology information is unchanged. • new—The sending agent is in a new state.

Configure a Forced Message Control Pattern

About This Task

Configure a forced message control pattern to enforce configured message control actions.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Chassis**.
2. Click the **Force Msg Patterns** tab.
3. Click **Insert**.
4. In the **PatternId** field, enter a pattern ID number.
5. In the **Pattern** field, enter a message control pattern.
6. Click **Insert**.

Force Msg Patterns Field Descriptions

Use the data in the following table to use the **Force Msg Patterns** tab.

Name	Description
PatternId	Specifies a pattern identification number in the range 1-32.
Pattern	Specifies a forced message control pattern of 4 characters. The software and the hardware log messages that use the first four bytes matching one of the patterns in the force-msg table undergo the configured message control action. You can specify up to 32 different patterns in the force-msg table, including a wildcard pattern (****). If you specify the wildcard pattern, all messages undergo message control.

View Fan Information

View fan information to monitor the alarm status of the cooling ports in the chassis.

**Note**

This tab does not apply on the VSP 8600 Series switch.

About This Task

For platforms that support both back-to-front and front-to-back airflow, the airflow direction must be the same for both the power supply fans and the chassis fan.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Chassis**.
4. Select the **Fan Info** tab.

Fan Info field descriptions

Use the data in the following tables to use the **Fan Info** tab.

Name	Description
Description	Specifies a description of the fan location.
OperStatus	Specifies the operation status of the fan.
OperSpeed	Specifies the actual fan speed.

Configure Ports Speeds for All VIM Ports

Note

This procedure only applies to VSP 4900 Series.

Configure all of the ports on an installed Versatile Interface Module (VIM) to operate at the same speed.

Note

Some VIMs must operate with all ports at the same speed, while others can operate with ports at different speeds. For more information, see [VOSS Release Notes](#). You can configure VIM ports speed only on VIMs that must operate with all ports at the same speed.

Before You Begin

Install the VIM before performing this procedure.

About This Task

Use this procedure to configure the speed of all ports in a multi-port VIM to operate at either 10 Gbps or 25 Gbps.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **VIM** tab.
4. Select **mbps10000** or **mbps25000**.
5. Select **Apply**.

VIM Field Descriptions

Use the data in the following table to use the VIM tab.

Name	Description
AdminSpeed	<ul style="list-style-type: none"> • mbps10000: Configures all ports in a multi-port VIM to operate at 10 Gbps. • mbps25000: Configures all ports in a multi-port VIM to operate at 25 Gbps. <p>The default is 25 Gbps.</p>

View Modular SSD Information

Note

This procedure only applies to VSP 4900 Series.

About This Task

Perform this procedure to display information about an installed Solid State Drive (SSD) on a switch.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **SSD** tab.

SSD Field Descriptions

Use the data in the following table to use the SSD tab.

Name	Description
ProductName	Specifies Solid State Drive (SSD) product name.
VendorName	Specifies the SSD vendor.
ManufactureDate	Specifies the date on which the SSD was manufactured.
SerialNum	Specifies the SSD serial number.
PartNum	Specifies the SSD part number.
DeviceVersion	Specifies the version of the SSD.
TotalSize	Specifies the total memory size of the SSD.

Prepare a slot for IOC Module Preconfiguration using EDM**Note**

This procedure only applies to VSP 8600 Series.

About This Task

Use this procedure to designate a slot in the switch for IOC Module Preconfiguration. A slot can be designated for only one module type at a time.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Card Preconfig**.
2. Click **Insert**.
3. Enter the slot number in the **Slot** field.
4. Select the IOC Module type in the **CardType** field.
5. Select the **Lock** field to lock the slot to the specified IOC Module type.
6. Click **Insert**.

Card Preconfig Field Descriptions

Use the data in the following table to use the **Card Preconfig** tab.

Field	Description
Slot	Specifies the slot number designated for pre-configuration.
CardType	Specifies the type of the IOC Module designated for the slot.
Lock	If selected, the slot is locked to only accept the type of IOC Module designated.

Graphing Chassis Statistics

Create graphs of chassis statistics to generate a visual representation of your data.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. On the Graph Chassis tab, select the tab with the data you want to graph:
 - System
 - SNMP
 - IP
 - ICMP In
 - ICMP Out
 - TCP
 - UDP
5. Select the statistic you want to graph.
6. Select the graph type:
 - line chart
 - area chart
 - bar chart
 - pie chart

Graphing Port Statistics

You can create a graph of the port statistics to generate a visual representation of your data.

Procedure

1. In the Device Physical View, select the port or ports for which you want to create a graph.
2. In the navigation pane, expand the **Configuration > Graph** folders, and then click **Port**.
OR, use the following shortcut:

Right-click the selected port or ports from Step 1, and choose **Graph**.

3. On the **Graph Port** tab for the selected port or ports, select the item you want to graph.
4. Click an icon to select the type of graph you require. The following list provides the graph types available:
 - Line Chart
 - Area Chart
 - Bar Chart
 - Pie Chart

Viewing Chassis System Statistics

Use the following procedure to create graphs for chassis statistics.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **System** tab.

System Field Descriptions

The following table describes the fields on the **System** tab.

Name	Description
MemUsed	The percentage of memory space used. Only the AbsoluteValue column is valid in the System tab. All other columns display as N/A because they are percentages and not actual memory counters.
MemFree	The amount in kilobytes of free memory.
CpuUtil	Percentage of CPU utilization.

Viewing Chassis SNMP Statistics

View chassis SNMP statistics to monitor network performance.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **SNMP** tab.

SNMP Field Descriptions

The following table describes parameters on the **SNMP** tab.

Name	Description
InPkts	The number of messages delivered to the SNMP entity from the transport service.
OutPkts	The number of SNMP messages passed from the SNMP protocol entity to the transport service.
InTotalReqVars	The number of MIB objects retrieved successfully by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs.
InTotalSetVars	The number of MIB objects altered successfully by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs.
InGetRequests	The number of SNMP Get-Request PDUs the SNMP protocol accepts and processes.
OutGetRequests	The number of SNMP Get-Request PDUs that are generated by the SNMP protocol entity.
InGetNexts	The number of SNMP Get-Next PDUs the SNMP protocol accepts and processes.
OutGetNexts	The number of SNMP Get-Next PDUs that are generated by the SNMP protocol entity.
InSetRequests	The number of SNMP Set-Request PDUs the SNMP protocol accepts and processes.
OutSetRequests	The number of SNMP Set-Request PDUs that are generated by the SNMP protocol entity.
InGetResponses	The number of SNMP Get-Response PDUs the SNMP protocol accepts and processes.
OutGetResponses	The number of SNMP Get-Response PDUs that are generated by the SNMP protocol entity.
InTraps	The number of SNMP Trap PDUs the SNMP protocol accepts.
OutTraps	The number of SNMP Trap PDUs the SNMP protocol generates.
OutTooBig	The number of SNMP PDUs the SNMP protocol generates for which the value of the error-status field is tooBig.
OutNoSuchNames	The number of SNMP PDUs the SNMP protocol generates for which the value of the error-status field is noSuchName.
OutBadValues	The number of SNMP PDUs the SNMP protocol generates for which the value of the error-status field is badValue.
OutGenErrs	The number of SNMP PDUs the SNMP protocol generates for which the value of the error-status field is genErr.
InBadVersions	The number of SNMP messages delivered to the SNMP protocol entity for an unsupported SNMP version.
InBadCommunityNames	The number of SNMP messages delivered to the SNMP protocol entity that used an SNMP community name not known to said entity.

Name	Description
InBadCommunityUses	The number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation not allowed by the SNMP community named in the message.
InASNParseErrs	The number of ASN.1 or BER errors the SNMP protocol encountered when decoding received SNMP messages.
InTooBigs	The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is tooBig.
InNoSuchNames	The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is noSuchName.
InBadValues	The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is badValue.
InReadOnlys	The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is readOnly. It is a protocol error to generate an SNMP PDU containing the value "readOnly" in the error-status field. This object is provided to detect incorrect implementations of the SNMP.
InGenErrs	The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is genErr.

Viewing Chassis IP Statistics

View chassis IP statistics to monitor network performance.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **IP** tab.

IP Field Descriptions

The following table describes parameters on the **IP** tab.

Name	Description
InReceives	The number of input datagrams received from interfaces, including those received in error.
InHdrErrors	The number of input datagrams discarded due to errors in the IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, errors discovered in processing their IP options.
InAddrErrors	The number of input datagrams discarded because the IP address in the IP header destination field was not a valid address to be received at this entity. This count includes invalid addresses (for example, 0.0.0.0) and addresses of unsupported Classes (for example, Class E). For entities that are not IP Gateways and therefore do not forward datagrams, this counter includes datagrams discarded because the destination address was not a local address.

Name	Description
ForwDatagrams	The number of input datagrams for which this entity was not their final IP destination, as a result of which an attempt was made to find a route to forward them to that final destination. In entities that do not act as IP Gateways, this counter includes only those packets that were Source-Routed by way of this entity and had successful Source-Route option processing.
InUnknownProtos	The number of locally addressed datagrams received successfully but discarded because of an unknown or unsupported protocol.
InDiscards	The number of input IP datagrams for which no problems were encountered to prevent their continued processing but that were discarded (for example, for lack of buffer space). This counter does not include any datagrams discarded while awaiting reassembly.
InDelivers	The number of input datagrams successfully delivered to IP user-protocols (including ICMP).
OutRequests	The number of IP datagrams that local IP user-protocols (including ICMP) supplied to IP in requests for transmission. This counter does not include any datagrams counted in ipForwDatagrams.
OutDiscards	The number of output IP datagrams for which no problem was encountered to prevent their transmission to their destination, but that were discarded (for example, for lack of buffer space). This counter includes datagrams counted in ipForwDatagrams if any such packets met this (discretionary) discard criterion.
OutNoRoutes	The number of IP datagrams discarded because no route was found to transmit them to their destination. This counter includes any packets counted in ipForwDatagrams that meet this no-route criterion. This counter includes any datagrams a host cannot route because all default gateways are down.
FragOKs	The number of IP datagrams that were successfully fragmented at this entity.
FragFails	The number of IP datagrams that were discarded because they needed to be fragmented at this entity but can not be, for example, because the Don't Fragment flags were set.
FragCreates	The number of IP datagram fragments that were generated as a result of fragmentation at this entity.
ReasmReqds	The number of IP fragments received that needed to be reassembled at this entity.
ReasmOKs	The number of IP datagrams successfully reassembled.
ReasmFails	The number of failures detected by the IP reassembly algorithm (for whatever reason: timed out, errors, and so on). This number is not necessarily a count of discarded IP fragments because some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received.

Viewing Chassis ICMP In Statistics

View chassis ICMP In statistics to monitor network performance.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **ICMP In** tab.

ICMP In Field Descriptions

The following table describes parameters on the **ICMP In** tab.

Name	Description
SrcQuenchs	The number of ICMP Source Quench messages received.
Redirects	The number of ICMP Redirect messages received.
Echos	The number of ICMP Echo (request) messages received.
EchoReps	The number of ICMP Echo Reply messages received.
Timestamps	The number of ICMP Timestamp (request) messages received.
TimestampReps	The number of ICMP Timestamp Reply messages received.
AddrMasks	The number of ICMP Address Mask Request messages received.
AddrMaskReps	The number of ICMP Address Mask Reply messages received.
ParmProbs	The number of ICMP Parameter Problem messages received.
DestUnreachs	The number of ICMP Destination Unreachable messages received.
TimeExcds	The number of ICMP Time Exceeded messages received.

Viewing Chassis ICMP Out Statistics

View chassis ICMP Out statistics to monitor network performance.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **ICMP Out** tab.

ICMP Out Field Descriptions

The following table describes parameters on the **ICMP Out** tab.

Name	Description
SrcQuenchs	The number of ICMP Source Quench messages sent.
Redirects	The number of ICMP Redirect messages received. For a host, this object is always zero, because hosts do not send redirects.
Echos	The number of ICMP Echo (request) messages sent.
EchoReps	The number of ICMP Echo Reply messages sent.

Name	Description
Timestamps	The number of ICMP Timestamp (request) messages sent.
TimestampReps	The number of ICMP Timestamp Reply messages sent.
AddrMasks	The number of ICMP Address Mask Request messages sent.
AddrMaskReps	The number of ICMP Address Mask Reply messages sent.
ParmProbs	The number of ICMP Parameter Problem messages sent.
DestUnreachs	The number of ICMP Destination Unreachable messages sent.
TimeExcds	The number of ICMP Time Exceeded messages sent.

Viewing Chassis TCP Statistics

View TCP statistics to monitor network performance.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **TCP** tab.

TCP Field Descriptions

The following table describes parameters on the **TCP** tab.

Name	Description
ActiveOpens	The number of times TCP connections made a direct transition to the SYN-SENT state from the CLOSED state.
PassiveOpens	The number of times TCP connections made a direct transition to the SYN-RCVD state from the LISTEN state.
AttemptFails	The number of times TCP connections made a direct transition to the CLOSED state from either the SYN-SENT state or the SYN-RCVD state, plus the number of times TCP connections made a direct transition to the LISTEN state from the SYN-RCVD state.
EstabResets	The number of times TCP connections made a direct transition to the CLOSED state from either the ESTABLISHED state or the CLOSE-WAIT state.
CurrEstab	The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT.
InSegs	The number of segments received, including those received in error. This count includes segments received on currently established connections.
OutSegs	The number of segments sent, including those on current connections, but excluding those containing only retransmitted octets.
RetransSegs	The number of segments retransmitted that is, the number of TCP segments transmitted containing one or more previously transmitted octets.

Name	Description
InErrs	The number of segments received in error (for example, bad TCP checksums).
OutRsts	The number of TCP segments sent containing the RST flag.
HCInSegs	The number of segments received, including those received in error. This count includes segments received on currently established connections. This object is the 64-bit equivalent of InSegs.
HCOutSegs	The number of segments sent, including those on current connections, but excluding those containing only retransmitted octets. This object is the 64-bit equivalent of OutSegs.

Viewing Chassis UDP Statistics

Display User Datagram Protocol (UDP) statistics to see information about the UDP datagrams.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Chassis**.
4. Click the **UDP** tab.
5. Select the information you want to graph.
6. Select the type of graph you want:
 - line
 - area
 - bar
 - pie
7. To clear counters, click **Clear Counters**. Discontinuities in the value of these counters can occur when the management system reinitializes, and at other times as indicated by discontinuities in the value of sysUpTime.

UDP Field Descriptions

Use the data in the following table to use the **UDP** tab.

Name	Description
NoPorts	The number of received UDP datagrams with no application at the destination port. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by discontinuities in the value of sysUpTime.
InErrors	The number of received UDP datagrams that were not delivered for reasons other than the lack of an application at the destination port. Discontinuities in the value of this counter can occur at reinitialization of the management system and at other times as indicated by discontinuities in the value of sysUpTime.

Name	Description
InDatagrams	The number of UDP datagrams delivered to UDP users, for devices that can receive more than 1 000 000 UDP datagrams for each second. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by discontinuities in the value of sysUpTime.
OutDatagrams	The number of UDP datagrams sent from this entity. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by discontinuities in the value of sysUpTime.
HCInDatagrams	The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT.
HCOutDatagrams	The number of UDP datagrams sent from this entity, for devices that can transmit more than 1 million UDP datagrams for each second. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by discontinuities in the value of sysUpTime.

Viewing Port Interface Statistics

View port interface statistics to manage network performance.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Port**.
4. Click the **Interface** tab.

Interface Field Descriptions

The following table describes parameters on the **Interface** tab.

Name	Description
InOctets	Specifies the number of octets received on the interface, including framing characters.
OutOctets	Specifies the number of octets transmitted from the interface, including framing characters.
InUcastPkts	Specifies the number of packets delivered by this sublayer to a higher sublayer that were not addressed to a multicast or broadcast address at this sublayer.
OutUcastPkts	Specifies the number of packets that higher-level protocols requested be transmitted that were not addressed to a multicast address at this sublayer. The total number includes those packets discarded or not sent.
InMulticastPkts	Specifies the number of packets delivered by this sublayer to a higher sublayer that were addressed to a multicast address at this sublayer. For a MAC layer protocol, this number includes both group and functional addresses.

Name	Description
OutMulticastPkts	Specifies the number of packets that higher-level protocols requested be transmitted, and that are addressed to a multicast address at this sublayer, including those that were discarded or not sent. For a MAC layer protocol, this number includes both group and functional addresses.
InBroadcastPkts	Specifies the number of packets delivered by this sublayer to a higher sublayer that are addressed to a broadcast address at this sublayer.
OutBroadcastPkts	Specifies the number of packets that higher-level protocols requested be transmitted, and that were addressed to a broadcast address at this sublayer, including those that were discarded or not sent.
InDiscards	Specifies the number of inbound packets that are discarded because of frames with errors or invalid frames or, in some cases, to fill up buffer space.
InErrors	For packet-oriented interfaces, specifies the number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. For character-oriented or fixed-length interfaces, the number of inbound transmission units that contained errors preventing them from being deliverable to a higher-layer protocol.
InUnknownProtos	For packet-oriented interfaces, specifies the number of packets received through the interface that are discarded because of an unknown or unsupported protocol. For character-oriented or fixed-length interfaces that support protocol multiplexing, the number of transmission units received through the interface that were discarded because of an unknown or unsupported protocol. For any interface that does not support protocol multiplexing, this counter is always 0.
HCInPfcPkts	Specifies the total number of Priority Flow Control (PFC) packets received by this interface. This number does not increment for port-level flow control.
HCOutPfcPkts	Specifies the total number of PFC packets transmitted by this interface. This number does not increment for port-level flow control.
InFlowCtrlPkts	Specifies the number of port-level flow control packets received by this interface.
OutFlowCtrlPkts	Specifies the number of port-level flow control packets transmitted by this interface.
InPfcPkts	Specifies the total number of port-level flow control packets received by this interface.
OutPfcPkts	Specifies the total number of port-level flow control packets transmitted by this interface.
NumStateTransition	Specifies the number of times the port went in and out of service; the number of state transitions from up to down.

Viewing Port Ethernet Errors Statistics

View port Ethernet errors statistics to manage network performance.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **Ethernet Errors** tab.

Ethernet Errors Field Descriptions

The following table describes parameters on the **Ethernet Errors** tab.

Name	Description
AlignmentErrors	Specifies account of frames received on a particular interface that are not an integral number of octets in length and do not pass the FCS check. The count represented by an instance of this object increments when the alignmentError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions obtain are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.
FCSErrors	Specifies a count of frames received on a particular interface that are an integral number of octets in length but do not pass the FCS check. The count represented by an instance of this object increments when the frameCheckError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions obtained are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.
InternalMacTransmitErrors	Specifies a count of frames for which transmission on a particular interface fails due to an internal MAC sublayer transmit error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the LateCollisions object, the ExcessiveCollisions object, or the CarrierSenseErrors object. The precise meaning of the count represented by an instance of this object is implementation-specific. In particular, an instance of this object can represent a count of transmission errors on a particular interface that are not otherwise counted.
InternalMacReceiveErrors	Specifies a count of frames for which reception on a particular interface fails due to an internal MAC sublayer receive error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the FrameTooLongs object, the AlignmentErrors object, or the FCSErrors object. The precise meaning of the count represented by an instance of this object is implementation-specific. In particular, an instance of this object can represent a count of receive errors on a particular interface that are not otherwise counted.

Name	Description
CarrierSenseErrors	Specifies the number of times that the carrier sense condition is lost or not asserted when the switch attempts to transmit a frame on a particular interface. The count represented by an instance of this object increments at most once for each transmission attempt, even if the carrier sense condition fluctuates during a transmission attempt.
FrameTooLongs	Specifies a count of frames received on a particular interface that exceed the maximum permitted frame size. The count represented by an instance of this object increments when the frameTooLong status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions obtained are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.
SQETestErrors	Specifies a count of times that the SQE TEST ERROR message is generated by the PLS sublayer for a particular interface. The SQE TEST ERROR message is defined in section 7.2.2.2.4 of ANSI/IEEE 802.3-1985 and its generation described in section 7.2.4.6 of the same document.
DeferredTransmissions	Specifies a count of frames for which the first transmission attempt on a particular interface is delayed because the medium is busy. The count represented by an instance of this object does not include frames involved in collisions.
SingleCollisionFrames	Specifies a count of successfully transmitted frames on a particular interface for which transmission is inhibited by exactly one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the UcastPkts, MulticastPkts, or BroadcastPkts objects and is not counted by the corresponding instance of the MultipleCollisionFrames object.
MultipleCollisionFrames	Specifies a count of successfully transmitted frames on a particular interface for which transmission is inhibited by more than one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the UcastPkts, MulticastPkts, or BroadcastPkts objects and is not counted by the corresponding instance of the SingleCollisionFrames object.
LateCollisions	Specifies the number of times that a collision is detected on a particular interface later than 512 bit-times into the transmission of a packet; 512 corresponds to 51.2 microseconds on a 10 Mb/s system. A (late) collision included in a count represented by an instance of this object is also considered as a (generic) collision for purposes of other collision-related statistics.
ExcessiveCollisions	Specifies a count of frames for which transmission on a particular interface fails due to excessive collisions.
FrameTooShorts	Specifies the number of frames, encountered on this interface, that are too short.
LinkFailures	Specifies the number of link failures encountered on this interface.
PacketErrors	Specifies the number of packet errors encountered on this interface.

Name	Description
CarrierErrors	Specifies the number of carrier errors encountered on this interface.
LinkInactiveErrors	Specifies the number of link inactive errors encountered on this interface.

View Port Bridging Statistics

Note

This procedure only applies to VSP 4450 Series.

View port bridging errors statistics to manage network performance.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand: **Configuration** > **Graph**.
3. Select **Port**.
4. Select the **Bridging** tab.

Bridging Field Descriptions

The following table describes parameters on the **Bridging** tab.

Name	Description
InUnicastFrames	The number of incoming unicast frames bridged.
InMulticastFrames	The number of incoming multicast frames bridged.
InBroadcastFrames	The number of incoming broadcast frames bridged.
InDiscards	The number of frames discarded by the bridging entity.
OutFrames	The number of outgoing frames bridged.

View Port Routing Statistics

Note

This procedure only applies to VSP 4450 Series.

View port routing statistics to manage network performance.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation tree, expand **Configuration** > **Graph**.
3. Select **Port**.
4. Select the **Routing** tab.

Routing Field Descriptions

Use the data in the following table to use the **Routing** tab.

Name	Description
InUnicastFrames	The number of incoming unicast frames routed.
InMulticastFrames	The number of incoming multicast frames routed.
InDiscards	The number of frames discarded by the routing entity.
OutUnicastFrames	The number of outgoing unicast frames routed.
OutMulticastFrames	The number of outgoing multicast frames routed.

Feature	Product	Release introduced
IPv6 DHCP Relay	VSP 4450 Series	VOSS 4.1
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 4.1
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 6.2
	XA1400 Series	Not Supported

DHCP option 82

The DHCP option 82 is the DHCP Relay Agent Information option. The DHCP relay agent inserts option 82 when it forwards the client-originated DHCP packets to a DHCP server. The Relay Agent Information option is organized as a single DHCP option that contains one or more sub-options that convey information known by the relay agent. The DHCP server echoes the option back to the relay agent in server-to-client replies, and the relay agent removes the option before forwarding the reply to the client.

The DHCP option 82 is added at the DHCP relay level as shown in the following image.

Figure 43: DHCP Client-Relay-Server Architecture

The Relay Agent Information option (code 82) is a container for specific agent-supplied suboptions; Agent Circuit ID (code 1) and Agent Remote ID (code 2). The suboptions can represent different information relevant for the relay. The fields are encoded in the following manner, where N or n is the total number of octets in the Agent Information Field (all bytes of the suboptions):

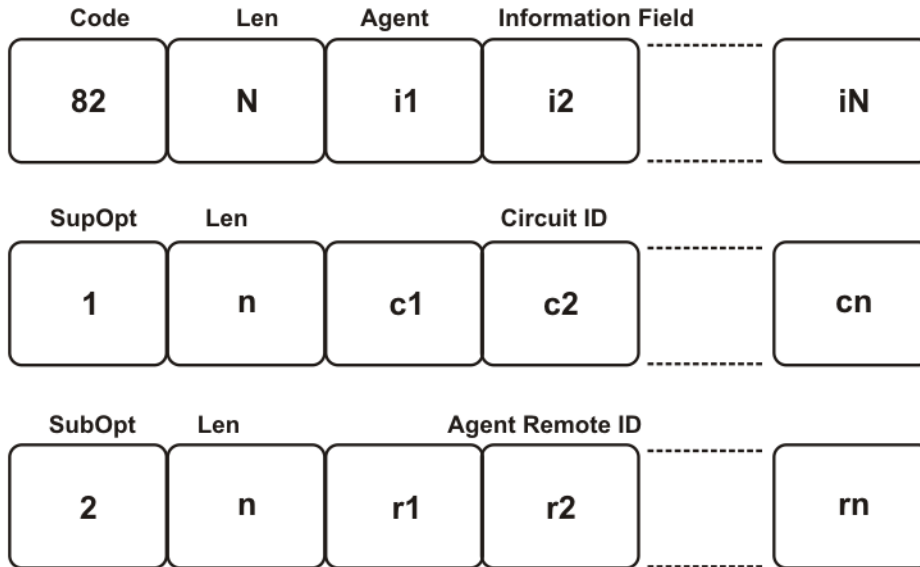

Figure 44: Format of the Relay Agent Information

Because at least one of the sub-options must be defined, the minimum Relay Agent Information length is two (2), and the length n of the suboption can be zero (0). The sub-options do not have to display in any particular order. No pad suboption is defined and the Information field is not terminated with 255 suboption.

DHCP Suboptions

The suboptions are Agent Circuit ID and Agent Remote ID.

The DHCP relay agents can add the Agent Circuit ID to terminate switched or permanent circuits. The Agent Circuit ID encodes an agent-local identifier of the circuit from which a DHCP client-to-server packet was received. Agents can use the Circuit ID to relay DHCP responses back to the proper circuit. In the switch, the Agent Circuit ID field contains the ifIndex of the interface on which the packet is received.

DHCP relay agents can add the Agent Remote ID to terminate switched or permanent circuits, and can identify the remote host end of the circuit. The switch uses the Agent Remote ID field to encode the MAC address of the interface on which the packet is received. The Agent Remote ID must be globally unique.

Agent Operations

A DHCP relay agent adds a Relay Agent Information field as the last option in the DHCP options field of any recognized BOOTP or DHCP packet forwarded from a client to a server. However, if the End Option

255 is present, then the DHCP relay agent adds a Relay Agent information field before the End Option 255 field.

Relay agents can receive a DHCP packet from an untrusted circuit with the gateway IP address (GIADDR) set to zero to indicate that the relay agent is the first-hop router from the gateway. If a Relay Agent Information option is present in the packet, the relay agent discards the packet and increments an error counter. A trusted circuit can contain a trusted downstream network element, for example, a bridge, between the relay agent and the client. The bridge can add a relay agent option but does not set the GIADDR field. In this case, the relay agent forwards the DHCP packet per normal DHCP relay agent operations, and sets the GIADDR field to the relay address. The relay agent does not add a second relay agent option.

You can distinguish between a trusted circuit and an untrusted circuit based on the type of circuit termination equipment you use. To make a circuit trusted, set the trusted flag under DHCP for each interface.

After packets append the Relay Agent Information option, the packets that exceed the MTU or the vendor size buffer of 64 bits, are forwarded without adding the Agent Information option, and an error counter is incremented.

The relay agent or the trusted downstream network element removes the Relay Agent Information option echoed by a server that is added when forwarding a server-to-client response back to the client.

The following list outlines the operations that the relay agent does not perform:

- The relay agent does not add an Option Overload option to the packet or use the file or sname fields to add the Relay Agent Information option. The agent does not parse or remove Relay Agent Information options, the system can display it in the sname or file fields of a server-to-client packet forwarded through the agent.
- The relay agent does not monitor or modify client-originated DHCP packets addressed to a server unicast address; this includes the DHCP-REQUEST sent when entering the RENEWING state.
- The relay agent does not modify DHCP packets that use the IPSEC Authentication Header or IPSEC Encapsulating Security Payload.

A DHCP relay agent can receive a client DHCP packet forwarded from a BOOTP/DHCP relay agent closer to the client. This packet has a GIADDR as non-zero, and may or may not already have a DHCP Relay Agent option in it.

Relay agents configured to add a Relay Agent option which receive a client DHCP packet with a nonzero GIADDR, discards the packet if the GIADDR spoofs a GIADDR address implemented by the local agent itself. Otherwise, the relay agent forwards any received DHCP packet with a valid non-zero GIADDR without adding any relay agent options. The GIADDR value does not change.

DHCP Relay for IPv6

The Dynamic Host Configuration Protocol (DHCP) for IPv6 (RFC 3315) enables DHCP servers to pass configuration parameters such as IPv6 network addresses to IPv6 nodes. DHCP supports automatic allocation of reusable network addresses and of additional configuration parameters. This protocol is a stateful counterpart to stateless address autoconfiguration, and you can use it separately or concurrently with the latter to obtain configuration parameters. For more information about stateless address autoconfiguration, see [Host autoconfiguration](#) on page 1993.

To request the assignment of one or more IPv6 addresses, a client first locates a DHCP server, and then requests the assignment of addresses and other configuration information from the server:

1. The client sends a solicit message to the All_DHCP_Relay_Agents_and_Servers (FF02::1:2) multicast address to find available DHCP servers.
2. Any server that can meet the requirements responds with an advertise message.
3. The client then chooses one of the servers and sends a request message to the server asking for confirmed assignment of addresses and other configuration information.
4. The server responds with a reply message that contains the confirmed addresses and configuration.

If a DHCP client does not need a DHCP server to assign it an IPv6 address, the client can obtain configuration information such as a list of available DNS servers or NTP servers through a single message and reply exchanged with a DHCP server.

IPv6 DHCP clients use link-local addresses to send and receive DHCP messages. To permit a DHCP client to send a message to a DHCP server that is not attached to the same link, you must configure a DHCP relay agent on the client link to relay messages between the client and server. The operation of the relay agent is transparent to the client.

A relay agent relays messages from clients and messages from other relay agents. The switch supports DHCP Relay for IPv6. Configure at least one relay agent when the client and server are in different networks.

You must configure the relay agent to use a list of destination addresses for available DHCP servers. The software does not support IPv6 multicast for site-local and global addresses.

The DHCP relay can be a Virtual Router Redundancy Protocol (VRRP) Address. The relay forwards the DHCP messages only if VRRP is in the Master state, otherwise the relay discards the messages.

Note

DHCP cannot work on the backup VRRP if the master fails. To achieve optimum results and to leverage redundancy, you must configure DHCP on the backup VRRP.

Clients listen for DHCP messages on UDP port 546. Servers and relay agents listen for DHCP messages on UDP port 547.

Remote ID

IPv6 DHCP Relay supports the remote ID parameter (RFC4649). After you enable remote ID on the switch, the relay agent adds information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The server can use the supplied information in the process of assigning the addresses, delegated prefixes, and configuration parameters that the client is to receive.

The remote ID option contains two fields:

- vendor ID
- MAC address of the client

The switch uses a vendor ID of 1584.

Limitations

The following list identifies configuration limitations:

- You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.
- The maximum number of servers to which a relay can send a message from one client, is 10.
- You can configure the number of forwarding paths per system. For information on the maximum limit, see [VOSS Release Notes](#).

DHCP Relay Network Topology and Workflow

The following example depicts the interaction between a DHCP client and a server:

Figure 45: DHCP Client-Relay-Server Architecture

The following list outlines the operations that the DHCP relay agent performs to forward the message to the server :

- When a client sends a request for the IP address or configuration parameters, the server responds with the details as requested by the client.

Note

There should be at least one relay agent when client and server are located in different networks.

- A DHCP Relay IPv6 is established only between agents within the context of each VRF and when no cross VRF interaction is present.

Note

All_DHCP_Servers multicast address option is not implemented for IPv6, as there is no IPv6 MCAST support for site-local and global address.

UDP broadcast forwarding

Some network applications, such as the NetBIOS name service, rely on a User Datagram Protocol (UDP) broadcast to request a service or locate a server for an application. If a host is on a network, subnet segment, or VLAN that does not include a server for the service, UDP broadcasts are by default not forwarded to the server located on a different network segment or VLAN. You can resolve this problem by forwarding the broadcasts to the server through physical or virtual router interfaces.

UDP broadcast forwarding is a general mechanism for selectively forwarding limited UDP broadcasts received on an IP interface out to other router IP interfaces as a rebroadcast or to a configured IP address. If the address is that of a server, the packet is sent as a unicast packet to this address. If the address is that of an interface on the router, the frame is rebroadcast.

After a UDP broadcast is received on a router interface, it must meet the following criteria to be eligible for forwarding:

- It must be a MAC-level broadcast.
- It must be an IP limited broadcast.
- It must be for the specified UDP protocol.
- It must have a time-to-live (TTL) value of at least 2.

For each ingress interface and protocol, the policy specifies how the UDP broadcast is retransmitted: to a unicast host address or to a broadcast address.

DHCP and UDP configuration using the CLI

Use Dynamic Host Configuration Protocol (DHCP), an extension of the Bootstrap Protocol (BootP), to provide host configuration information to the workstations dynamically. Use the DHCP relay commands to configure DHCP relay behavior on a port or on a VLAN.

This section describes CLI commands for DHCP and User Datagram Protocol (UDP) configuration.

Configure DHCP Parameters Globally

Before You Begin

Configure an IP address on the interface to be used as the DHCP relay interface.

About This Task

Configure DHCP relay parameters for the port or the VLAN.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Create the forwarding path from the client to the server:

```
ip dhcp-relay fwd-path <A.B.C.D> <A.B.C.D>
```

3. Enable the forwarding path from the client to the server:

```
ip dhcp-relay fwd-path <A.B.C.D> <A.B.C.D> enable
```

Note

If the agent IP address (the first <A.B.C.D> variable) is a VLAN or port IP address, you must enable DHCP Relay on that VLAN or port by running **ip dhcp-relay** within the VLAN context. However, if the first <A.B.C.D> variable is a VRRP address, you do not need to enable DHCP Relay on the VLAN or port in which the VRRP address resides.

4. Modify DHCP mode to forward BOOTP messages only, DHCP messages only, or both:

```
ip dhcp-relay fwd-path <A.B.C.D> <A.B.C.D> mode <bootp|bootp_dhcp|dhcp>
```

5. (Optional) Configure the forwarding path with source port 67 from client to the server.

```
ip dhcp-relay fwd-path {A.B.C.D} {A.B.C.D} src-port-67
```

Note

This step does not apply to VSP 8600 Series.

Example

Create the forwarding path from the client to the server. Enable the forwarding path from the client the server. Modify DHCP mode to forward both BOOTP and DHCP messages. Configure the forwarding path with source port 67 for BOOTP request.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.120 192.0.2.50
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.128 192.0.2.50 enable
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.128 192.0.2.50 mode bootp_dhcp
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.128 192.0.2.50 src-port-67
```

Variable Definitions

The following table defines parameters for the **ip dhcp-relay fwd-path** command.

Variable	Value
{A.B.C.D}	The {A.B.C.D} variable is the agent IP address configured on an interface (a locally configured IP address).
{A.B.C.D}	The {A.B.C.D} variable is the IP address of the DHCP server in the network.
disable	Disables DHCP Relay globally.
enable	Enables DHCP Relay globally.
mode {bootp bootp_dhcp dhcp>	Modifies DHCP mode to forward BOOTP messages only, DHCP messages only, or both. The default is both.
src-port-67	Configures the UDP source port to 67 for BOOTP request. The default is 68.
Note: Exception: not supported on VSP 8600 Series.	

Showing DHCP relay information

Display relay information to show relay information about DHCP routes and counters.

For scaling information on DHCP Relay forwarding (IPv4 or IPv6), see [VOSS Release Notes](#).

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display information about DHCP relay forward paths:
show ip dhcp-relay fwd-path [vrf WORD<1-16>] [vrfids WORD<0-512>]
3. Display information about DHCP relay counters:
show ip dhcp-relay counters [vrf WORD<1-16>] [vrfids WORD<0-512>]
4. Display the options for each listed interface:
show ip dhcp-relay interface [gigabitethernet {slot/port[/sub-port]} [-slot/port[/sub-port]][,...]] [vlan <1-4059>] [vrf WORD <1-16>] [vrfids WORD <0-512>]

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1#show ip dhcp-relay interface

=====
Port Dhcp
=====
PORT VRF          MAX MIN          ALWAYS CIRCUIT REMOTE TRUST
NUM  NAME          ENABLE HOP SEC   MODE   BCAST  ID      ID      CIRC
-----
Vlan Dhcp
=====
VLAN VRF          MAX MIN          ALWAYS CIRCUIT REMOTE TRUST

-----

All 0 out of 0 of Vlan Dhcp Entries displayed
```

Variable definitions

Use the data in the following table to use the **show ip dhcp-relay** command.

Variable	Value
vrf WORD<1-16>	The name of the VRF.
vrfids WORD<0-512>	The ID of the VRF. The value is an integer in the range of 0-512.

Use the data in the following table to use the **show ip dhcp-relay interface** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>[vlan <1-4059>]</code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<code>[vrf WORD<1-16>]</code>	Specifies the name of the VRF.
<code>[vrfids WORD<0-512>]</code>	Specifies the ID of the VRF. The value is an integer from 0- 512.

Configuring DHCP option 82

Configure the DHCP option 82 to enable the circuit ID to encode an agent-local identifier of the circuit from which a DHCP client-to-server packet is received. Configure the DHCP option 82 to enable the remote ID to encode the MAC address of the interface on which the packet is received. By default, the DHCP option 82 is disabled.

Before You Begin

- You must enable ip and dhcp-relay on the VLAN.

About This Task

To configure the DHCP option 82 on a VLAN, you must enter the VLAN Interface Configuration mode.

To configure the DHCP option 82 on a router port, you must enter the GigabitEthernet Interface Configuration mode.

Procedure

- Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable the circuit ID:

```
ip dhcp-relay circuitID
```
3. Enable the remote ID:

```
ip dhcp-relay remoteID
```
4. Configure the circuit as trusted:

```
ip dhcp-relay trusted
```
5. Show statistics for option 82, which is the relay agent information option:

```
show ip dhcp-relay counters option82 [vrf WORD<1-16>] [vrfids WORD <0-512>]
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/10
```

Enable the circuit ID:

```
Switch:1(config-if)# ip dhcp-relay circuitID
```

Enable the remote ID:

```
Switch:1(config-if)# ip dhcp-relay remoteID
```

Configure the circuit as trusted:

```
Switch:1(config-if)# ip dhcp-relay trusted
```

Show statistics for option 82, which is the relay agent information option:

```
Switch:1(config-if)# show ip dhcp-relay counters option82
```

Variable Definitions

Use the data in the following table to configure the DHCP option 82.

Variable	Value
<i>circuitID</i>	Enables the Circuit ID.
<i>remoteID</i>	Enables the Remote ID.
<i>trusted</i>	Sets the circuit as trusted.

Use the data in the following table to use the **show ip dhcp-relay counters option82 [vrf WORD<1-16>] [vrfids WORD <0-512>]** command.

Variable	Value
<i>vrf WORD<1-16></i>	Displays DHCP counters for a particular VRF. WORD<1-16> specifies the VRF name.
<i>vrfids WORD <0-512></i>	Displays a DHCP forward path for a particular VRF. WORD <0-512> specifies the VRF ID.

Configuring DHCP relay on a port or VLAN

You can view and configure the DHCP parameters on specific ports or on a VLAN.

Before You Begin

- You must configure IP on the interface.

Procedure

- Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Enable DHCP parameters on a specified port or VLAN:

```
ip dhcp-relay
```

Example

```
Switch:1> enable  
Switch:1# configure terminal  
Switch:1(config)# interface gigabitethernet 1/10
```

Enable DHCP parameters on a specified port or VLAN:

```
Switch:1(config-if)# ip dhcp-relay
```

Variable definitions

Use the data in the following table to use the **ip dhcp-relay** command.

Use the **no** operator to disable DHCP parameters on specified ports: **no ip dhcp-relay**.

Note

The **no ip dhcp-relay** command disables DHCP Relay, it does not delete the DHCP entry.

To configure this option to the default value, use the **default** operator with this command.

Variable	Value
<code>broadcast</code>	Enables the device to send the server reply as a broadcast to the end station. After you disable this variable, the device sends the server reply as a unicast to the end station. Use the no operator to disable broadcast: <code>no ip dhcp-relay broadcast</code> . To configure this option to the default value, use the default operator with this command.
<code>circuitId</code>	Enables Option 82 circuit ID on the interface.
<code>clear-counters</code>	Clears DHCP Relay counters for the interface.
<code>fwd-path <A.B.C.D> [vrid <1-255>]</code>	Creates a forward path server with a virtual router ID (or VRRP ID), a mode, and a state. <i>A.B.C.D</i> is the IP address. <i>vrid <1-255></i> is the ID of the virtual router and is an integer from 1 to 255. Use the no operator to delete a forward path server with a specific value and virtual router ID: <code>no ip dhcp-relay fwd-path <A.B.C.D> [vrid <1-255>]</code> To configure this option to the default value, use the default operator with this command.
<code>fwd-path <A.B.C.D> disable [vrid <1-255>]</code>	Disables a forward path server with a specific value and virtual router ID. <i>A.B.C.D</i> is the IP address. <i>vrid <1-255></i> is the ID of the virtual router (or VRRP ID) and is an integer from 1 to 255.
<code>fwd-path <A.B.C.D> enable [vrid <1-255>]</code>	Enables a forward path server with a specific value and virtual router ID (or VRRP ID). <i>A.B.C.D</i> is the IP address in the form a.b.c.d. <i>vrid <1-255></i> is the ID of the virtual router and is an integer from 1 to 255.
<code>fwd-path <A.B.C.D> mode <bootp bootp_dhcp dhcp> [vrid <1-255>]</code>	Configures the forward path mode for a VLAN. This command string is available only in VLAN Interface Configuration mode. <i>A.B.C.D</i> is the IP address in the form a.b.c.d. <i>mode</i> is a choice of bootp, dhcp, or bootp_dhcp. <i>vrid <1-255></i> is the ID of the virtual router (or VRRP ID) and is an integer from 1 to 255. To configure this option to the default value, use the default operator with this command.
<code>max-hop <1-16></code>	Configures the maximum number of hops before a BootP/DHCP packet is discarded (1 to 16). The default is 4. To configure this option to the default value, use the default operator with this command.
<code>min-sec <0-65535></code>	Configures the minimum seconds count for DHCP. If the secs field in the BootP/DHCP packet header is greater than this value, the device relays or forwards the packet; otherwise, the packet is dropped (0 to 65535). The default is 0 seconds. To configure this option to the default value, use the default operator with this command.

Variable	Value
<i>mode</i> <bootp bootp_dhcp dhcp>	Configures DHCP mode to forward BootP messages only, DHCP messages only, or both. The default is both. To configure this option to the default value, use the default operator with this command.
<i>remoteId</i>	Enables Option82 remote ID on the interface.
<i>trusted</i>	Configures the DHCP circuit as trusted.

Displaying DHCP-relay Statistics for Specific Ports

Display individual DHCP-relay statistics for specific ports to manage network performance.

Note

Slot and port information can differ depending on hardware platform.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View DHCP-relay statistics for a specific port or VRF.
show interfaces GigabitEthernet statistics dhcp-relay [vrf WORD<1-16>] [vrfids WORD<0-255>] [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]

Example

View DHCP-relay statistics:

```
Switch:1>enable
Switch:1#show interfaces gigabitethernet statistics dhcp-relay

=====
                        Port Stats Dhcp
=====
PORT_NUM VRF NAME          NUMREQUEST NUMREPLY
-----
1/12     GlobalRouter             0           2
1/13     GlobalRouter             3           2
2/3      GlobalRouter             0           2
=====
```

Variable Definitions

Use the data in the following table to use the **show interfaces GigabitEthernet statistics dhcp-relay** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies a VRF instance by VRF name.
<code>vrfids WORD<0-255></code>	Specifies the ID of the VRF.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (1/1). Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Displaying DHCP-relay Statistics for all Interfaces

About This Task

Display DHCP-relay statistics for all interfaces to manage network performance.

Note

Slot and port information can differ depending on hardware platform.

Procedure

1. Show the number of requests and replies for each interface:
`show ip dhcp-relay counters [vrf WORD<1-16>] [vrfids WORD<0-512>]`
2. Show counters for Option 82:
`show ip dhcp-relay counters option82 [vrf WORD<1-16>] [vrfids WORD<0-512>]`

Example

```
Switch:1>show ip dhcp-relay counters option82
=====
DHCP Counters Option82 - GlobalRouter
=====
      FOUND DROP  CIRCUIT ADD  REMOVE REMOTE      ADD  REMOVE
INTERFACE OPT82 PKT   ID    CIRC  CIRC  ID          REMOTE REMOTE
-----
Port 1/12  0    0   395    0    0    00:24:7f:9d:0a:00  0    0
Vlan40    0    0  2088    0    0    00:24:7f:9d:0a:01  0    0
```

Variable Definitions

Use the data in the following table to use the **show ip dhcp-relay counters** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies a VRF instance by the VRF name.
<code>vrfids WORD<0-512></code>	Specifies the ID of the VRF.

Configuring UDP broadcast forwarding

About This Task

By default, routers do not forward broadcasts. UDP broadcast forwarding is a generalized mechanism for the router to selectively forward UDP broadcasts. You must set up UDP broadcast forwarding on the system. Configure UDP broadcast forwarding to forward the UDP broadcasts of network applications to the required server through physical or virtual router interfaces.

Procedure

1. Enter protocols into a table.
2. Create policies (protocol/server pairs).
3. Assemble the policies into lists or profiles.
4. Apply the list to the appropriate interfaces.

Configuring UDP protocols

About This Task

Configure UDP protocols to determine which UDP broadcasts are forwarded.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```
2. Configure a UDP protocol:

```
ip forward-protocol udp <1-65535> WORD<1-15>
```
3. Confirm your configuration:

```
show ip forward-protocol udp interface [vrf WORD<1-16>][vrfids
WORD<0-512>] portfwd [vrf WORD<1-16>][vrfids WORD<0-512>]
portfwddlist <1-1000>[vrf WORD<1-16>][vrfids WORD<0-512>] vrf
WORD<1-16> vrfids WORD<0-512>
```

Example

Configure a UDP protocol and confirm your configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip forward-protocol udp 53 DNS
Switch:1(config)#show ip forward-protocol udp

=====
                        UDP Protocol Tbl - GlobalRouter
=====
UDP_PORT  PROTOCOL_NAME
-----
37         Time Service
49         TACACS Service
53         DNS
69         TFTP
137        NetBIOS NameSrv
138        NetBIOS DataSrv
```

Variable definitions

Use the data in the following table to use the **ip forward-protocol udp** command.

Variable	Value
<1-65535> WORD<1-15>	Creates a new UDP protocol. <1-65535> WORD<1-15> is the UDP protocol name as a string. Use the no operator to delete a UDP protocol no ip forward-protocol udp <1-65535>.
portfwd	Displays portfwd information.
portfwdlist	Displays port forward list information.
vrf WORD<1-16>	Specifies the name of the VRF.
vrfids WORD<0-512>	Specifies the ID of the VRF.

Configuring a UDP port forward entry

Configure a UDP port forward entry to add or remove a port forward entry.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```
2. Configure a UDP port forward entry:

```
ip forward-protocol udp portfwd <1-65535> {A.B.C.D}
```
3. Confirm your configuration:

```
show ip forward-protocol udp portfwd [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

Configure a UDP port forward entry:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip forward-protocol udp portfwd 150 192.0.2.10
```

Variable definitions

Use the data in the following table to use the **ip forward-protocol udp portfwd** command.

Variable	Value
<code><1-65535> {A.B.C.D}</code>	Adds a UDP protocol port to the specified port forwarding list. <code>1-65535</code> is a UDP protocol port in the range of 1-65535. <code>A.B.C.D</code> is an IP address in a.b.c.d format. Use the no operator to remove a protocol port forwarding entry and IP address from the list: <code>no ip forward-protocol udp portfwd <1-65535> <A.B.C.D></code> . To configure this option to the default value, use the default operator with this command.
<code>vrf WORD<1-16></code>	Specifies the name of the VRF.
<code>vrfids WORD<0-512></code>	Specifies the ID of the VRF.

Configuring the UDP port forwarding list

Configure the UDP port forwarding list to assign protocols and servers to the port forward list.

About This Task

You can perform this procedure in Global Configuration mode, VLAN Interface Configuration mode, or VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the UDP port forwarding list:

```
ip forward-protocol udp portfwdlist <1-1000>
```

**Important**

The following two steps are not available in the Global Configuration or VRF Router Configuration mode. The following two commands are available in VLAN Interface Configuration mode only.

3. Enter VLAN Interface Configuration mode:

```
interface vlan <1-4059>
```
4. Configure the broadcast mask:

```
ip forward-protocol udp broadcastmask {A.B.C.D}
```

5. Configure the maximum time to live:

```
ip forward-protocol udp maxttl <1-16>
```

6. Confirm your configuration:

```
show ip forward-protocol udp portfwddlist <1-1000> [vrf WORD<1-16>]
[vrfids WORD<0-512>]
```

Example

```
Switch:1> enable
Switch:1# configure terminal
```

Configure the UDP port forwarding list:

```
Switch:1(config)# ip forward-protocol udp portfwddlist 1
```

Log on to the VLAN interface configuration mode:

```
Switch:1(config)# interface vlan 3
```

Configure the broadcast mask:

```
Switch:1(config-if)# ip forward-protocol udp broadcastmask 192.0.2.255
```

Configure the maximum time to live:

```
Switch:1(config-if)# ip forward-protocol udp maxttl 10
```

Confirm the configuration:

```
Switch:1(config-if)# show ip forward-protocol udp portfwddlist
```

Variable definitions

Use the data in the following table to use the **ip forward-protocol udp portfwddlist** command.

Variable	Value
<1-1000>	Creates a UDP port forwarding list in the range of 1-1000.
<1-65535> {A.B.C.D}	Adds a UDP protocol port to the specified port forwarding list. 1-65535 is a UDP protocol port in the range of 1-65535. A.B.C.D is an IP address in a.b.c.d format. Use the no operator to remove or delete a port forwarding list ID, no ip forward-protocol udp portfwddlist <1-1000> <1-65535> <A.B.C.D>. To configure this option to use the default value, use the default operator with this command.
name WORD<0-15>	Changes the name of the port forwarding list.

Use the data in the following table to use the **ip forward-protocol udp** command.

Variable	Value
<code>broadcastmask {A.B.C.D}</code>	Configures the interface broadcast mask (the interface broadcast mask can be different from the interface mask). <i>A.B.C.D</i> is an IP address in a.b.c.d format. Use the no operator to delete the broadcast mask: <pre>no ip forward-protocol udp broadcastmask {A.B.C.D}</pre> To configure this option to the default value, use the default operator with this command.
<code>maxttl <1-16></code>	Configures the maximum time-to-live value (TTL) for the UDP broadcast forwarded by the interface. The range is 1-16.
<code>portfwddlist <1-1000></code>	Assigns the list to the VLAN.
<code>vlan <1-4059></code> <code>[portfwddlist <1-1000>]</code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. If you use the portfwddlist variable with the VLAN variable, it assigns the list to the specified VLAN, regardless of which VLAN context you currently configure.

Showing UDP forward information

Show UDP forward information to view information about the UDP forwarding characteristics of the device. UDP forwarding only supports 128 entries.

About This Task

There are four show options:

- Show the interface information
- Show the port forward information
- Show the port forward list information
- Show the protocol information

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Display information about the UDP interface for all IP addresses or a specified IP address:

```
show ip forward-protocol udp interface [<A.B.C.D>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
3. Display the UDP port forwarding table:

```
show ip forward-protocol udp portfwd [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

4. Display the UDP port forwarding list table for the specified list or all lists on the device:

```
show ip forward-protocol udp portfwldlist [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
5. Display the UDP protocol table with the UDP port numbers for each supported or designated protocol:

```
show ip forward-protocol udp [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

Display the UDP protocol table with the UDP port numbers for each supported or designated protocol:

```
Switch:1>enable
Switch:1#show ip forward-protocol udp

=====
                        Udp Protocol Tbl - GlobalRouter
=====
UDP_PORT  PROTOCOL_NAME
-----
37        Time Service
49        TACACS Service
53        DNS
69        TFTP
137       NetBIOS NameSrv
138       NetBIOS DataSrv
```

Variable Definitions

Use the data in the following table to use the **show ip forward-protocol udp interface** command.

Variable	Value
<A.B.C.D>	Specifies the IP address for the interface in a.b.c.d format.
vrf WORD<1-16>	Specifies the name of the VRF.
vrfids WORD<0-512>	Specifies the ID of the VRF and is an integer in the range of 0 to 512.

IPv6 DHCP Relay Configuration using CLI

Configure a DHCP Relay Forwarding Path

Configure a forwarding path to specify the relay agent address and the DHCP server address to which to forward packets.

To use DHCP Relay for IPv6, you must configure at least one forwarding path and enable the relay on one interface.

Before You Begin

For a VRF other than GlobalRouter, the interface must be first associated to that VRF.

About This Task

The relay agent can use the IPv6 address of the interface or the VRRP global address linked to that interface. The relay forwards the DHCP messages only if VRRP is in the master state, otherwise the relay discards the messages.

You can configure only one relay agent on an interface. If you need to change the relay agent, you must delete all the forwarding paths with the old relay agent, and then configure the new relay agent.

For scaling information on DHCP Relay forwarding paths, see [VOSS Release Notes](#).

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure a forwarding path:

```
ipv6 dhcp-relay fwd-path WORD<0-255> WORD<0-255> [enable]
```

If you configure the forwarding path globally, the relay agent address can be any configured IP address of the relay interface or the VRRP global address linked to the relay interface.

3. To configure a forwarding path on an interface, enter Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

OR

```
interface vlan <1-4059>
```

4. Configure a forwarding path:

```
ipv6 dhcp-relay fwd-path WORD<0-255> [enable] [vrid WORD<1-255>]
```

If you configure the forwarding path on an interface, the relay agent address is either the smallest IP configured on the interface or the first VRRP global address configured, if the relay is the VRRP master. You do not specify the relay agent address as part of the command.

Note

IPv6 DHCP Relay is established only between agents within the context of each VRF.

Examples

Configure a forwarding path globally:

```
Switch:1(config)#ipv6 dhcp-relay fwd-path 1111::1111 1234::1234 enable
```

Configure a forwarding path on an interface:

```
Switch:1(config)#interface GigabitEthernet 1/1
Switch:1(config-if)#ipv6 dhcp-relay fwd-path 1234::1234 enable
```

Configure the VRRP master as the relay:

```
Switch:1(config-if)#ipv6 dhcp-relay fwd-path 1234::1234 vrid 12 enable
```

Variable Definitions

Use the data in the following table to use the **ipv6 dhcp-relay fwd-path** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<i>enable</i>	Enables the forwarding path. The default is disabled.
{ <i>slot/port</i> [/sub-port] [-slot/port] [/sub-port]] [, ...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>vrid</i> WORD<1-255>	Specifies the VRRP ID to use the VRRP master as the relay agent interface.
WORD<0-255>	Specifies the IPv6 address of the DHCP server for the interface configuration.
WORD<0-255> WORD<0-255>	Specifies the IPv6 address of the relay agent interface and the IPv6 address of the DHCP server for the global configuration.

Configuring DHCP Relay for an interface

Configure the DHCP relay behavior on the interface.

About This Task

You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[, ...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable DHCP on the interface:
`ipv6 dhcp-relay`
3. Configure the maximum hop count:
`ipv6 dhcp-relay max-hop <1-32>`
4. Enable the remote ID:
`ipv6 dhcp-relay remote-id`

Example

Configure the maximum hop count:

```
Switch:1(config-if)#ipv6 dhcp-relay max-hop 30
```

Disable the remote ID:

```
Switch:1(config-if)#no ipv6 dhcp-relay remote-id
```

Variable Definitions

Use the data in the following table to use the **ipv6 dhcp-relay** command.

Variable	Value
<code>max-hop <1-32></code>	Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.
<code>remote-id</code>	Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled

Use the data in the following table to use the **interface** command.

Variable	Value
<code><1-4059></code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View DHCP Relay Information

View DHCP Relay information to display the current configuration for the forwarding path and the interface configuration.

About This Task

Not all parameters are available in non-default VRFs.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View DHCP Relay global information:
show ipv6 dhcp-relay {counters [vrf WORD<1-16> | vrfids WORD<0-512>] | fwd-path [vrf WORD<1-16> | vrfids WORD<0-512>]}
3. View IPv6 DHCP Relay interface configuration:
show ipv6 dhcp-relay interface {gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | vlan <1-4059>}

Note

The **no ipv6 dhcp-relay** command disables DHCP on the interface but does not delete the entry.

Example

```
Switch:1(config-if)#show ipv6 dhcp-relay fwd-path

=====
                        DHCPv6 Fwd-path - GlobalRouter
=====
INTERFACE                SERVER                ENABLE
-----
1111:0:0:0:0:0:1111      1234:0:0:0:0:0:1234      enable
```

Variable Definitions

Use the information in the following table to help you use the **show ipv6 dhcp-relay** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
vrf WORD<1-16>	Specifies the VRF name.
vrfids WORD<0-512>	Specifies the VRF ID.

Viewing IPv6 DHCP Relay Statistics

Display individual IPv6 DHCP Relay statistics for specific interfaces to manage network performance.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View statistics:

```
show ipv6 dhcp-relay counters
```

Note

Use the `sys action reset counters` command to clear DHCP Relay statistics.

Example

```
Switch:1#show ipv6 dhcp-relay counters
```

```
=====
                                DHCPv6 Counters
=====
INTERFACE                        REQUESTS  REPLIES
-----
1111:0:0:0:0:0:1111              1         1
=====
```

DHCP and UDP configuration using Enterprise Device Manager

Dynamic Host Configuration Protocol (DHCP), an extension of the Bootstrap Protocol (BootP), dynamically provides host configuration information to workstations. To lower administrative overhead, network managers prefer to configure a small number of DHCP servers in a central location. Using few DHCP servers requires the routers connecting to the subnets or bridge (or VLAN) domains to support the BootP/DHCP relay function so that hosts can retrieve the configuration information from servers several router hops away.

User datagram protocol (UDP) is a connectionless protocol that adds reliability and multiplexing to IP. It describes how messages reach application programs within a destination computer. Some network applications, such as the NetBIOS name service, rely on a UDP broadcast to request a service or to locate a service. By default, broadcasts are not forwarded by a router. UDP broadcast forwarding is a generalized mechanism for the router to selectively forward UDP broadcasts.

Important

BootP/DHCP relays are supported only on IP routed port-based VLANs and protocol-based VLANs.

Before You Begin

You must enable DHCP relay on the path for port or VLAN configuration to take effect.

Configuring DHCP on a brouter port or a VRF instance

Before You Begin

- You must first enable BootP/DHCP relay on a port (or VLAN).
- You must enable DHCP and forwarding path.
- You must enable IP Routing on the interface.

About This Task

Use the DHCP tab to configure the DHCP behavior on a brouter port or a VRF instance. The DHCP tab is available only if the port is routed (that is, assigned an IP address).

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **DHCP Relay** tab.
5. Click **Enable** to select the DHCP option. The default is disable.
6. Configure the other parameters as needed.
7. Click **Apply**.

DHCP field descriptions

Use data from the following table in the DHCP Relay tab.

Name	Description
Enable	Lets you use BootP/DHCP on the port. The default is disable.
MaxHop	Sets the maximum number of hops before a BootP/DHCP packet is discarded (1 to 16). The default is 4.
MinSec	The secs field in the BootP/DHCP packet header represents the elapsed time since the client first sent the message. If the secs field in the packet header is greater than this value, the system relays or forwards the packet; otherwise, the packet is dropped. The default is 0 seconds.
Mode	Sets the interface to process only BootP, only DHCP, or both types of packets. The default is both.
AlwaysBroadcast	When enabled, the server reply is sent as a broadcast back to the end station. The default is disable.
CircuitId	Indicates whether DHCP Relay inserted the option 82 circuit ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.
Remoteld	Indicates whether DHCP Relay inserted the option 82 remote ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.
Trusted	Indicates if DHCP packets come through a trusted DHCP circuit. Only packets with GIADDR configured to 0 and containing option 82 are forwarded if the circuit is trusted. The default value is false.

Configuring BootP/DHCP on a VLAN or VRF instance

Before You Begin

- You must enable IP Routing on the interface.

About This Task

Use the DHCP Relay tab to configure the DHCP behavior on a VLAN. The DHCP Relay tab is available only if the VLAN is routed and is assigned an IP address.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs > Basic**.
3. Select a VLAN.
4. Click **IP**.
5. Click the **DHCP Relay** tab.
6. Select **Enable**.
7. Configure the parameters as required.
8. Click **Apply**.

DHCP Relay field descriptions

Use the data in the following table to use the **DHCP Relay** tab.

Variable	Value
Enable	Lets you use BootP/DHCP on the port. The default is disable.
MaxHop	Sets the maximum number of hops a BootP/DHCP packet can take from the DHCP client to the DHCP server. The maximum number of hops is 16. The default is 4.
MinSec	Represents the minimum number of seconds to wait between receiving a DHCP packet and forwarding the DHCP packet to the DHCP server. A value of 0 indicates that forwarding is done immediately. The default value is 0.
Mode	Indicates the type of DHCP packet required. The options are: <ul style="list-style-type: none"> • bootp • dhcp • both The default is both.
AlwaysBroadcast	When enabled, the DHCP Reply packets are sent as a broadcast to the DHCP client. The default is disable.
CircuitId	Indicates whether DHCP Relay inserted the option 82 circuit ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.

Variable	Value
Remoteld	Indicates whether DHCP Relay inserted the option 82 remote ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.
Trusted	Indicates if DHCP packets come through a trusted DHCP circuit. Only packets with GIADDR configured to 0 and containing option 82 are forwarded if the circuit is trusted. The default value is false.

Configure DHCP Relay

About This Task

After you configure the BOOTP/DHCP relay on an IP interface, you can configure forwarding paths to indicate where packets are forwarded. The forwarding paths are based on the type of packet and where the packet is received.

About This Task

Procedure

1. In the navigation tree, expand **Configuration > IP**.
2. Select **DHCP Relay**.
3. Select the **Globals** tab.
4. Select **Insert**.
5. In the **AgentAddr** box, type the agent address.
6. In the **ServerAddr** list, type the server address.
7. Select **Enable** to enable BOOTP/DHCP relay. You can enable or disable each agent server forwarding policy. The default is enabled.
8. In the **Mode** box, select the type of messages to relay.
Both the mode setting for the DHCP interface and the mode setting for the agent interface determine which packets are forwarded.
9. Select **SrcPort67** to configure the source port for the BOOTP/DHCP relay request.

Note

This step does not apply to VSP 8600 Series.

10. Select **Insert**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AgentAddr	The IP address of the input interface (agent) on which the BOOTP/DHCP request packets are received for forwarding. This address is the IP address of either a brouter port or a VLAN for which forwarding is enabled.
ServerAddr	This parameter is either the IP address of the BOOTP/DHCP server or the address of another local interface. <ul style="list-style-type: none"> • If it is the address of the BOOTP/DHCP server, the request is unicast to the server address. • If the address is one of the IP addresses of an interface on the system, the BOOTP/DHCP requests are broadcast out of that local interface.
Enable	Enables BOOTP/DHCP relay.
Mode	Specifies the type of messages relayed: <ul style="list-style-type: none"> • Only BOOTP • Only DHCP • Both types of messages <p>The default is to forward both BOOTP and DHCP messages.</p>
SrcPort67 Note: Exception: not supported on VSP 8600 Series.	Assigns source port 67 to the UDP forwarding path. The default is source port 68.

Viewing DHCP relay configuration information

About This Task

Use the DHCP Relay Interfaces tab to view configuration information about the DHCP relay. To change the configuration information, double-click the value in the field under the required interface, and enter a new value.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **DHCP Relay**.
3. Click the **Interfaces** tab.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

Variable	Value
IfIndex	A read-only interface number that represents a physical interface, or the VLAN logical interface.
MaxHop	Sets the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The maximum number of hops is 16. The default is 4.
MinSec	Represents the minimum number of seconds to wait between receiving a DHCP packet and forwarding the DHCP packet to the DHCP server. A value of 0 indicates that forwarding is done immediately. The default value is 0.
Mode	Indicates the type of DHCP packet required. The options are: <ul style="list-style-type: none"> • bootp • dhcp • both The default is both.
AlwaysBroadcast	Indicates if DHCP Reply packets can be sent as a broadcast to the DHCP client. The default is false.
CircuitId	Indicates whether DHCP Relay inserted the option 82 circuit ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.
RemotId	Indicates whether DHCP Relay inserted the option 82 remote ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.
Trusted	Indicates if DHCP packets come through a trusted DHCP circuit. Only packets with GIADDR configured to 0 and containing option 82 are forwarded if the circuit is trusted. The default value is false.

Viewing DHCP Statistics for an Interface

View DHCP statistics to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **DHCP Relay**.
3. Click the **Interfaces Stats** tab.

Interfaces Stats Field Descriptions

Use the data in the following table to use the **Interfaces Stats** tab.

Name	Description
IfIndex	Identifies the physical interface.
AgentAddr	Shows the IP address configured as the relay on this interface. This address is either the IP of the physical interface or the IP of the VRRP address.
NumRequests	Shows the number of DHCP and BootP requests on this interface.
NumReplies	Shows the number of DHCP and BootP replies on this interface.

Graphing DHCP Statistics for a Port

View DHCP statistics to manage network performance.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **DHCP** tab.
5. Select one or more values.
6. Click the type of graph to create.

DHCP Field Descriptions

The following table describes parameters on the **DHCP** tab.

Name	Description
NumRequests	The number of DHCP and/or BootP requests on this interface.
NumReplies	The number of DHCP and/or BootP replies on this interface.

Viewing DHCP Statistics for a Port

View DHCP statistics to manage network performance.

Procedure

1. In the Device Physical view, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **IP**.
4. Click the **DHCP Relay** tab.
5. Click **Graph**.
6. Select one or more values.
7. Click the type of graph.

DHCP Stats Field Descriptions

Use the data in the following table to use the **DHCP Stats** tab.

Name	Description
NumRequests	The number of DHCP and BootP requests on this interface.
NumReplies	The number of DHCP and BootP replies on this interface.

Displaying DHCP-relay Statistics for Option 82

Display DHCP-relay statistics for all interfaces to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **DHCP-Relay**.
3. Click the **Option 82 Stats** tab.

Option 82 Stats Field Descriptions

Use the data in the following table to use the **Option 82 Stats** tab.

Name	Description
IfIndex	Shows the name of the interface on which you enabled option 82. Shows the port number if the interface is a brouter port or the VLAN number if the interface is a VLAN.
AgentAddr	Shows the IP address configured as the relay on this interface. This address is either the IP of the physical interface or the IP of the VRRP address.
FoundOp82	Shows the number of packets that the interface received that already had option82 in them.
Dropped	Shows the number of packets the interface dropped because of option 82-related issues. These reasons could be that the packet was received from an untrusted source or spoofing was detected. To determine the cause of the drop, you must enable trace on level 170.
CircuitId	Shows the value inserted in the packets as the circuit ID. The value is the index of the interface.
AddedCircuitId	Shows how many packets (requests from client to server) the circuit ID was inserted for that interface. If you expect this value to increase but it does not, and the interface does not drop a packet, it is possible the packet does not have enough space to insert the option. You must enable trace on level 170 to determine the cause.

Name	Description
RemovedCircuitId	Shows how many packets (replies from server to client) the circuit id was removed for that interface.
Remoteld	Shows the value inserted in the packets as the remote ID. The value is the MAC address of the interface.
AddedRemoteld	Shows how many packets (requests from client to server) the remote ID was inserted for that interface. If you expect this value to increase but it does not, and the interface does not drop a packet, it is possible the packet does not have enough space to insert the option. You must enable trace on level 170 to determine the cause.
RemovedRemoteld	Shows how many packets (replies from server to client) the remote ID was removed for that interface.

Graphing DHCP Statistics for a VLAN

View DHCP statistics to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **VLANs**.
3. On the **Basic** tab, select a VLAN.
4. Click **IP**.
5. Click the **DHCP Relay** tab.
6. Click **Graph**.
7. Select one or more values.
8. Click the type of graph.

DHCP Stats Field Descriptions

Use the data in the following table to use the **DHCP Stats** tab.

Name	Description
NumRequests	The number of DHCP and BootP requests on this interface.
NumReplies	The number of DHCP and BootP replies on this interface.

Managing UDP forwarding protocols

About This Task

The switch configures the following protocols, by default:

- Time Service
- Terminal Access Controller Access Control System (TACACS) Service
- Domain Name System (DNS)
- Trivial file transfer protocol (TFTP)
- Network Basic Input/Output System (NetBIOS) NameSrv
- NetBIOS DataSrv

You can use these protocols to create forwarding entries and lists but you cannot delete them; you can add or remove other protocols to the list of protocols.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **UDP Forwarding**.
3. Click **Insert**.
4. In the **PortNumber** field, type a UDP port number.
This number defines the UDP port used by the server process as its contact port. The range is from 1 to 65535 and cannot be one of the UDP port numbers or a number previously assigned.
5. In the **Name** field, type a name for the protocol.
6. Click **Insert**.
The protocol is added to the Protocol table. After you create a protocol, you cannot change its name or number.

Protocols field descriptions

Use the data in the following table to use the **Protocols** tab.

Name	Description
PortNumber	Defines the UDP port (1 to 65535).
Name	Specifies an administratively assigned name for this list (0 to 15 characters).

Managing UDP forwarding

About This Task

You manage UDP forwarding by defining the destination addresses for the UDP protocol.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **UDP Forwarding**.
3. Click the **Forwardings** tab.

4. Click **Insert**.
5. In the Insert Forwardings dialog box, select a destination UDP port from the defined protocols in the **DestPort** box.
6. Enter a destination IP address in the **DestAddr** box.
The destination address can be any IP server address for the protocol application or the IP address of an interface on the router.
7. Click **Insert**. The information is added to the Forwarding tab.

Forwardings field descriptions

Use the data in the following table to use the **Forwardings** tab.

Name	Description
DestPort	Specifies the port number defined for UDP, depending upon the protocol type.
DestAddr	Specifies the destination address can be any IP server address for the protocol application or the IP address of an interface on the router: <ul style="list-style-type: none"> • If the address is that of a server, the packet is sent as a unicast packet to this address. • If the address is that of an interface on the router, the frame is rebroadcast.
Id	Specifies an integer that identifies this entry internally.
NumFwdPackets	Specifies the total number of UDP broadcast packets forwarded using this policy.
NumDropPacketsTtlExpired	Specifies the total number of UDP broadcast packets dropped because the time-to-live value (TTL) expired.
NumDropPacketsDestUnreach	Specifies the total number of UDP broadcast packets dropped because the specified destination address was unreachable.

Creating the forwarding profile

About This Task

A forwarding profile is a collection of port and destination pairs. When you configure UDP forwarding list entries, be sure to first configure the UDP forwarding list. Then, configure your UDP forwarding list entries and assign them to a UDP forwarding list. If you do not assign a UDP forwarding list entry to at least one UDP forwarding list, the UDP forwarding list is lost after a restart.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **UDP Forwarding**.
3. Click the **Forwarding Lists** tab.
4. Click **Insert**.
5. In the **Id** field, type the forwarding list ID.

6. In the **Name** field, type the name of the forwarding list if required.
The system displays the forwarding list in the **FwdIdList** box.
7. Click **Insert**.

Forwarding Lists *field descriptions*

Use the data in the following table to use the **Forwarding Lists** tab and **Insert Forwarding Lists** dialog box.

Name	Description
Id	Specifies a value that uniquely identifies this list of entries (1 to 1000).
Name	Specifies an administratively assigned name for this list (0 to 15 characters).
FwdIdList	Specifies the zero or more port forwarding entries associated with this list. Each list identifier is stored as 2 bytes in this array, starting from 0 bytes (size=64). Clicking on the ellipsis (...) button in this field displays the ID list.

Managing the broadcast interface

About This Task

Manage the broadcast interface by specifying and displaying which router interfaces can receive UDP broadcasts to forward.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **UDP Forwarding**.
3. Click the **Broadcast Interfaces** tab.
4. Click **Insert**.
5. In the **LocalIfAddr** field, click the ellipsis (...) to select a local interface IP address from the list, and then click **OK**.
6. In the **UdpPortFwdListId** field, click the ellipsis (...) to select a forwarding list ID from the list, and then click **OK**.
7. In the **MaxTtl** field, type the maximum number of hops an IP broadcast can take from the source device to the destination device (the default is 4; the range is 1 to 16).
8. In the **BroadCastMask** field, enter the subnet mask of the local interface that broadcasts the UDP broadcast packets.

When you configure the UDP forwarding broadcast mask, the broadcast mask must be less specific (shorter in length) or equally specific (equal in length) to the subnet mask of the IP interface on which it is configured. If the UDP forwarding broadcast mask is more specific than the subnet mask of the corresponding IP interface, UDP forwarding does not function properly.
9. Click **Insert**.

Broadcast Interfaces field descriptions

Use the data in the following table to use the **Broadcast Interfaces** tab.

Name	Description
LocalIfAddr	Specifies the IP address of the local router interface that receives forwarded UDP broadcast packets.
UdpPortFwdListId	Specifies the number of the UDP lists or profiles that this interface is configured to forward (0 to 100). A value of 0 indicates that the interface cannot forward any UDP broadcast packets.
MaxTtl	Specifies the maximum number of hops an IP broadcast packet can take from the source device to the destination device (the default is 4; the range is 1 to 16).
NumRxPkts	Specifies the total number of UDP broadcast packets received by this local interface.
NumFwdPkts	Specifies the total number of UDP broadcast packets forwarded by this local interface.
NumDropPktsMaxTtlExpired	Specifies the total number of UDP broadcast packets dropped because the time-to-live (TTL) value expired.
NumDropPktsDestUnreach	Specifies the total number of UDP broadcast packets dropped because the destination was unreachable.
NumDropPktsUnknownPort	Specifies the total number of UDP broadcast packets dropped because the destination port or protocol specified has no matching forwarding policy.
BroadCastMask	Specifies the subnet mask of the local interface that broadcasts the UDP broadcast packets.

Viewing UDP endpoint information

View UDP Endpoints to confirm correct configuration.

About This Task

You can use UDP endpoint information to display local and remote UDP activity.

Since UDP is a protocol used to establish connectionless network sessions, you need to monitor local and remote UDP activity and to know which applications are running over UDP.

You can determine which applications are active by checking the port number.

Processes are further identified with a UDP session to allow for the multiplexing of a port mapping for UDP.

Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **TCP/UDP**.
3. Click the **UDP Endpoints** tab.

UDP Endpoints field descriptions

Use the data in the following table to use the **UDP Endpoints** tab.

Name	Description
LocalAddressType	Displays the local address type (IPv6 or IPv4).
LocalAddress	Displays the local IPv6 address.
LocalPort	Displays the local port number.
RemoteAddressType	Displays the remote address type (IPv6 or IPv4).
RemoteAddress	Displays the remote IPv6 address.
RemotePort	Displays the remote port number.
Instance	Distinguishes between multiple processes connected to the UDP endpoint.
Process	Displays the ID for the UDP process.

IPv6 DHCP Relay Configuration using EDM

Configure a DHCP Relay Forwarding Path

Configure a forwarding path to specify the relay agent address and the DHCP server address to which to forward packets.

To use DHCP Relay for IPv6, you must configure at least one forwarding path and enable the relay on one interface.

Before You Begin

Change the VRF instance as required to configure a DHCP Relay forwarding path on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

The relay agent can use the IPv6 address of the interface or the VRRP global address linked to that interface. The relay forwards the DHCP messages only if VRRP is in the Master state, otherwise the relay discards the messages.

You can configure only one relay agent on an interface. If you need to change the relay agent, you must delete all the forwarding paths with the old relay agent, and then configure the new relay agent.

For scaling information on DHCP Relay forwarding paths, see [VOSS Release Notes](#).

Procedure

1. In the navigation tree, expand **Configuration > IPv6**.
2. Select **DHCP Relay**.
3. Select the **Forward Path** tab.
4. Select **Insert**.

5. In the **AgentAddr** field, type the address of the input interface that forwards the packets.
6. In the **ServerAddr** field, type the address of the DHCP server.
7. Select **Enabled**.
8. Select **Insert**.

Forward Path field descriptions

Use the data in the following table to use the **Forward Path** tab.

Name	Description
AgentAddr	Specifies the IP address of the input interface (relay agent) on which the DHCP request packets are received for forwarding. This address is the IPv6 or VRRP global address of either a brouter port or a VLAN for which forwarding is enabled.
ServerAddr	Specifies the IP address of the DHCP server. The request is unicast to the server address.
Enabled	Enables DHCP Relay for the system. The default is disabled (clear).

Configuring DHCP Relay for an interface

Configure the DHCP relay behavior on the interface.

Before You Begin

Change the VRF instance as required to configure DHCP Relay for an interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

You can modify the DHCP Relay configuration for a brouter port through the **Edit > Port > IPv6** navigation path, and for a VLAN through the **VLAN > VLANs > Basic > IPv6** navigation path. This procedure uses the main IPv6 navigation path where you can configure both types of interfaces.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **DHCP Relay**.
3. Click the **Interface** tab.
4. Click **Insert**.
5. Beside the **IfIndex** field, click **Port** or **Vlan**.
6. Select a port or VLAN, and then click **OK**.
7. Click **Insert**.

Interface field descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
IfIndex	Shows the unique value to identify an IPv6 interface. For the brouter port, the value is the ifindex of the port and, in the case of the VLAN, the value is the ifindex of the VLAN.
MaxHop	Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.
RemoteIdEnabled	Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled (clear or false).

Modifying DHCP Relay for a VLAN

Modify the existing DHCP relay behavior on the VLAN interface.

About This Task

You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IPv6**.
6. Click the **DHCP Relay** tab.
7. Double-click a cell to change the value.
8. Click **Apply**.

DHCP field descriptions

Use the data in the following table to use the **DHCP Relay** tab.

Name	Description
IfIndex	Shows the unique value to identify an IPv6 interface.
MaxHop	Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.

Name	Description
RemoteldEnabled	Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled (clear or false).
DhcpEnabled	Enables (true) or disables (false) DHCP Relay for an interface with an existing DHCP Relay configuration.

Modifying DHCP Relay for a port

Modify the existing DHCP relay behavior on the router port interface.

About This Task

The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

Procedure

1. In the Device Physical View, select the port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IPv6**.
4. Click **DHCP Relay**.
5. Double-click a cell to change the value.
6. Click **Apply**.

DHCP Relay field descriptions

Use the data in the following table to use the **DHCP Relay** tab.

Name	Description
IfIndex	Shows the unique value to identify an IPv6 interface. For the router port, the value is the ifindex of the port and, in the case of the VLAN, the value is the ifindex of the VLAN.
MaxHop	Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.

Name	Description
RemoteldEnabled	Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled (clear or false).
DhcpEnabled	Enables (true) or disables (false) DHCP Relay for an interface with an existing DHCP Relay configuration. The system displays this field on the DHCP Relay tab for a brouter port only if you modify an existing configuration. The system does not display this field if you create a new DHCP Relay port configuration.

Viewing DHCP Statistics for an IPv6 Interface

View IPv6 DHCP statistics to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Select **DHCP Relay**.
3. Select the **Interfaces Stats** tab.

Interfaces Stats Field Descriptions

Use the data in the following table to use the **Interfaces Stats** tab.

Name	Description
IfIndex	Identifies the physical interface.
NumRequests	Shows the number of DHCP and BootP requests on this interface.
NumReplies	Shows the number of DHCP and BootP replies on this interface.

Viewing IPv6 DHCP Relay Statistics for a Port

Display individual IPv6 DHCP Relay statistics for specific ports to manage network performance. You can also create a graph of selected statistical values.

Procedure

1. On the Device Physical view, select a port.
2. In the navigation pane, expand the **Configuration > IPv6** folders.
3. Click the **DHCP Relay** tab.
4. Click the **Interface** tab.
5. Select the interface on which you want to view the IPv6 DHCP Relay statistics.
6. Click **Statistics**.
7. Select one or more values.
8. Click the type of graph.

Statistics *Field Descriptions*

Use the data in the following table to use the **Statistics** tab.

Name	Description
NumRequests	Shows the number of DHCP and BootP requests on this interface.
NumReplies	Shows the number of DHCP and BootP replies on this interface.

Domain Name Service

	XA1400 Series	Not Supported

The following sections provide information on the Domain Name Service (DNS) implementation for the switch.

DNS fundamentals

This section provides conceptual material on the Domain Name Service (DNS) implementation for the switch. Review this content before you make changes to the configurable DNS options.

DNS client

Every equipment interface connected to a Transmission Control Protocol over IP (TCP/IP) network is identified with a unique IPv4 or IPv6 address. You can assign a name to every machine that uses an IPv4 or IPv6 address. The TCP/IP does not require the usage of names, but these names make the task easier for network managers in the following ways:

- An IP client can contact a machine with its name, which is converted to an IP address, based on a mapping table. All applications that use this specific machine do not depend on the addressing scheme.
- It is easier to remember a name than a full IP address.

To establish the mapping between an IP name and an IPv4 or an IPv6 address you use the Domain Name Service (DNS). DNS is a hierarchical database that you can distribute on several servers for backup and load sharing. After you add a new hostname, update this database. The information is sent to all the different hosts. An IP client that resolves the mapping between the hostname and the IP address sends a request to one of the database servers to resolve the name.

After you establish the mapping of IP name and IP address, the application is modified to use a hostname instead of an IP address. The switch converts the hostname to an IP address.

If the entry to translate the hostname to IP address is not in the host file, the switch queries the configured DNS server for the mapping from hostname to IP address. You can configure connections for up to three different DNS servers—primary, secondary and tertiary. First the primary server is queried, and then the secondary, and finally the tertiary.

The DNS client tracks any server addresses or domain names provided from a DHCP server. If a DHCP server provides info to the DNS client, the DNS configuration is classified as dynamic. You can manually delete dynamic DNS entries, but cannot manually add dynamic DNS entries. You can view the Dynamic DNS entries with **show ip dns** or **show sys dns**. Dynamic DNS entries are not saved in the configuration file. The status monitoring of DNS occurs every 60 seconds.

DNS modifies Ping, Telnet, and copy applications. You can enter a hostname or an IP address to invoke Ping, Telnet, and copy applications.

A log/debug report is generated for all the DNS requests sent to DNS servers and all successful DNS responses received from the DNS servers.

IPv6 Support

The Domain Name Service (DNS) used by the switch supports both IPv4 and IPv6 addresses with no difference in functionality or configuration.

DNS configuration using CLI

This section describes how to configure the Domain Name Service (DNS) client using Command Line Interface (CLI).

DNS supports IPv4 and IPv6 addresses.

Configuring the DNS client

About This Task

Configure the Domain Name Service to establish the mapping between an IP name and an IPv4 or IPv6 address. DNS supports IPv4 and IPv6 addresses with no difference in

functionality or configuration using CLI.

You can configure connection for up to three different DNS servers—primary, secondary and tertiary. First the primary server is queried, and then the secondary, and finally the tertiary.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the DNS client:

```
ip domain-name WORD<0-255>
```
3. (Optional) Add addresses for primary, secondary, or tertiary DNS servers:

```
ip name-server <primary|secondary|tertiary> WORD<0-46>
```
4. (Optional) Delete addresses for primary, secondary, or tertiary DNS servers:

```
no ip name-server <primary|primary-dynamic|secondary|secondary-dynamic|tertiary|tertiary-dynamic> WORD<0-46>
```
5. View the DNS client system status:

```
show ip dns
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Add addresses for a tertiary DNS server:

```
Switch:1(config)# ip name-server tertiary 254.104.201.141
```

Delete address for a secondary dynamic DNS server:

```
Switch:1(config)#no ip name-server secondary-dynamic 192.0.2.12
```

Variable Definitions

The following table defines parameters for the **ip domain-name** command.

Variable	Value
<i>WORD<0-255></i>	Configures the default domain name. <i>WORD<0-255></i> is a string 0-255 characters.

The following table defines parameters for the **ip name-server** command.

Variable	Value
<i>primary secondary tertiary</i> <i>WORD</i> <0-46>	Configures the primary, secondary, or tertiary DNS server address. Enter the IP address in a.b.c.d format for IPv4 or hexadecimal format (string length 0-46) for IPv6. You can specify the IP address for only one server at a time; you cannot specify all three servers in one command. Use the no operator before this parameter, no <code>ip name-server <primary secondary tertiary></code>

Querying the DNS host

About This Task

Query the DNS host for information about host addresses.

You can enter either a hostname, an IPv4 or IPv6 address. If you enter the hostname, this command shows the IP address that corresponds to the hostname and if you enter an IP address, this command shows the hostname for the IP address. DNS supports IPv4 and IPv6 addresses with no difference in functionality or configuration using CLI.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. View the host information:
`show hosts WORD<0-256>`

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

View the host information:

```
Switch:1(config)# show hosts 192.0.2.1
```

Variable Definitions

The following table defines parameters for the **show hosts** command.

Variable	Value
<code>WORD<0-256></code>	Specifies one of the following: <ul style="list-style-type: none"> the name of the host DNS server as a string of 0-256 characters. the IP address of the host DNS server in a.b.c.d format. The IPv6 address of the host DNS server in hexadecimal format (string length 0-46).

DNS configuration using EDM

This section describes how to configure the Domain Name Service (DNS) using Enterprise Device Manager (EDM).

DNS supports IPv4 and IPv6 addresses with no difference in functionality or configuration except for the following. Under the **DNS Servers** tab, in the **DnsServerListAddressType** box, you must select **ipv4** or **ipv6**.

Configure the DNS Client

About This Task

You can configure connections for up to three different DNS servers—primary, secondary and tertiary. First the primary server is queried, and then the secondary, and finally the tertiary.

DNS supports IPv4 and IPv6 addresses. Under the **DNS Servers** tab, in the **DnsServerListAddressType** box, you must select **ipv4** or **ipv6**.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **DNS**.
3. Click the **DNS Servers** tab.
4. Click **Insert**.
5. In the **DnsServerListType** box, select the DNS server type.
6. In the **DnsServerListAddressType** box, select the IP version.
7. In the **DnsServerListAddress** box, enter the DNS server IP address.
8. Click **Insert**.

DNS Servers Field Descriptions

Use the data in the following table to use the **DNS Servers** tab.

Name	Description
DnsServerListType	Configures the DNS server as primary, secondary, or tertiary. OR Removes a DNS server as primary, primaryDynamic, secondary, secondaryDynamic, tertiary, or tertiaryDynamic.
DnsServerListAddressType	Configures the DNS server address type as IPv4 or IPv6.
DnsServerListAddress	Specifies the DNS server address.
DnsServerListStatus	Specifies the status of the DNS server.
DnsServerListRequestCount	Specifies the number of requests sent to the DNS server.
DnsServerListSuccessCount	Specifies the number of successful requests sent to the DNS server.

Query the DNS Host

About This Task

Query the DNS host for information about host addresses.

You can enter either a hostname or an IPv4 or IPv6 address. If you enter the hostname, this command shows the IP address that corresponds to the hostname and if you enter an IP address, this command shows the hostname for the IP address. DNS supports IPv4 addresses with no difference in functionality or configuration in this procedure.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **DNS**.
3. Click the **DNS Host** tab.
4. In the **HostData** text box, enter the DNS host name, IPv4 or the IPv6 address.
5. Click **Query**.

DNS Host Field Descriptions

Use the data in the following table to use the **DNS Host** tab.

Name	Description
HostData	Enter hostname or host IPv4 or IPv6 address to be identified.
HostName	Identifies the host name. This variable is a read-only field.
HostAddressType	Identifies the address type of the host.
HostAddress	Identifies the host IP address. This variable is a read-only field.
HostSource	Identifies the DNS server IP or host file. This variable is a read-only field.

Distributed Virtual Routing (DvR) is a technology for router redundancy in a Fabric deployment where IP subnets are stretched across multiple switches. DvR provides Default Gateway Redundancy and optimizes traffic flows to avoid traffic tromboning due to inefficient routing, thereby increasing the total routing throughput.

The topics in this section provide DvR concepts and configuration procedures.

Distributed Virtual Routing Fundamentals

You can deploy Distributed Virtual Routing (DvR) in Campus environments for stretching IP subnets between multiple aggregation layer switches and also simplifies data center deployments by introducing a Controller-Leaf architecture. In this architecture, Layer 3 configuration is required only on the Controller nodes, whereas the Leaf nodes require only Layer 2 configuration. All Layer 3 configuration is automatically distributed to the Leaf nodes by the Controller nodes.

For typical Campus DvR deployments, configure aggregation layer switches as DvR Controllers. Wiring closet access switches are then typically dual-homed to a pair of DvR Controllers.

IP subnets, which stretch between aggregation layer switches and multiple wiring closets, enable seamless IP roaming for wireless users while at the same time ensure optimal traffic forwarding. To optimize automation, Fabric Attach is typically deployed between wiring closet and aggregation switches. In this construct, there would likely be no DvR Leaf configured.

In Fabric deployments, DvR replaces VRRP (with VRRP-BackupMaster or RSMLT). The operator can chose for each I-SID/IP subnet what router redundancy method to use.

To migrate to a DvR-enabled I-SID/IP subnet, all member Fabric switches of this I-SID must be either DvR Controllers or DvR Leafs. You can connect non Fabric switches to DvR Leafs and DvR Controllers with manual configuration or Fabric Attach configuration. Until all Fabric switches that are members of the I-SID/IP subnet are DvR-enabled, use VRRP or RSMLT as the router redundancy protocol.

DvR Domain

To enable multi-site DvR deployments, a DvR domain concept has been introduced. Within a DvR domain, a set of up to eight DvR Controllers control the DvR domain Leaf switches. A domain can also

include just DvR controllers without DvR Leafs. Typically, a DvR domain is restricted to one physical location. Traffic leaving this physical location always passes through DvR Controllers.

A DvR domain is a logical group of switches or nodes that are DvR enabled. These nodes are not physically connected but are connected over the SPB Fabric such that each node is aware of the BMAC addresses of all other nodes within the domain. A DvR domain does not contain nodes that are not DvR enabled. However, those nodes can co-exist with other DvR enabled nodes within the same SPB Fabric network.

You configure a common DvR domain ID for all nodes belonging to a DvR domain. This domain ID translates internally to a Domain Data Distribution (DDD) I-SID. All switch nodes that share the same DvR domain ID or DDD I-SID receive the Layer 3 information that is distributed from all other nodes belonging to that DvR domain.

A DvR domain can contain multiple Layer 3 VSNs and Layer 2 VSNs. Layer 2 and Layer 3 VSNs can span multiple DvR domains.

A DvR domain typically has the following members:

1. DvR Controller(s)
2. DvR Leaf nodes

For scaling information on the number of Controllers and Leaf nodes to configure in a DvR domain, see [VOSS Release Notes](#).

DvR Controller

In a DvR domain, the Controller nodes are the central nodes on which Layer 3 is configured. They own all the Layer 3 configuration and push the configuration information to the Leaf nodes within the SPB network.

A DvR domain can have one or more controllers for redundancy and you must configure every Layer 2 VSN (VLAN) and Layer 3 VSN within the domain, on the Controller(s). A node that you configure as a DvR Controller is considered the controller for all the Layer 2 and Layer 3 VSNs configured on that node. A Controller is configured with its own subnet IP address for every DvR enabled Layer 2 VSN within the domain.

All Layer 2 VSNs on a DvR Controller need not be DvR enabled. A controller can be configured with individual Layer 2 VSNs that are DvR disabled.

The Layer 3 configuration data that is pushed to the Leaf nodes include the Layer 3 IP subnet information for all Layer 2 VSNs within the DvR domain. It also includes the IP routes learned or redistributed by the Controllers from networks outside the SPB network, into the DvR Domain. Controllers also send information on whether Multicast is enabled on a specific DvR enabled Layer 2 VSN, and the version of IGMP. DvR Controllers inject a default route into the DvR domain for external route reachability. Use route policies to inject specific routes into a DvR domain or inject host routes into OSPF or BGP.

A Controller can only belong to one DvR domain, based on the domain ID that you configure on the node.

DvR Controllers include all DvR Leaf functions, thus a Leaf node free deployment is a valid network deployment. Especially if you use DvR in Campus deployments to replace VRRP or RSMLT, a Controller-only deployment, as Fabric Attach server nodes, is a valid deployment option.

DvR Leaf Node

DvR Leaf nodes are typically data center top of the rack (TOR) Fabric switches that aggregate physical and virtual servers or storage devices. DvR Leaf nodes operate in a reduced configuration mode, where Layer 3 is not configured locally, but pushed to them from the DvR Controller(s) within the domain. You need to configure only the IS-IS infrastructure and the Layer 2 VSNs on the Leaf nodes.

A DvR Leaf node also monitors local host attachments and communicates updates about the current state of those host attachments to the DvR domain. All DvR nodes exchange host attachment information using the DvR host distribution protocol, which leverages a DvR domain I-SID.

DvR leaf nodes are managed in-band through a local loopback address, which is exchanged using the IP Shortcut protocol.

Eligibility Criteria for a Leaf Node

A Leaf node must support the following criteria:

- configuration of basic parameters of IP Multicast over Fabric Connect, such as the system ID, nickname, B-VLANs, SPBM instance, area, peer system ID and virtual BMAC
- configuration of a physical port as either an SPB NNI interface, a FLEX-UNI interface or an FA interface
- configuration of an MLT as either an SPB NNI interface, a FLEX-UNI interface or an FA interface
- configuration of an SMLT as a Flex-UNI Interface or an FA Interface
- configuration of Layer 2 VSN I-SID instances of type ELAN
- configuration of FLEX-UNI end-points as part of a Layer 2 VSN
- FA Server functionality on FA enabled interfaces
- SMLT and vIST
- configuration of a in-band management interface for in-band management of the node

Summary of Controller and Leaf Node Functions

A DvR Controller performs the following functions:

- pushes Layer 3 configuration data (IPv4 Unicast and Multicast) to the Leaf nodes for all the Layer 2 VSNs or subnets within the DvR domain.
- pushes the Layer 3 learned host routes (host routes learned on its own UNI ports) and route data learned through route redistribution or route policies, to the Leaf nodes.
- configures learned remote host routes from other Controllers and Leaf nodes, on its own device.

A DvR enabled Leaf node performs the following functions:

- configures the gateway MAC when the gateway IPv4 address is learned.
- pushes the Layer 3 learned remote host routes to other Controllers and Leaf nodes in the domain.
- configures learned remote host routes from other Controllers and Leaf nodes on its own device.

- configures ECMP routes (in the datapath only) for the Layer 2 VSN subnets, with each next hop as the Controller in the DvR domain.
- configures learned routes from the Controllers that are redistributed using DvR.
- handles host route response packet interception based on the Controller VLAN MAC or the gateway MAC.

DvR backbone

The DvR backbone is automatically established among the DvR Controllers from all DvR domains. Every Controller node has an edge gateway to its DvR domain, to the DvR backbone and all other non-DvR domains within the network.

Controllers exchange host route information such that any host can be reached in a shortcut switched manner, irrespective of its location. For these host route information exchanges, controllers use an automatically assigned backbone I-SID. Local subnets to the Controllers are automatically injected into the DvR host route exchanges.

To redistribute DvR host routes into OSPF or BGP, you can configure route policies. These host routes are not injected into IS-IS.

DvR Backbone Members

You can configure a non-DvR backbone edge bridge (BEB) to join the DvR backbone. This enables the node to receive redistributed DvR host routes from all DvR Controllers in the SPB network, just like a DvR Controller. However, unlike the Controller, you can neither configure a DvR interface on this node nor can the node inject its host routes into the DvR domain.

DvR operation

In a DvR domain, DvR enabled Controller(s) handle the learning and distribution of Layer 3 configuration and route data to the DvR enabled Leaf nodes. The Leaf nodes in turn, use this data to automatically create distributed Layer 3 datapaths on themselves. In this way, Layer 3 configuration and learning remains only with the Controller(s) and there are distributed Layer 3 datapaths at the edges of the fabric network. This allows for destination lookups at the edge to happen quickly, and traffic is sent directly to their destinations without multiple lookups.

An important benefit of DvR is that only minimal configuration is required on the Leaf node. Based on the Layer 2 VSN that the Leaf node is a part of, all Layer 3 configuration information (IPv4 Unicast and Multicast configuration) is pushed from the Controllers in the domain. Thus the leaf nodes, although basically Layer 2 configured switches, become fully layer 3 capable devices.

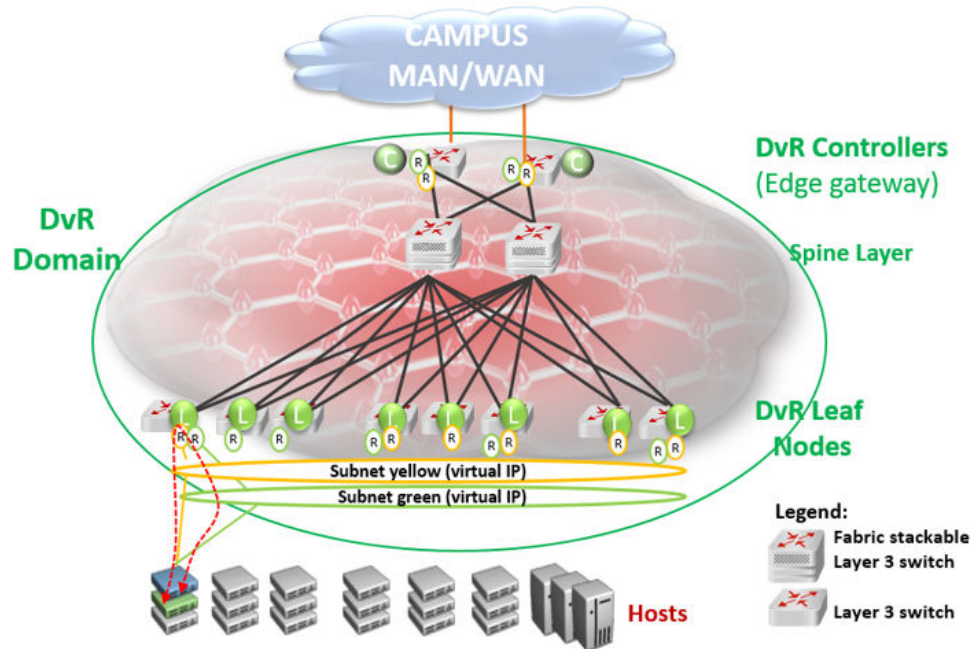

Figure 46: SPB Fabric network with central Layer 3 Controller and distributed Layer 3 datapath at the edges

ARP Learning

When DvR is enabled on a Controller, it initiates ARP requests for traffic to be routed to unknown destination hosts.

DvR enabled Controllers learn ARP requests from:

- DvR enabled Leaf nodes (here the Leaf node owns the ARPs)
- its own local UNI ports. Here, the controller owns the ARPs
- other DvR enabled Controllers

DvR enabled Leaf nodes learn ARP requests from:

- its own local UNI ports (here the Leaf node owns the ARPs)
- other DvR enabled Leaf nodes (that own the ARPs) and respond to ARP requests on their UNI ports
- DvR enabled Controllers (that own the local UNI ARPs)

Controllers only distribute ARP entries that are locally learned on its own UNI ports, to other DvR enabled nodes in the domain.

dvr-leaf-mode boot flag

To configure a node to operate as a DvR Leaf node, you must first enable the `dvr-leaf-mode` boot flag.

- The `dvr-leaf-mode` boot flag is disabled by default. You must explicitly enable this flag before you configure a switch node to operate as a Leaf node.

When you enable the `dvr-leaf-mode` boot flag, you can configure the node as a DvR leaf node without rebooting, as long as there is no unsupported configuration discovered on the switch.

- After you enable or disable the boot flag, you must save the configuration.

**Important**

A node on which the `dvr-leaf-mode` boot flag is enabled cannot be configured as a DvR Controller.

In-band management

Use in-band management to manage a DvR enabled Leaf node that does not have an out-of-band management port or a console port.

For in-band management of the node within the management subnet (for example, from a Controller node), you must configure a unique IPv4 address to be used as the in-band management IP address, on that node. This IPv4 address functions like a CLIP address.

DvR deployment scenarios

The following sections describe typical deployments of the DvR infrastructure.

DvR deployment in a single data center

The following topology shows DvR deployment in a single data center. This deployment consists of a single DvR domain comprising a Controller layer and a Leaf node layer. The Controller layer has two controllers (for redundancy), which are deployed closer to the boundary of the DvR domain and the rest of the SPB Fabric network. The DvR Leaf nodes or Top of Rack (TOR) switches are typically access or edge switches.

All switches that belong to the DvR domain are configured with the same DvR domain ID and communicate with each other over a predefined I-SID.

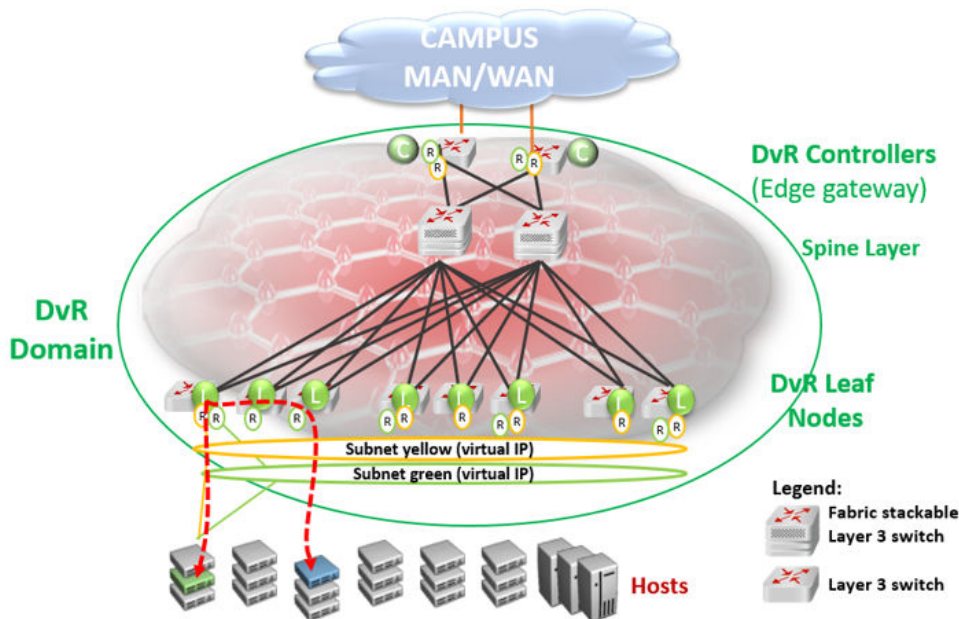

The Controller nodes control the Leaf nodes and also build the gateway between the DvR domain and the rest of the Fabric infrastructure. So traffic is either routed between the Leaf nodes, or through the Controllers, to the rest of the fabric infrastructure.

Two IP subnets (Layer 2 VSNs), yellow and green, span the Leaf nodes. Each subnet is configured with a virtual IP address that is a shared among all Controller and Leaf nodes that belong to the subnet. The Controller and Leaf nodes are configured with routing interfaces to the subnets, as shown in the figure.

DvR works by enabling each Leaf node or Top of Rack (TOR) switch to bi-directionally route traffic for each IP subnet of which it is a member. This is done by distributing the Layer 3 configuration information (IP Unicast, IP Multicast and virtual IP configuration) needed to handle Layer 3 routing, from the Controllers to the Leaf nodes. Configuration information is pushed over the DvR Domain I-SID, as indicated by the blue arrows in the above figure.

Routing between the two IP subnets is achieved directly at the Leaf nodes when the Layer 3 distributed datapath is programmed at the Leaf Nodes, based on the Layer 3 configuration data that is pushed. Thus traffic within and between IP subnets is shortcut switched without having to traverse the central routing nodes, as shown in the figure below, if there are direct physical connections between them.

Thus, in a DvR deployment, all virtual IP and Layer 3 configuration is performed on the Controller nodes and pushed to the Leaf nodes, so that the Leaf nodes though basically Layer 2 configured switches, become fully layer 3 capable devices.

DvR deployment in a dual data center

The following example deployment shows two data centers each having its own DvR domain, connected through a backbone.

All nodes in data center Campus 1 belong to DvR domain shown in green, and the nodes in the data center Campus 3 belong to the DvR domain shown in orange. The two DvR domains are individually managed, so in this scenario, the controllers colored orange manage the orange Leaf nodes and the controllers colored green manage the green Leaf nodes. However, subnets can still be stretched across the DvR domains (and possibly between buildings), as shown in the figure.

Each DvR domain learns its own Layer 3 data and distributes this information to its own Leaf nodes. Layer 3 host information that is redistributed from other DvR Domains is learned by the Controllers only (through inter-DvR domain redistribution) and is programmed on the Leaf nodes in the same domain, but not in the other Domain. For example, Layer 3 information redistributed from domain 2 is learned by all controllers including the domain 1 controllers, but this information is not distributed to the Leaf nodes in domain 1. Hosts in one DvR domain can reach the hosts in the other DvR domain only through the Controllers.

Figure 47: Shortest path routing between servers in different data centers

All controllers in all domains are always part of the DvR backbone by default, as they are connected by the SPB Fabric. The DvR backbone connects many DvR domains.

Thus DvR can scale to multiple campuses, allowing a simplified way to deploy a large scale fully-routed infrastructure.

DvR Route Redistribution

The following sections describe redistribution of IPv4 local and static routes from DvR Controllers into the DvR domain. It also describes redistribution of host routes that are learned on DvR enabled VLANs, to BGP and OSPF. You can configure route policies to control the selection of routes to be distributed. You can also configure IS-IS accept policies on DvR Controllers and non-DvR BEBs, to determine which DvR host routes to accept into the routing-table from the DvR backbone.

Redistribution of IPv4 Local and Static Routes

The DvR feature supports redistribution of IPv4 local and static routes into the DvR domain.

Note

For every VRF instance and the Global Router, the Controller automatically injects a default route to the Leaf node, with a next hop as the advertising Controller. However, if you require only local or static routes to be advertised to the Leaf nodes, you can manually disable the injection of default routes on the Controller.

On a DvR Controller, you can configure (enable or disable) the redistribution of direct or static routes. Direct routes are redistributed with the route type as internal. Static routes are redistributed with the route type as external. You can apply route policies on the Controller to selectively permit the redistribution of these routes and also configure a metric value for the route that is redistributed. The default metric for imported local routes is 1. For static routes, the configured route metric or cost is honored.

You can configure redistribution of static and direct routes from the Global Router, or within a VRF instance. For redistributed routes, the Controller configures the Layer 3 VSN as that of the VRF redistributing the route, and the next hop BEB as the system ID of the Controller injecting the route into the DvR domain.

The following example demonstrates how a DvR Leaf node benefits from the redistribution of local and static routes.

By default, if the injection of default routes is enabled on a DvR Controller, the DvR Leaf node can only route traffic to other nodes within the DvR enabled subnet. For the Leaf node to reach networks outside of the DvR enabled subnet, the Controllers must redistribute local and static routes from non-DvR subnets into the DvR domain. In the following figure, the DvR Leaf L1 can route traffic only to nodes in the DvR enabled subnet 10.10.10.0/24. To be able to reach hosts in VLAN 20 (20.20.20.0/24) or VLAN 30 (30.30.30.0/24), redistribution of local routes into DvR is required at each of the Controllers C1 and C2. For the Leaf node to reach hosts in remote networks 40.40.40.0/24 or 50.50.50.0/24, redistribution of static routes to the DvR domain is required.

You can apply route policies to control which local or static routes are to be redistributed into the DvR domain.

Figure 48: Redistribution of IPv4 local and static routes

Redistribution of Routes to OSPF or BGP

For non-SPB routers to benefit from the host accessibility information learned within a DvR domain, DvR supports the redistribution of host routes into OSPF or BGP. Redistribution of these host routes is only by the DvR Controllers and only for the intra-domain host routes within the DvR enabled subnets.

A DvR Controller can redistribute host routes for all hosts from a DvR domain into OSPF or BGP. You can also apply route policies on the Controller to select the routes to be redistributed. The Controller supports redistribution of routes from the Global Router or within a VRF instance. You can also configure the metric of the route before redistribution.

The following example demonstrates the benefit of redistribution of routes to BGP.

Consider a 10.1.0.0/16 network with a stretched Layer 2 VSN spanning two data centers. On the campus side of the network, BGP peering is configured between a non-Extreme router and one or more routers in the data center. BGP advertises the network route 10.1.0.0/16 to the campus BGP routers. Depending on which edge router the traffic is delivered to, it is possible that traffic from a host on the campus traverses the WAN a second time to reach the server that is physically connected to one segment of the data center, as shown in the following figure.

Figure 49: Inefficient traffic flow

Redistribution of the host routes from the DvR Controller to BGP solves this problem.

The following figure shows two DvR domains (shown in green and orange) configured at each data center. Each campus edge router establishes a BGP peering session with one or more Controllers in each data center (DvR domain). This enables BGP to advertise more specific routes to the campus BGP router so that the optimal routing path is always taken. So, there is no need for traffic to traverse the WAN multiple times. Also, in the case of server movement within or between data centers, the updated DvR host routes are propagated to BGP, thus ensuring that traffic flowing into the data center continues along the most optimal path.

For example, in the following figure, only the Controller attached to the Leaf node where the 10.1.0.111 server exists, advertises its accessibility over the 10.1.0.111/32 route. Similarly, the DvR Controller associated with the Leaf node connected to the 10.1.0.222 server advertises the 10.1.0.222/32 host route.

Figure 50: Traffic flow optimized with route redistribution

Controllers in each data center learn all host routes through the DvR backbone, but since those routes belong to different DvR domains, they are not all eligible for redistribution to OSPF or BGP.

Route Redistribution and IS-IS Accept Policies

DvR route redistribution leverages IS-IS accept policies to control (accept or reject) DvR routes learned from the DvR backbone. You can configure accept policies on both Controllers and non-DvR BEBs in the SPB network.

For more information about accept policies, see [IS-IS Accept Policies](#) on page 1356.

DvR Deployment for Wireless Roaming in Campus Deployments

In fabric deployments where IP subnets/I-SIDs stretch between multiple buildings, you can use DvR instead of VRRP or RSMLT to avoid traffic tromboning issues. This deployment is supported with non-fabric switches that have Fabric Attach enabled, or switches that do not support Fabric Attach. You can use VSP 4450 Series as DvR Leafs in this context as well. IP subnets can stretch across one or multiple DvR domains as shown in the following figure.

Figure 51: Wireless roaming in Campus

Management I-SID Assignment to DvR Leaf

The Management I-SID Assignment to DvR Leaf feature simplifies the process of creating a Management Instance VLAN interface on a DvR Leaf.

You can configure a Management Instance VLAN on a DvR Leaf node by specifying the I-SID. When you specify the I-SID, an internal VLAN is created and associated with the I-SID.

Operational Considerations

The following section describes operational considerations for assigning a Management I-SID to DvR Leaf node.

- If the specified I-SID is not associated with a VLAN, the Management Instance VLAN interface is created with the specified I-SID and an internal VLAN.

Note

The internal VLAN is not configurable.

- You cannot create a Management Instance VLAN interface if the I-SID is already associated with a VLAN. However, you can configure a Management Instance VLAN interface if the I-SID is associated with the onboarding VLAN.

- The I-SID cannot be learned dynamically. You cannot create a Management Instance VLAN interface if the I-SID sent from the DvR Controller is the same as the Management Instance VLAN I-SID.
- When you delete the Management Instance VLAN interface, the internal VLAN is deleted. You cannot delete the onboarding VLAN.
- You can migrate from a previous configuration or to a DvR Leaf only if an I-SID is associated with the Management Instance VLAN. If you disable DvR on a DvR Leaf by disabling the **dvr-leaf-mode** boot flag, the Management Instance VLAN is deleted. You can either restart the onboarding process or configure a Management Instance CLIP or Management Instance OOB interface.
- In DvR Leaf, you can create a Management Instance VLAN interface using the quick-config-mgmt utility script with the Management I-SID but not with port number or VLAN ID. This I-SID cannot be used if the Management Instance interface is already created. You can issue the **convert** command to use this I-SID.
- Migration from DvR leaf to non-DvR leaf deletes the Management Instance VLAN configuration.

DvR Restrictions

Review the following limitations and behavioral characteristics associated with DvR.

- The DvR feature does not affect out-of-band management on a switch chassis, if the chassis supports it.
- The DvR feature does not support a non-DvR BEB in a DvR enabled Layer 2 VSN.
- The number of host route records that can be stored in the datapath of a Leaf node is limited to the scaling capacity of the switch node. Different switch platforms have different scaling capacities.

For information on the scaling capacities of different platforms, see [VOSS Release Notes](#).

- You must first disable DvR on a Controller or Leaf node, before you attempt to change the domain ID of the node.
- You cannot configure IGMP snooping on DvR enabled nodes.
- DvR is only supported in warm standby High Availability mode on the VSP 8600 Series.

Configuration Restrictions on a DvR Controller

- If you are using two different IP addresses for the DvR VLAN and the DvR GW IP, you must first configure a gateway IPv4 address and then configure an IP interface for the VLAN before you enable DvR on a Layer 2 VSN (VLAN). Both the VLAN IP address and the gateway IPv4 address must be in the same subnet.

If you use same IP address for VLAN interface and DvR GW IP, you can use the command **ip address {A.B.C.D/X} dvr-one-ip**.

For more information, see [Enable DvR on a Layer 2 VSN \(VLAN\)](#) on page 3800 and [Configure a Single IP Address for All DvR Controllers on a VLAN Subnet](#) on page 3801.

- You cannot configure IPv4 VRRP on a DvR-enabled VLAN.

Note

This restriction does not apply to VSP 8600 Series.

- You cannot configure RSMLT on a DvR-enabled VLAN.
- You cannot configure SPB-PIM Gateway (SPB-PIM GW) on a DvR VLAN.

- You cannot configure dynamic routing protocols, such as OSPF, RIP, BGP, IPv6 OSPFv3, IPv6 RIPng, IPv6 MLD, and IPv6 PIM-GW on a DvR-enabled VLAN.

**Note**

IPv6 OSPFv3, IPv6 RIPng, IPv6 MLD, and IPv6 PIM-GW do not apply to VSP 8600 Series.

- You can configure DvR on a VLAN that has configured IPv6 interface. You must first delete the IPv6 interface, configure DvR, and then reconfigure IPv6 interface.

**Note**

This restriction does not apply to VSP 8600 Series.

A DvR VLAN is a VLAN configured on a DvR Controller with a VLAN IP address, a VLAN/I-SID, the DvR gateway IP address, and DvR enabled. This Layer 3 configuration for the DvR VLAN (the DvR gateway IP address and this DvR subnet) is pushed to the DvR Leaf nodes. The DvR gateway IP address must be the same address across all DvR Controllers for that DvR VLAN.

- You cannot configure an IPv6 interface on a DvR-enabled VLAN from a subnet that is used as next-hop in a IPv6 static route.
- You cannot configure an IPv6 address on a DvR-enabled VLAN from a subnet used as an IPv6 BGP Peer.

**Note**

This restriction does not apply to VSP 8600 Series.

- DvR-enabled VLAN/I-SIDs are for host connectivity only; you cannot connect a router to a DvR-enabled VLAN/I-SID and use dynamic or static routing. Use a non-DvR VLAN/I-SID instead to connect an external router.

Configuration Limitations on a DvR Leaf

- Enabling the **DvR-leaf-mode** boot flag before you configure a node as a DvR Leaf, automatically removes all existing non-DvR configuration on the node such as platform VLANs and their IP address configuration, CLIP configuration, routing protocol configuration and VRF configuration. The gateway IPv4 address, if configured, is also removed.
- You cannot configure SPB-PIM GW on a Leaf node. The configuration is supported only on a DvR Controller.
- You cannot perform Layer 3 configuration (for example, IP interfaces, IP routing, and VRFs). You can only perform Layer 2 configuration.

You cannot configure Microsoft NLB on a Leaf node.

- You cannot configure Fabric Extend on a Leaf node.
- You cannot configure the VXLAN Gateway on a Leaf node.
- You cannot configure a T-UNI on a Leaf node.
- You cannot configure IPv4 multicast on a Leaf node. The configuration is supported only on a DvR Controller.
- You can configure only one instance of vIST on a Leaf node pair. Also, you cannot configure vIST on Leaf nodes from different domains.

- Platform VLANs are not supported. You cannot configure a platform VLAN directly on a DvR leaf node. However, you can configure a VLAN Management Instance on a DvR leaf node. After you configure the management VLAN, you can configure a platform VLAN.
- You cannot configure IP Shortcuts and IP Multicast over Fabric Connect on Leaf nodes. This configuration is pushed from the DvR Controllers in the domain.
- You must manually configure an I-SID on a Layer 2 VSN Leaf node. This configuration is not pushed from a DvR Controller.
- DvR-enabled VLAN/I-SIDs are for host connectivity only; you cannot connect a router to a DvR-enabled VLAN/I-SID and use dynamic or static routing. Use a non-DvR VLAN/I-SID instead to connect an external router.

Migrate from VRRP to DvR

About This Task

If you have a VRRP network with a mix of existing routers that do not support DvR and devices that do support DvR, you can migrate your VRRP network to DvR using this high-level process. This migration process assumes the following design:

- Existing routers are the VRRP masters.
- Existing routers are the default gateways for all subnets.
- Fabric Connect network with DvR-capable nodes where DvR is configured globally, but not on I-SIDs, on the VOSS devices; and VOSS devices operate in Layer 2 mode for the VRRP VLANs that need to be migrated.

Important

When you configure DvR on Controllers with existing VRRP VLANs, ensure there is no VRRP VLAN with VRID 37 or VRID 38. VRID 37 conflicts with the DvR gateway MAC used by all DvR nodes. The DvR gateway MAC is a constant value 00:00:5e:00:01:25; VRRP VRID 37 translates to the same MAC. Similarly, VRRP VRID 38 translates to 00:00:5e:00:01:26, and is used within DvR. If you have a VRRP VLAN with either of these VRIDs, change the VRID to a different value.

Procedure

1. Enable VRRP interfaces on the DvR Controllers but keep VRRP mastership on the existing routers.
2. Change VRRP mastership on the VLAN or IP Subnet in question on the DvR Controller by applying a higher priority than the current master.

Note

You can easily fall back to the original VRRP master to change VRRP priorities back.

3. Disable VRRP on the existing routers.

4. Subnet by subnet (VLAN/I-SID), delete VRRP interfaces on all DvR Controllers first (this includes removing VRRP and removing the VLAN IP address), and then configure DvR interfaces (this includes adding the DVR-GW-IP, enabling DvR, and then adding the VLAN IP address) on the VLAN/I-SID instead. This might lead to a short traffic interruption.

Note

For each VLAN/I-SID, ensure that VRRP is disabled on all nodes before you configure DvR interfaces on the Controllers for the VLAN/I-SID.

Keep in mind that you can only enable DvR on VLAN or I-SIDs where all participating BEBs are DvR-capable.

Anytime when falling back, you can delete the DvR interface on the I-SID (this includes disabling DvR, removing the DVR-GW-IP and removing the VLAN IP address) and configure the VRRP interface again (this includes adding the VLAN IP address and adding VRRP again), however, ensure you delete the DvR interfaces on all Controllers first before you enable VRRP again.

Example

Start with VRRP VLAN:

```
vlan create 250 name vlan_test250 type port-mstprstp 0
vlan i-sid 250 111250
interface vlan 250
ip address 192.0.2.3 255.255.255.0
interface vlan 250
ip vrrp version 2
ip vrrp address 10 192.0.2.1
ip vrrp 10 priority 180
ip vrrp 10 backup-master enable
ip vrrp 10 enable
exit
```

Change to DvR VLAN:

```
interface vlan 250
no ip vrrp address 10 192.0.2.1
no ip address 192.0.2.3
exit
interface vlan 250
dvr gw-ipv4 192.0.2.1
dvr enable
ip address 192.0.2.3 255.255.255.0
exit
```

Change back to VRRP VLAN:

```
interface vlan 250
no dvr enable
no dvr gw-ipv4
no ip address 192.0.2.3
exit
interface vlan 250
ip address 192.0.2.3 255.255.255.0
ip vrrp version 2
ip vrrp address 10 192.0.2.1
ip vrrp 10 priority 180
ip vrrp 10 backup-master enable
```

```
ip vrrp 10 enable
exit
```

DvR and IPv6 VRRP Coexistence on the Same I-SID

You can configure IPv6 VRRP and IPv6 DHCP relay on a DvR-enabled VLAN or I-SID.

You must perform the following steps in order:

1. Enable DvR on a VLAN interface.
2. Configure an IPv6 interface.
3. Configure IPv6 VRRP.

Configuration Examples

The following example shows how you can configure an IPv6 interface and IPv6 VRRP on a DvR-enabled VLAN:

```
vlan create 10 name vlan_test10 type port-mstprstp 0
vlan i-sid 10 111010
interface vlan 10
dvr gw-ipv4 192.0.2.1
dvr enable
ip address 192.0.2.2 255.255.255.0
ipv6 interface enable
ipv6 interface address 2001:DB8:0::1/64
ipv6 vrrp address 1 link-local fe80::1234
ipv6 vrrp address 1 global 2001:DB8:0::1234/64
ipv6 vrrp 1 enable
exit
```

You cannot enable DvR on a VLAN interface that has IPv6 VRRP configuration. You must first delete IPv6 interface from the VLAN, configure DvR and then reconfigure IPv6 interface.

```
interface vlan 10
no ipv6 vrrp 1
no ipv6 interface
dvr gw-ipv4 192.0.2.1
dvr enable
ip address 192.0.2.2 255.255.255.0
ipv6 interface enable
ipv6 interface address 2001:DB8:0::1/64
ipv6 vrrp address 12 link-local fe80::1234
ipv6 vrrp address 1 global 2001:DB8:0::1234/64
ipv6 vrrp 1 enable
exit
```

DvR configuration using the CLI

The following sections describe configuration of Distributed Virtual Routing (DvR) using the Command Line Interface (CLI).

Configuring a DvR Controller

About This Task

Configuring a node as a DvR Controller enables DvR globally on that node.

Perform this procedure to create a DvR domain with the domain ID that you specify, and configure the role of the node as the Controller of that domain. A Controller can belong to only one DvR domain.

Note

For a node to perform the role of both a Controller and a Leaf within a DvR domain, you must configure it as a Controller.

Before You Begin

- Ensure that you configure IP Shortcuts on the node. This is necessary for proper functioning of the node as a DvR Controller.
- Ensure that the `dvr-leaf-mode` boot flag is disabled on the node.

To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure a DvR Controller.

```
dvr controller <1-255>
```
3. (Optional) Disable DvR on a DvR Controller.

```
no dvr controller
```

Caution

Disabling DvR on a DvR Controller destroys the domain ID and all dynamic content learned within the DvR domain.

However the switch retains the VLAN specific configuration and you can view the information using the command **show running-config**.

4. View a summary of the Controller configuration. Enter:

```
show dvr
```

Example

Configure a node as a DvR Controller:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#dvr controller 5
Switch:1(config)#show dvr
```

```
=====
                        DVR Summary Info
=====
Domain ID                : 5
Domain ISID              : 16678219
Backbone ISID           : 16678216

```

```
GW MAC : 00:00:5e:00:01:25
InjectDefaultRouteDisable (GRT) : Disabled
```

Variable definitions

Use the data in the following table to use the **dvr controller** command.

Variable	Value
<1-255>	Specifies the domain ID of the DvR domain that the controller belongs.

Disabling injection of default routes on a Controller

About This Task

By default, a DvR Controller injects default routes into the DvR domain and all the Leaf nodes in that domain learn these routes with the next hop as the Controller that advertised them.

You can however disable default route injection for the GRT or a specific VRF on a Controller, to override this behavior.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Disable default route injection for the GRT or a specific VRF, on the Controller.

On the GRT:

```
dvr controller inject-default-route-disable
```

The `default` or the `no` operator enables injection of default routes for the GRT into the domain.

On a VRF instance:

```
dvr inject-default-route-disable
```

The `default` or the `no` operator enables injection of default routes for a specific VRF into the domain.

3. Verify the configuration.

On the GRT:

```
show dvr
```

On a VRF instance:

```
show dvr l3vsn
```

Example

Disable injection of default routes for the GRT on a Controller.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#dvr controller inject-default-route-disable
Switch:1(config)#show dvr
```

```

Configuring DvR route redistribution

About This Task

Configure redistribution of direct or static routes into the DvR domain, on the Global Router or for a specific VRF instance.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

 Optional: `router vrf WORD<1-16>`

2. Configure route redistribution of direct routes:
 - a. Configure route redistribution of direct routes on a VRF. The route type is internal.
`dvr redistribute direct [metric <0-65535>] |[route-map WORD<1-64>]`
 - b. Enable route redistribution.
`dvr redistribute direct enable`
 - c. Apply the configuration:
`dvr apply redistribute direct`
 - d. (Optional) Disable route redistribution of direct routes.
`no dvr redistribute direct`
3. Configure route redistribution of static routes:
 - a. Configure route redistribution of static routes on a VRF. The route type is external.
`dvr redistribute static [metric <0-65535>] |[route-map WORD<1-64>]`
 - b. Enable route redistribution.
`dvr redistribute static enable`
 - c. Apply the configuration.
`dvr apply redistribute static`
 - d. (Optional) Disable route redistribution of static routes.
`no dvr redistribute static`
4. Verify the route redistribution configuration. You can also verify it on a specific VRF instance.
`show dvr redistribute [vrf WORD<1-16>]`

Example

Configure route redistribution of direct and static routes on the Global Router. Ensure that you apply the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#dvr redistribute static
Switch:1(config)#dvr redistribute static metric 200
Switch:1(config)#dvr redistribute static enable
Switch:1(config)#dvr apply redistribute static

Switch:1(config)#dvr redistribute direct
Switch:1(config)#dvr redistribute direct metric 100
Switch:1(config)#dvr redistribute direct enable
Switch:1(config)#dvr apply redistribute direct
```

Verify configuration on the Global Router:

```
Switch:1(config)#show dvr redistribute
=====
                        DVR Redistribute List - GlobalRouter
=====
SOURCE MET MTYPE      ENABLE RPOLICY
-----
STAT   200 External  TRUE  -
LOC    100 Internal  TRUE  -
```

Configure redistribution of direct and static routes on the specific VRF instance `vrf1`. Ensure that you apply the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#router vrf vrf1
Switch:1(router-vrf)#dvr redistribute static
Switch:1(router-vrf)#dvr redistribute static metric 20000
Switch:1(router-vrf)#dvr redistribute static enable
Switch:1(router-vrf)#exit
Switch:1(config)#dvr apply redistribute static

Switch:1(router-vrf)#dvr redistribute direct
Switch:1(router-vrf)#dvr redistribute direct metric 10000
Switch:1(router-vrf)#dvr redistribute direct enable
Switch:1(router-vrf)#exit
Switch:1(config)#dvr apply redistribute static
```

Verify configuration on `vrf1`:

```
Switch:1(router-vrf)#show dvr redistribute vrf vrf1
=====
                        DVR Redistribute List - VRF vrf1
=====
SOURCE MET MTYPE      ENABLE RPOLICY
-----
STAT  20000 External   TRUE  -
LOC   10000 Internal   TRUE  -
```

Variable definitions

Use the data in the following table to use the **dvr redistribute direct** or the **dvr redistribute static** commands.

Variable	Value
<i>enable</i>	Enables DvR route redistribution on the VRF instance. Route redistribution is enabled by default.
<i>metric</i> <0-65535>	Specifies the DvR route redistribution metric.
<i>route-map</i> WORD<1-64>	Specifies the route policy for DvR route redistribution.

Use the data in the following table to use the **show dvr redistribute** command.

Variable	Value
<i>vrf</i> WORD<1-16>	Specifies the VRF name.

Clearing DvR host entries

About This Task

Clear DvR host entries (IPv4 remote host routes) on a Controller. The host entries are learned on the switch, either locally on its UNI port or dynamically from other nodes in the DvR domain.

Note

You can clear DvR host entries only on a DvR Controller.

An error message displays if you attempt clearing of host entries on a DvR Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Clear the DvR host entries.

```
clear dvr host-entries [ipv4 {A.B.C.D}] | [l2isid <0-16777215>] |  
[l3isid <0-16777215>]
```

Example

In this example, you clear host entries for IP address 50.0.1.0 to clear host entries for IP addresses 50.0.1.2 and 50.0.1.3.

```
Switch:1>enable  
Switch:1#configure terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
Switch:1(config)#clear dvr host-entries 50.0.1.0
```

Variable definitions

Use the data in the following table to use the **clear dvr host-entries** command.

Variable	Value
<i>ipv4</i>	Specifies the IP address (IPv4) of the DvR host entries to clear.
<i>l2isid</i>	Specifies the Layer 2 VSN I-SID of the DvR host entries to clear The range is 1 to 16777215.
<i>l3isid</i>	Specifies the Layer 3 VSN I-SID of the DvR host entries to clear. The range is 0 to 16777215.

Configuring a DvR Leaf

About This Task

Perform this procedure to create a DvR domain with the domain ID that you specify, and configure the role of the node as a Leaf node. Configuring a node as a DvR Leaf automatically enables DvR globally on the node.

A Leaf node can belong to only one DvR domain.

Note

For a node to perform the role of both a Controller and a Leaf within the domain, you must configure it as a Controller.

Note

You must enable the VRF-scaling boot configuration flag on a DvR Leaf node, if more than 24 VRFs are required in the DvR domain.

For additional scaling information, see [VOSS Release Notes](#).

Before You Begin

- You must enable the `dvr-leaf-mode` boot flag before you configure a node as a DvR Leaf node.

Note

When you enable the `dvr-leaf-mode` boot flag, you can configure the node as a DvR leaf node without rebooting, as long as there is no unsupported configuration discovered on the switch.

To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

Caution

Ensure that you save the current configuration on the switch, before you enable the flag. Enabling the flag removes all existing non-DvR configuration on the switch, such as platform VLANs and their IP address configuration, circuitless IP (CLIP) configuration, routing protocol configuration and VRF configuration. The gateway IPv4 address, if configured, is also removed.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Configure a node as a DvR Leaf.

```
dvr leaf <1-255>
```

- (Optional) Disable DvR on a DvR Leaf.

```
no dvr Leaf
```

Caution

Disabling DvR on a Leaf node removes its membership with the DvR domain and all the dynamic content learned from the Controllers of that domain.

- View a summary of the Leaf configuration.

```
show dvr
```

- Restart the switch for your change to take effect.

Example

Configure a node as a DvR Leaf:

```
Switch2:1>enable
Switch2:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch2:1(config)#boot config flags dvr-leaf-mode
Switch2:1(config)#save config
Switch2:1(config)#dvr Leaf 5

Switch2:1(config)#show dvr

=====
                        DVR Summary Info
=====

Virtual Ist cluster-id  :
Virtual Ist ISID        :
```

Variable definitions

Use the data in the following table to use the **dvr leaf** command.

Variable	Value
<1-255>	Specifies the domain ID of the DvR domain to which the Leaf node belongs.

Configuring vIST on a DvR Leaf node pair

Before You Begin

Ensure that the nodes are configured as DvR Leaf nodes, before you configure vIST.

About This Task

When you configure vIST on a DvR Leaf node pair, the switch generates an I-SID from the configured cluster ID. This I-SID is unique across the SPB network as long as the cluster ID is unique across the SPB network, for the vIST pair. You can configure only one instance of vIST on the Leaf node pair.

To configure vIST, both nodes must be Leaf nodes. You cannot configure vIST, for example, on a Controller-Leaf node pair.

Also both the nodes must belong to the same DvR domain. vIST configuration over Leaf nodes in different domains is not supported.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure vIST on the Leaf nodes:

```
dvr leaf virtual-ist {<A.B.C.D/X|<A.B.C.D> <A.B.C.D>} peer-ip
{A.B.C.D} cluster-id <1-1000>
```
3. (Optional) Disable vIST on the DvR Leaf node pair.

```
no dvr leaf virtual-ist
```

Caution

Disabling DvR on a Leaf node in a vIST pair removes all vIST configuration on that node, but not on the pair. The node on which DvR is disabled also loses its membership with the DvR domain and all the dynamic content learned from the Controllers in that domain. If DvR is re-enabled on the node, you must manually configure vIST on that node again.

4. View a summary of vIST configuration on the Leaf nodes.

```
show dvr
```

Example

Configure vIST on DvR Leaf nodes, with IP addresses 51.51.51.1 and 51.51.51.2 respectively:

```
Switch2:1>enable
Switch2:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch2:1(config)#dvr leaf virtual-ist 51.51.51.1 peer-ip 51.51.51.2 cluster-id 255
Switch2:1#show dvr

Virtual Ist cluster-id      : 255
Virtual Ist ISID             : 16677226

```

Variable definitions

Use the data in the following table to use the **dvr leaf virtual-ist** command.

Variable	Value
{<A.B.C.D/X <A.B.C.D> <A.B.C.D>}	Specifies the local IP (IPv4) address and subnet mask of the node.
{<A.B.C.D>}	Specifies the IP address (IPv4) of the vIST peer.
<1-1000>	Specifies the cluster ID of vIST. It is set to 0 if vIST is not configured.

Configure a Management VLAN on a DvR Leaf Node

Note

This procedure does not apply to VSP 8600 Series.

About This Task

On a DvR leaf node, you can configure a Management Instance VLAN by specifying the I-SID. Use the following procedure to configure a Management Instance VLAN on a DvR leaf node.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure a Management Instance VLAN I-SID:

```
mgmt vlan i-sid <1-16777215>
```

Variable Definitions

The following table defines parameters for the **mgmt vlan i-sid** command.

Variable	Value
1-16777215	Specifies the VLAN I-SID to associate with the management VLAN.

Delete a Management VLAN on a DvR Leaf Node

Note

This procedure does not apply to VSP 8600 Series.

About This Task

Perform this procedure to delete a Management Instance VLAN on a DvR leaf node.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Delete the management VLAN:

```
no mgmt vlan
```

Moving a vIST Leaf node pair from one domain to another

About This Task

Use this procedure to move a vIST Leaf node pair from one DvR domain to another.

For vIST to work properly, both Leaf nodes must be in the same domain.

Procedure

1. Disable IS-IS on each vIST peer Leaf node, to remove the node from the SPB network.

```
no router isis enable
```
2. Disable DvR on each Leaf node.

```
no dvr leaf
```

**Caution**

Disabling DvR on a Leaf node in a vIST pair automatically removes all vIST configuration on that node, but not on the pair. The node on which DvR is disabled also loses its membership with the DvR domain and all the dynamic content learned from the Controllers in that domain.

When you re-enable DvR on the node, you must manually configure vIST on that node again.

3. Configure each node as a DvR Leaf node, with the new domain ID.
 Ensure that you configure both nodes as Leaf nodes and with the same domain ID.

```
dvr leaf <1-255>
```
4. Configure vIST on the DvR Leaf nodes.

```
dvr leaf virtual-ist {<A.B.C.D/X|<A.B.C.D> <A.B.C.D>} peer-ip  
{A.B.C.D} cluster-id <1-1000>
```
5. Enable IS-IS on each vIST peer Leaf node, to add back the node to the SPB network.

```
router isis enable
```

Example

Consider two vIST peer Leaf nodes `Switch1` (IP address `51.51.51.1`) and `Switch2` (`51.51.51.2`) that belong to a DvR domain (with domain ID 4), that you need to move to another domain (with domain ID 5).

View a summary of existing Leaf configuration on each node.

```
Switch1:1(config)#show dvr

Virtual Ist peer address  : 51.51.51.2
Virtual Ist cluster-id   : 255
Virtual Ist ISID        : 16677226
```

Disable IS-IS globally on each Leaf node.

```
Switch1:1>en
Switch1:1>conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch1:1(config)#router isis
Switch1:1(config-isis)#no router isis enable
Switch1:1(config-isis)#exit
Switch1:1(config)#

Switch2:1>en
Switch2:1>conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch2:1(config)#router isis
Switch2:1(config-isis)#no router isis enable
Switch1:1(config-isis)#exit
Switch1:1(config)#
```

Disable DvR on each node. This automatically removes all vIST configuration on the node, but not on the vIST pair. The node also loses its membership with the DvR domain and all the dynamic content learned from the Controllers in that domain.

```
Switch1:1(config)#no dvr leaf
Switch2:1(config)#no dvr leaf
```

Configure each node as a DvR Leaf, with domain ID 5.

```
Switch1:1(config)#dvr leaf 5
Switch2:1(config)#dvr leaf 5
```

Configure vIST on each of the DvR Leaf nodes.

```
Switch1:1(config)#dvr leaf virtual-ist 51.51.51.1 peer-ip 51.51.51.2 cluster-id 255
Switch2:1(config)#dvr leaf virtual-ist 51.51.51.2 peer-ip 51.51.51.1 cluster-id 255
```

Enable IS-IS globally on each Leaf node.

```
Switch1:1(config)#router isis
Switch1:1(config-isis)#router isis enable
Switch1:1(config-isis)#exit
Switch1:1(config)#

Switch2:1(config)#router isis
Switch2:1(config-isis)#router isis enable
Switch2:1(config-isis)#exit
Switch2:1(config)#
```

View a summary of Leaf configuration on each node.

```
Switch1:1(config)#show dvr

Moving a vIST Controller pair from one domain to another

About This Task

Use this procedure to move a vIST Controller node pair from one DvR domain to another.

For vIST to work properly, both Controller nodes must be in the same domain.

Procedure

1. Disable IS-IS on each vIST peer Controller node, to remove the node from the SPB network.

```
no router isis enable
```

2. Disable DvR on each Controller node:

```
no dvr controller
```

Caution

Disabling DvR on a DvR Controller destroys the domain ID and all dynamic content learned within the DvR domain. However, the switch retains the VLAN specific configuration which you can view using the command **show running-config**.

3. Configure each node as a DvR Controller node, with the new domain ID. Ensure that you configure both nodes as Controller nodes and with the same domain ID.

```
dvr controller <1-255>
```

4. Enable IS-IS on each vIST peer Controller node, to add back the node to the SPB network.

```
router isis enable
```

Example

Consider two vIST peer Controller nodes Switch1 (IP address 51.51.51.3) and Switch2 (51.51.51.4) that belong to a DvR domain (with domain ID 4), that you need to move to another domain (with domain ID 5).

View a summary of Controller configuration on each node:

```
Switch1:1(config)#show dvr

Configure a non-DvR BEB to Join the DvR Backbone

About This Task

Configure a non-DvR backbone edge bridge (BEB) to join the DvR backbone so that it can receive redistributed DvR host routes from all DvR Controllers in the SPB network.

Note

On a non-DVR BEB, the redistributed host routes from the DvR backbone are not automatically installed in the IP routing table. To utilize the backbone host routes to optimize traffic forwarding (forwarding in the data plane), you must explicitly configure an IS-IS accept policy with a backbone route policy using the command **accept backbone-route-map <route-map-name>**, and specifying a suitable route-map to select the list or range of DvR backbone host routes to be installed in the routing table.

For more information on configuring an IS-IS accept policy with a backbone route policy, see [Configuring IS-IS Accept Policies](#) on page 1373.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Configure a non-DvR BEB to join the DvR backbone.

```
[no] [[default] backbone enable
```
3. Verify the configuration using the following commands.
 - `show dvr backbone-members`
 - `show dvr backbone-members non-dvr-beb`
 - `show dvr backbone-entries`
 - `show isis`

Example

```
Switch3:1>enable
Switch3:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch3:1(config)#router isis
Switch3:1(config-isis)#show dvr
```

```

```

Viewing members of a DvR domain

About This Task

View the members of all DvR domains, namely the Controllers and Leaf nodes.

You can view this information on either a Controller or a Leaf node. Both the Controller and the Leaf node displays those members of the DvR domain to which it belongs.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:
enable
2. show dvr members [controller|leaf]

Example

View all members of a DvR domain:

```

Switch:1#show dvr members

=====
DVR Members (Domain ID: 255)
=====
System Name           Nick-Name           Nodal MAC           Role

-----
```

Viewing DvR interfaces

View the DvR interfaces on either a Controller or a Leaf node.

On Controllers, DvR interfaces are created when you configure IP on a DvR enabled Layer 2 VSN (VLAN, I-SID). Only Controllers display the administrative state of the interfaces because this is where you enable or disable the interfaces. The Leaf nodes display DvR interface information that is pushed from the Controllers, for example, subnet routes or gateway IP addresses for the Layer 2 VSNs.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:
2. View the DvR interface information.

On a Controller:

```
show dvr interfaces [l3isid <0-16777215>] [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

On a Leaf node:

```
show dvr interfaces [l3isid <0-16777215>]
```

Viewing the DvR interface information for a specific VRF or VRF ID is not supported on a DvR Leaf node.

Example

View DvR interfaces on a Controller node:

You can view DvR interface information on all interfaces or for a specific Layer 3 I-SID, VRF, or VRF ID.

```
Switch:1#show dvr interfaces

=====

Variable definitions

Use the data in the following table to use the **show dvr interfaces** command.

Variable	Value
<i>l3isid</i>	Specifies the Layer 3 I-SID of the DvR interface. The range is 0 to 16777215.
<i>vrf</i>	Specifies the VRF name.
<i>vrfids</i>	Specifies the VRF ID. The range is 0 to 512.

Viewing DvR host entries

About This Task

View DvR host entries (IPv4 remote host routes) on either a Controller or a Leaf node. The node displays the host entries learned either locally on its Switched UNI port or dynamically from other nodes within the DvR domain.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the DvR host entries.

On a Controller:

```
show dvr host-entries [domain-id <1-255>] [[ipv4 {A.B.C.D}]] [[l2isid
<1-16777215>]] [[l3isid <0-16777215>]] [[nh-as-mac]] [[type <1-2>]] [[vrf
WORD<1-16>]] [vrfids WORD<0-512>]
```

On a Leaf node:

```
show dvr host-entries [domain-id <1-255>] [[ipv4 {A.B.C.D}]] [[l2isid
<1-16777215>]] [[l3isid <0-16777215>]] [[nh-as-mac]] [[type <1-2>]]
```

Viewing the DvR host entries for a specific VRF or VRF ID is not supported on a DvR Leaf node.

Example

View DvR host entries on either a Controller or a Leaf node.

Viewing the DvR host entries for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr host-entries domain-id 255 l3isid 55500
```

DVR Host-Entries								
IP-ADDRESS	HOST MAC-ADDRESS	L3VSN ISID	L2VSN ISID	VRFID	PORT	DOMAIN ID	TYPE	NEXT HOP
50.0.1.2	b0:ad:aa:42:ed:04	55500	50500	0	2/23	255	DYNAMIC	Cont-1:121
50.0.1.3	b0:ad:aa:4c:3d:01	55500	50500	0	cpp	255	LOCAL	Cont-2:122

```
2 out of 2 Total Num of DVR Host Entries displayed
```

View DvR host entries for a specific IP address.

In this example, you enter IP address 50.0.1.0 to display host entries for IP addresses 50.0.1.2 and 50.0.1.3.

```
Switch:1#show dvr host-entries ipv4 50.0.1.0
```

DVR Host-Entries								
IP-ADDRESS	HOST MAC-ADDRESS	L3VSN ISID	L2VSN ISID	VRFID	PORT	DOMAIN ID	TYPE	NEXT HOP
50.0.1.2	b0:ad:aa:42:ed:04	55500	50500	0	2/23	2	DYNAMIC	Cont-1:121
50.0.1.3	b0:ad:aa:4c:3d:01	55500	50005	0	cpp	2	LOCAL	Cont-2:122

```
2 out of 2 Total Num of DVR Host Entries displayed
```

View DvR host entries where the next hop displays the MAC address instead of the system name.

```
Switch:1#show dvr host-entries nh-as-mac
```

```

Variable definitions

Use the data in the following table to use the **show dvr host-entries** command.

Variable	Value
<i>domain-id</i>	Specifies the domain ID of the DvR host entry. The range is 1 to 255.
<i>ipv4</i>	Specifies the IP address (IPv4) of the DvR host entry.
<i>l2isid</i>	Specifies the Layer 2 VSN I-SID of the DvR host entry. The range is 1 to 16777215.
<i>l3isid</i>	Specifies the Layer 3 VSN I-SID of the DvR host entry. The range is 0 to 16777215.
<i>nh-as-mac</i>	Specifies the MAC address of the next hop node instead of the system name.
<i>type</i>	Specifies the host type of the DvR host entry. A value of 1 indicates local hosts and a value of 2 indicates dynamic hosts.
<i>vrf</i>	Specifies the VRF name of the DvR host entry.
<i>vrfids</i>	Specifies the VRF ID of the DvR host entry. The range is 0 to 512.

Viewing DvR routes

About This Task

View the DvR routes (IPv4 network routes) on a DvR Controller or a Leaf node.

Controllers display all the IP subnet routes configured for that DvR domain. The Leaf nodes display the IP subnet routes that are learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. Leaf nodes also display routes that are redistributed by Controllers (direct routes, static routes and the default route), into the DvR domain.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the DvR routes.

On a Controller:

```
show dvr routes [ipv4 {A.B.C.D}]|[l3isid <0-16777215>]|[nh-as-mac] |
[vrf WORD<1-16>]|[vrfids WORD<0-512>]
```

On a Leaf node:

```
show dvr routes [ipv4 {A.B.C.D}]|[l3isid <0-16777215>]|[nh-as-mac]
```

Viewing the DvR routes for a specific VRF or VRF ID is not supported on a DvR Leaf node.

Example

View DvR routes on either a Controller or a Leaf node.

Viewing the DvR routes for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr routes

=====

1 out of 1 Total Num of DVR Routes displayed							
TYPE Legend: E=Ecmp Route							

Variable definitions

Use the data in the following table to use the **show dvr routes** command.

Variable	Value
<i>ipv4</i> {A.B.C.D}	Specifies the IP address (IPv4) of the DvR route.
<i>l3isid</i> <0-16777215>	Specifies the Layer 3 I-SID of the DvR route. The range is 0 to 16777215.
<i>nh-as-mac</i>	Specifies the MAC address of the next hop node instead of the system name.
<i>vrf</i>	Specifies the VRF name of the DvR route.
<i>vrfids</i>	Specifies the VRF ID of the DvR route. The range is 0 to 512.

Viewing DvR database information

About This Task

View all DvR routes on a Controller or a Leaf node.

The Controller node displays all the IP subnet routes configured for that DvR domain. A Leaf node displays all IP subnet routes learned from the Controller(s) for the Layer 2 VSNS in the DvR Domain. It also displays the Host Routes (ARPs) learned from other DvR enabled nodes.

Before You Begin

Ensure that DvR is enabled globally on the node.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the DvR database.

On a Controller:

```
show dvr database [home] |[ipv4 {A.B.C.D}] |[l3isid<0-16777215>] |[nh-as-mac] |[remote] |[vrf WORD<1-16>] |[vrfids WORD<0-512>]
```

On a Leaf node:

```
show dvr database [home] |[ipv4 {A.B.C.D}] |[l3isid<0-16777215>] |[nh-as-mac] |[remote]
```

Viewing the DvR database for a specific VRF or VRF ID is not supported on a DvR Leaf node.

Example

View the DvR database on either a Controller or a Leaf node.

Viewing the DvR database for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr database

Variable definitions

Use the data in the following table to use the **show dvr database** command.

Variable	Value
<i>home</i>	Specifies the DvR database information for home instance.
<i>ipv4 {A.B.C.D}</i>	Specifies the IP address (IPv4) of the DvR database entry.
<i>l3isid <0-16777215></i>	Specifies the Layer 3 I-SID of the DvR database entry. The range is 0 to 16777215.
<i>nh-as-mac</i>	Specifies the MAC address of the next hop node instead of the system name.
<i>remote</i>	Specifies the DvR database information for remote instance.
<i>vrf</i>	Specifies the VRF name of the DvR database entry.
<i>vrfids</i>	Specifies the VRF ID of the DvR database entry. The range is 0 to 512.

Viewing DvR Backbone Entries

About This Task

View the DvR backbone entries (redistributed host routes) learned from all Controllers in all DvR domains.

Note

DvR backbone entries can be viewed only on a Controller. Viewing backbone entries is not applicable on a Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View DvR backbone entries:

```
show dvr backbone-entries [adv-controller WORD<1-255>] |[domain-id
<1-255>] |[home] |[host-mac-address 0x00:0x00:0x00:0x00:0x00:0x00] |[ipv4
{A.B.C.D}] |[l2isid <1-16777215>] |[l3isid <0-16777215>] |[next-hop
WORD<1-255>] |[nh-as-mac] |[remote]
```

Example

View all DvR backbone entries:

```
Switch:1#show dvr backbone-entries

Variable definitions

Use the data in the following table to use the **show dvr backbone entries** command.

Variable	Value
<i>adv-controller</i> WORD<1-255>	Specifies the system name of the advertising Controller.
<i>domain-id</i> <1-255>	Specifies the domain ID of the DvR backbone entry. The range is 1 to 255.
<i>home</i>	Display the DvR backbone entries for the home instance.
<i>host-mac-address</i> 0x00:0x00:0x00:0x00:0x00:0x00	Specifies the host MAC address of the DvR backbone entry.
<i>ipv4</i> {A.B.C.D}	Specifies the IP address (IPv4) of the DvR backbone entry.
<i>l2isid</i> <1-16777215>	Specifies the Layer 2 I-SID of the DvR backbone entry. The range is 1 to 16777215.

Variable	Value
<code>l3isid <0-16777215></code>	Specifies the Layer 3 I-SID of the DvR backbone entry. The range is 0 to 16777215.
<code>next-hop WORD <1-255></code>	Specifies the system name of the next hop node.
<code>nh-as-mac</code>	Specifies the MAC address of the next hop node instead of the system name.
<code>remote</code>	Display the DvR backbone entries for the remote instance.

Viewing DvR backbone members

About This Task

DvR backbone members are either DvR Controllers or non-DvR BEBs that receive redistributed host routes from all other DvR Controllers in the SPB network.

Before You Begin

Ensure that DvR is enabled globally on the node.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. View DvR backbone member information:

```
show dvr backbone-members [controller | home | non-dvr-beb | remote]
```

Example

View all DvR backbone members:

```
Switch:1#show dvr backbone-members

=====
DVR BB Members
=====
System Name      Nick-Name      Nodal MAC      Role      Domain Id  Area      Area-Name
-----
DVR-D2-C1-40    0.82.40       00:00:82:84:40:00  NON-DVR-BEB  2          HOME      area-0.00.20
Ctrl-2:8200:122 0.81.22       00:bb:00:00:81:22  Controller  2          HOME      area-0.00.20

```

Variable definitions

Use the data in the following table to use the **show dvr backbone-members** command.

Variable	Value
<i>controller</i>	Specifies backbone members that are DvR Controllers.
<i>home</i>	Specifies DvR backbone members information for the home instance.
<i>non-dvr-beb</i>	Specifies backbone members that are non-DvR BEBs.
<i>remote</i>	Specifies DvR backbone members information for the remote instance.

Viewing Layer 3 VSN information

About This Task

View VRFs corresponding to Layer 3 (routed) VSN I-SIDs on either a Controller or a Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

- Enter Privileged EXEC mode:

```
enable
```
- View the Layer 3 VSN information:

```
show dvr l3vsn [l3isid <0-16777215>] | [vrf WORD<1-16>] | [vrfids WORD<0-512>]
```

Example

View Layer 3 VSN information on a DvR Controller:

```
Switch:1#show dvr l3vsn
```

```
=====
                                DVR L3VSN
=====
```

```

VRF ID          L3VSN ISID    VRF NAME    INJECT-DEFAULT-ROUTE-DISABLE
-----
1                55500        vrf600      Disabled
2                55501        vrf601      Disabled
3                55502        vrf602      Disabled
4                55503        vrf603      Disabled

4 out of 4 Total Num of DVR L3VSN displayed
-----

```

View Layer 3 VSN information on a DvR Leaf node:

```

Switch2:1#show dvr l3vsn

=====
                        DVR L3VSN
=====
VRF ID          L3VSN ISID    VRF NAME
-----
1                55500        vrf600
2                55501        vrf601
3                55502        vrf602

3 out of 3 Total Num of DVR L3VSN displayed
-----

```

Variable definitions

Use the data in the following table to use the **show dvr l3vsn** command.

Variable	Value
<i>l3isid</i> <0-16777215>	Specifies the Layer 3 VSN I-SID. The range is 0 to 16777215.
<i>vrf WORD</i> <1-16>	Specifies the VRF name of the VRF corresponding to the Layer 3 VSN I-SID.
<i>vrfids WORD</i> <0-512>	Specifies the VRF ID of the VRF.

Viewing DvR domain redistribution information

About This Task

View DvR domain redistribution information on a Controller or a Leaf node.

Note

You can view DvR domain redistribution information only on a DvR Controller. An error message displays if you attempt to view this information on a DvR Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:
enable

- View DvR domain redistribution information:

```
show dvr redistribute [vrf WORD<1-16>] | [vrfids WORD<0-512>]
```

Example

View DvR domain redistribution information on a Controller:

```
Switch:1#show dvr redistribute
=====
                        DVR Redistribute List - GlobalRouter
=====

SOURCE MET MTYPE      ENABLE RPOLICY
-----
STAT   1   External  TRUE  -
```

View DvR domain redistribution information for a particular VRF.

```
Switch:1#show dvr redistribute vrf vrf1
=====
                        DVR Redistribute List - VRF vrf1
=====

SOURCE MET MTYPE      ENABLE RPOLICY
-----
STAT   20000 External  TRUE  -
LOC    10000 Internal  TRUE  -
```

Variable definitions

Use the data in the following table to use the **show dvr redistribute** command.

Variable	Definitions
<i>vrf</i> WORD<1-16>	Specifies the VRF name.
<i>vrfids</i> WORD<0-512>	Specifies the VRF ID of the VRF.

Configure a DvR Solution

The following section describes a simple configuration example to configure Distributed Virtual Routing (DvR) over a Fabric Connect (SPB) network.

About This Task

In this example, you configure two DvR Controllers (with IP addresses 10.133.226.101 and 10.133.226.102) and two DvR Leaf nodes (with IP addresses 10.133.226.103 and 10.133.226.104), in a single DvR domain with domain ID 9. Hosts connect to the DvR nodes as shown in the figure.

Before You Begin

On the switches to be configured as DvR Controllers:

- Ensure that you configure Fabric Connect.
- Ensure that you configure IP Shortcuts on the node. This is necessary for proper functioning of the node as a DvR Controller.
- Verify that the `dvr-leaf-mode` boot flag is disabled on the node. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

On the switches to be configured as DvR Leaf nodes:

- Ensure that you configure Fabric Connect.

Procedure

DvR Controller configuration — Controller 1 and Controller 2:

1. Verify configuration of Fabric Connect on each of the switches to be configured as the DvR Controllers.

The following examples show verification on one of the switches. Perform this verification on both switches.

- a. Verify the SPB configuration:

```
Switch1:1>en
Switch1:1#show spbm
```

```

        spbm : enable
        ethertype : 0x8100
        nick-name server : enable
        nick-name allocation : static
        nick-name server range : B.00.00-B.FF.FF
Switch1:1#show isis spbm

=====
                        ISIS SPBM Info
=====
SPBM      B-VID      PRIMARY      NICK      LSDB      IP      IPV6      MULTICAST      SPB-PIM-GW
INSTANCE  VLAN          VLAN          NAME      TRAP
-----
1         4051-4052    4051         0.10.01   disable   enable   disable   enable         disable

=====
                        ISIS SPBM SMLT Info
=====

Layer 2 VSN (VLAN) configuration on the DvR Controllers:

3. Configure Layer 2 VSN on the DvR Controllers, Controller 1 and Controller 2.

- a. Configure platform VLANs on Controller 1 (VLAN ID=200 and VLAN ID=202). Associate the VLANs with the I-SIDs 20200 and 20202 respectively. Configure gateway IPv4 addresses 20.0.1.1 and 20.2.1.1 respectively, and enable DvR on those interfaces.

```
Switch1:1(config)#vlan create 200 type port-mstprstp 0
Switch1:1(config)#vlan i-sid 200 20200
Switch1:1(config)#interface vlan 200
```

```
Switch1:1(config)#dvr gw-ipv4 20.0.1.1
Switch1:1(config)#dvr enable
Switch1:1(config)#ip address 20.0.1.2 255.255.0.0

Switch1:1(config)#vlan create 202 type port-mstprstp 0
Switch1:1(config)#vlan i-sid 202 20202
Switch1:1(config)#interface vlan 202
Switch1:1(config)#dvr gw-ipv4 20.2.1.1
Switch1:1(config)#dvr enable
Switch1:1(config)#ip address 20.2.1.2 255.255.0.0
Switch1:1(config)#exit
Switch1:1#
```

- b. Configure the platform VLANs on Controller 2. Ensure that you configure the same gateway IPv4 addresses on the corresponding VLANs, as on Controller 1.

```
Switch2:1(config)#vlan create 200 type port-mstprstp 0
Switch2:1(config)#vlan i-sid 200 20200
Switch2:1(config)#interface vlan 200
Switch2:1(config)#dvr gw-ipv4 20.0.1.1
Switch2:1(config)#dvr enable
Switch2:1(config)#ip address 20.0.1.3 255.255.0.0

Switch2:1(config)#vlan create 202 type port-mstprstp 0
Switch2:1(config)#vlan i-sid 202 20202
Switch2:1(config)#interface vlan 202
Switch2:1(config)#dvr gw-ipv4 20.2.1.1
Switch2:1(config)#dvr enable
Switch2:1(config)#ip address 20.2.1.3 255.255.0.0
Switch2:1(config)#exit
Switch2:1#
```

- c. Verify Layer 2 VSN (VLAN) configuration on the Controllers. The following example shows the verification on Controller 1. Perform this verification on both Controllers.

View the DvR interfaces.

On Controllers, DvR interfaces are created when you configure IP on a DvR enabled Layer 2 VSN (VLAN, I-SID). You can also view the administrative state of these interfaces on the Controller.

```
Switch1:1#show dvr interfaces

=====

Layer 3 configuration on the DvR Controllers

4. Configure Layer 3 (VRF) on the DvR Controllers, Controller 1 and Controller 2.
 - a. Configure Layer 3 on Controller 1. As part of this configuration, you configure a VRF `vrf501` and associate it with a DvR VLAN.

```
Switch1:1(config)#ip vrf vrf501 vrfid 501
Switch1:1(config)#vlan create 501 type port-mstprstp 0
Switch1:1(config)#vlan i-sid 501 50501
Switch1:1(config)#interface Vlan 501
Switch1:1(config)#vrf vrf501
Switch1:1(config)#dvr gw-ipv4 50.1.1.1
Switch1:1(config)#dvr enable
Switch1:1(config)#ip address 50.1.1.2 255.255.0.0

Switch1:1(config)#router vrf vrf501
Switch1:1(router-vrf)#i-sid 55501
Switch1:1(router-vrf)#ipvpn enable
Switch1:1(router-vrf)#exit
Switch1:1(config)#
```

- b. Configure Layer 3 on Controller 2.

```
Switch2:1(config)#ip vrf vrf501 vrfid 501
Switch2:1(config)#vlan create 501 type port-mstprstp 0
Switch2:1(config)#vlan i-sid 501 50501
Switch2:1(config)#interface Vlan 501
Switch2:1(config)#vrf vrf501
Switch2:1(config)#dvr gw-ipv4 50.1.1.1
```

```
Switch2:1(config)#dvr enable
Switch2:1(config)#ip address 50.1.1.3 255.255.0.0

Switch2:1(config)#router vrf vrf501
Switch2:1(router-vrf)#i-sid 55501
Switch2:1(router-vrf)#ipvpn enable
Switch2:1(router-vrf)#exit
Switch2:1(config)#
```

- c. Verify Layer 3 configuration. The following example shows verification on Controller 1. Perform this verification on both Controllers.

View the DvR host entries.

```
Switch2:1(config)#show dvr host-entries l3isid 55501
```

```

DvR Leaf configuration – Leaf 1 and Leaf 2

- Configure the boot flag `dvr-leaf-mode` on the switches to be configured as DvR Leaf nodes.

Caution

Ensure that you save the current configuration on the switch, before you enable the flag. Enabling the flag removes all existing non-DvR configuration on the switch, such as platform VLANs and their IP address configuration, CLIP configuration, routing protocol configuration and VRF configuration. The gateway IPv4 address, if configured, is also removed.

On switch with IP address 10.133.226.104, configure the boot flag and reboot the switch.

```
Switch3:1>en
Switch3:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch3:1(config)#boot config flags dvr-leaf-mode
Switch3:1(config)#save config
Switch3:1(config)#reset
```

On switch with IP address 10.133.226.105, configure the boot flag and reboot the switch.

```
Switch4:1>en
Switch4:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch4:1(config)#boot config flags dvr-leaf-mode
Switch4:1(config)#save config
Switch4:1(config)#reset
```

- After the switches come back up, configure the nodes as DvR Leaf nodes.

Configure switch with IP address 10.133.226.104 as DvR Leaf 1; verify the configuration.

```
Switch3:1(config)#dvr Leaf 9
Switch3:1(config)#show dvr

DvR Configuration Using the EDM

The following sections describe configuration of Distributed Virtual Routing (DvR) using the Enterprise Device Manager (EDM).

Configure a DvR Controller or a DvR Leaf Globally

About This Task

Configure a node to perform the role of either a Controller or a Leaf, within the DvR domain.

Before You Begin

Important

For DvR Leaf Configuration only:

You must enable the `dvr-leaf-mode` boot flag before you configure a node as a DvR Leaf node. Navigate to **Configuration > Edit > Chassis**. On the **Boot Config** tab, select **EnableDvrLeafMode**.

Ensure that you save the current configuration on the switch, before you enable the flag. Enabling the flag removes all non-DvR configuration on the switch.

Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Click **DVR**.
3. Click the **Globals** tab.
4. Enter the domain ID in the **DomainId** field.

Note

A Controller or a Leaf node can belong to only one DvR domain.

5. Select the role of the node in the **Role** field.
6. (Optional) On a Controller node, disable injection of default routes into the DvR domain. Select **InjectDefaultRouteDisable**.

Note

This field applies only to Controllers. Attempting to select this field on a Leaf node displays an error message.

7. Update the fields as necessary, and then click **Apply** to save your configuration.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Field	Descriptions
DomainId	Uniquely identifies the domain that the node belongs to. The range for a Controller or a Leaf is 1 to 255. Set to 0 if is not configured.
Role	Specifies the role of the node in the domain, that is, either a Controller or a Leaf.
Enable	Specifies whether DvR is enabled on the node. Configuring a Controller or Leaf sets this parameter to true.
DomainIsid	Uniquely identifies the domain I-SID that the node belongs to. 0 indicates that is not configured.
BackboneIsid	Uniquely identifies the backbone I-SID that the node belongs to. The valid backbone I-SID is 16678216. It is set to 0 if is not configured.
GatewayMac	Specifies the Gateway MAC address used by all Domains.
InbandMgmtIp Note: Exception: not supported on VSP 8600 Series or XA1400 Series.	Specifies the In-band Management IP address configured under IS-IS. You can use this IP address to manage the node, irrespective of whether DvR is enabled on it.
InjectDefaultRouteDisable	Specifies whether injection of default routes is disabled on the Controller in the domain. By default, Controllers inject default routes into the domain so that all Leaf nodes in the domain learn these routes with the next hop as the Controller that advertised it. Selecting this field disables this behavior.
VirtualIstLocalAddr	Specifies the local IP address of vIST, if vIST is configured on a Leaf. vIST cannot be configured on a Controller.
VirtualIstLocalMask	Specifies the local subnet mask of vIST, if vIST is configured on a Leaf. vIST cannot be configured on a Controller.
VirtualIstPeerAddr	Specifies the peer IP address of vIST, if vIST is configured on a Leaf. vIST cannot be configured on a Controller.
VirtualIstClusterId	Specifies the cluster ID of vIST, if vIST is configured on a Leaf. vIST cannot be configured on a Controller. Set to 0 if vIST is not configured.
VirtualIstIsid	Specifies the I-SID if vIST is configured.
OperState	Specifies the operational state of the node.

View DvR Routes

About This Task

View the DvR routes (host routes and the IPv4 network routes) that are learned on a DvR Controller or a Leaf node.

Controllers display all the IP subnet routes configured for that DvR domain. Leaf nodes display the IP subnet routes learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. Leaf nodes also display any redistributed routes into the DvR Domain that are learned from the Controllers (direct routes, static routes and the default route).

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Click **DVR**.
3. Click the **Routes** tab.
4. To filter the rows based on the specific criteria, click **Filter**.

Routes field descriptions

Use the data in the following table to use the **Routes** tab.

Name	Description
DestIpAddrType	Specifies the IPv4 destination address type of the DvR route.
DestIpAddr	Specifies the IPv4 destination address of the DvR route.
DestMask	Specifies the destination mask of the DvR route.
L3lsid	Specifies the Layer 3 I-SID of the DvR route.
EcmpIndex	Specifies the ECMP index for the ECMP routes of the DvR route.
NextHopMac	Specifies the MAC address of the next hop BEB in the DvR route.
L2lsid	Specifies the Layer 2 I-SID of the DvR route.
Vrfid	Specifies the VRF ID.
Cost	Specifies the SPB cost of the DvR route.
NextHopName	Specifies the host name of the next hop BEB, in the DvR route.
Type	Specifies the route type of the DvR route.

View Members of a DvR Domain

About This Task

View the members of all DvR domains namely the Controllers and Leaf nodes.

You can view this information on either a Controller or a Leaf node. Both the Controller and the Leaf node displays the members of the DvR domain to which it belongs.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **DVR**.
3. Select the **Members** tab.
4. (Optional) To filter the rows based on specific criteria, click **Filter**.

Members field descriptions

Use the data in the following table to use the **Members** tab.

Name	Description
MacAddress	Specifies the system ID or the nodal MAC address of this DvR member.
SysName	Specifies the system name of this DvR member.
NickName	Specifies the nick name of this DvR member.
Role	Specifies the DvR role (Controller or Leaf) of this DvR member.
DomainId	Specifies the domain ID of the DvR domain that this member belongs to.

View DvR Backbone Members

About This Task

DvR backbone members are either DvR Controllers or non-DvR BEBs that receive redistributed host routes from all other DvR Controllers in the SPB network.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Click **DVR**.
3. Click the **Backbone Members** tab.
4. (Optional) To filter the rows based on specific criteria, click **Filter**.

Backbone Members field descriptions

Use the data in the following table to use the **Backbone Members** tab.

Name	Description
MacAddress	Specifies the system ID or the nodal MAC address of this DVR backbone member.
SysName	Specifies the system name of this DVR backbone member.
NickName	Specifies the nick name of this DVR backbone member.
Role	Specifies the role of this DVR backbone member. It is either a DVR Controller or a non-DVR BEB.
DomainId	Specifies the domain ID of the DVR domain that this backbone member belongs to. The domain ID is 0 for a non-DVR BEB.

View Remote DVR Backbone Members

**Note**

This procedure only applies to the VSP 7400 Series.

Before You Begin

Ensure that you enable DVR globally on the node.

About This Task

Perform this procedure to view the remote DVR backbone members. DVR backbone members are either DVR Controllers or non-DVR BEBs that receive redistributed host routes from all other DVR Controllers in the SPB network.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **DVR Remote**.
3. Select the **Backbone Members** tab.
4. (Optional) To filter the rows based on specific criteria, click **Filter**.

Backbone Members Field Descriptions

Use the data in the following table to use the **Backbone Members** tab.

Name	Description
MacAddress	Specifies the system ID or the nodal MAC address of this DVR backbone member.
SysName	Specifies the system name of this DVR backbone member.

Name	Description
NickName	Specifies the nick name of this DvR backbone member.
Role	Specifies the role of this DvR backbone member. It is either a DvR Controller or a non-DvR BEB.
DomainId	Specifies the domain ID of the DvR domain that this backbone member belongs to. The domain ID is 0 for a non-DvR BEB.

View DvR Interfaces

About This Task

View the DvR interfaces on either a Controller or a Leaf node.

On Controllers, DvR interfaces are created when you configure IP on a DvR enabled Layer 2 VSN (VLAN, I-SID). Only Controllers display the administrative state of the interfaces because this is where you enable or disable the interfaces. On a Leaf node, the DvR interface information that the Controllers push, for example, subnet routes and the gateway IP addresses for the Layer 2 VSNs, are displayed.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Click **DVR**.
3. Click the **Interfaces** tab.

Click **Filter** to filter rows based on specific filter criteria.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
VlanIpAddrType	Specifies the VLAN IP address type of the DvR interface.
VlanIpAddr	Specifies the VLAN IP address (IPv4) of the DvR interface.
L3Isid	Specifies the Layer 3 I-SID of the DvR interface. The range is 1 to 16777215.
L2Isid	Specifies the Layer 2 I-SID of the DvR interface. The range is 1 to 16777215.
VlanIpMask	Specifies the VLAN IP address mask of the DvR interface.
VrfId	Specifies the VRF ID of the DvR interface. The VRF ID is 0 for the GRT.

Name	Description
VlanId	Specifies the VLAN ID of the DvR interface.
GwIpAddrType	Specifies the address type of the DvR gateway IP address (IPv4).
GwIpAddr	Specifies the DvR gateway IP address (IPv4).
AdminState	Specifies the administrative state of the DvR interface.
SpbmcState	Specifies the state of IP Multicast over Fabric Connect, on the DvR interface.
IgmpVersion	Specifies the version of IGMP that runs on the DvR interface.

View DvR Host Entries

About This Task

View DvR host entries (IPv4 remote ARPs) on either a Controller or a Leaf node. The node displays the host entries learned either locally on its UNI port or dynamically from other nodes in the DvR domain.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Click **DVR**.
3. Click the **Host Entries** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

Host Entries field descriptions

Use the data in the following table to use the **Host Entries** tab.

Name	Description
IpAddrType	Specifies the address type of the DvR host entry (IPv4 remote ARP).
IpAddr	Specifies the IPv4 address of the DvR host entry.
Mask	Specifies the subnet mask of the DvR host entry.
L3Isid	Specifies the Layer 3 I-SID of the DvR host entry.
MacAddr	Specifies the MAC address of the DvR host entry.
L2Isid	Specifies the Layer 2 I-SID of the DvR host entry.
VrfId	Specifies the VRF ID associated with the DvR host entry.
Port	Specifies the port of the DvR host entry.

Name	Description
DomainId	Specifies the DvR domain ID of the DvR host entry.
Type	Specifies the host type of the DvR host entry.
NextHopName	Specifies the next hop system name of the DvR host entry.
NextHopMac	Specifies the next hop system MAC address of the DvR host entry.
ClearEntry	Clears the entry if the configured value is true.

View Remote DvR Host Entries

Note

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to view the remote DvR host entries (IPv4 remote ARPs) on either a Controller or a Leaf node. The node displays the host entries learned either locally on its UNI port or dynamically from other nodes in the DvR domain.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **DVR Remote**.
3. Select the **Host Entries** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

Host Entries Field Descriptions

Use the data in the following table to use the **Host Entries** tab.

Name	Description
IpAddrType	Specifies the address type of the DvR host entry (IPv4 remote ARP).
IpAddr	Specifies the IPv4 address of the DvR host entry.
Mask	Specifies the subnet mask of the DvR host entry.
L3lsid	Specifies the Layer 3 I-SID of the DvR host entry.
MacAddr	Specifies the MAC address of the DvR host entry.
L2lsid	Specifies the Layer 2 I-SID of the DvR host entry.

Name	Description
VrfId	Specifies the VRF ID associated with the DvR host entry.
Port	Specifies the port of the DvR host entry.
DomainId	Specifies the DvR domain ID of the DvR host entry.
Type	Specifies the host type of the DvR host entry.
NextHopName	Specifies the next hop system name of the DvR host entry.
NextHopMac	Specifies the next hop system MAC address of the DvR host entry.
ClearEntry	Clears the entry if the configured value is true.

Clear DvR Host Entries

About This Task

Clear DvR host entries (IPv4 remote host routes) on a Controller. The host entries are learned on the switch either locally on its UNI port or dynamically from other nodes in the DvR domain.

Note

You can clear DvR host entries only on a DvR Controller.

An error message displays if you attempt clearing of host entries on a DvR Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Click **DVR**.
3. Click the **Clear Host Entries** tab.
4. Update the fields as necessary, and then click **Apply** to save your configuration.

Clear Host Entries field descriptions

Use the data in the following table to use the **Clear Host Entries** tab.

Name	Description
ClearAll	Select to clear all DvR host entries.
ClearIpv4	Specifies the IPv4 address of the DvR host entries to clear. The IPv4 address must not be the VLAN IP address on any Controller within the DvR domain.

Name	Description
ClearL2Isid	Specifies the Layer 2 VSN I-SID of the DvR host entries to clear. The range is 0 to 16777215.
ClearL3Isid	Specifies the Layer 3 VSN I-SID of the DvR host entries to clear. The range is 0 to 16777215.

View Layer 3 VSN Information

About This Task

View VRFs corresponding to Layer 3 (routed) VSN I-SIDs on either a Controller or a Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Click **DVR**.
3. Click the **L3-VSN** tab.

Click **Filter** to filter rows based on specific filter criteria.

L3-VSN field descriptions

Use the data in the following table to use the **L3-VSN** tab.

Name	Description
VrfId	Specifies the VRF ID of the VRF corresponding to the Layer 3 VSN I-SID.
Isid	Specifies the Layer 3 VSN I-SID.
VrfName	Specifies the VRF name of the VRF corresponding to the Layer 3 VSN I-SID.
InjectDefaultRouteDisable	Specifies whether injection of default routes is disabled.

View the DvR Database

About This Task

View all DvR routes on a Controller or a Leaf node.

The Controller node displays all the IP subnet routes configured for that DvR domain. A Leaf node displays all IP subnet routes learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. It also displays the Host Routes (ARPs) learned from other DvR enabled nodes.

Before You Begin

Ensure that you enable DvR on the node.

Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Click **DVR**.
3. Click the **Database** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

Database field descriptions

Use the data in the following table to use the **Database** tab.

Name	Description
DestIpAddrType	Specifies the address type of the IPv4 destination address of the DvR database entry.
DestIpAddr	Specifies the IPv4 destination address of the DvR database entry.
DestMask	Specifies the destination mask of the DvR database entry.
L3Isid	Specifies the Layer 3 I-SID of the DvR database entry.
EcmpIndex	Specifies the ECMP index for the DvR database entry.
NextHop	Specifies the MAC address of the next hop BEB, in the DvR database entry.
L2Isid	Specifies the Layer 2 I-SID of the DvR database entry.
VrfId	Specifies the VRF ID for the DvR database entry.
OutgoingInterface	Specifies the outgoing interface (port or MLT) of the DvR database entry.
SpbCost	Specifies the SPB cost of the DvR database entry.
PrefixCost	Specifies the prefix cost of the DvR database entry.
NextHopName	Specifies the host name of the next hop BEB, in the DvR database table entry.
Age	Specifies the uptime since creation of the DvR database table entry.

View the Remote DvR Database

Note

This procedure only applies to the VSP 7400 Series.

Before You Begin

Ensure that you enable DvR on the node.

About This Task

Perform this procedure to view all remote DvR routes on a Controller or a Leaf node.

The Controller node displays all the IP subnet routes configured for that DvR domain. A Leaf node displays all IP subnet routes learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. It also displays the Host Routes (ARPs) learned from other DvR enabled nodes.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **DVR Remote**.
3. Select the **Database** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

Database Field Descriptions

Use the data in the following table to use the **Database** tab.

Name	Description
DestIpAddrType	Specifies the address type of the IPv4 destination address of the DvR database entry.
DestIpAddr	Specifies the IPv4 destination address of the DvR database entry.
DestMask	Specifies the destination mask of the DvR database entry.
L3Isid	Specifies the Layer 3 I-SID of the DvR database entry.
EcmpIndex	Specifies the ECMP index for the DvR database entry.
NextHop	Specifies the MAC address of the next hop BEB, in the DvR database entry.
L2Isid	Specifies the Layer 2 I-SID of the DvR database entry.
VrfId	Specifies the VRF ID for the DvR database entry.
OutgoingInterface	Specifies the outgoing interface (port or MLT) of the DvR database entry.
SpbCost	Specifies the SPB cost of the DvR database entry.
PrefixCost	Specifies the prefix cost of the DvR database entry.
NextHopName	Specifies the host name of the next hop BEB, in the DvR database table entry.
Age	Specifies the uptime since creation of the DvR database table entry.

View DvR Backbone Entries on a Controller

About This Task

View the DvR backbone entries (redistributed host routes) learned from all Controllers in all DvR domains.

Note

You can view DvR backbone entries only on a Controller. Viewing backbone entries does not apply to a Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric** folders.
2. Select **DVR**.
3. Select the **Backbone Entries** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

Backbone Entries field descriptions

Use the data in the following table to use the **Backbone Entries** tab.

Name	Description
IpAddrType	Specifies the address type of the DvR backbone host (IPv4 remote ARP).
IpAddr	Specifies the IPv4 address of the DvR backbone host.
L3Isid	Specifies the Layer 3 I-SID of the DvR backbone host.
DomainId	Specifies the domain ID of the DvR backbone host.
EcmpIndex	Specifies the ECMP index of the DvR backbone host.
HostMacAddr	Specifies the MAC address of DvR backbone host.
L2Isid	Specifies the Layer 2 I-SID of the DvR backbone host.
AdvControllerName	Specifies the host name of the advertising Controller.
AdvController	Specifies the host MAC address of the advertising Controller.
NextHopName	Specifies the host name of the next hop Backbone host in the DvR route.
NextHopMac	Specifies the MAC address of the next hop Backbone host in the DvR route.

View Remote DvR Backbone Entries on a Controller

Note

This procedure only applies to the VSP 7400 Series.

Before You Begin

Ensure that you enable DvR globally on the node.

About This Task

Perform this procedure to view the remote DvR backbone entries (redistributed host routes) learned from all Controllers in all DvR domains.

Note

You can view DvR backbone entries only on a Controller. Viewing backbone entries does not apply to a Leaf node.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **DVR Remote**.
3. Select the **Backbone Entries** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

Backbone Entries Field Descriptions

Use the data in the following table to use the **Backbone Entries** tab.

Name	Description
IpAddrType	Specifies the address type of the DvRbackbone host (IPv4 remote ARP).
IpAddr	Specifies the IPv4 address of the DvR backbone host.
L3lsid	Specifies the Layer 3 I-SID of the DvR backbone host.
DomainId	Specifies the domain ID of the DvR backbone host.
EcmpIndex	Specifies the ECMP index of the DvR backbone host.
HostMacAddr	Specifies the MAC address of DvR backbone host.
L2lsid	Specifies the Layer 2 I-SID of the DvR backbone host.
AdvControllerName	Specifies the host name of the advertising Controller.
AdvController	Specifies the host MAC address of the advertising Controller.

Name	Description
NextHopName	Specifies the host name of the next hop Backbone host in the DvR route.
NextHopMac	Specifies the MAC address of the next hop Backbone host in the DvR route.

View DvR Multi-area SPB Backbone Entries on a Controller

Note

This procedure only applies to the VSP 7400 Series.

Before You Begin

Enable Distributed Virtual Routing (DvR) globally on the node.

About This Task

Perform this procedure to view the DvR Multi-area SPB backbone entries that the system learns from all Controllers in all DvR domains.

Note

You can view the backbone entries only on a DvR Controller. Viewing backbone entries does not apply to a DvR Leaf node.

Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **DVR**.
3. Select the **MultiArea Backbone Entries** tab.
4. (Optional) Select the **Filter** button to filter the rows on basis of specific criteria.

MultiArea Backbone Entries Field Descriptions

Use the data in the following table to use the **MultiArea Backbone Entries** tab.

Name	Description
IpAddrType	Specifies the address type of the DvR backbone host (IPv4 remote ARP).
IpAddr	Specifies the IPv4 address of the DvR backbone host.
L3Isid	Specifies the Layer 3 I-SID of the DvR backbone host.
DomainId	Specifies the domain ID of the DvR backbone host.
EcmpIndex	Specifies the ECMP index of the DvR backbone host.
HostMacAddr	Specifies the MAC address of DvR backbone host.

Name	Description
L2Isid	Specifies the Layer 2 I-SID of the DvR backbone host.
AdvControllerName	Specifies the host name of the advertising Controller.
AdvController	Specifies the host MAC address of the advertising Controller.
NextHopName	Specifies the host name of the next hop Backbone host in the DvR route.
NextHopMac	Specifies the MAC address of the next hop Backbone host in the DvR route.
Area	Specifies the type of area as home or remote.

View Remote DvR Multi-area SPB Backbone Entries on a Controller

Note

This procedure only applies to the VSP 7400 Series.

Before You Begin

Enable Distributed Virtual Routing (DvR) globally on the node.

About This Task

Perform this procedure to view the remote DvR Multi-area SPB backbone entries that the system learns from all Controllers in all DvR domains.

Note

You can view the backbone entries only on a DvR Controller. Viewing backbone entries does not apply to a DvR Leaf node.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **DVR Remote**.
3. Select the **MultiArea Backbone Entries** tab.
4. (Optional) Select the **Filter** button to filter the rows on basis of specific criteria.

MultiArea Backbone Entries Field Descriptions

Use the data in the following table to use the **MultiArea Backbone Entries** tab.

Name	Description
IpAddrType	Specifies the address type of the DvR backbone host (IPv4 remote ARP).
IpAddr	Specifies the IPv4 address of the DvR backbone host.

Name	Description
L3Isid	Specifies the Layer 3 I-SID of the DvR backbone host.
DomainId	Specifies the domain ID of the DvR backbone host.
EcmpIndex	Specifies the ECMP index of the DvR backbone host.
HostMacAddr	Specifies the MAC address of DvR backbone host.
L2Isid	Specifies the Layer 2 I-SID of the DvR backbone host.
AdvControllerName	Specifies the host name of the advertising Controller.
AdvController	Specifies the host MAC address of the advertising Controller.
NextHopName	Specifies the host name of the next hop Backbone host in the DvR route.
NextHopMac	Specifies the MAC address of the next hop Backbone host in the DvR route.
Area	Specifies the type of area as home or remote.

EAPoL

Extensible Authentication Protocol over LAN (EAPoL or EAP) is a port-based network access control protocol. EAP provides security by preventing users from accessing network resources before they are authenticated. The EAP authentication feature prevents users from accessing a network to assume a valid identity and access confidential material or launch denial-of-service attacks.

You can use EAP to set up network access control on internal LANs and to exchange authentication information between an end station or server that connects to a switch and an authentication server (such as a RADIUS server). This security feature extends the benefits of remote authentication to internal LAN clients. For example, if a new client PC fails the authentication process, EAP prevents the new client PC from accessing the network.

EAP terminology

This section lists some components and terms used with EAP-based security.

- Supplicant—a device, such as a PC, that applies for access to the network.
- Authenticator—software on a switch that authorizes or rejects a Supplicant attached to the other end of a LAN segment.
 - Port Access Entity (PAE)—software that controls each port on the device. The PAE, which resides on the switch, supports the Authenticator functionality.
 - Controlled Port—any port on the device with EAP enabled.
- Authentication Server—a RADIUS server that provides AAA services to the authenticator.

EAP Configuration Considerations

This section lists EAP configuration considerations.

- You must configure at least one EAP RADIUS server and shared secret fields.
- You cannot configure EAP on ports that are currently configured for the following:
 - Shared segments
 - MultiLink Trunking
- Change the authentication status to `auto` for each port that you want to control. The `auto` setting automatically authenticates the port according to the results of the RADIUS server. The default authentication setting for each port is `authorized`.
- When multiple clients are authenticated on the same port, the priority of the latest incoming client is applied on the port, and this priority is retained until all the clients log out on that port.

Configuration Process

The Authenticator facilitates the authentication exchanges that occur between the Supplicant and the Authentication Server. The Authenticator PORT ACCESS ENTITY (PAE) encapsulates the EAP message into a RADIUS packet, and then sends the packet to the Authentication Server.

The Authenticator manages the access to controlled port. At system initialization, or when a Supplicant initially connects to one of the controlled ports on the device, the system blocks data traffic of the Supplicant until gets authenticated. After the Authentication Server notifies the Authenticator PAE about the success or failure of the authentication, the Authenticator decides whether to permit/deny the traffic of client on controlled port.

non-EAPoL (NEAP) frames transmit according to the following rules:

- If authentication succeeds, the client blocked from accessing is allowed to the controlled port, which means the system allows all the incoming and outgoing traffic from that client through the port.
- If authentication fails, client is blocked from accessing, which means both incoming and outgoing traffic is not allowed to client.

The following figure illustrates how the switch, configured with EAP, reacts to a new network connection.

Figure 52: EAP configuration example

In the preceding figure, the switch uses the following steps to authenticate a new client:

1. The switch detects a new connection on one of its EAP-enabled ports and requests a user ID from the new client PC.
2. The new client sends its user ID to the switch.
3. The switch uses RADIUS to forward the user ID to the RADIUS server.
4. The RADIUS server responds with a request for the password of the user.
5. The switch forwards the request from the RADIUS server to the new client.
6. The new client sends an encrypted password to the switch, within the EAP packet.
7. The switch forwards the EAP packet to the RADIUS server.
8. The RADIUS server authenticates the password.
9. The switch grants the new client access to the network.
10. The new client accesses the network.

If the RADIUS server cannot authenticate the new client, it denies the new client access to the network.

The following figure shows the Ethernet frames and the corresponding codes for EAP as specified by 802.1x.

Figure 53: 802.1x Ethernet frame

The following figure shows the flow diagram for EAP on a switch.

Figure 54: EAP flow diagram

EAP System Requirements

The following are the minimum system requirements for EAP:

- RADIUS server

- Client software that supports EAP

You must specify the RADIUS server that supports EAP as the primary RADIUS server for the switch. You must configure your switch for VLANs and EAP security.

If you configure EAP on a port, the following limitations apply:

- You cannot enable EAP on ports that belong to an MLT group.
- You cannot add EAP-enabled ports to an MLT group.
- You can configure a total of 32 MAC clients, EAP and NEAP hosts, on an EAP-enabled port. Two MAC clients per port is a typical configuration.
- You cannot configure EAP on MLT/LACP interfaces.
- You cannot add EAP-enabled ports to an MLT/LACP group.
- You cannot enable VLACP on EAP enabled ports.
- Manual VLAN changes on a EAP enabled port is restricted.
- You cannot change the VLAN port tagging on EAP enabled ports.
- You cannot configure the default VLAN ID. Use the Guest VLAN configuration to access unauthenticated devices.
- You cannot enable MACsec on EAP enabled ports.
- You cannot enable EAP on NNI interfaces.
- You cannot egress mirror an EAP PDU.
- Do not use EAP with a brouter port.
- Ping to and from services between nodes over the NNI will work even when it contains only EAP enabled ports with no authenticated clients on it.
- MHSa and Fail Open VLAN are mutually exclusive.
- Fail-Open I-SID is not supported in MHSa mode.
- You cannot change the EAP operation mode on EAP enabled ports.
- You cannot configure private VLANs as Fail Open VLAN or Guest VLAN.
- You cannot configure SPBM B-VLAN as Fail Open VLAN or Guest VLAN.
- You cannot delete a VLAN if the VLAN is configured as Fail Open VLAN or Guest VLAN.

EAP Dynamic VLAN Assignment

If you configure a RADIUS server to send a VLAN ID in the Access-Accept response, the EAP feature dynamically changes the VLAN configuration of the port by adding the port to the specified VLAN.

EAP dynamic VLAN assignment affects the following VLAN configuration values:

- Port membership
- Port priority
- Default VLAN ID

When you disable EAP on a port that was previously authorized, VLAN configuration values for that port are restored directly from the nonvolatile random access memory (NVRAM) of the device.

You can set up your Authentication Server (RADIUS server) for EAP dynamic VLAN assignments. You can use the Authentication Server to configure user-specific settings for VLAN memberships and port priority.

When you log on to a system that is configured for EAP authentication, the Authentication Server recognizes your user ID and notifies the device to assign preconfigured (user-specific) VLAN membership and port priorities to the device. The configuration settings are based on configuration parameters that were customized for your user ID and previously stored on the Authentication Server.

**Note**

Static entries like IGMP, ARP, FDB configured on a port of a VLAN interface, will not be retained if the port is assigned a same VLAN by the RADIUS server and the client authenticated on the port gets disconnected or unauthenticated.

Multiple Host Multiple VLAN

With the MHMV feature, you can assign multiple authenticated devices to different VLANs on the same EAP-enabled port using device MAC addresses. Using RADIUS VLAN attributes, different clients can access different VLANs. This separates traffic for different MAC clients.

In MHMV mode, the port-priority assigned by the RADIUS server is configured by MAC address for each authenticated client. After configuration, the QoS level on the port does not change.

Use MHMV to assign multiple authenticated devices to different VLANs on the same port. Clients can access different VLANs access using the MAC address of the devices. Different clients with different level of access (unauthorized to authorized) in different VLANs and with different QoS priorities, can exist on the same port.

With MHMV, EAP Multihost VLAN supports tagged and untagged ports. A port can be a member of multiple tagged and untagged VLANs.

In MHMV mode, MAC based VLANs support traffic separation between different authenticated MAC clients. MAC based VLAN traffic separation applies only to untagged VLAN traffic. If the data traffic is tagged and if VLAN is configured on the port, then the traffic is forwarded to the VLAN associated with the tag.

Multiple Host Multiple VLAN Usage

The following example illustrates the usage scenario for a MHMV port with n unauthenticated clients:

- Clients (n) connect to a switch port. The maximum number of clients (EAP + NEAP) allowed on a port is 8192.
- EAP is enabled and the default operation mode is MHMV.
- Modify client counters to authenticate n clients.
- Initial VLANs are the VLANs which are manually set up before EAP is enabled.
- Port default VLAN ID is equal to one of the initial VLAN ID.
- All clients are unauthenticated, hence the clients cannot access the network.

The following figure represents the functionality when clients are not authenticated.

Note

The clients cannot access the network as they are not authenticated.

When client PC1 authenticates, there are two scenarios:

1. Client PC1 does not receive RADIUS VLAN attribute:
 - There are no changes to the port membership and port default VLAN ID.
 - PC1 is the only client that is allowed access to the initial VLANs.
 - A VLAN MAC rule is added that associates the MAC with the default VLAN ID.
 - If the VLAN is configured on the port, then the tagged traffic from PC1 is forwarded to the VLAN associated with the tag.
 - Untagged traffic from PC1 is forwarded to the port default VLAN.
2. Client PC1 receives RADIUS VLAN attribute:
 - The port is left in all initial VLANs and added to the VLAN corresponding to the RADIUS VLAN attribute.
 - Port default VLAN remains unchanged.
 - A VLAN MAC based rule is configured for client PC1.
 - Using the VLAN MAC based capabilities, the untagged traffic from PC1 goes to the RADIUS assigned VLAN 1 as shown in the figure below.

- Client PC1 can access all initial VLANs using tagged frames.
- The remaining clients stay unauthenticated and cannot access any VLANs.

The following figure represents the functionality when client PC1 authenticates.

Note

PC1 is authenticated with RADIUS VLAN 1. The other clients cannot access the network as they are unauthenticated.

When a client disconnects the following happens:

- The MAC VLAN rule is removed from the switch.
- If the RADIUS VLAN attribute was used with the client was authenticated and no other clients are authenticated on that RADIUS VLAN, then the port is removed from the VLAN.
- The RADIUS accounting attribute Acct-Terminate-Cause indicates how a session was terminated.
- The RADIUS accounting attribute Event-Timestamp indicates the time that an event occurred on the Network Access Server (NAS).

EAP Functionality on Flex UNI Ports

After you enable EAP on a port, all client MACs (MHMV mode) must be authenticated by the RADIUS server in order to have network access. In Multiple Host Multiple VLAN (MHMV) mode, the RADIUS server allocates a MAC to I-SID binding to each client that connects to the switch and uses it to transmit

traffic. The binding is not between the MAC and the VLAN. Untagged S-UNIs generated from the RADIUS server for a MAC or MACs are considered as MAC-based S-UNIs.

The RADIUS server also provides the VLAN:ISID binding for the MAC, which results in the addition of an untagged Switched UNI (S-UNI) for that particular I-SID. Only the MAC or MACs that receive the I-SID from the RADIUS server can transmit traffic to Extensible Authentication Protocol (EAP)-enabled Flex UNI ports.

The switch uses MAC-based S-UNIs with EAP-enabled Flex UNI ports in MHMV mode only.

The MAC-based S-UNI model does not apply to MHSA mode. In Multiple Host Single Authentication (MHSA) mode used in the untagged S-UNI model that exists on VOSS switches. S-UNIs generated from the information obtained from the RADIUS server are considered as classic or default untagged S-UNIs.

**Note**

EAP is not supported on MLT/SMLTs. Only the EAP I-SIDs are synchronized between one vIST peer and another vIST peer. S-UNIs are not synchronized with the vIST peer.

EAP with Flex UNI is supported on Distributed Virtual Routing (DvR) Leafs. An untagged S-UNI (where the system learns MACs based on the I-SID to MAC binding) must have a platform VLAN associated with it. If a default untagged S-UNI is used, the corresponding S-UNI must be received from the DvR Controllers.

EAP and Fabric Attach

With Extensible Authentication Protocol (EAP) and Fabric Attach (FA), FA-capable switches can forward traffic from EAP/NEAP clients over the SPB cloud. The traffic for authenticated clients is mapped to I-SIDs received from RADIUS server.

You must configure the desired bindings for EAP/NEAP clients on the RADIUS server. When confirming the authentication request, the RADIUS server also sends the corresponding binding for the EAP/NEAP client.

The FA Proxy sends to the FA Server the binding received from the RADIUS server. If the FA Server rejects all the bindings, the client is disconnected. EAP clients are moved from AUTHENTICATED state to HELD state.

On an FA Server, when an EAP/NEAP device is authenticated and an FA binding is received from the RADIUS server, a Switched UNI (S-UNI) is created.

After an EAP/NEAP client is disconnected, the switch cleans-up the binding associated with the client, if no other EAP/NEAP client on that port uses it.

EAP and FA can be enabled in any order; however, EAP must have Flex UNI enabled in order to function on an FA-enabled port.

FA clients that generate S-UNI bindings must be used with EAP MHSA mode, while FA clients that do not generate S-UNI bindings should be used with EAP MHMV mode.

MAC Move Detection on EAP Ports

The MAC moves mechanism detects when a MAC address migrates from one port to another port, such as:

- EAPoL-enabled port to EAPoL-enabled port
- EAPoL-enabled port to non-EAPoL (NEAP)-enabled port
- non EAPoL-enabled port to EAPoL-enabled port

When a MAC address migrates from one port to another port, the new EAPoL-enabled port triggers a new RADIUS authentication. New bindings are applied on the new EAPoL-enabled port. The old port detects the MAC is moved and automatically deletes the old binding or bindings.

The Mac moves mechanism works between vIST peers when a MAC address on one peer migrates to the other peer but only if the I-SID in which the MAC address is learned exists on the new and the old peer.

Auto-sense Ports

EAP and NEAP is integrated with Auto-sense infrastructure. If a RADIUS server is configured on the switch, Auto-sense-enabled ports activate EAP and NEAP authentication automatically.

For more information about Auto-sense functionality, see [Auto-sense](#) on page 14.

RADIUS-Assigned VLAN or VLAN:ISID Bindings

RADIUS-assigned VLAN and VLAN:ISID bindings provide greater flexibility and a more centralized assignment. The RADIUS server can dynamically assign VLANs or VLAN:ISID bindings to a port.

Use VLAN attributes for RADIUS assignments in VLAN mode. This mode applies when the EAP-enabled port does not have Flex-UNI enabled.

Use VLAN:ISID attributes for RADIUS assignments in I-SID mode. This mode applies when the EAP-enabled port does have Flex-UNI enabled.

For more information, see [RADIUS Attributes](#) on page 2782.

RADIUS Port and VLAN Based Attributes

RADIUS port and VLAN based attributes automate switch configuration using port and VLAN based attributes received from the RADIUS Server.

Extreme-Dynamic-Config Vendor Specific Attribute (VSA) dynamically configures the following features:

- VLAN Based Features
 - IGMP Snooping
 - DHCP Snooping
 - Dynamic ARP Inspection (DAI)

- Port Based Features
 - IP Source Guard (IPSG)
 - Simple Loop Prevention Protocol (SLPP) Guard
 - Bridge Protocol Data Unit (BPDU) Guard
 - Traffic Control (Wake on LAN - WoL)
 - Custom Auto-Negotiation Advertisements

SBP Support

In an SPB environment, settings for VLAN based features are enabled on the platform VLANs associated with the I-SID received from the RADIUS server. If the I-SID received from the RADIUS server does not have a platform VLAN associated with it, settings are not applied. When a platform VLAN is then associated with the I-SID, EAP reauthentication is generated to apply the settings by bouncing a port, bouncing EAP on a port, or by using CoA Reauthenticate.

When a platform VLAN is removed from the I-SID, all applied dynamic settings for the VLAN are also removed.

MHSA Support

When port is configured in Multiple Host Single Authentication (MHSA) mode and VLAN based attributes are received from the RADIUS server, features enable on all VLANs containing the authentication port. If Flex-UNI is enabled on a port, features enable on all platform VLANs containing the authentication port.

MHMV Support

When port is configured in Multiple Host Multiple VLAN (MHMV) mode and VLAN based attributes are received from the RADIUS server, features enable on the default VLAN and on all VLANs containing the authentication port. If Flex-UNI is enabled on a port, features enable on any untagged I-SIDs and on all platform VLANs associated with the I-SID received from the RADIUS server.

Operational Considerations

Consider the following when you use port and VLAN based attributes:

- Configuring Custom Auto-Negotiation Advertisements on a port triggers a port bounce, which generates new client authentication.
- DHCP Snooping Option 82 is not supported.
- IGMP is not supported on DVR Leaf.
- Change-of-Authorization (CoA) functionality is not supported; Disconnect and Reauthenticate options are supported.
- Only settings that can be configured manually can be configured dynamically using EAP.
- IP Source Guard restrictions apply even if the feature is configured on the RADIUS server.
 - Maximum 10 entries per port
 - Maximum 1000 entries per server
 - DHCP Snooping and DAI must be enabled on all VLAN members of the RADIUS configured port.
- If multiple client authentication is permitted in MHMV mode, RADIUS settings can be applied incrementally as subsequent clients authenticate.

If a client authenticates with DHCP Snooping, DAI, and IP Source Guard attributes on the VLAN and a second client attempts to authenticate with the same attributes, consider the following:

- If the second client uses the same VLAN as the first client, only IP Source Guard applies on the RADIUS configuration port.
- If the second client uses a different VLAN, DHCP Snooping and DAI apply on the VLAN and the IP Source Guard applies on the RADIUS configuration port.
- If you configure a Guest VLAN on a port and the RADIUS server returns IP Source Guard as a result of EAP or NEAP authentication, then you should manually remove static VLANs from that port. Alternatively, you can enable DHCP Snooping and DAI on static VLANs.
- If you configure a port with multiple platform VLANs and the RADIUS server returns IP Source Guard as a result of EAP/NEAP authentication, then you must manually configure DHCP Snooping and DAI on static platform VLANs.
- Dynamic cleanup is supported. When the last client to authenticate using a dynamic setting is removed, the following dynamic settings are also removed:
 - Dynamic ARP Inspection (DAI)
 - DHCP Snooping
 - IGMP Snooping
 - IP Source Guard

However, the following settings can only be removed by disabling EAP:

- SLPP Guard
- BPDU Guard
- Traffic Control (Wake on LAN)
- Custom Auto-Negotiation Advertisements

For more information, see [Extreme-Dynamic-Config](#) on page 2784.

RADIUS Configuration Prerequisites for EAP

Connect the RADIUS server to a force-authorized port. This ensures that the port is always available and not tied to whether or not the device is EAP-enabled.

RADIUS Accounting for EAP

The switch provides the ability to account EAP and NEAP sessions using the RADIUS accounting protocol. A user session is defined as the time frame between when a user is authenticated until the user is unauthenticated.

The following table summarizes the accounting events and information logged.

Table 80: Summary of accounting events and information logged

Event	RADIUS attributes	Description
User is authenticated by EAP	Acct-Status-Type	Start
	Nas-IP-Address	IP address to represent the switch
	Nas-Port	Port number on which the user is EAP or NEAP authorized
	Acct-Session-ID	Unique string representing the session
	User-Name	EAP user name or NEAP MAC
User logs off	Acct-Status-Type	Stop
	Nas-IP-Address	IP address to represent the switch
	Nas-Port	Port number on which the user is EAP or NEAP unauthorized
	Acct-Session-ID	Unique string representing the session
	User-Name	EAP user name
	Acct-Input-Octets	Number of octets input to the port during the session
	Acct-Output-Octets	Number of octets output to the port during the session
	Acct-Terminate-Cause	Reason for terminating user session. For more information about the mapping of 802.1x session termination cause to RADIUS accounting attribute, see the following table.
Acct-Session-Time	Session interval	

The following table describes the mapping of the causes of 802.1x session terminations to the corresponding RADIUS accounting attributes.

Table 81: 802.1x session termination mapping

IEEE 802.1Xdot1xAuthSessionTerminateCause Value	RADIUSAcct-Terminate-Cause Value
supplicantLogoff(1)	User Request (1)
portFailure(2)	Lost Carrier (2)
supplicantRestart(3)	Supplicant Restart (19)
reauthFailed(4)	Reauthentication Failure (20)
authControlForceUnauth(5)	Admin Reset (6)
portRelnit(6)	Port Reinitialized (21)

Table 81: 802.1x session termination mapping (continued)

IEEE 802.1Xdot1xAuthSessionTerminateCause Value	RADIUSAcct-Terminate-Cause Value
portAdminDisabled(7)	Port Administratively Disabled (22)
notTerminatedYet(999)	—

RADIUS Dynamic User-Based Policies

RADIUS Dynamic User-Based Policies is a security feature to control access services on user devices that connect to the network. Before enabling any services on the user device, the RADIUS server authenticates each device that connects to the switch port and assigns that port to a VLAN or a VLAN to I-SID binding. RADIUS Dynamic User-Based Policies implement a dynamic method to apply filter Access Control List (ACL) rules to Extensible Authentication Protocol (EAP) and Non-EAP (NEAP) authenticated user traffic. The RADIUS server authenticates the user device for switch access and sends rules for that user device to the switch.

The system clears the rules when the following events occur:

- You disable EAPoL globally on the switch.
- EAP and NEAP sessions are cleared.
- You shutdown the port.

Note

- You must enable RADIUS and EAP over LAN (EAPoL) on the switch. For more information, see [Enabling RADIUS authentication](#) on page 2736 and [Globally enabling EAP on the device](#) on page 789.
- You must configure an EAP-enabled RADIUS server. For more information, see [Configure an EAP-enabled RADIUS Server](#) on page 792.

RADIUS Dynamic User-Based Policies support one time configuration of policy attributes on the RADIUS server and dynamically creates the policies on multiple switches within the network. This process of automatically creating policies enhances the speed of network access for authenticated users and also facilitates faster network synchronization in the event of network-wide policy changes.

Extreme Vendor ID 1916 supports the following RADIUS Vendor Specific Attribute (VSA) for RADIUS Dynamic User-Based Policies:

- Extreme-Dynamic-ACL (ID 251)

For more information, see [RADIUS Attributes](#) on page 2782.

The RADIUS server contains the RADIUS VSAs in a configuration file for each EAP or NEAP client that the switch authenticates. Following is an example of a RADIUS VSA configured on the RADIUS server:

```
00000000000a Cleartext-Password := "000000000000a"
Service-Type = Framed-User,
Framed-Protocol = PPP,
Auth-Type := Accept,
Fabric-Attach-ISID = 10:100,
Extreme-Dynamic-ACL = "CLIENT RadiusGuest",
```

```
Extreme-Dynamic-ACL += "acl inPort",
Extreme-Dynamic-ACL += "ace 1 sec name ACE-A1 ethernet ether-type eq 0x800 & action deny count & ip ip-

```

When the switch receives a new VSA with ACL and Access Control Entries (ACE) rules from the RADIUS server, the switch dynamically creates the ACL infrastructure based on the following:

- Dynamic ACLs - the switch allocates one dynamic ACL for each EAP enabled port. You cannot manually configure the dynamic ACL. The dynamic behavior of the ACL depends on the EAP port state (MHMV or MHSA). RADIUS Dynamic User-Based Policies support the inPort and outPort ACL types. You can display the filter ACL configuration on the switch using the **show filter acl** command, to identify the source of ACL configuration (static or dynamic).
- Dynamic ACEs - after the switch configures an ACL as dynamic, the system automatically considers the ACEs in that ACL as dynamic. You cannot manually configure the ACEs in a dynamic ACL. When the switch receives an ACE rule from the RADIUS server, the system allocates an ACE ID to it. Each ACE rule carries a relative order that helps the switch to set priority for the ACE rules that the switch receives. For handling of Radius ACL rules, the switch parses the rules first. Based on the actions, the system classifies the rules as security ACEs or QoS ACEs. If the switch is unable to recognize the qualifiers or actions in a rule, then the switch ignores that rule.
- Multiple Host Multiple VLAN (MHMV) operating mode - the system authenticates each MAC that the switch receives on the EAP-enabled port and assigns the MAC to a specific VLAN or VLAN to I-SID binding. The system uses the VLAN to I-SID binding when Flex UNI is enabled on a port. The system processes the ACE rules that the switch receives from the RADIUS server on a per MAC basis, the system translates the default-action into an ACE rule with actions, deny or permit. When the switch processes the RADIUS VSAs, the system adds the MAC as a qualifier for each ACE rule.
- Multiple Host Single Authentication (MHSA) operating mode - the system processes the ACE rules that it receives from the RADIUS server on a per port basis.

NEAP host

The following section provides information about NEAP hosts on EAP-enabled ports and RADIUS authentication.

NEAP Hosts on EAP Enabled Ports

For an EAP-enabled port configured for NEAP host support, devices with MAC addresses getting authenticated are allowed access to the port.

The switch allows the following types of NEAP users:

- NEAP hosts whose MAC addresses are authenticated by RADIUS.

Support for NEAP hosts on EAP-enabled ports is primarily intended to accommodate printers and other passive devices sharing a hub with EAP clients.

Support for NEAP hosts on EAP-enabled ports includes the following features:

- Authenticated NEAP clients are hosts that satisfy one of the following criteria:
 - Host MAC address is authenticated by RADIUS.
- NEAP hosts are allowed even if no authenticated EAP hosts exist on the port.

- When a new host is seen on the port, NEAP authentication is performed as follows:
 - The switch generates a <username, password> pair, which it forwards to the network RADIUS server for authentication.

NEAP MAC RADIUS Authentication

For RADIUS authentication of a NEAP host MAC address, the switch generates a <username, password> pair as follows:

- The username is the NEAP MAC address in string format.
- The password is a string that combines the switch IP address, MAC address, port number and user-configurable key string. If padding option is enabled, the system will specify a dot(.) for every missing parameter. IP address is represented by three decimal characters per octet.

Important

Follow these Global Configuration examples to select a password format that combines one or more of these three elements:

- Padding enabled , password = 010010011253..05. (when the switch IP address and port are used).
- Padding enabled, password = 010010011253... (when only the switch IP address is used).
- No padding (default option). Password = 000011220001 (when only the user's MAC address is used).

The following example illustrates the <username, password> pair format with no padding enabled and using the IP address, MAC address, and key-string as the password.

```
switch IP address = 192.0.2.5
non-EAP host MAC address = 00 C0 C1 C2 C3 C4
port = 25
Key-String = abcdef
```

- username = 00C0C1C2C3C4
- password = 010010011253.00C0C1C2C3C4.25.abcdef

Use the command **show eapol system** to verify the formatting.

```
Switch:1>show eapol system
```

```
=====
                               Eapol System
=====
                               eap : enabled
                               Eapol Version : 3
                               non-eap-pwd-fmt : mac-addr
                               non-eap-pwd-fmt key : *****
                               non-eap-pwd-fmt padding : disabled
                               auto-isid-offset status : disabled
                               auto-isid-offset value : 15980000
```

NEAP client

The following section provides information for NEAP client.

NEAP Client Re-Authentication

The NEAP client re-authentication feature supports the re-authentication of NEAP clients at defined intervals.

When you enable NEAP client re-authentication, an authenticated NEAP client is only removed from the authenticated client list if you remove the client account from the RADIUS server, or if you clear the NEAP authenticated client from the switch.

If an authenticated NEAP client does not generate traffic on the network, the system removes the MAC address for that client from the MAC address table when MAC ages out. Although the system does not display the client MAC address in the MAC Address table and it can display the client as an authenticated client.

If you enable NEAP client re-authentication and the RADIUS server that the switch connects to becomes unavailable, the system clears all authenticated NEAP and removes those clients from the switch NEAP client list.

You cannot authenticate one NEAP client on more than one switch port simultaneously. If you connect NEAP clients to a switch port through a hub, those clients are authenticated on that switch port. If you disconnect a NEAP client from the hub and connect it directly to another switch port, the client is authenticated on the new port and its authentication is removed from the port to which the hub is connected.

MAC Move for Authenticated Non-EAP Clients

When you move a Non-EAP client that is authenticated on a specific port, to another port on which EAPoL or Non-EAP is enabled, MAC move of the client to the new port does not automatically happen. This is as designed.

As a workaround, do one of the following:

- Clear the non-EAP session on the port that the client is first authenticated on, before you move the client to another port.
- Create a VLAN on the switch with the same VLAN ID as that dynamically assigned by the RADIUS server during client authentication. Use the command **vlan create <2-4059> type port-mstprstp <0-63>**. Ensure that the new port is a member of this VLAN.

NEAP MAC Learning and Authentication

The system learns the MACs based on the I-SID to MAC binding. When a packet ingresses on a port, which is associated with Switched UNI (S-UNI) I-SID, the system performs MAC look up based on the I-SID. The RADIUS server provides the VLAN:I-SID assignment.

Important

If the default untagged S-UNI is used, you must have a platform VLAN associated with it. This is required to properly transmit traffic and to generate MAC learning events for traffic sent to MAC-based S-UNIs.

When an untagged S-UNI is present on the port, the untagged MAC is initially learned on that S-UNI. When an untagged S-UNI does not exist on the port, the untagged MAC is learned on a special (internal) VLAN. The RADIUS server provides the VLAN:I-SID assignment.

MAC learning for tagged traffic occurs only if there is a tagged S-UNI with the corresponding C-VID on that port. The RADIUS server reconfirms the S-UNI that performed MAC learning.

EAP and NEAP Limitations

The EAP and NEAP MAC clients on port limits the maximum number of all EAP and NEAP clients per port. EAP and NEAP MAC clients on port enhancements independently limits the EAP and NEAP clients per port.

The following enhancements are added:

- EAP-MAC-MAX : Limits the total number of EAP clients
- NON-EAP-MAC-MAX: Limits the total number of NEAP clients

Note

Do not connect more than 100 EAP and 100 NEAP devices on the switch.

EAP and NEAP mac-max Settings

The total number of EAP clients can be set between 0 and 32, while the total number of NEAP clients can be set between 0 and 8192.

Note

EAP-MAC-MAX is overwritten by MAC-MAX. Even if EAP-MAC-MAX is set to a higher limit, then MAC-MAX must not exceed and you must not authenticate more than MAC-MAX clients.

Note

NON-EAP-MAC-MAX is overwritten by MAC-MAX. Even if NON-EAP-MAC-MAX is set to a higher limit, then MAC-MAX must not exceed and you must not authenticate more than MAC-MAX clients.

Example Scenarios

1. Scenario 1:
 - EAP-MAC-MAX 32
 - NON-EAP-MAC-MAX 32
 - MAC-MAX 10

In this scenario, there are ten EAP and NEAP authenticated clients, in the order of authentication.

2. Scenario 2:
 - EAP-MAC-MAX 1
 - NON-EAP-MAC-MAX 1
 - MAC-MAX 1

In this scenario, only one EAP or one NEAP client is authenticated, in the order of authentication.

3. Scenario 3:
 - EAP-MAC-MAX 5
 - NON-EAP-MAC-MAX 10
 - MAC-MAX 32

In this scenario, up to five EAP clients and ten NEAP clients are allowed.

4. Scenario 4:

- EAP-MAC-MAX 5
- NON-EAP-MAC-MAX 8
- MAC-MAX 7

In this scenario, up to five EAP clients and seven NEAP clients are allowed. The total number of EAP or NEAP clients is limited to seven.

Multiple Host Single Authentication

Multiple Host Single Authentication (MHSA) allows MACs to access the network without EAP and NEAP authentication. Unauthenticated devices can access the network only after an EAP or NEAP client is successfully authenticated on a port. The VLAN to which the devices are allowed is the client authenticated VLAN. Unless Guest VLAN is configured, there is no authenticated client on the port, and no MAC is allowed to access the network.

MHSA is primarily intended to accommodate printers and other passive devices sharing a hub with EAP and NEAP clients.

MHSA support is on a port-by-port basis for EAP enabled ports.

MHSA supports the following functionality:

- The port remains unauthorized when no authenticated hosts exist on the port. Before the first successful authentication occurs, both EAP and NEAP clients are allowed to negotiate access on that port but only one host is allowed to perform authentication.
- In MHSA mode, QoS level is configured when processing the Port-Priority attribute, because there can only be one authenticated client. The devices behind the authenticated client use the port priority established by the main client.
- In MHSA mode, the Guest VLAN applies only when no authenticated client is present on the port.
- After the first EAP or NEAP client successfully authenticates on a port, other clients cannot negotiate authentication on that port.
- After the first successful authentication, MACs that are already learned on that port is flushed.
- NEAP clients are not removed at age event in MHSA mode.
- There is no limit to the number of MACs that are allowed after first successful authentication.

EAP and NEAP MAC Clients on a Port with MHSA

EAP and NEAP client counters, such as MAC-MAX, EAP-MAC-MAX, and NON-EAP-MAC-MAX do not apply when the port operates in MHSA mode. In MHSA mode, there can be only one authenticated client (EAP or NEAP). Subsequent MACs seen on the port are allowed automatically without authentication.

Guest VLAN

Guest VLAN support provides limited network access until the client is authenticated. Guest VLAN is configured irrespective of the number of authenticated clients present on the port. Guest VLAN is

available for each port. Only port based VLANs are used as Guest VLANs. When the Guest VLAN is active, port is added to the VLAN ID, and port default VLAN ID changes to Guest VLAN ID.

Guest VLAN on a MHMV Port Usage Scenario

The following example illustrates the configuration of Guest VLAN support with an EAP MHMV port:

- Clients connect to a switch port through a hub.
- The initial VLANs are the VLANs on which the ports resides after a switch reboot.
- EAP is enabled.
- The port is a member of initial VLANs. The clients cannot access the VLANs since the VLANs are not authenticated. The port default VLAN ID corresponds to one of the initial VLAN IDs.
- Guest VLAN support is not activated.

The following figure represents the functionality when clients are not authenticated.

Note

The clients cannot access the network as they are not authenticated and Guest VLAN is not configured.

- Guest VLAN support is activated.
- The MHMV port is in the initial VLAN stage but gets added to the Guest VLAN ID. The default VLAN ID is updates to correspond to the Guest VLAN ID.

- All Clients behind the port can access the Guest VLAN.

The following figure represents the functionality when Guest VLAN is activated.

Note

All clients have Guest VLAN access.

- A client behind the MHSV port gets authenticated. For this usage scenario let us consider PC1 as the authenticated client.
- The port default VLAN ID is equal to the Guest VLAN ID and remains unchanged.
- The port is copied into the RADIUS assigned VLAN (if any).
- The untagged traffic that originates from PC1 (identified by MAC address) can access only the RADIUS assigned VLAN or the initial port default VLAN ID, if the RADIUS VLAN attribute is missing.
- The remaining clients that send untagged traffic are unauthenticated devices. The unauthenticated devices can access only the Guest VLAN because the port VLAN ID is equal to the Guest VLAN ID.
- The initial VLANs are accessed by the following devices:
 - Authenticated devices that are missing RADIUS VLAN attributes.
 - Authenticated devices that send corresponding tagged packets.
- When another client gets authenticated, the authenticated client undergoes the same process as PC1.

The following figure represents the functionality when a client gets authenticated:

Note

PC1 is authenticated with RADIUS VLAN 1. The remain clients have guest VLAN access.

When a client disconnects the following happens:

- The MAC VLAN rule is removed from the switch.
- If the RADIUS VLAN attribute was used with the client was authenticated and no other clients are authenticated on that RADIUS VLAN, then the port is removed from the VLAN. If other clients are authenticated on that RADIUS VLAN, then the VLAN MAC rule is deleted.
- If RADIUS VLAN attribute is not used when the client is authenticated, then only the VLAN MAC rule is deleted.

Guest VLAN on a MHSV Port Usage Scenario

The following is a usage example when Guest VLAN is configured with an EAP MHSV port:

- There are no authenticated EAP or NEAP clients on a port.
- The port is removed from the initial VLANs and moved to Guest VLAN ID.
- The default port VLAN ID changes to Guest VLAN ID.
- All MACs seen on the port have Guest VLAN access.
- Port is removed from the Guest VLAN ID.
- If no RADIUS assigned VLAN is present, then the VLAN membership and the default port VLAN ID is restored to default settings.

- If the RADIUS assigned VLAN is present, then the VLAN membership and the default port VLAN ID is changed according to its value.
- Guest VLAN loses its purpose because all MACs are allowed automatically without authentication

In MHSa mode, the Guest VLAN applies only when no authenticated client is present on the port.

Guest I-SID

Guest I-SID support provides limited network access until the client is authenticated. The switches uses the Guest I-SID to forward traffic until the client authenticates and receives other VLAN:ISID bindings from the RADIUS server.

Guest I-SID is a per-port option. You must configure an I-SID either as a C-VLAN or as an ELAN with an associated platform VLAN before you can configure it as the Guest I-SID. After you configure the Guest I-SID and you enable EAP, an untagged S-UNI is created based on the supplied I-SID. When you change the Guest I-SID while EAP is enabled, the untagged S-UNI is replaced on the port.

In MHSa mode, only one untagged S-UNI can exist on a port at one time. Consider the following:

- If there is a manually configured untagged S-UNI on the port, the untagged S-UNI, which uses the Guest I-SID replaces it.
- If the RADIUS server provides an untagged S-UNI after the client is authenticated, it replaces the untagged S-UNI, which was created based on the Guest I-SID.
- If the Guest I-SID is removed, the previous manually configured untagged S-UNI is automatically restored.
- If the RADIUS-assigned untagged S-UNI is no longer present, EAP recreates the untagged S-UNI created base on the Guest I-SID.

In MHMV mode, the untagged S-UNIs provided by the RADIUS server are treated as MAC-based untagged S-UNIs, which are different from the untagged S-UNI on the port. Consider the following factors:

- If there is a manually configured untagged S-UNI on the port, the untagged S-UNI, which uses the Guest I-SID, replaces it.
- If the Fail-Open I-SID and the Guest I-SID are both configured, the Guest I-SID is applied, as long as a RADIUS server is reachable.
- If the RADIUS server becomes unreachable, the untagged S-UNI based on the Fail-Open I-SID is removed and the untagged S-UNI is created based on the Guest I-SID.

EAP and NEAP separation

EAP and NEAP separation provide the ability to have only NEAP clients allowed on one port. This is done by allowing `eap-mac-max` to be set to 0. This enhancement gives you the ability to disable EAP clients authentication without disabling NEAP clients. There are no additional configuration commands. For more information, see [Configuring maximum EAP clients](#) on page 805 and [Configuring maximum NEAP clients](#) on page 806.

EAP and NEAP VLAN names

VLAN names configures VLAN membership of EAP and NEAP clients. You do not have to configure this feature as this mode is always enabled by default.

Fail Open VLAN with Continuity Mode

Fail Open VLAN provides network connectivity when the switch cannot connect to a RADIUS server. If an authentication failure occurs that is based on a RADIUS timeout, the port immediately transitions to the Fail Open VLAN.

Note

Prior to releases that support Continuity Mode, transition to the Fail Open VLAN is based on interval-based RADIUS server reachability checks. If the RADIUS server is reachable, the switch continues to check the reachability at a default interval of three minutes. This interval-based check can lead to a transition delay of up to three minutes, from the moment when the RADIUS Server becomes unreachable until the port moves to the Fail Open VLAN.

If the switch cannot connect to the primary and secondary RADIUS servers, then after a specified number of attempts to restore connectivity, the switch declares the RADIUS servers unreachable.

Fail Open VLAN provides the below functionality:

- When the EAP RADIUS servers are not reachable, Fail Open VLAN provides restricted access to devices, which is separate from the Guest VLAN.
- The EAP and NEAP clients are not affected when the RADIUS servers are not reachable.

To use Fail Open VLAN:

- Fail Open VLAN is a per-port configuration.
- Enable Fail Open VLAN by configuring a valid Fail Open VLAN ID and configure the selected VLAN ID on the switch.
- Use only port-based VLANs as Fail Open VLANs.

When you configure Fail Open VLAN on a port and the RADIUS servers are not reachable, then the Fail Open VLAN provides the following functionality:

- The port is removed from Guest VLAN, if configured, but all other VLAN membership is kept and the port is added to the Fail Open VLAN.
- The default VLAN ID is changed to the Fail Open VLAN ID.
- Traffic from the authenticated EAP and NEAP clients are forwarded as before.
- If re-authentication is enabled in Fail Open VLAN mode, then EAP and NEAP clients stop performing re-authentication.
- All new MACs seen on the port are considered as potential EAP and NEAP clients and are granted Fail Open VLAN access.

When at least one RADIUS server recovers, all EAP-enabled ports are removed from the Fail Open VLAN. All unauthenticated MACs are flushed to give the MACs an opportunity to authenticate.

Fail Open VLAN with Guest VLAN scenarios

When an EAP port is configured with both Fail Open VLAN and Guest VLAN, consider the following scenarios:

1. EAP port operating in MHMV mode:
 - If the EAP RADIUS servers are reachable, then all the authenticated clients have Guest VLAN ID access.
 - If the EAP RADIUS servers are not reachable, then Guest VLAN must be removed from the port completely. The Fail Open VLAN is the new default VLAN. All unauthenticated MACs have Fail Open VLAN access.
2. EAP port operating in MHSA mode:
 - Fail Open VLAN has no impact on the Guest VLAN functionality in MHSA mode.

Fail Open I-SID with Continuity Mode

Fail Open I-SID provides network connectivity with restricted access to devices when the switch cannot connect to a RADIUS server. If a failure occurs that is based on a RADIUS timeout, the port immediately transitions to the Fail Open I-SID.

Note

Prior to releases that support Continuity Mode, transition to the Fail Open I-SID is based on interval-based RADIUS server reachability checks. If the RADIUS server is reachable, the switch continues to check the reachability at a default interval of three minutes. This interval-based check can lead to a transition delay of up to three minutes, from the moment when the RADIUS Server becomes unreachable until the port moves to the Fail Open I-SID.

Note

EAP and NEAP clients are not affected when the RADIUS servers are unreachable.

To use Fail Open I-SID:

- Fail Open I-SID is a per-port configuration.
- You must configure an I-SID either as a C-VLAN or as an ELAN with an associated platform VLAN before you can configure it as the Fail-Open I-SID.
- After you configure the Fail Open I-SID and you enable EAP, an untagged S-UNI is created based on the supplied I-SID. When you change the Fail Open I-SID while EAP is enabled, the untagged S-UNI is replaced on the port.

Note

Fail Open I-SID is not supported in MHSA mode.

In MHMV mode, the untagged S-UNIs provided by the RADIUS server are treated as MAC-based untagged S-UNIs, which are different from the untagged S-UNIs on the port. Consider the following factors:

- If there is a manually configured untagged S-UNI on the port, the untagged S-UNI, which uses the Fail Open I-SID, replaces it.

- Caution is advised when both Fail-Open I-SID and Guest I-SID are configured. In this scenario, if a RADIUS server becomes reachable, the untagged S-UNI created based on the Fail-Open I-SID is removed and another untagged S-UNI based on the Guest I-SID is created.

EAP Auto-ISID-Offset

EAP auto-isid-offset functionality is used for MACs that do not receive an I-SID attribute from the RADIUS server. The configured I-SID offset value is used to calculate an I-SID value for a Switched UNI (S-UNI) when the switch receives only the VLAN attribute from the RADIUS server (not the FA VLAN:I-SID binding). In that case, the I-SID value is calculated as follows: I-SID = VLAN ID + configured I-SID offset value.

Wake On LAN

Wake On LAN (WoL) networking standard enables remotely powering-up a shutdown computer from a sleeping state. In this process, the computer is shutdown with power reserved for the network card. A packet known as Magic Packet is broadcast on the local LAN or subnet. The network card on, receiving the Magic Packet, verifies the information. If the information is valid, the network card powers-up the shutdown computer.

The WoL Magic Packet is a broadcast frame sent over a variety of connectionless protocols, such as UDP. The most commonly used connectionless protocol is UDP. The Magic Packet contains data that is a defined constant represented in hexadecimal as FF:FF:FF:FF:FF:FF, followed by 16 repetitions of the target computer MAC address and possibly by a four or six byte password.

If you implement enhanced network security using 802.1X, the transmission of Magic Packets to sleeping or unauthorized network devices is blocked. You can use an interface specific 802.1X feature known as traffic-control to address this requirement of supporting both WoL and 802.1X Authentication simultaneously. The default mode is *in-out*. This mode blocks both ingress and egress unauthenticated traffic on an 802.1X port. Configuring the traffic control mode to *in* enables the transmission of Magic Packets to sleeping or unauthenticated devices. This mode allows any network control traffic, such as a WoL Magic Packet, to be sent to a workstation irrespective of the authentication or sleep status.

Important

If a PC client is assigned to a VLAN based on a previous RADIUS Assigned VLAN, when the client goes into sleep or hibernation mode it reverts to either the default port-based VLAN or Guest VLAN configured for that port. Therefore, the WoL Magic Packet must be sent to the default VLAN or Guest VLAN.

EAPoL Configuration Using CLI

EAPoL (EAP) uses RADIUS protocol for EAP-authorized logons. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Before configuring your device, you must configure at least one EAP RADIUS server and shared secret fields.

You cannot configure EAP on ports that are currently configured for:

- Shared segments
- MultiLink Trunking (MLT)

Change the status of each port that you want to be controlled to auto. The auto setting automatically authenticates the port according to the results of the RADIUS server. The default authentication setting for each port is authorized.

Globally enabling EAP on the device

Enable EAP globally on the switch before you enable it on a port or interface.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Globally configure EAP:
`eapol enable`

Example

Enable EAP globally:

```
Switch:1> enable
Switch:1#config t
Switch:1(config)#eapol enable
```

Configure EAP on an Interface

Configure EAP on an interface.

Before You Begin

- EAP must be globally enabled.

About This Task

When you configure a port with the EAP status of auto (Authorization depends on result of EAP authentication), only one supplicant is allowed on this port. Multiple EAP supplicants are not allowed on the same physical switch port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable EAP on an interface:

```
eapol status {authorized|auto}
```

3. Disable EAP on on interface:

```
no eapol status
```

Examples

Enable EAP on an interface:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)# eapol status auto
```

Disable EAP on an interface:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)# no eapol status
```

Variable Definitions

The following table defines parameters for the **eapol status** command.

Variable	Value
<i>authorized</i>	Specifies that the port is always authorized. The default value is authorized.
<i>auto</i>	Specifies that port authorization depends on the results of the EAP authentication by the RADIUS server. The default value is authorized.

Configuring EAP on a port

Configure EAP on a specific port when you do not want to apply EAP to all of the switch ports.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum EAP requests sent to the supplicant before timing out the session:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} max-
request <1-10>
```

3. Configure the time interval between authentication failure and the start of a new authentication:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
quiet-interval <1-65535>
```

4. Enable reauthentication:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} re-
authentication enable
```

5. Configure the time interval between successive authentications:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} re-
authentication-period <1-65535>
```

**Note**

The EAP re-authentication period value is between 1-65535. Early releases support up to 2147483647. To maintain backward compatibility the CLI value is between 1-2147483647. Trying to configure above 65535 results in an error.

6. Configure the EAP authentication status:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
status {authorized|auto}
```

Example

Configure the maximum EAP requests sent to the supplicant before timing out the session:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)#eapol max-request 10
Switch:1(config-if)#eapol port 1/2 quiet-interval 500
```

Variable Definitions

The following table defines parameters for the **eapol port** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [...]}</code>	Specifies the port or list of ports used by EAP. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>max-request <1-10></code>	Specifies the maximum EAP requests sent to the supplicant before timing out the session. The default is 2.
<code>quiet-interval <1-65535></code>	Specifies the time interval in seconds between the authentication failure and start of a new authentication. The default is 60.
<code>re-authentication enable</code>	Enables reauthentication of an existing supplicant at a specified time interval.
<code>re-authentication-period <1-65535></code>	Specifies the time interval in seconds between successive reauthentications. The default is 3600 (1 hour). Note: The EAP re-authentication period value is between 1-65535. Early releases support up to 2147483647. To maintain backward compatibility the CLI value is between 1-2147483647. Trying to configure above 65535 results in an error.
<code>status {authorized auto}</code>	Specifies the desired EAP authentication status for this port.

Configure an EAP-enabled RADIUS Server

The switch uses RADIUS servers for authentication and accounting services. Use the no form to delete a RADIUS server.

Before You Begin

- You must enable EAP globally.

About This Task

The RADIUS server uses the secret key to validate users.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Procedure

- Enter Global Configuration mode:

```
enable
configure terminal
```

2. Add an EAP-enabled RADIUS server:

```

radius server host WORD <0-46> used-by eapol acct-enable
radius server host WORD <0-46> used-by eapol acct-port <1-65536>
radius server host WORD <0-46> used-by eapol enable
radius server host WORD <0-46> used-by eapol key WORD<0-20>
radius server host WORD <0-46> used-by eapol port <1-65536>
radius server host WORD <0-46> used-by eapol priority <1-10>
radius server host WORD <0-46> used-by eapol retry <0-6>
radius server host WORD <0-46> used-by eapol secure-enable
radius server host WORD <0-46> used-by eapol secure-log-level
radius server host WORD <0-46> used-by eapol secure-mode
radius server host WORD <0-46> used-by eapol secure-profile
radius server host WORD <0-46> used-by eapol source-ip WORD <0-46>
radius server host WORD <0-46> used-by eapol timeout <1-180>

```

By default, the switch uses RADIUS UDP port 1812 for authentication, and port 1813 for accounting. You can change the port numbers or other RADIUS server options.

Example

Add an EAP RADIUS server:

```

Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#radius server host fe80:0:0:0:21b:4fff:fe5e:73fd key radiustest used-
by eapol

```

Variable Definitions

The following table defines parameters to configure an EAP-enabled RADIUS server with the **radius server host** command.

Variable	Value
<i>host WORD<0-46></i>	Specifies the IP address of the selected server. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.
<i>WORD<0-20></i>	Specifies the secret key, which is a string of up to 20 characters.

The following table defines parameters to use optional arguments of the **radius server host** command.

Variable	Value
<i>port</i> <1-65535>	Specifies the port ID number.
<i>priority</i> <1-10>	Specifies the priority number. The lowest number is the highest priority.
<i>retry</i> <0-6>	Specifies the retry count of the account.
<i>timeout</i> <1-180>	Specifies the timeout of the server. The default is 30.
<i>enable</i>	Enables the functions used by the RADIUS server host.
<i>acct-port</i> <1-65536>	Specifies the port account.
<i>acct-enable</i>	Enables the account.
<i>secure-enable</i>	Enable secure mode on the server.
<i>secure-log-level</i>	Specifies the RADIUS secure server log severity level. Possible values are: <ul style="list-style-type: none"> critical debug error info warning
<i>secure-mode</i>	Specifies the protocol for establishing the secure connection with the server.
<i>secure-profile</i>	Specifies the secure profile name.
<i>source-ip</i> WORD<0-46> Note: Exception: only supported on VSP 8600 Series.	Specifies the IP source. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Configure the Switch for EAP and RADIUS

Perform the following procedure to configure the switch for EAP and RADIUS.

About This Task

You must configure the switch, through which user-based-policy (UBP) users connect to communicate with the RADIUS server to exchange EAP authentication information, as well as user role information. You must specify the IP address of the RADIUS server, as well as the shared secret (a password that authenticates the device with the RADIUS server as an EAP access point). You must enable EAP globally on each device, and you must configure EAP authentication on each device port, through which EAP/UBP users connect.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

For more information about EPM and UBP, see the user documentation for your Enterprise Policy Manager (EPM) application.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Create a RADIUS server that is used by EAP:
`radius server host WORD <0-46> key WORD<0-20> used-by eapol`
3. Log on to the Interface Configuration mode:
`interface vlan <1-4059>`
4. Enable the device to communicate through EAP:
`eapol enable`
5. Exit from VLAN interface mode:
`exit`
6. Enter Interface Configuration mode:
`interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}`
7. Enable device ports for EAP authentication:
`eapol port {slot/port[/sub-port] [-slot/port[/sub-port]][,...]} status
auto`
8. Enable periodic supplicant re-authenticating:
`eapol port {slot/port[/sub-port] [-slot/port[/sub-port]][,...]} re-
authentication enable`
9. Save your changes:
`save config`

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Create a RADIUS server that is used by EAP:

```
Switch:1(config)# radius server host fe90:0:0:0:21b:4eee:fe5e:75fd key  
radiustest used-by eapol
```

```
Switch:1(config)# interface vlan 2
```

Enable the device to communicate through EAP:

```
Switch:1(config-if)# eapol enable
```

Save your changes:

```
Switch:1(config-if)# save config
```

Variable Definitions

The following table defines parameters for the **radius server host WORD<0-46> usedby eapol** command.

Variable	Value
<i>host WORD<0-46></i>	Specifies the IP address of the selected server. This address tells the device where to find the RADIUS server, from which it obtains EAP authentication and user role information. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.
<i>key WORD<0-20></i>	Specifies the shared secret key that you use for RADIUS authentication. The shared secret is held in common by the RADIUS server and all EAP-enabled devices in your network. It authenticates each device with the RADIUS server as an EAP access point. When you configure your RADIUS server, you must configure the same shared secret value as you specify here.

Change the Authentication Status of a Port

The switch authorizes ports by default, which means that the ports are always authorized and are not authenticated by the RADIUS server.

You can also make the ports controlled so that they are dependent on being authorized by the Radius Server when you globally enable EAP (auto).

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the authorization status of a port:

```
eapol status {authorized|auto}
```

Example

Configure the authorization status of a port:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface GigabitEthernet 3/1  
Switch:1(config-if)#eapol status auto
```

Variable Definitions

The following table defines parameters for the **eapol status** command.

Variable	Value
<i>authorized</i>	Specifies that the port is always authorized. The default value is authorized.
<i>auto</i>	Specifies that port authorization depends on the results of the EAP authentication by the RADIUS server. The default value is authorized.

Deleting an EAP-enabled RADIUS server

Delete an EAP-enabled RADIUS server if you want to remove the server.

About This Task

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Delete an EAP-enabled RADIUS server:

```
no radius server host WORD<0-46> used-by eapol
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# no radius server host fe79:0:0:0:21d:4fdf:fe5e:73fd
```

```
used-by eapol
```

Variable Definitions

The following table defines parameters for the **radius server host WORD<0-46> usedby eapol** command.

Variable	Value
<i>host WORD<0-46></i>	Specifies the IP address of the selected server. This address tells the device where to find the RADIUS server, from which it obtains EAP authentication and user role information. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.
<i>key WORD<0-20></i>	Specifies the shared secret key that you use for RADIUS authentication. The shared secret is held in common by the RADIUS server and all EAP-enabled devices in your network. It authenticates each device with the RADIUS server as an EAP access point. When you configure your RADIUS server, you must configure the same shared secret value as you specify here.

Configuring Fail Open VLAN

About This Task

Use this procedure to configure Fail Open VLAN.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Fail Open VLAN:

```
eapol fail-open-vlan <1-4059>
```

Example

Configure the Fail Open VLAN.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol fail-open-vlan 10
```

Variable Definitions

The following table defines parameters for the **eapol fail-open-vlan** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Display the Current EAP-Based Security Status

Use the following procedure to display the status of the EAP-based security.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display the current EAP-based security status:

- `show eapol auth-stats interface [gigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]`

-  **Note**
The following command only applies to VSP 8600 Series:

```
show eapol multihost non-eap-mac status [vlan <1-4059>] [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```

- `show eapol port {interface [gigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]] | {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]`
- `show eapol session-stats interface [gigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]`

-  **Note**
The following command only applies to VSP 8600 Series:

```
show eapol status interface [vlan <1-4059>] [gigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```

- `show eapol sessions {eap | neap} [vlan <1-4059>] [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]] [verbose]`
-  **Note**
The following command does not apply to VSP 8600 Series or XA1400 Series:

```
show eapol summary port [{slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]]
```

- show eapol system

Examples

Note

Product Notice: auto-isid-offset functionality is not available on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

```
Switch:1>show eapol system
=====
                        Eapol System

```

Variable Definitions

The following table defines parameters for the **show eapol** command.

Variable	Value
<pre>auth-stats [gigabitEthernet {slot/ port[/sub-port] [-slot/ port[/sub-port]] [,...]]</pre>	<p>Displays the authentication statistics interface.</p> <p>Note: <i>auth-stats [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]</i> is useful only for EAP supplicants. The command output changes only when the EAP supplicant tries to access the network.</p>
<pre>multihost non-eap-mac status [vlan <1-4059>] [{slot/port[/sub-port] [- slot/port[/sub-port]] [,...]]</pre> <p>Note: Exception: This parameter applies to VSP 8600 Series only.</p>	<p>Displays EAP multihost configuration.</p>
<pre>port {interface [gigabitEthernet {slot/ port[/sub-port] [-slot/ port[/sub-port]] [,...]] {slot/port[/sub-port] [- slot/port[/sub-port]] [,...]]}</pre>	<p>Specifies the ports to display. If no port is entered, all ports are displayed.</p>
<pre>session-stats interface [gigabitEthernet {slot/ port[/sub-port] [-slot/ port[/sub-port]] [,...]]</pre>	<p>Displays the authentication session statistics interface.</p>
<pre>sessions {eap neap} [vlan<1-4059>][{slot/ port[/sub-port] [-slot/ port[/sub-port]] [,...]]] [verbose]</pre> <p>Note: Exception: This parameter does not apply to VSP 8600 Series or XA1400 Series.</p>	<p>Displays EAP and non-EAP authentication sessions on the port.</p>
<pre>status interface [vlan <1-4059>] [gigabitEthernet {slot/port[/sub-port] [- slot/port[/sub-port]] [,...]]</pre> <p>Note: Exception: This parameter applies to VSP 8600 Series only.</p>	<p>Displays the port EAP operation statistics.</p>

Variable	Value
<code>summary port[{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]</code>	Displays EAP and NEAP clients.
<code>system</code>	Displays EAP settings.

Displaying the port VLAN information

Use the following procedure to display the port VLAN information.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display the port VLAN information:

```
show interfaces [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]] [vlan <1-4059>]
```

Example

```
Switch:#enable
Switch:1#show interfaces gigabitEthernet vlan
=====
                        Port Vlans
=====
PORT          DISCARD DISCARD  DEFAULT VLAN      PORT  UNTAG  DYNAMIC  UNTAG
NUM   TAGGING  TAGFRAM  UNTAGFRAM  VLANID  IDS    TYPE   DEFVLAN  VLANS   VLANS
-----
1/1   disable  false   false     1       1      normal  disable  P       1
1/2   enable   false   false     1       1,3,10 normal  disable  P       1,10
1/3   enable   false   false     1       1,10,20 normal  disable  P
```

Variable Definitions

The following table defines parameters for the **show interfaces** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code><1-4059></code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Configuring the format of the RADIUS password attribute when authenticating NEAP MAC addresses using RADIUS

Use the following procedure to configure the format of the RADIUS password when authenticating NEAP MAC addresses using RADIUS.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the RADIUS password format:

```
eapol multihost non-eap-pwd-fmt {[ip-addr] [key WORD<1-32>] [mac-addr] [padding] [port-number]}
```

Variable Definitions

The following table defines parameters for the **eapol multihost non-eap-pwd-fmt** command.

Variable	Value
<i>ip-addr</i>	Management ip-address of the switch.
<i>key WORD<1-32></i>	Key value used for non-eap password format.
<i>mac-addr</i>	Mac-Address of the client.
<i>padding</i>	Includes a dot in the RADIUS password for every missing parameter.
<i>port-number</i>	Index of the port on which MAC is received.

Note

To derive the port number for an interface, use the command **show interfaces gigabit** **[{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]** .

If you configure interface 1/6 on the product, to derive the port-number for this interface, use the command **show interfaces gigabitEthernet 1/6**. From this command, you can ascertain that port number used in the NEAP password is 197.

```
Switch:1(config)# show interfaces gigabitEthernet 1/6
```

```
=====
```

Port Interface									
PORT NUM	INDEX	DESCRIPTION	LINK TRAP	PORT LOCK	MTU	PHYSICAL ADDRESS	STATUS ADMIN OPERATE		
1/6	197	1000BaseTX	true	false	1950	f8:15:47:e1:dd:05	up		up

```
=====
```

Enabling RADIUS authentication of NEAP hosts on EAP enabled ports

For RADIUS authentication of NEAP hosts on EAP-enabled ports, you must enable EAP globally on the switch and then enable NEAP hosts on the local interface.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable RADIUS authentication of NEAP hosts on the local interface:

```
eapol multihost radius-non-eap-enable
```

Configuring the maximum MAC clients

Use this procedure to configure the maximum EAP and NEAP MAC clients supported on a port.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Set the maximum limit of allowed EAP and NEAP MAC clients supported on the port:

```
eapol multihost mac-max <1-8192>
```

Example

```
Switch:1> enable  
Switch:1# configure terminal  
Switch:1(config)# interface GigabitEthernet 1/16  
Switch:1(config-if)# eapol multihost mac-max <1-8192>
```

Variable Definitions

The following table defines parameters for the **eapol multihost mac-max** command.

Variable	Value
<i>mac-max</i> <1-8192>	Specifies the maximum number of EAP and NEAP MAC addresses allowed on the port. The maximum limit is 8192 MAC addresses.

Configuring maximum EAP clients

About This Task

Use this procedure to configure the maximum EAP clients allowed on the port at one time.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum EAP clients:

```
eapol multihost eap-mac-max <0-32>
```

Note

eap-mac-max is also used to provide EAP and NEAP separation functionality. By default the EAP clients are enabled per port and *eap-mac-max* limit is 2. If *eap-mac-max* is set to 0 then EAP client authentication is disabled.

Example

Configure the maximum EAP clients allowed on the port at one time.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol multihost eap-mac-max 10
```

Variable Definitions

The following table defines parameters for the `eapol multihost eap-mac-max` command.

Variable	Value
<0-32>	Specifies the maximum EAP clients allowed on the port at one time. The default is 2.

Configuring maximum NEAP clients

About This Task

Use this procedure to configure the maximum NEAP clients allowed on the port at one time.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum NEAP clients:

```
eapol multihost non-eap-mac-max <0-8192>
```

Note

`non-eap-mac-max` is also used to provide EAP and NEAP separation functionality. By default the NEAP clients are enabled per port and `non-eap-mac-max` limit is 2. If `non-eap-mac-max` is set to 0 then NEAP client authentication is disabled.

Example

Configure the maximum NEAP clients allowed on the port at one time.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol multihost non-eap-mac-max 10
```

Variable Definitions

The following table defines parameters for the **eapol multihost non-eap-mac-max** command.

Variable	Value
<0-8192>	Specifies the maximum NEAP clients allowed on the port at one time. The default is 2.

Configuring the Guest VLAN ID

About This Task

Use this procedure to configure the Guest VLAN ID.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Guest VLAN ID:

```
eapol guest-vlan <1-4059>
```

Example

Configure the Guest VLAN ID.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol guest-vlan 10
```

Variable Definitions

The following table defines parameters for the **eapol guest-vlan** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Clearing NEAP session

Use this procedure to clear the NEAP session that is learnt on the switch.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Clear the NEAP session:

```
clear eapol non-eap [<0x00:0x00:0x00:0x00:0x00:0x00>] [{slot/port[/sub-port]
sub-port} [-slot/port[/sub-port]][, ...]]
<0x00:0x00:0x00:0x00:0x00:0x00>]
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# clear 1/16 00:1b:63:84:45:e6
```

Variable Definitions

The following table defines parameters for the **clear eapol non-eap** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}	Specifies the port list on which the NEAP MAC is learnt.
0x00:0x00:0x00:0x00:0x00:0x00	Specifies the MAC-Address on the NEAP session.

Configuring EAP operational mode

About This Task

Use this procedure to configure the EAP operational mode.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. configure the EAP operational mode:

```
eapol multihost eap-oper-mode {mhmV | mhSa}
```

**Note**

The default EAP operational mode is MHMV.

Example

Configure the EAP operational mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol eap-oper-mode mhSa
```

Variable Definitions

The following table defines parameters for the **eapol multihost eap-oper-mode** command.

Variable	Value
<i>mhmV</i>	Specifies the EAP operational mode as Multiple Host Multiple VLAN.
<i>mhSa</i>	Specifies the EAP operational mode as Multiple Host Single Authentication.

Enabling dynamic changes to EAP sessions on a port**About This Task**

Configure a port to allow dynamic changes to EAP sessions. The default is enable.

Before You Begin

You must enable EAP globally and at the port level.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable RADIUS dynamic authorization server processing requests.

```
eapol radius-dynamic-server enable
```

Example

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/4
Switch:1(config-if)#eapol radius-dynamic-server enable
```

Configure EAP auto-isid-offset

**Note**

This procedure does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

Before You Begin

- Enable EAP globally or on the port.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an I-SID offset value:

```
eapol auto-isid-offset <0-15995903>
```

3. Enable EAP globally:

```
eapol enable
```

4. Confirm that your configuration is correct:

```
show eapol system
```

Examples

Configure an I-SID offset value and enable I-SID offset globally on the switch:

```
Switch:1> enable
Switch:1#config terminal
```

```
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#eapol auto-isid-offset 1000
Switch:1(config)#eapol enable
```

View the current device configuration:

```
Switch:1>show eapol system
=====
                        Eapol System
=====
                        eap : disabled
                        Eapol Version : 3
                        non-eap-pwd-fmt : mac-addr
                        non-eap-pwd-fmt key : *****
                        non-eap-pwd-fmt padding : disabled
                        auto-isid-offset status : disabled
                        auto-isid-offset value : 1000
```

Variable Definitions

The following table defines parameters for the **eapol auto-isid-offset** command.

Variable	Value
<0-15995903>	Specifies the auto I-SID offset value. The default is 15995903.
<i>enable</i>	Enables auto I-SID offset. The default is disabled.

Configure the Guest I-SID

Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

Before You Begin

Configure a platform VLAN and associate the Guest I-SID. 0 indicates that Guest I-SID is not enabled for this port.

About This Task

Use this procedure to configure the Guest I-SID.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Guest I-SID:

```
eapol guest-isid <1-16000000>
```

Example

Configure the Guest I-SID.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/10
Switch:1(config-if)#eapol guest-isid 1000
```

Variable Definitions

The following table defines parameters for the **eapol guest-isid** command.

Variable	Value
<0-16000000>	Specifies the Guest I-SID value. 0 indicates that Guest I-SID is not enabled for this port.

Configure Fail Open I-SID**Note**

This procedure does not apply to VSP 8600 Series or XA1400 Series.

Before You Begin

Configure a platform VLAN and associate the Fail Open I-SID.

About This Task

Use this procedure to configure Fail Open I-SID. If the switch declares the RADIUS servers unreachable, then all new devices gain access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Fail Open I-SID:

```
eapol fail-open-isid <0-16000000>
```

Example

Configure the Fail Open I-SID.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#interface gigabitEthernet 1/10
Switch:1(config-if)#eapol fail-open-isid 1000
```

Variable Definitions

The following table defines parameters for the **eapol fail-open-isid** command.

Variable	Value
<0-16000000>	Specifies the Fail Open I-SID value. 0 indicates that Fail Open I-SID is not enabled for this port.

Configure Wake-On-LAN

Use the following procedure to configure Wake-On-LAN functionality.

**Note**

This procedure does not apply to VSP 8600 Series or XA1400 Series.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Wake-On-LAN:

```
eapol traffic-control <in | in-out>
```

Variable Definitions

The following table defines parameters for the **eapol traffic-control** command.

Variable	Value
<i>in</i>	Specifies incoming traffic is blocked when there is no authenticated device.
<i>in-out</i>	Specifies incoming and outgoing traffic is blocked when there is no authenticated device. The default value is in-out.

Show the EAPoL Status of the Device

Display the current device configuration.

**Note**

Use the **clear-stats** command to clear EAP or NEAP statistics.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the current device configuration by using the following command:

```
show eapol system
```

Example**Note**

Product Notice: auto-isid-offset functionality is not available on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

```
Switch:1>show eapol system
```

```
=====
                        Eapol System
=====
```

```

        eap : disabled
        Eapol Version : 3
        non-eap-pwd-fmt : mac-addr
        non-eap-pwd-fmt key : *****
        non-eap-pwd-fmt padding : disabled
        auto-isid-offset status : disabled
        auto-isid-offset value : 1000
    
```

Show EAPoL Authenticator Statistics

Display the authenticator statistics to manage network performance.

Note

Use the **clear-stats** command to clear EAP or NEAP statistics.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the authenticator statistics:

```

show eapol auth-stats interface [gigabitEthernet [{slot/port[/sub-
port] [-slot/port[/sub-port]] [, ...] }]
    
```

Example

```

Switch:1#show eapol auth-stats interface

--More-- (q = quit)
    
```

Variable Definitions

Use the data in the following table to use the **show eapol auth-stats interface** command.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View EAPoL Session Statistics

View EAPoL session statistics to manage network performance.

Note

Use the **clear-stats** command to clear EAP/NEAP statistics.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the session statistics:

```
show eapol session-stats interface [gigabitEthernet [{slot/port[/sub-
port] [-slot/port[/sub-port]] [,...]]]
```

Example

```
Switch:1#show eapol session-stats interface
=====
                        Eap Authenticator Session Statistics
=====
PORT  MAC                SESSION  AUTHENTIC  SESSION  TERMINATE  USER
NUM   MAC                ID        METHOD      TIME      CAUSE      NAME
-----
1/1   18:a9:05:b1:04:ce   cb000000 remote-server 0 day(s), 05:58:16 not-terminated sachin

=====
```

Variable Definitions

Use the data in the following table to use the **show eapol session-stats interface** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View Non-EAPoL MAC Information

Note

This procedure only applies to VSP 8600 Series.

Use this procedure to view non-EAPoL client MAC information on a port.

Note

Use the **clear-stats** command to clear EAP and NEAP statistics.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display the non-EAPoL MAC information:

```
show eapol multihost non-eap-mac status [vlan <1-4059>] [verbose]
[{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
```

Example

Note
Not all fields are supported on all hardware platforms.

```
Switch:1(config)#show eapol multihost non-eap-mac status
=====
Eap Oper Status
=====
PORT  MAC              STATE      VLAN  PRI  Flex-UNI  I-SID  NON-EAP  VLAN:I-SID

-----
Total Number of NEAP Sessions: 1
```

Variable Definitions

Use the data in the following table to use the **show eapol multihost non-eap-mac status** command.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i><1-4059></i>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<i>verbose</i>	Displays non-EAPoL client MAC information.

View Port EAPoL Operation Statistics

Note
This procedure only applies to VSP 8600 Series.

Use this procedure to view port EAPoL operation statistics.

Note

Use the **clear-stats** command to clear EAP/NEAP statistics.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the port EAPoL operation statistics information:

```
show eapol status interface [gigabitEthernet [{slot/port[/sub-port]}[-slot/port[/sub-port]][, ...]] [vlan <1-4059>] [verbose]
```

Examples

```
Switch:1(config)#show eapol status interface

Total Number of EAP sessions : 8
```

Variable Definitions

Use the data in the following table to use the **show eapol status** command.

Variable	Value
<i>{slot/port[/sub-port]}[-slot/port[/sub-port]][, ...]</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i><1-4059></i>	Specifies the VLAN ID for which to show the statistics.
<i>verbose</i>	Displays detailed statistics information.

EAP Configuration Using Enterprise Device Manager

EAPoL (EAP) uses RADIUS protocol for EAP-authorized logons. RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration in all but the following case. When adding a RADIUS server in Enterprise Device Manager (EDM) or modifying a RADIUS configuration in EDM, you must specify if the address type is an IPv4 or an IPv6 address.

Before You Begin

- Before configuring your device, you must configure at least one EAP RADIUS server and shared secret fields.
- You cannot configure EAP on ports that are currently configured for:
 - Shared segments
 - MultiLink Trunking (MLT)
- Change the status of each port that you want to be controlled to auto. For more information on changing the status, see [Configure EAP on a Port](#) on page 820. The auto setting automatically authenticates the port according to the results of the RADIUS server. The default authentication setting for each port is force-authorized.

Globally Configure EAP on the Server

About This Task

Globally enable or disable EAP on the switch. By default, EAP is disabled.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **802.1X - EAPOL**.
3. Select the **Global** tab.
4. From the AccessControl options, select **enable**.
5. (Optional) Select the appropriate **NonEapRadiusPwdAttrFmt** check boxes to configure the format of the RADIUS password when authenticating non-EAP MAC addresses using RADIUS.
6. (Optional) Enter the key string in the **NonNonEapRadiusPwdAttkeystring** field.
7. (Optional) Check the **ClearNonEap** check box to clear the NEAP session that is learned on the switch.
8. (Optional) Type an I-SID offset number in the **AutolsidOffset** field.
This step does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.
9. (Optional) Select the **AutolsidOffsetEnable** check box to enable Auto I-SID offset on the switch.
This step does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.
10. Select **Apply**.

Global field descriptions

Use the data in the following table to use the **Global** tab.

Name	Description
EapolVersion	Displays the EAP version on the switch.
AccessControl	Enables system authentication control. EAP is disabled by default.
NonEapRadiusPwdAttrFmt	Specifies the password attribute format for non EAP RADIUS authentication. <ul style="list-style-type: none"> ipAdd: Specifies IP address. macAddr: Specifies MAC address. portNumber: Specifies port number padding: Specifies padding.
NonEapRadiusPwdAttrKeyString	Specifies the attribute key string for non EAP RADIUS password.
ClearNonEap	Clears the NEAP session that is learned on the switch.
AutolsidOffset Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Specifies the Auto I-SID Offset value.
AutolsidOffsetEnable Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Enables or disables the Auto I-SID Offset feature.

Configure EAP on a Port

About This Task

Configure EAP or change the authentication status on one or more ports.

Ports are force-authorized by default. Force-authorized ports are always authorized and are not authenticated by the RADIUS server. You can change this setting so that the ports are always unauthorized.

Procedure

1. In the Device Physical View tab, select the port you need to configure.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **EAPOL** tab.
5. (Optional) Select the **AllowNonEapHost** check box to enable hosts that do not participate in 802.1X authentication to get network access.
6. Select the **Status** option as **auto** or **forceAuthorized**.

7. In the **MultiHostMaxClients** field, type the maximum limit of allowed EAP and NEAP clients supported on this port.
8. In the **GuestVlanId** field, type the VLAN ID to be used as a Guest VLAN ID.
This step does not apply to VSP 8600 Series or XA1400 Series.
9. In the **FailOpenVlanId** field, type the Fail Open VLAN ID.
This step does not apply to VSP 8600 Series or XA1400 Series.
10. In the **NonEapMaxClients** field, type the maximum number NEAP authentication MAC addresses allowed on this port.
11. In the **EapMaxClients** field, type the maximum number of EAP authentication MAC addresses allowed on this port.
12. Select the **MultiHostSingleAuthEnabled** check box to automatically authenticate NEAP MAC addresses on this port.
13. In the **PortGuestIsid** field, type the I-SID to be used as a Guest I-SID.
This step does not apply to VSP 8600 Series or XA1400 Series.
14. In the **FailOpensid** field, type the Fail Open I-SID.
This step does not apply to VSP 8600 Series or XA1400 Series.
15. Select the **AdminTrafficControl** option as **inOut** or **in**.
16. (Optional) Select the **LldpAuthEnabled** check box to enable LLDP authentication for network access.
This step does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.
17. Select the **ReAuthEnabled** field.
18. In the **QuietPeriod** field, type the time interval.
19. In the **ReauthPeriod** field, type the time between reauthentication.
20. In the **RetryMax** field, type the number of times.
21. Select **Apply**.

EAPoL Field Descriptions

Use the data in the following table to use the **EAPoL** tab.

Name	Description
PortCapabilities	Displays the capabilities of the Port Access Entity (PAE) associated with the port. This parameter indicates whether Authenticator functionality, supplicant functionality, both, or neither, is supported by the PAE of the port. The following capabilities are supported by the PAE of the port: <ul style="list-style-type: none"> • authImplemented: A Port Access Controller Protocol (PACP) Extensible Authentication Protocol (EAP) authenticator functions are implemented. • virtualPortsImplemented: Virtual Port functions are implemented.
PortVirtualPortsEnable	Displays the status of the Virtual Ports function for the real port as True or False.
PortCurrentVirtualPorts	Displays the current number of virtual ports running in the port

Name	Description
PortAuthenticatorEnable	Displays the status of the Authenticator function in the Port Access Entity (PAE) as True or False.
PortSupplicantEnable	Displays the Supplicant function in the Port Access Entity (PAE) as True or False.
AllowNonEapHost	Enables network access to hosts that do not participate in 802.1X authentication. The default is disabled.
Status	Configures the authentication status for this port. The default is forceAuthorized. <ul style="list-style-type: none"> • auto: enables the EAP authentication process by sending the EAP request messages to the RADIUS server. • forceAuthorized: disables the EAP authentication and puts the port into force-full authorized mode.
MultiHostMaxClients	Specifies the value representing the maximum number of supplicants allowed to get authenticated on the port.
GuestVlanId	Specifies the VLAN to be used as a Guest VLAN. Access to unauthenticated hosts connected to this port is provided through this VLAN. 0 indicates that Guest VLAN is not enabled for this port.
FailOpenVlanId	Specifies the Fail Open VLAN ID for this port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open VLAN. 0 indicates that Fail Open VLAN is not enabled for this port.
NonEapMaxClients	Specifies the maximum number of NEAP authentication MAC addresses allowed on this port. Zero indicates that NEAP authentication is disabled for this port.
EAPMaxClients	Specifies the maximum number of EAP authentication MAC addresses allowed on this port. Zero indicates that EAP authentication is disabled for this port.
MultiHostSingleAuthEnabled	Indicates that the unauthenticated devices can access the network only after an EAP or NEAP client is successfully authenticated on the port. The VLAN to which the devices are allowed access is the authenticated client's VLAN. The default is false.
PortGuestIsid Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	Specifies the I-SID to be used as a Guest I-SID. Access to unauthenticated hosts connected to this port is provided through this I-SID. 0 indicates that Guest I-SID is not enabled for this port.
FailOpenIsid Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	Specifies the Fail Open I-SID for this port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.

Name	Description
FlexUniStatus Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Displays the current Flex-UNI status for this port.
AdminTrafficControl Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	Configures the Administrative Traffic Control. The default is inOut. <ul style="list-style-type: none"> • inOut: enables the Admin Traffic Control for input and output traffic. • in: enables the Admin Traffic Control for input traffic only.
OperTrafficControl Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	Displays the current Operational Traffic Control status.
LldpAuthEnabled Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Enables LLDP authentication for this port. The default is disabled.
PortOrigin Note: Exception: not supported on VSP 8600 Series and XA1400 Series.	Specifies the source of EAP configuration on the port: <ul style="list-style-type: none"> • config - through CLI or EDM • autoSense - through Zero Touch Fabric Configuration
DynamicMHSAAEnabled Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Displays the Dynamic MHSAA configuration status.
TrafficControlOrigin	Specifies the origin of Traffic Control configuration on the port. The supported values are: <ul style="list-style-type: none"> • config - Traffic Control is enabled by the user. • radius - Traffic Control is enabled by Extensible Authentication Protocol (EAP) through Remote Authentication Dial-In User Service (RADIUS) response.
Authenticator configuration	Displays the current Authenticator Port Access Entity (PAE) state. The states are: <ul style="list-style-type: none"> • authenticate • authenticated • Failed
ReAuthEnabled	Reauthenticates an existing supplicant at the time interval specified in ReAuthPeriod. The default is disabled.
QuietPeriod	Configures the time interval (in seconds) between authentication failure and the start of a new authentication.

Name	Description
ReAuthPeriod	Reauthenticates an existing supplicant at the time interval specified in ReAuthPeriod. Configures the time interval (in seconds) between successive reauthentications. The default is 3600 (1 hour).
RetryMax	Specifies the maximum Extensible Authentication Protocol (EAP) requests sent to the supplicant before timing out the session. The default is 2.
RetryCount	Specifies the maximum number of retries attempted.

Configure EAP on an Extreme Integrated Application Hosting Port

Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series.

About This Task

Perform this procedure to configure EAP or change the authentication status on Extreme Integrated Application Hosting (IAH) ports. IAH ports are force-authorized by default and are not authenticated by the RADIUS server. You can change this setting so that the IAH ports stay unauthorized.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **EAPOL** tab.
4. (Optional) Select **AllowNonEapHost**.
5. In the **Status** field, select the required option.
6. In the **MultiHostMaxClients** field, enter a value.
7. In the **GuestVlanId** field, enter a VLAN ID.
8. In the **FailOpenVlanId** field, enter a VLAN ID.
9. In the **NonEapMaxClients** field, enter a value.
10. In the **EapMaxClients** field, enter a value.
11. Select **MultiHostSingleAuthEnabled**.
12. In the **PortGuestIsid** field, type the I-SID to be used as a Guest I-SID.
13. In the **FailOpenIsid** field, type the Fail Open I-SID.
14. Select the **AdminTrafficControl** option as **inOut** or **in**.
15. Select the **LldpAuthEnabled** check box to enable LLDP authentication for network access.
16. Select **ReAuthEnabled**.
17. In the **QuietPeriod** field, enter a time interval.
18. In the **ReAuthPeriod** field, enter a time interval.
19. In the **RetryMax** field, type a value.
20. Select **Apply**.

EAPOL Field Descriptions

Use data in the following table to use the **EAPOL** tab.

Name	Description
PortCapabilities	Shows the capabilities of the Port Access Entity (PAE) associated with the Extreme Integrated Application Hosting (IAH) port. This parameter indicates whether Authenticator functionality, supplicant functionality, both, or neither, is supported by the PAE of the IAH port. The following capabilities are supported by the PAE of the IAH port: <ul style="list-style-type: none"> • authImplemented: A Port Access Controller Protocol (PACP) Extensible Authentication Protocol (EAP) authenticator functions are implemented. • virtualPortsImplemented: Virtual Port functions are implemented.
PortVirtualPortsEnable	Shows the status of the Virtual Ports function for the IAH port.
PortCurrentVirtualPorts	Shows the current number of virtual ports running on the IAH port.
PortAuthenticatorEnable	Shows the status of the Authenticator function in the PAE.
PortSupplicantEnable	Shows the Supplicant function in the PAE.
AllowNonEapHost	Enables network access to hosts that do not participate in 802.1X authentication. The default is disabled.
Status	Specifies the authentication status for the IAH port. <ul style="list-style-type: none"> • auto - enables EAP authentication process by sending the EAP request messages to the RADIUS server. • forceAuthorized - disables EAP authentication and puts the IAH port into force-full authorized mode. <p>The default is forceAuthorized.</p>
MultiHostMaxClients	Specifies the maximum number of supplicants authenticated on the IAH port.
GuestVlanId	Specifies the VLAN ID to be used as a Guest. Access to unauthenticated hosts connected to the IAH port is provided through this VLAN. 0 indicates that Guest VLAN is not enabled.
FailOpenVlanId	Specifies the Fail Open VLAN ID for the specific IAH port. If RADIUS server is not reachable on the switch, then all new devices are allowed access to the configured Fail Open VLAN ID. 0 indicates that Fail Open VLAN ID is not enabled.

Name	Description
NonEapMaxClients	Specifies the maximum number of NEAP authentication MAC addresses allowed on the specific IAH port. 0 indicates that NEAP authentication is disabled.
EAPMaxClients	Specifies the maximum number of EAP authentication MAC addresses allowed on the specific IAH port. 0 indicates that EAP authentication is disabled.
MultiHostSingleAuthEnabled	Enables the functionality for network access to the unauthenticated devices only after an EAP or NEAP client is successfully authenticated on the IAH port. The VLAN ID to which the devices are allowed access is the authenticated client's VLAN. The default is disabled.
PortGuestIsid	Specifies the I-SID to be used as a Guest I-SID. Access to unauthenticated hosts connected to the IAH port is provided through this I-SID. 0 indicates that Guest I-SID is not enabled for this port.
FailOpenIsid	Specifies the Fail Open I-SID for the IAH port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.
FlexUniStatus	Displays the current Flex-UNI status for this IAH port.
AdminTrafficControl	Configures the Administrative Traffic Control. The default is inOut. <ul style="list-style-type: none"> • inOut: enables the Admin Traffic Control for input and output traffic. • in: enables the Admin Traffic Control for input traffic only.
OperTrafficControl	Displays the current Operational Traffic Control status.
LldpAuthEnabled	Enables LLDP authentication for this IAH port. The default is disabled.
PortOrigin	Specifies the source of EAP configuration on the IAH port: <ul style="list-style-type: none"> • config - through CLI or EDM • autoSense - through Zero Touch Fabric Configuration
DynamicMHSAEnabled	Displays the Dynamic MHSA configuration status.

Name	Description
TrafficControlOrigin	Indicates the origin of Traffic Control configuration on the port. The supported values are: <ul style="list-style-type: none"> • config - Traffic Control is enabled by the user. • radius - Traffic Control is enabled by Extensible Authentication Protocol (EAP) through Remote Authentication Dial-In User Service (RADIUS) response.
Authenticate	Shows the current Authenticator Port Access Entity (PAE) authenticate status.
Authenticated	Shows the current Authenticator Port Access Entity (PAE) authenticated status.
Failed	Shows the current Authenticator Port Access Entity (PAE) failure status.
ReAuthEnabled	Enables reauthentication of an existing supplicant based on the specified reauthentication time interval. The default is disabled.
QuietPeriod	Specifies the time interval (in seconds) between authentication failure and start of authentication.
ReauthPeriod	Specifies the time interval (in seconds) between successive reauthentications. The default is 3600 (1 hour).
RetryMax	Specifies the maximum Extensible Authentication Protocol (EAP) requests sent to the supplicant before timing out the session. The default is 2.
RetryCount	Specifies the maximum number of retries attempted.

Show the Port Access Entity Port Table

About This Task

Use the Port Access Entity (PAE) Port Table to display system-level information for each port the PAE supports. An entry display in this table for each port of this system.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **802.1X - EAPOL**.
3. Select the **EAP Security** tab.

EAP Security Field Descriptions

Use the data in the following table to use the **EAP Security** tab.

Name	Description
PortNumber	Indicates the port number associated with this port.
PortCapabilities	Indicates the capabilities of this PAE port. <ul style="list-style-type: none"> • authImplemented—PACP EAP authenticator functions are implemented in this PAE. • virtualPortsImplemented—Virtual Port functions are implemented in this PAE.
PortVirtualPortsEnable	Displays the status of the Virtual Ports function for the real port as True or False.
PortCurrentVirtualPorts	Displays the current number of virtual ports running in the port
PortAuthenticatorEnable	Displays the status of the Authenticator function in the Port Access Entity (PAE) as True or False.
PortSupplicantEnable	Displays the Supplicant function in the Port Access Entity (PAE) as True or False.
AllowNonEapHost	Displays the status if the system is enabled to allow hosts that do not participate in 802.1X authentication to get network access.
Status	Displays the authentication status for this port. The default is <code>forceAuthorized</code> .
MultiHostMaxClients	Indicates the value representing the maximum number of supplicants allowed to get authenticated on the port.
GuestVlanId	Specifies the VLAN to be used as a Guest VLAN. Access to unauthenticated hosts connected to this port is provided through this VLAN. 0 indicates that Guest VLAN is not enabled for this port.
FailOpenVlanId	Specifies the Fail Open VLAN ID for the port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open VLAN. 0 indicates that Fail Open VLAN is not enabled for this port.
NonEapMaxClients	Indicates the maximum number of non-EAPoL authentication MAC addresses allowed on this port. Zero indicates that non-EAPoL authentication is disabled for this port.
EapMaxClients	Indicates the maximum number of EAPoL authentication MAC addresses allowed on this port. Zero indicates that EAPoL authentication is disabled for this port.
MultiHostSingleAuthEnabled	Indicates that the unauthenticated devices can access the network only after an EAP or NEAP client is successfully authenticated on the port. The VLAN to which the devices are allowed access is the authenticated client's VLAN. The default is false.
ProcessRadiusCOAPackets	Specifies whether to process any RADIUS requests-server packets that are received on this port.

Name	Description
PortGuestIsid Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	Specifies the I-SID to be used as a Guest I-SID. Access to unauthenticated hosts connected to this port is provided through this I-SID. 0 indicates that Guest I-SID is not enabled for this port.
FailOpensid Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	Specifies the Fail Open I-SID for the port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.
FlexUniStatus Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Displays the Flex-UNI status for the port.
AdminTrafficControl Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	Specifies the Administrative Traffic Control for the port. The default is inOut.
OperTrafficControl Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	Displays the Operating Traffic Control for the port.
LldpAuthEnabled Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	Specifies if LLDP Authentication is enabled. The default is 0 (disabled).
PortOrigin Note: Exception: Not supported on VSP 8600 Series or XA1400 Series.	Displays the Port Origin configuration status for the port.
DynamicMHSAEnabled Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Displays the Dynamic MHSA status for the port.
TrafficControlOrigin	Specifies the origin of Traffic Control configuration on the port. The supported values are: <ul style="list-style-type: none"> • config - Traffic Control is enabled by the user. • radius - Traffic Control is enabled by Extensible Authentication Protocol (EAP) through Remote Authentication Dial-In User Service (RADIUS) response.

Show EAP Authentication

About This Task

Use the Authenticator Configuration table to display configuration objects for the Authenticator PAE associated with each port.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Click **802.1X - EAPOL**.
3. Click the **Authentication** tab.

Authentication Field Descriptions

Use the data in the following table to use the **Authentication** tab.

Name	Description
PortNumber	Indicates the number associated with this port.
Authenticate	Indicates the status of the Port Access Entity (PAE) authenticator requesting authentication.
Authenticated	Indicates the current authentication status of the Port Access Entity (PAE) authenticator.
Failed	Indicates the authentication status for failed or terminated state .
ReAuthEnabled	Indicates the re-authentication status of an existing supplicant at the time interval specified in ReAuthPeriod. The default is false.
QuietPeriod	Indicates the time interval (in seconds) between authentication failure and the start of a new authentication. The default is 60.
ReAuthPeriod	Indicates the time interval in seconds between successive re-authentications. The default is 3600 (1 hour).
RetryMax	Indicates the maximum Extensible Authentication Protocol (EAP) requests sent to the supplicant before timing out the session. The default is 2.
RetryCount	Indicates the count of the number of authentication attempts.

View Multihost Status Information

Use the following procedure to display multiple host status for a port.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **802.1X - EAPOL**.
3. Select the **MultiHost Status** tab.

MultiHost Status Field Descriptions

The following table describes values on the **MultiHost Status** tab.

Name	Description
PortNumber	Indicates the port number associated with this port.
ClientMACAddr	Indicates the MAC address of the client.
PaeState	Indicates the current state of the authenticator PAE state machine.
VlanId	Indicates the VLAN assigned to the client.
Priority	Specifies the priority associated with this client MAC. This priority could be the Radius assigned priority or the port QOS level.
SwUniBindings Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Indicates the Extensible Authentication Protocol (EAP) VLAN:ISID bindings that the switch represents as an hexadecimal value.
IsidSource Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Indicates the origin of I-SID value: <ul style="list-style-type: none"> radius - received from the RADIUS server. autoconfig - calculated using the auto-isid-offset command, that the user configures on the switch. config - configured statically. notAvaliable - does not use EAP with FlexUNI, hence there is no I-SID to use.
AcId Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Indicates the dynamic Access Control List (ACL) on the specific port.
AceldList Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Indicates the list of dynamic Access Control Entries (ACE) on the specific port.
DynamicSettings	Displays the Dynamic settings received from the Remote Authentication Dial-In User Service (RADIUS) server.

View EAP Session Statistics

Use the following procedure to display multiple host session information for a port.

Procedure

1. In the navigation pane, expand **Configuration --> Security --> Data Path**.
2. Click **802.1X - EAPOL**.
3. Click the **MultiHost Session** tab.

MultiHost Session Field Descriptions

The following table describes values on the **MultiHost Session** tab.

Name	Description
StatsPortNumber	Indicates the port number associated with this port.
StatsClientMACAddr	Indicates the MAC address of the client.
Id	Indicates the unique identifier for the session.
AuthenticMethod	Indicates the authentication method used to establish the session.
Time	Indicates the elapsed time of the session.
TerminateCause	Indicates the cause of the session termination.
UserName	Indicates the user name that represents the identity of the supplicant PAE.

Viewing EAPoL Authenticator Statistics

Use EAPoL Authenticator statistics to display the Authenticator Port Access Entity (PAE) statistics for each selected port.

Procedure

- On the Device Physical View, select the port you want to graph.
The system displays a yellow outline around the selected ports

If you want to select multiple ports, press Ctrl and hold down the key while you click the ports you want to configure. The system displays a yellow outline around the selected ports.
- In the navigation pane, expand the **Configuration > Graph** folders.
- Click **Port**.
- Click **EAPOL Stats**.
- If you selected multiple ports, from the Graph port EAPoL Stats tab Show list, select: Absolute Value, Cumulative, Average/sec, Minimum/sec, Maximum/sec, or LastVal/sec.

EAPOL Stats Field Descriptions

The following table describes values on the **EAPOL Stats** tab.

Name	Description
InvalidFramesRx	Displays the number of EAPoL frames received by this Authenticator in which the frame type is not recognized.
EapLengthErrorFramesRx	Displays the number of EAPoL frames received by this Authenticator in which the Packet Body Length field is invalid.
StartFramesRx	Displays the number of EAPoL start frames received by this Authenticator.

Name	Description
EapFramesRx	Displays the number of EAPoL-EAP frames received by this Authenticator.
LogoffFramesRx	Displays the number of EAPoL Logoff frames received by this Authenticator.
LastRxFrameVersion	Displays the last received version of the EAPoL frame by this Authenticator.
LastRxFrameSource	Displays the source MAC address of the last received EAPoL frame by this Authenticator.
AuthEapFramesTx	Displays the number of EAPoL-EAP frames transmitted by the Authenticator.

View NEAP MAC Information

Use this procedure to view NEAP client MAC information on a port.

Procedure

1. In the navigation pane, expand **Configuration --> Security --> Data Path**.
2. Select **802.1X - EAPOL**.
3. Select **NEAP Radius** tab.

NEAP Radius Field Descriptions

The following table describes values on the **NEAP Radius** tab.

Name	Description
MacPort	Indicates the port number associated with this port.
MacAddr	Indicates the MAC address of the client.
MacStatus	Indicates the authentication status of the NEAP host that is authenticated using the RADIUS server.
VlanId	Indicates the VLAN assigned to the client.
MacClear	Clears the non EAP MAC entry associated with a specific index.
MacPriority	Indicates the priority associated with this Non-EAP client MAC. This priority could be the Radius assigned priority or the port QOS level.
SwUniBindings Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.	Indicates the VLAN and I-SID bindings. VLAN is represented with 2 bytes and I-SID is represented with 4 bytes. The output is a continuous hexadecimal representation of the VLAN that is followed by the corresponding I-SID.

Name	Description
<p>IsidSource</p> <p>Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.</p>	<p>Indicates the source of the I-SID value. An I-SID value is generated in one of the following ways:</p> <ul style="list-style-type: none"> • radius—Indicates that that I-SID value is learned from the RADIUS server. • autoconfig—Indicates that I-SID value is calculated by using the auto-isid-offset that you configured. • config—Indicates that the I-SID value is statically configured. • notAvailable—Indicates that no I-SID value is available because EAP with FlexUNI is not used.
<p>NonEapAuthType</p> <p>Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.</p>	<p>Indicates the authentication type of the Non-EAP client:</p> <ul style="list-style-type: none"> • radius - received from RADIUS server. • lldp - received from Link Layer Discovery Protocol (LLDP).
<p>AcId</p> <p>Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.</p>	<p>Indicates the dynamic Access Control List (ACL) on the specific port.</p>
<p>AcIdList</p> <p>Note: Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.</p>	<p>Indicates the list of dynamic Access Control Entries (ACE) on the specific port.</p>
<p>DynamicSettings</p>	<p>Displays the Dynamic settings received from the Remote Authentication Dial-In User Service (RADIUS) server.</p>

ExtremeCloud IQ Agent

Table 82: IQ Agent product support

Feature	Product	Release introduced
ExtremeCloud IQ Agent	VSP 4450 Series	Not supported
	VSP 4900 Series	VOSS 8.2 <ul style="list-style-type: none"> • VSP4900-48P • VIMs: VIM5-4YE, VIM5-4X, VIM5-4XE, and VIM5-2Y VOSS 8.2.5 <ul style="list-style-type: none"> • VSP4900-24S • VSP4900-24XE • VSP4900-12MXU-12XE • VIMs: VIM5-4Y
	VSP 7200 Series	Not supported
	VSP 7400 Series	VOSS 8.2
	VSP 8200 Series	Not supported
	VSP 8400 Series	Not supported
	VSP 8600 Series	Not supported
	XA1400 Series	VOSS 8.2

For the most current information on switches supported by ExtremeCloud™ IQ, see [ExtremeCloud™ IQ Learning What's New](#).

ExtremeCloud IQ provides cloud-managed networking, and delivers unified, full-stack management of wireless access points, switches, and routers. It enables onboarding, configuration, monitoring, troubleshooting, reporting, and more. Using innovative machine learning and artificial intelligence technologies, ExtremeCloud IQ analyzes and interprets millions of network and user data points, from the network edge to the data center, to power actionable business and IT insights, and to deliver new levels of network automation and intelligence.

The switch supports a zero touch connection to ExtremeCloud IQ. Zero touch deployment is used to deploy and configure a switch using ExtremeCloud IQ.

The switch integrates with ExtremeCloud IQ using ExtremeCloud IQ Agent. When you enable IQAgent, you can configure and monitor VOSS devices using ExtremeCloud IQ.

ExtremeCloud IQ supports the following features for the switch:

- Firmware upgrade
- IQAgent upgrade
- Supplemental CLI

You can configure the following features using the ExtremeCloud IQ interface:

- Hostname configuration
- SNMP location
- Device-level MTU
- Flow control
- Port state, usage type, and settings
- VLAN configuration
- DNS, NTP, SNMP, and Syslog servers

For more information about ExtremeCloud IQ, see <https://www.extremenetworks.com/support/documentation/extremecloud-iq/>.

ExtremeCloud IQ Agent Configuration Considerations

The following configuration considerations apply to ExtremeCloud IQ Agent:

- SSH and SSH password authentication is required.

boot config flag ssh is enabled when ExtremeCloud IQ Agent is enabled. **boot config flag ssh** cannot be disabled while ExtremeCloud IQ Agent is enabled.

- SNMP is required.

boot config flag block-snmp is disabled when ExtremeCloud IQ Agent is enabled. **boot config flag block-snmp** cannot be enabled while ExtremeCloud IQ Agent is enabled.

- High Secure mode disables ExtremeCloud IQ Agent automatically. ExtremeCloud IQ Agent must be enabled manually when this mode is enabled.
- ExtremeCloud IQ Agent is not supported in Enhanced Secure mode.
- An IP address that corresponds to the ExtremeCloud IQ pool and can display it in the NTP list. The IP does not try to synchronize if NTP is globally disabled on the switch. If NTP is enabled, you can see synchronization failure messages if the IP for the pool is blocked or is unreachable. As a best practice, if you have issues connecting to the cloud, check the clock on the switch and if it is incorrect, resolve this by either configuring an NTP server or manually configuring the correct time.

Note

You must configure a Segmented Management Instance to use ExtremeCloud IQ Agent. For more information, see [Segmented Management](#) on page 67.

For information about onboarding switches, see <https://www.extremenetworks.com/support/documentation/extremecloud-iq/>.

Zero Touch Deployment

Zero Touch Deployment enables a VOSS switch to be deployed automatically with ExtremeCloud IQ but you still must onboard the switch on the ExtremeCloud IQ side. When the switch powers on, the DHCP Client obtains the IP address and gateway from the DHCP Server, and discovers the Domain Name Server, connecting the switch automatically to Extreme Management Center or ExtremeCloud IQ - Site Engine or to ExtremeCloud IQ cloud management applications.

With Zero Touch Deployment, ExtremeCloud IQ Agent is enabled by default.

To use zero touch functionality, your switch must be in a Zero Touch Deployment-ready configuration mode, which means the switch cannot have existing primary or secondary configuration files loaded. Factory shipped switches are Zero Touch Deployment ready because they deploy without configuration files. However, existing switches require manual preparation before Zero Touch Deployment can function.

For more information about preparing your switch for Zero Touch Deployment, see [Zero Touch Deployment](#) on page 56.

DHCP Option 43 Support

With the support of DHCP option 43, DHCP can dynamically configure the IP address of a private/non-public ExtremeCloud IQ server for zero touch deployments when the default ExtremeCloud IQ server (nac.extremecloudiq.com) is not desired.

To use this functionality, DHCP Client must be enabled. For information about DHCP Client for a Segmented Management Instance, see [DHCP Client for Segmented Management Instance](#) on page 82.

Considerations

The following considerations apply with DHCP option 43:

- A dynamic IP address overwrites the default value (nac.extremecloudiq.com) or 0.0.0.0.
- A static server IP address overwrites a dynamic server IP address.
- A dynamic server IP address does not overwrite an existing static server IP address.

If a static server IP address is already configured and a new value is received from the DHCP server, the following warning displays on the console: `WARNING Dynamic Cloud IQ Server Address x.x.x.x provided by DHCP option 43 could not be set. Static configured server address y.y.y.y cannot be overwritten by a dynamic address.`

- The default value (nac.extremecloudiq.com) replaces the dynamic server IP address if the DHCP Client is disabled on the switch.
- The dynamic server IP address is not saved in the running configuration.

ExtremeCloud IQ Agent Configuration using CLI

After your device is onboarded (that is, the serial number for the device is associated with your ExtremeCloud IQ account), you are only required to enable ExtremeCloud IQ Agent. Other feature configuration, such as configuring proxy parameters and configuring access to ExtremeCloud IQ is optional.

Note

You must configure a Segmented Management Instance to use ExtremeCloud IQ Agent. For more information, see [Segmented Management Instance Configuration using the CLI](#) on page 85.

For information about onboarding switches, see <https://www.extremenetworks.com/support/documentation/extremecloud-iq/>.

Configure ExtremeCloud IQ Agent

You must first onboard the device. When zero touch connection establishes, IQ Agent is enabled, by default. Before IQ Agent is operational, you must first disable IQ Agent, configure the ExtremeCloud IQ IPv4 address or DNS name, and then reenable IQ Agent.

Before You Begin

You must first onboard the device.

Procedure

1. Enter Application Configuration mode:
`enable`
`configure terminal`
`application`
2. Disable IQ Agent:
`no iqagent enable`
3. Configure the ExtremeCloud IQ IPv4 address or DNS name:
`iqagent server address WORD<1-255>`
4. Enable IQ Agent:
`iqagent enable`

Example

Configure IQ Agent:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#no iqagent enable
Switch:1(config-app)#iqagent server address hac.extremecloudiq.com
Switch:1(config-app)#iqagent enable
```

Display default IQ Agent configuration:

```
Switch:1>show application iqagent

```

Configure Access to ExtremeCloud IQ

Use this task to configure IQ Agent parameters to access ExtremeCloud IQ.

Before You Begin

You must onboard the device and configure any optional IQ Agent parameters on the supported device before you enable IQ Agent.

You can configure the IQ Agent parameters on the supported devices first, and then onboard the devices (that is, add the serial numbers for the devices in the ExtremeCloud IQ GUI) or vice versa.

For information about onboarding switches, see <https://www.extremenetworks.com/support>.

Procedure

1. Enter Application Configuration mode:

```
enable

configure terminal

application
```
2. Configure the ExtremeCloud IQ IPv4 address or DNS name:

```
iqagent server address WORD<1-255>
```

Examples

Configure access to ExtremeCloud IQ using an IPv4 address:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent server address 192.0.2.1
```

Configure access to ExtremeCloud IQ using a DNS name:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent server address extremecloudiq.com
```

Variable Definitions

The following table defines parameters for the **iqagent server** command.

Variable	Value
<code>address <WORD 1-255></code>	Specifies the ExtremeCloud IQ IPv4 address or DNS name.

Configure Proxy Parameters

If you use a proxy https server in your network, you must configure proxy parameters so that the IQ Agent on the device can communicate with ExtremeCloud IQ through the proxy.

Use this task to configure the proxy parameters for ExtremeCloud IQ on the IQ Agent.

Note

You must onboard the device and configure any optional IQ Agent parameters on the supported device before you enable IQAgent.

You can configure the IQ Agent parameters on the supported devices first, and then onboard the devices (that is, add the serial numbers for the devices in the ExtremeCloud IQ GUI) or vice versa.

For information about onboarding switches, see <https://www.extremenetworks.com/support>.

Procedure

1. Enter Application Configuration mode:

```
enable

configure terminal

application
```
2. Configure the proxy IPv4 address or DNS name:

```
iqagent proxy address <WORD 1-255> tcp-port <1-49151>
```
3. Configure the proxy username and password for the ExtremeCloud IQ account:

```
iqagent proxy username <WORD 1-64> password <WORD 1-128>
```

Examples

Configure proxy parameters using an IPv4 address:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent proxy address 192.0.2.254 tcp-port 21
Switch:1(config-app)#iqagent proxy username admin password ****
```

Configure proxy parameters using a DNS name:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent proxy address hac.extremecouldiq.com tcp-port 21
Switch:1(config-app)#iqagent proxy username admin password ****
```

Variable Definitions

The following table defines parameters for the **iqagent proxy** command.

Variable	Value
<i>address</i> <WORD 1-255>	Specifies the proxy IPv4 address or DNS name.
<i>tcp-port</i> <1-49151>	Specifies the TCP port.
<i>username</i> <WORD 1-64>	Specifies the proxy server username.
<i>password</i> <WORD 1-128>	Specifies the proxy server password.

Display ExtremeCloud IQ Agent Information

About This Task

Use this task to display ExtremeCloud IQ Agent configuration information and status.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IQ Agent configuration information and status:

```
show application iqagent
```

Example

Display IQ Agent configuration information and status when IQ Agent is enabled using the default ExtremeCloud IQ server:

```
Switch:1>show application iqagent

=====
                          IQAgent Info
=====
Agent Admin State       : true
Agent Version           : 0.2.7
Agent Oper State        : connected
Server Address          : hac.extremecloudiq.com
Server Address Origin   : None
Proxy Address           : extremeiq.com
Proxy TCP Port          : 21
Proxy Username          : admin
```

Display IQ Agent disabled state:

```
Switch:1>show application iqagent

=====
                          IQAgent Info
=====
Agent Admin State       : false
Agent Version           : 0.2.7
Agent Oper State        : disconnected
Server Address          : 0.0.0.0
Server Address Origin   : None
Proxy Address           : 0.0.0.0
Proxy TCP Port          : 0
Proxy Username          :
```

Display IQ Agent configuration information and status when DHCP provides a dynamic server IP address:

```
Switch:1>show application iqagent

=====
IQAgent Info
=====
Agent Admin State      : true
Agent Version          : 0.2.7
Agent Oper State       : disconnected
Server Address         : 192.0.2.1
Server Address Origin  : DHCP
Proxy Address          : 0.0.0.0
Proxy TCP Port         : 0
Proxy Username         :
```

Display IQ Agent configuration information and status when DHCP Client is disabled on the switch:

```
Switch:1>show application iqagent

=====
IQAgent Info
=====
Agent Admin State      : false
Agent Version          : 0.2.7
Agent Oper State       : disconnected
Server Address         : hac.extremecloudiq.com
Server Address Origin  : None
Proxy Address          : 0.0.0.0
Proxy TCP Port         : 0
Proxy Username         :
```

Display ExtremeCloud IQ Agent Status

About This Task

Use this task to display IQ Agent status information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IQ Agent status information:

```
show application iqagent status
```

Example

```
Switch:1>show application iqagent status

=====
IQAgent Status
=====
Connection Status      : Connected

```

Reinstall ExtremeCloud IQ Agent Firmware

Perform this procedure to return the ExtremeCloud IQ Agent firmware version on the switch to the version bundled with the OS image currently installed on the switch, for example, if you downgrade the OS image version and do not reconnect to ExtremeCloud IQ automatically.

Procedure

1. Enter Application Configuration mode:
`enable`

`configure terminal`

`application`
2. Disable ExtremeCloud IQ Agent:
`no iqagent enable`
3. Reinstall the ExtremeCloud IQ Agent firmware:
`software iqagent reinstall`
4. Enable ExtremeCloud IQ Agent:
`iqagent enable`

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#application
Switch:1(config-app)#no iqagent enable
Switch:1(config-app)#software iqagent reinstall

Reinstalling IQAgent from VOSS image
Switch:1(config-app)#iqagent enable
```

ExtremeCloud IQ Agent Configuration using EDM

Perform the procedures in this section to configure ExtremeCloud IQ Agent on the switch using the Enterprise Device Manager (EDM).

Configure ExtremeCloud IQ Agent

Before You Begin

You must first onboard the device and configure any optional IQ Agent parameters before you enable IQ Agent.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability**.
2. Select **IQAgent**.

3. Select the **Globals** tab.
4. Configure optional parameters as required.
5. Select **Apply**.
6. Select **Enable**.
7. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Global** tab to configure the ExtremeCloud IQ Agent.

Name	Description
Enable	Specifies whether IQ Agent is enabled. The default is enabled.
Version	Displays the ExtremeCloud IQ Agent firmware version running on the switch.
OperStatus	Displays the operational status of ExtremeCloud IQ Agent on the switch.
ServerAddressType	Specifies the address type of the ExtremeCloud IQ server address.
Server/Address	Specifies the ExtremeCloud IQ IPv4 address or DNS name. The default is hac.extremcloudiq.com.
ServerAddressOrigin	Specifies the origin for the ExtremeCloud IQ server address: <ul style="list-style-type: none"> • none—not configured • configured—manual configuration • dhcp—obtained through DHCP
Address	Specifies the proxy IPv4 address or DNS name.
TcpPort	Specifies the TCP connection port.
UserName	Specifies the proxy server password.
Password	Specifies the proxy server username.
AssociationUrl	Displays the association URL of ExtremeCloud IQ.
PollUrl	Displays the poll URL of ExtremeCloud IQ.
MonitorFreq	Displays the monitoring frequency, in seconds, of ExtremeCloud IQ.
PollFreq	Displays the polling frequency, in seconds, of ExtremeCloud IQ.
LastOnboardTime	Displays the last onboard time of ExtremeCloud IQ.
LastPollStatus	Displays the last poll status of ExtremeCloud IQ.
LastPollTime	Displays the last poll time for a successful attempt.
LastMonitorStatus	Displays the last monitoring status of ExtremeCloud IQ.

Name	Description
LastMonitorTime	Displays the last monitor time for a successful attempt.
LastHealthStatus	Displays the last health status of ExtremeCloud IQ.
LastHealthTime	Displays the last health time for a successful attempt.

Extreme Integrated Application Hosting

Extreme Integrated Application Hosting (IAH) architecture provides a flexible and open solution that enables organizations to deploy high-performance and flexible visibility applications pervasively throughout their network for improved monitoring and troubleshooting. Enabled by VOSS, this preconfigured Quick Emulator (QEMU) Kernel-based Virtual Machine (KVM) environment leverages high performance x86 CPUs to host these applications, extending visibility customized to the business and operational needs of the organization across the entire network.

The QEMU KVM environment supports several pretested and well-known packet capture applications in a Linux virtual machine, including Wireshark and tcpdump. There are a wide variety of additional applications, tools, and utilities that organizations are able to run in this environment, such as data analytics applications, packet generators, monitoring tools, troubleshooting utilities, and many others. While the QEMU KVM environment is open and can host any application, it is designed and ideally suited for networking applications, tools, and utilities.

IAH architecture supports the creation and use of virtualization domains, such as virtual machines, and Docker containers. This design creates a common-use host, which coordinates and automates multiple guest-networking functions into chains. The hardware boots into the virtual Linux OS, providing the ability to run additional applications or services within a specific virtual machine or a Docker container, and simultaneously supporting the regular functionality of the switch.

Yet Another Next Generation (YANG) model is used to manage configuration and retrieve operational data. You access the YANG model through Representational State Transfer Configuration Protocol (RESTCONF) using a northbound interface, namely Extreme Management Center or ExtremeCloud IQ - Site Engine, that provides an additional way to configure and monitor the switch. For more information on RESTCONF, see [Representational State Transfer Configuration Protocol \(RESTCONF\) Fundamentals](#) on page 2791.

Virtual Services Resources

The virtual services resources are isolated from each other, as well as from the Network Operating System (NOS) running the switch.

The resources available for all virtual services on VSP 7400 Series switches are as follows:

- Six Central Processing Unit (CPU) cores
- 12 GB Random Access Memory (RAM)
- 100 GB Solid State Drive (SSD) flash memory

The resources available for all virtual services on VSP 4900 Series switches are as follows:

**Note**

You must install a modular SSD unit to use virtual services on VSP 4900 Series switches.

- Two CPU cores
- 4 GB RAM
- 120 GB SSD flash memory (separately available modular SSD unit), with 104 GB dedicated for IAH storage.

The switch OS uses the following resources on VSP 7400 Series and VSP 4900 Series:

- Two CPU cores
- 4 GB RAM
- 8 GB internal flash memory storage

Extreme Integrated Application Hosting Ports

Extreme Integrated Application Hosting (IAH) ports are labeled as Insight ports, which are internal ports used to support Ethernet connectivity by the virtual services configured on the switch. IAH ports operate at 10 Gigabits per second (Gbps). The following features support IAH ports on the switch:

- VLANs
- Filters
- Port Statistics
- Basic Interface Configuration
- Mirroring
- Switched UNI
- Transparent Port UNI

**Note**

Network-to-network (NNI) interface support is not available for IAH ports. IS-IS adjacencies cannot be established on IAH ports.

For information about how to configure IAH ports, see the following tasks:

- [Configure a Virtual Service](#) on page 856
- [Configure Virtual Ports](#) on page 872

Connection Types

The VM and Docker virtual ports map to a physical Extreme Integrated Application Hosting port using the following connection types:

- Open vSwitch (OVS)

- Single Root I/O Virtualization (SR-IOV).
- Virtualization Technology for Directed I/O (VT-d)

Note

You must enable trunking on the Extreme Integrated Application Hosting port when you use SR-IOV and OVS connection types. For more information about enabling trunking, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2356.

You can configure Extreme Integrated Application Hosting ports 1/s1 and 1/s2 to accommodate different connect types. Extreme Integrated Application Hosting ports 1/s1 and 1/s2 can accommodate virtual ports of SR-IOV, OVS, or VT-d connect types. Two VT-d connection types are supported on either 1/s1 or 1/s2 Extreme Integrated Application Hosting ports. Using the **virtual-service** command, you can specify which Extreme Integrated Application Hosting port is associated with the configured connect type. You can also configure the Network Interface Card (NIC) type of the virtual port using the **virtual-service** command.

The following table lists the compatible Extreme Integrated Application Hosting port connect type configurations.

Note

You cannot configure two virtual services with conflicting connect types or two virtual services with VT-d connect type on the same Extreme Integrated Application Hosting port.

Extreme Integrated Application Hosting port 1/s1	Extreme Integrated Application Hosting port 1/s2
SR-IOV	OVS
SR-IOV	SR-IOV
OVS	SR-IOV
OVS	OVS
VT-d	VT-d

Link Flapping

When the switch initializes, the Extreme Integrated Application Hosting ports connect to the underlying Linux hypervisor. When a virtual port of connection type OVS or SR-IOV is configured on the switch, the Linux hypervisor saves this connection, and the link state of the Extreme Integrated Application Hosting port does not change. However, when a virtual port of connection type VT-d is configured on the switch, control of the Extreme Integrated Application Hosting port is passed from the Linux hypervisor to the configured Virtual Machine (VM). The Extreme Integrated Application Hosting port flaps due to this transition, and the switch reports it in the system log. The Extreme Integrated Application Hosting port flaps twice during the transition:

1. when the Extreme Integrated Application Hosting port is removed from the Linux hypervisor.
2. when the Extreme Integrated Application Hosting port is added to the VM.

A similar link flap sequence takes place on the Extreme Integrated Application Hosting port when the associated VM is disabled on the switch, and the control of the Extreme Integrated Application Hosting port is passed from the VM back to the Linux hypervisor.

Configuration Requirements

- To use an Extreme Integrated Application Hosting port as an analyzer port on a monitoring BEB for Fabric RSPAN (Mirror to I-SID), you must associate outer-tag 4091 to egress port 1/s1 or 1/s2 if the connect type is OVS or SR-IOV. Use the **monitor-by-isid <1-1000> map-to-vid <1-4093>** command to configure VLAN 4091 for Fabric RSPAN.
- To use an Extreme Integrated Application Hosting port with a connect type as OVS or SR-IOV for Port Mirroring, associate VLAN 4091 to the virtual machine (VM) vport to send the mirrored packets to the VM.
- To enable Flex UNI on an Extreme Integrated Application Hosting port with a connect type of VT-d, enable dot1q encapsulation on the VM interfaces. Flex UNI enables tagging on these ports by default; you must tag the VM ports with the VLANs that these ports use.

Third Party Virtual Machine

The Extreme Integrated Application Hosting (IAH) feature supports the pre-installed Third Party Virtual Machine (TPVM). For switches that use a modular Solid State Drive (SSD) for IAH, the virtual machine is pre-installed on the modular SSD. For switches that do not use a modular Solid State Drive (SSD) for IAH, the virtual machine is pre-installed on the switch.

You can use the **show virtual-service config** command to view the information about the pre-installed virtual machine on the switch. For more information, see [Display Virtual Service Configuration](#) on page 862.

Important

You must upgrade virtual services independently of a VOSS upgrade; separate images for virtual services are available. For more information, see [Upgrade a Virtual Service](#) on page 867.

For more information about how to configure virtual services, see [Virtual Services Configuration using CLI](#) on page 854 and [Virtual Services Configuration using EDM](#) on page 868.

Third Party Virtual Machine (TPVM) provides a set of troubleshooting tools on the switch. The following installed packages are available on TPVM:

- build-essential
- checkinstall
- iperf
- mtools
- netperf
- qemu-guest-agent
- tshark
- valgrind
- vim-gnome

- wireshark
- xterm

Important

TPVM includes an administrator account with a default username and password. To ensure security, you must change the default password when you access TPVM for the first time, before enabling the IAH ports using the **no shutdown** command. The software automatically prompts you to change this password at first boot; no action can be taken with the VM until you change the password.

The following user applications are available on TPVM:

- Dynamic Host Configuration Protocol (DHCP) server
- Domain Name Server (DNS)
- Authentication, authorization, and accounting (AAA) server for Remote Access Dial-In User Service (RADIUS) and Terminal Access Controller Access Control Service Plus (TACACS+).
- Syslog server
- Simple Network Management Protocol (SNMP) trap receiver
- Suricata - a free and open-source robust network threat detection engine that provides real time intrusion detection (IDS), inline intrusion prevention (IPS), network security monitoring (NSM), and offline packet capture (pcap) processing.
- Wireshark - a protocol analyzer that provides packet capturing and analysis.
- Ostinato - provides packet crafting, network traffic generation, and analysis with a user-friendly Graphical User Interface (GUI).

Note

If you start the console for TPVM without network connectivity to a DHCP server, the VM remains in a retry loop for approximately 5 minutes while it tries to obtain a DHCP address. The system displays the following message: `[FAILED] Failed to start Raise network interfaces`, and then the VM continues to boot. The VM does start but with the virtual port, eth0, in the administratively down state.

The following are the virtual services resources for TPVM:

- Two CPU cores
- 4 GB RAM

- One virtual port of VT-d connection type
- 1.8 GB up to 32 GB SSD

**Note**

To use this feature on the applicable models of VSP 4900 Series, you must install an SSD module in the switch.

**Important**

To enable SR-IOV and VT-d, the guest OS must have Ethernet drivers (ixgbe) that support these Intel technologies. These drivers are not available by default in many OS distribution versions. The TPVM version based on Ubuntu 16.04 is enhanced to include updated driver versions to support SR-IOV and VT-d. If you upgrade the TPVM guest OS kernel, you override these drivers and the VM does not support SR-IOV or VT-d vport connection types.

Do not perform a kernel upgrade from within the TPVM. If necessary, you can upgrade individual packages. You can upgrade to Ubuntu 18.04, which includes support for these new driver versions by default.

Fabric IPsec Gateway Fundamentals

The Fabric IPsec Gateway feature introduces a Virtual Machine (VM) that supports aggregation of Fabric Extend Tunnels with fragmentation, reassembly, and Internet Protocol Security (IPsec) encryption functions.

The minimum configuration requirements for the Fabric IPsec Gateway VM are as follows:

- Two Central Processing Unit (CPU) cores
- 4 GB Random Access Memory (RAM)
- One Virtualization Technology for Directed I/O (VT-d) vport (eth0)
- Minimum 10 GB SSD

**Note**

To use this feature on the applicable models of VSP 4900 Series, you must install an SSD module in the switch.

To configure IPsec on a switch through the Fabric IPsec Gateway VM, see [Fabric IPsec Gateway Configuration using CLI](#) on page 876.

Fabric IPsec Gateway supports the following services through the VM:

- IPsec with fragmentation and reassembly - for the VXLAN traffic that needs IPsec, the network routes the packets through the Fabric IPsec Gateway VM that provides IPsec encryption and decryption for VXLAN packets. The system also supports fragmentation and reassembly for IPsec tunnels that you configure on the VM, and a minimum of 1300 bytes of Maximum Transmission Unit (MTU) value. You can configure fragmentation to occur before the packets are encrypted.
- Fragmentation and reassembly - the Fabric IPsec Gateway VM performs fragmentation and reassembly for VXLAN and IPsec tunnels, for which the network routes the packets through the VM. The system supports a minimum of 750 bytes of Maximum Transmission Unit (MTU) value.

IPsec Coupled and Decoupled Mode

A device is in IPsec decoupled mode when IPsec and Fabric Extend (FE) termination takes place on two different IP addresses. A device is in IPsec coupled mode when IPsec and Fabric Extend (FE) termination takes place on the same IP address.

The XA1400 Series devices, which use VOSS for Fabric Extend over IPsec, support both IPsec decoupled and coupled modes. The VSP 4900 Series and VSP 7400 Series devices, which use Fabric IPsec Gateway for Fabric Extend over IPsec, support IPsec in decoupled mode only. You must configure the IPsec tunnel in decoupled mode to enable IPsec termination in the Fabric IPsec Gateway VM. For more information about how to configure IPsec tunnels on the VM, see [Configure IPsec Tunnels on Fabric IPsec Gateway VM](#) on page 882.

Digital Certificates for Fabric IPsec Gateway

Fabric IPsec Gateway supports digital certificates for IPsec authentication of Fabric Extend tunnels. To support different certificates for different IPsec tunnels, you can configure multiple certificate authority (CA) trustpoints and identity subject certificates.

If you are not familiar with digital certificates, see [Digital Certificate/PKI](#) on page 3003 for additional background information like digital certificate terminology.

Online Certificate Provisioning

The switch uses IPsec Simple Certificate Enrollment Protocol (SCEP) to obtain the CA certificate, and then validates the CA certificate against the certificate chain.

Note

Extreme validated the Fabric IPsec Gateway SCEP implementation with EJBCA CA Server only. Fabric IPsec Gateway SCEP cannot currently use Win CA like digital certificate support in VOSS.

Use trustpoints to manage and track CAs and certificates. The switch can enroll with a trustpoint to obtain an identity certificate. You must configure the CA URL, the CA common name, and select the HTTP request type to configure the CA server trustpoint.

Configure the certificate subject parameters to provide the device distinguished name (DN) and key name for the generated key pair (the private key). If you do not configure a private key, the switch generates one. The switch validates the returned certificate against the trustpoint's CA certificate.

You can remove subject certificates from the CA trustpoint or clean the CA trustpoint only if the subject-label is not configured on an IPsec tunnel.

Offline Certificate Provisioning

Offline certificate management supports switches that cannot communicate with the CA to obtain the identity certificate online by certificate enrollment operation.

The switch generates the certificate signing request (CSR) using the subject DN and the private key that you configure in the CLI. If you do not configure a private key, the switch generates one.

Transfer the CSR to the offline CA to be signed. Retrieve the signed certificate to validate against the original CSR. You must manually transfer all certificates in the certificate chain to the switch. The signed certificate must include the subject-label to map it to a locally-generated CSR for validation.

You must manually download Certificate Revocation List (CRL) files. You can remove offline subject certificates only if the subject-label is not configured on an IPsec tunnel.

Egress Shaping for Fabric Extend Tunnels on Fabric IPsec Gateway

You can configure the egress shaping rate to limit egress bandwidth for tunnels on the Fabric IPsec Gateway Virtual Machine (VM).

Considerations

Consider the following when you configure the egress shaper rate:

- If the ingress data traffic receives excessive packets with the following DSCP or 802.1p values (high priority control packets) and egress shaping is configured, a IS-IS flap can be seen.

DHCP value	802.1p value
0x28	6
0x2E	6
0x2F	6
0x30	7
0x38	7

- The egress tunnel shaping rate is impacted if the incoming packet size is greater than the Fabric Extend tunnel MTU. This is due to the additional packet header required for fragmentation.

Operational Considerations and Restrictions

Consider the following when deploying Extreme Integrated Application Hosting (IAH) on various switches:

Table 84: Operational Considerations

	VSP 7400 Series	VSP 4900 Series
Number of IAH ports	VSP 7432CQ: 2 VSP 7400-48Y: 1	VSP4900-12MXU-12XE: 2 VSP4900-24XE: 2
Multiple simultaneous VMs	Supported	Not supported
Pre-installed VM	Third Party Virtual Machine Fabric IPsec Gateway	Third Party Virtual Machine Fabric IPsec Gateway
Additional components required	None	Modular Solid State Drive (SSD)

Virtual Services Configuration using CLI

Perform the procedures in this section to configure Extreme Integrated Application Hosting (IAH) virtual services on the switch using the command line interface (CLI).

Access a Virtual Service Console

The virtual services running on a Virtual Machine (VM) require a console for configuration and monitoring purposes.

About This Task

Perform this procedure to access the virtual service console port for the specific VM.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Enter the following command to access the virtual service console:
`virtual-service WORD<1-128> console`

Note

Type CTRL+Y to exit the console.

Example

```
Switch:1>enable
Switch:1#virtual-service tpvm console
```

Variable Definitions

The following table defines parameters for the **virtual-service** command.

Variable	Value
<i>WORD<1-128></i>	Specifies the virtual service name.
<i>console</i>	Accesses the console for the specific virtual service.

Install a Virtual Service

A virtual service provides the ability to support additional applications or services and simultaneously support the regular switching functionality. Each virtual service provides an Open Virtual Appliance (OVA) image, which is installed on Extreme Integrated Application Hosting (IAH) through Extreme Management Center or ExtremeCloud IQ - Site Engine.

Before You Begin

Use FTP or SFTP to transfer the OVA image to the `/var/lib/insight/packages/` directory on the switch.

Note

The Fabric IPsec Gateway image includes no integrity check. Use SCP to copy the file to the switch and confirm the file size before installation.

About This Task

Perform this procedure to install a package file to a specific location indicated by a virtual service name. This procedure also verifies if the package is in OVA format, and if a certificate is provided in the package.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Install the virtual service package:

```
virtual-service WORD<1-128> install package WORD<1-512>
```

Variable Definitions

The following table defines parameters for the **virtual-service** command.

Variable	Value
<i>WORD<1-128></i>	Specifies the virtual service name.
<i>install</i>	Installs the virtual service package.
<i>package WORD<1-512></i>	Specifies the package name and path.

Configure a Virtual Service

About This Task

Perform this procedure to configure a virtual service on the switch.

Note

- Following procedure lists the general sequence to configure a virtual service.
- The names of Ethernet ports appearing in a specific Virtual Machine (VM) are not correlated to the configured virtual port names. Each VM renames the Ethernet ports as per its requirements, after they are discovered during the VM initialization.
- By default, the system displays all virtual ports of OVS connection type first in the alphabetical order of their configured names, followed by the virtual ports of SR-IOV and VT-d connection types.

Before You Begin

- You must enable trunking on the Extreme Integrated Application Hosting (IAH) port when you use SR-IOV and OVS connection types. For more information about enabling trunking, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2356.
- Ensure the switch has the Ethernet drivers installed as per the SR-IOV standard, to support the VT-d and the SR-IOV connection type for the configured virtual ports.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a VLAN:

**Note**

Virtual service configuration supports port-based VLANs only.

```
vlan create <2-4059> name WORD<0-64> type {port-mstprstp <0-63>}
[color <0-32>]
```

3. Add the IAH and faceplate port to the VLAN:

```
vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

4. Enter GigabitEthernet Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

5. Enable the IAH and faceplate ports:

```
no shutdown
```

6. Exit to Global Configuration mode:

```
exit
```

7. (Optional) Create a virtual service:

```
virtual-service WORD<1-128>
```

8. (Optional) Configure the number of CPU cores to be assigned to the virtual service created:

```
virtual-service WORD<1-128> num-cores <1-6>
```

9. (Optional) Configure the memory size to be assigned to the virtual service created:

```
virtual-service WORD<1-128> mem-size <1-50000>
```

10. (Optional) Configure the disk to be assigned to the virtual service created:

```
virtual-service WORD<1-128> disk WORD<1-32> size <1-30>
```

11. Configure the virtual port connection type:

**Note**

Ensure the connection type you configure for the virtual port matches the connection type supported by the IAH port.

```
virtual-service WORD<1-128> vport WORD<1-32> connect-type {ovs | sriov
| vtd}
```

12. Configure the IAH port to associate with the connection type:

```
virtual-service WORD<1-128> vport WORD<1-32> port WORD<1-32>
```

Important

You cannot configure two virtual services with conflicting connect types on the same IAH port. You cannot configure two virtual services with VT-d connect type on the same IAH port.

13. Configure the NIC type of the IAH port:

```
virtual-service WORD<1-128> vport WORD<1-32> port WORD<1-32> nic-type  
{virtio | e1000}
```

14. Add the virtual port to the VLAN created:

```
virtual-service WORD<1-128> vport WORD<1-32> vlan <1-4096>
```

15. Enable the virtual service:

```
virtual-service WORD<1-128> enable
```

Example

Configuring the TPVM virtual service using IAH port 1/s1 with an SR-IOV connection type:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/s1
Switch:1(config-if)#encapsulation dot1q
Switch:1(config-if)#exit
Switch:1(config)#vlan create 10 name tpvm-lan-vlan type port-mstprstp 0
Switch:1(config)#vlan members add 10 1/s1,1/6/2
Switch:1(config)#interface GigabitEthernet 1/s1,1/6/2
Switch:1(config-if)#no shutdown
Switch:1(config-if)#exit
Switch:1(config)#virtual-service tpvm vport eth0 connect-type sriov
Switch:1(config)#virtual-service tpvm vport eth0 vlan 10
Switch:1(config)#virtual-service tpvm enable
```

Configuring the TPVM virtual service on IAH port 1/s2 with a VT-d connection type:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan create 10 type port-mstprstp 0
Switch:1(config)#vlan member add 10 1/1,1/s2
Switch:1(config)#interface GigabitEthernet 1/s2,1/1
Switch:1(config-if)#no shutdown
Switch:1(config-if)#exit
Switch:1(config-if)#virtual-service tpvm vport eth0 port 1/s2
Switch:1(config)#virtual-service tpvm enable
```

Variable Definitions

The following table defines parameters for the **vlan create** command.

Variable	Value
<2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
color<0-32>	Specifies the color of the VLAN.
nameWORD<0-64>	Specifies a name for the VLAN to be created.
type {port-mstp prstp<0-63>}	Creates a VLAN by port, with the STP instance ID ranging from 0 to 63. Note: MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.

The following table defines parameters for the **vlan members** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
add	Adds ports to a specified VLAN ID.

The following table defines parameters for the **virtual-service** command.

Variable	Value
<code>WORD<1-128></code>	Specifies a name for virtual service.
<code>connect-type {ovs sriov vtd}</code>	Specifies the connection type for the virtual port created. The default is VT-d. The switch supports the following maximums for virtual ports: <ul style="list-style-type: none"> • OVS - 16 • SR-IOV - 16 • VT-d - 2
<code>disk WORD<1-32></code>	Specifies the disk assigned to the virtual service.
<code>mem-size <1-50000></code>	Specifies the memory size in Megabytes assigned to the virtual service. The default value is 1024 Megabytes.
<code>nic-type [virtio e1000]</code>	Specifies the Virtual Port NIC type. The default is e1000. Note: Configure this value only when the connect-type parameter is ovs .
<code>num-cores <1-6></code>	Specifies the number of cores assigned to the virtual service. The default value is 1.
<code>port WORD<1-32></code>	Specifies the name of the Extreme Integrated Application Hosting (IAH) port associated with the virtual port. Depending on the hardware, the switch can support the following IAH ports: <ul style="list-style-type: none"> • 1/s1 • 1/s2
<code>size <1-30></code>	Specifies the size of the disk in Gigabytes.
<code>vlan <1-4096></code>	Specifies the VLAN ID used by the virtual port.
<code>vport WORD<1-32></code>	Specifies the name of the virtual port.

Shut Down a Virtual Service

About This Task

Perform this procedure to disable the virtual service.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Disable the virtual service:

```
no virtual-service WORD<1-128> enable
```

Example

Disable the virtual service.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no virtual-service tpvm enable
```

Delete Virtual Service Resources

About This Task

Perform this procedure to delete the virtual service resource allocation.

Note

If a corresponding virtual machine is running, it is stopped, and then the virtual service configuration is deleted.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Delete the virtual service resource allocation:
no virtual-service WORD<1-128> [disk WORD<1-32>] [vport WORD<1-32>]

Example

Delete all virtual service resource allocation.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no virtual-service tpvm
```

Uninstall a Virtual Service

About This Task

Perform this procedure to uninstall a configured virtual service.

Note

If a virtual machine is running, it is stopped, and then the service directory is uninstalled.

Before You Begin

You must disable the virtual service before you uninstall it.

Procedure

1. Enter Privileged EXEC mode:
enable

2. Uninstall a specific virtual service:

```
virtual-service WORD<1-128> uninstall
```

Example

```
Switch:1>enable
Switch:1#virtual-service tpvm uninstall
```

Variable Definitions

Use data in the following table to use the **virtual-service** command.

Variable	Value
<i>WORD<1-128></i>	Specifies the virtual service name.
<i>uninstall</i>	Uninstalls the specified virtual service name.

Display Virtual Service Configuration

About This Task

Perform this procedure to display the virtual service configuration on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the virtual-service configuration:

```
show virtual-service config [WORD<1-128>]
```

Example

Display the configuration of all virtual services:

```
Switch:1>show virtual-service config
=====
                        Installed Packages
=====
Package:                figw

Management Status :           Enabled
=====
```

Display Virtual Service Installation Status

About This Task

Perform this procedure to display the installation status for the specific virtual service. This procedure indicates if the installation finished successfully or failed to complete.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display installation status for a specific virtual service:

```
show virtual-service install WORD<1-128>
```

Example

Display installation status for a specific virtual service:

```
Switch:1>show virtual-service install tpvm
  Stage:   Convert
  Status:  In Progress
```

Display Virtual Services Resources

About This Task

Perform the following procedure to display the number of remaining virtual services resources on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display statistics for all virtual services configured on the switch or a specific virtual service:

```
show virtual-service statistics [WORD<1-128>]
```

Example

```
Switch:1>show virtual-service statistics

Run a VM command from Network Operating System (NOS) CLI

About This Task

Perform this task to run a virtual machine (VM) command from the NOS CLI.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Run the **ls** command for the VM configs directory from the CLI:
`virtual-service WORD<1-128> exec-command WORD<1-256>`
3. Run a Fabric IPsec Gateway command from the CLI:
`virtual-service WORD<1-128> figw-cli WORD<1-256>`

Examples

From NOS, list the contents of the `home/rwa/configs` directory in the Fabric IPsec Gateway VM:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#virtual-service figw exec-command "ls /home/rwa/configs"
config.cfg
figw_cli.log
shadov.txt
```

From NOS, configure the source VLAN ID for the IPsec tunnel in the Fabric IPsec Gateway VM:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#virtual-service figw figw-cli "set global ipsec-tunnel-src-vlan 71"
```

Variable Definitions

The following table defines parameters for the **virtual-service** command.

Variable	Value
<i>WORD</i> <1-128>	Specifies the virtual service name.
<i>WORD</i> <1-256>	Specifies the VM command to run. To include spaces in the syntax, include the text string in quotation marks ("").

Copy VM Files

About This Task

Perform this task to copy files between the Network Operating System (NOS) and a VM, or between VMs.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Copy a file:

```
virtual-service copy-file WORD<1-256> WORD<1-256>
```

Examples

Copy a file from the NOS to a VM:

```
Switch:1>enable
Switch:1#virtual-service copy-file /intflash/config_figw.cfg figw:/home/rwa/configs/
config.cfg
```

Copy a file from a VM to the NOS:

```
Switch:1>enable
Switch:1#virtual-service copy-file figw:/home/rwa/configs/config.cfg /intflash/
config_figw.cfg
```

Copy a file between VMs:

```
Switch:1>enable
Switch:1#virtual-service copy-file figw:/home/rwa/configs/config.cfg figw2:/home/rwa/
configs/config.cfg
```

Variable Definitions

The following table defines parameters for the **virtual-service copy-file** command.

Variable	Value
<i>WORD</i> <1-256>	Specifies the source and destination file to copy. To specify a VM location, use the format <VM_name>:<VM_file_path/filename>. To specify a NOS location, use the format </file_path/filename> where the valid path can be one of the following: <ul style="list-style-type: none"> • /intflash • /extflash • /usb • /var/lib/insight/packages

Change a VM User Password from Network Operating System (NOS) CLI

About This Task

Perform this task to change the password for a VM user. The password must be greater than, or equal to, 8 characters.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Change the password:

```
virtual-service WORD<1-128> change-user-pass WORD<1-20>
```
3. Enter the new password.
4. Enter the new password a second time.

Example

Change the password for the rwa user account in the Fabric IPsec Gateway VM:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#virtual-service figw change-user-pass rwa
Enter password : *****
Re-enter password : *****
```

Variable Definitions

The following table defines parameters for the **virtual-service WORD<1-128> change-user-pass** command.

Variable	Value
<i>WORD<1-20></i>	Specifies the username.
<i>WORD<1-128></i>	Specifies the virtual service name.

Upgrade a Virtual Service

If Extreme Networks makes a new version of the virtual service available, uninstall the original virtual service and install the newer virtual service.

Important

You can perform an upgrade of Linux inside the virtual service by standard Linux upgrade procedures. For example, TPVM is Ubuntu based, so you can use **sudo apt-get update** and **sudo apt-get upgrade**. If you complete such an upgrade, Extreme Networks is not responsible for the behavior of the VM; it has not been tested with that version on the OS.

Before You Begin

- Ensure the new virtual service image version is compatible with the VOSS release that runs on the switch. For compatibility statements, see [VOSS Release Notes](#). If necessary, upgrade the VOSS image before you upgrade the virtual service image.
- If you installed applications in the Third Party Virtual Machine (TPVM), you must migrate important data for those applications before you perform this procedure.
- If you created new users in the TPVM, follow standard Linux procedures to back up user names and passwords.
- For Fabric IPsec Gateway, back up the configuration files (*.cfg) and the `shadow.txt` file, which is an encrypted file that contains the authentication keys for the IPsec tunnels. You can use the **ls** command within the VM to see the file list. Use FTP within the VM to transfer the files for backup or see [Copy VM Files](#) on page 865.
- Use FTP or SFTP to transfer the new OVA image to the `/var/lib/insight/packages/` directory on the switch.

Note

The Fabric IPsec Gateway image includes no integrity check. Use SCP to copy the file to the switch and confirm the file size before installation.

About This Task

When you uninstall the original virtual service, the system removes the complete virtual service configuration from the configuration file.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Disable the virtual service:

```
no virtual-service WORD<1-128> enable
```
3. Return to Privileged EXEC mode:

```
end
```
4. Uninstall the virtual service:

```
virtual-service WORD<1-128> uninstall
```
5. Install the virtual service package using the new OVA image:

```
virtual-service WORD<1-128> install package WORD<1-512>
```
6. Reconfigure the virtual service; for more information, see [Configure a Virtual Service](#) on page 856.
7. Remove the original OVA image from the `/var/lib/insight/packages/` directory on the switch:

```
remove WORD<1-255>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no virtual-service tpvm enable
Switch:1(config)#end
Switch:1#virtual-service tpvm uninstall
Switch:1#virtual service tpvm install package var/lib/insight/packages/
TPVM_4900_8.2.0.0.img
Switch:1#configure terminal
Switch:1(config)#virtual-service tpvm vport eth0 connect-type sriov
Switch:1(config)#virtual-service tpvm vport eth0 vlan 10
Switch:1(config)#virtual-service tpvm enable
Switch:1(config)#remove /intflash/var/lib/insight/packages/TPVM_4900_8.1.5.0.img
```

Virtual Services Configuration using EDM

Perform the procedures in this section to configure Extreme Integrated Application Hosting (IAH) virtual services on the switch using the Enterprise Device Manager (EDM).

Viewing Virtual Services Resources

About This Task

Perform the following procedure to view the number of remaining virtual services resources on the switch.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Virtual Service**.
3. Click the **Globals** tab.

Globals Field Descriptions

Use data in the following table to use the **Globals** tab.

Name	Description
DiskRemain	Shows the remaining disk space available, in Gigabytes (GB).
NumCoresRemain	Shows the remaining number of CPU cores available.
MemSizeRemain	Shows the remaining amount of memory size available, in Megabytes (MB).
CopySourceFile	Specifies the source file to copy. To specify a location, use the format: {VM_NAME_SRC}: {VM_FILE_PATH} or {NOS_FILE_PATH}. For example, <code>figw:/home/rwa/configs/ipsec1.cfg</code> identifies a file located in the VM. <code>/intflash/ipsec1.cfg</code> identifies a file located in the NOS. The valid path for a NOS location can be one of the following: <ul style="list-style-type: none"> • <code>/intflash</code> • <code>/extflash</code> • <code>/usb</code> • <code>/var/lib/insight/packages</code>
CopyDestinationFile	Specifies the destination file to copy. To specify a location, use the format: {VM_NAME_DST}: {VM_FILE_PATH} or {NOS_FILE_PATH}. For example, <code>figw:/home/rwa/configs/ipsec1.cfg</code> identifies a file located in the VM. <code>/intflash/ipsec1.cfg</code> identifies a file located in the NOS. The valid path for a NOS location can be one of the following: <ul style="list-style-type: none"> • <code>/intflash</code> • <code>/extflash</code> • <code>/usb</code> • <code>/var/lib/insight/packages</code>
CopyAction	Specifies an action to copy a file from source to destination. The switch supports the following action: <ul style="list-style-type: none"> • Copy • None
ScalarsName	Specifies the virtual service name. You must specify the virtual service name if you use this tab to change the password or run a command.
ExecuteCommand	Specifies the Virtual Machine (VM) command to run. To include spaces in the syntax, include the text string in quotation marks (").
User	Specifies the virtual service user name. The range is 0-20 characters.

Name	Description
Password	Specifies the virtual service password.
FigwCli	Specifies the command to send to the Fabric IPsec Gateway VM. For more information about Fabric IPsec Gateway commands, see VOSS CLI Commands Reference .

Configure a Virtual Service

About This Task

Perform this procedure to configure a virtual service on the switch.

Before You Begin

You must configure at least one virtual port to enable the virtual service. For more information, see [Configure Virtual Ports](#) on page 872.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Select **Virtual Service**.
3. Select the **Virtual Service** tab.
4. Select **Insert**.
5. In the **Name** field, enter a unique name.
6. (Optional) In the **NumCores** field, enter a value.
7. (Optional) In the **MemSize** field, enter a value.
8. Select **Insert**.
9. In the **Enable** field for the newly inserted row, change the value to true.
10. Select **Apply**.

Virtual Service Field Descriptions

Use data in the following table to use the **Virtual Service** tab.

Name	Description
Name	Specifies the name of the virtual service. Every virtual service must have a unique name.
NumCores	Specifies the number of CPU cores assigned to the virtual service. The default is 1.
MemSize	Specifies the memory size (in Megabytes) assigned to the virtual service. The default value is 1024 Megabytes.

Name	Description
Enable	Enables the virtual service. Note: You must configure at least one virtual port to enable the virtual service.
PackageInfoName	Shows the package name used by the virtual service.
PackageAppName	Shows the application name used by the virtual service.
PackageAppVersion	Shows the application version used by the virtual service.
UtilCpuAllot	Specifies the number of CPUs allocated to the virtual service.
UtilCpuUtil	Specifies the average percentage of CPU utilization over the past 30 seconds.
UtilMemAllot	Specifies the memory (in Megabytes) allocated to the virtual service.
UtilMemUsed	Specifies the memory used (in Megabytes) by the virtual service.
UtilMemAvailable	Specifies the memory available (in Megabytes) for the virtual service.
State	Specifies the operational state of the virtual service.
UpTime	Specifies the operational time of the virtual service.

Configuring Disks to be used by the Virtual Service

About This Task

Perform the following procedure to configure the number of disks to be used by the virtual service configured on the switch.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Virtual Service**.
3. Click the **Disks** tab.
4. Click **Insert**.
5. In the **ServName** field, enter the virtual service name.
6. In the **Name** field, enter the disk name.
7. (Optional) In the **Size** field, enter a value.
8. Click **Insert**.

Disks Field Descriptions

Use data in the following table to use the **Disks** tab.

Name	Description
ServName	Specifies the virtual service name. Note: The specified name must match the virtual service name configured on the switch.
Name	Specifies the name of the disk used by the virtual service.
Size	Specifies the disk size (in Gigabytes). The default is 10 Gigabytes.
SizeAllot	Shows the disk size (in Megabytes) allocated to the virtual service.
SizeAvailable	Shows the available disk storage space (in Megabytes).
SizeUsed	Shows the amount of disk storage space (in Megabytes) used by the virtual service.

Configure Virtual Ports

About This Task

Perform the following procedure to configure virtual ports to be used by the virtual service configured on the switch.

**Note**

The names of Ethernet ports appearing in a specific Virtual Machine (VM) are not correlated to the configured virtual port names. Each VM renames the Ethernet ports as per its requirements, after they are discovered during the VM initialization.

By default, the system displays all virtual ports of OVS connection type first in the alphabetical order of their configured names, followed by the virtual ports of SR-IOV and VT-d connection types.

Before You Begin

- You must enable trunking on the Extreme Integrated Application Hosting (IAH) port when you use SR-IOV and OVS connection types.
- Ensure the switch has the Ethernet drivers installed as per the SR-IOV standard, to support the VT-d and the SR-IOV connection type for the configured virtual ports.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Select **Virtual Service**.
3. Select the **VPorts** tab.
4. Select **Insert**.

5. In the **Virtual Service Name** field, enter the virtual service name.
6. In the **Interface Name** field, enter a name for the virtual port.
7. (Optional) In the **VlanIdList** field, enter a VLAN ID.
8. (Optional) In the **ConnectType** field, select a connection type.

**Note**

Ensure the connection type you configure for the virtual port matches the connection type supported by the IAH port.

9. Select **Insert**.

VPorts Field Descriptions

Use data in the following table to use the **VPorts** tab.

Name	Description
Virtual Service Name	Specifies the virtual service name. Note: The specified name must match the virtual service name configured on the switch.
Interface Name	Specifies the virtual port.
VlanIdList	Specifies the VLAN ID to which the virtual port is assigned.
ConnectType	Specifies the virtual port connect type. The default is VT-d. The switch supports the following maximums for virtual ports: <ul style="list-style-type: none"> • OVS - 16 • SR-IOV - 16 • VT-d - 2
Port	Specifies the name of the Extreme Integrated Application Hosting port associated with the virtual port. Depending on hardware, the switch can support the following Extreme Integrated Application Hosting ports: <ul style="list-style-type: none"> • 1/s1 • 1/s2
NicType	Specifies the Virtual Port NIC type. The default is e1000. <ul style="list-style-type: none"> • virtio • e1000 Note: Configure this value only when the ConnectType field is ovs.

Install a Virtual Service

Before You Begin

- Use FTP or SFTP to transfer the OVA image to the `/var/lib/insight/packages/` directory on the switch.

About This Task

Perform the following procedure to configure the package information to be used by the virtual service.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability**.
2. Select **Virtual Service**.
3. Select the **Application** tab.
4. Select **Insert**.
5. In the **Name** field, enter the virtual service name.
6. Next to the **PackageName** field, select the ellipsis, select the package to install, and then select **Ok**.
7. Select **Insert**.

Application Field Descriptions

Use data in the following table to use the **Application** tab.

Name	Description
Name	Specifies the name of the virtual service.
PackageName	Specifies the name and location of the package.
InstallResult	Shows the status of the virtual service installation.
InstallStage	Shows the stages of a package installation.
PackageAppName	Shows the application name used by the virtual service.
PackageAppVersion	Shows the application version used by the virtual service.

Run a VM command from EDM

About This Task

Perform this task to run a VM command from EDM. To include spaces in the syntax, include the text string in quotation marks ("").

Procedure

1. In the navigation pane, expand **Configuration > Serviceability**.
2. Select the **Virtual Service**.
3. Select the **Globals** tab.
4. In the **ScalarsName** field, type a virtual service name.

5. In the **ExecuteCommand** field, type the **ls** command for the VM `configs` directory. For example, `"ls /home/rwa/configs"`.
6. In the **FigwCli** field, type a command to send it to the Fabric IPsec Gateway. For more information about Fabric IPsec Gateway commands, see [VOSS CLI Commands Reference](#).
7. Select **Apply**.

Copy VM Files

About This Task

Perform this task to copy files between the Network Operating System (NOS) and a VM or between VMs. The valid path for a NOS location can be one of the following:

- `/intflash`
- `/extflash`
- `/usb`
- `/var/lib/insight/packages`

Procedure

1. In the navigation pane, expand **Configuration > Serviceability**.
2. Select **Virtual Service**.
3. Select the **Globals** tab.
4. In the **CopySourceFile** field, type a location of the source file using the following format: `{VM_NAME_SRC}:{VM_FILE_PATH}` or `{NOS_FILE_PATH}`. For example, `figw:/home/rwa/configs/ipsec1.cfg` identifies a file located in the VM. `/intflash/ipsec1.cfg` identifies a file located in the NOS.
5. In the **CopyDestinationFile** field, type a location of the destination file using the following format: `{VM_NAME_DST}:{VM_FILE_PATH}` or `{NOS_FILE_PATH}`. For example, `figw:/home/rwa/configs/ipsec1.cfg` identifies a file located in the VM. `/intflash/ipsec1.cfg` identifies a file located in the NOS.
6. In the **CopyAction** field, select **Copy**.
7. Select **Apply**.

Change a VM User Password from EDM

About This Task

Perform this task to change the password for a VM user.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability**.
2. Select **Virtual Service**.
3. Select the **Globals** tab.
4. In the **ScalarsName** field, type a virtual service name.
5. In the **User** field, type the user name.
6. In the **Password** field, type a password.

7. Select **Apply**.

Viewing Virtual Services Package File Information

About This Task

Perform the following procedure to view information about the package files available in the `/var/lib/insight/packages` directory, which you can use to install a new virtual service.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Virtual Service**.
3. Click the **PackageFile** tab.

PackageFile Field Descriptions

Use data in the following table to use the **PackageFile** tab.

Name	Description
Name	Shows the name and absolute path information for package files available in the <code>/var/lib/insight/packages</code> directory.
Date	Shows the date and time when the package file was added to the directory.
Size	Shows the size (in bytes) of the package file.

Fabric IPsec Gateway Configuration using CLI

Perform the procedures in this section to configure services like IPsec, fragmentation and reassembly, and to manage the Fabric IPsec Gateway Virtual Machine using the command line interface (CLI).

Configure FTP Connection to an IP Address

Fabric IPsec Gateway Virtual Machine (VM) provides a File Transfer Protocol (FTP) CLI to copy the configuration files to the VM.

About This Task

Perform this procedure to configure an FTP connection to a specific IP Address.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Configure FTP connection:

```
ftp {A.B.C.D}
```

Example

Configuring FTP connection to 192.0.2.50:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> ftp 192.0.2.50
```

Variable Definitions

The following table defines the variable for **ftp** command.

Variable	Value
{A.B.C.D}	Specifies the IP Address to establish the FTP connection with.

Display the Default Directory on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display content in the default directory on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Display the configured directory:

```
ls
```

Example

Displaying the configured directory on the VM.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> ls
coupled.cfg
```

Load Configuration File to Fabric IPsec Gateway VM

About This Task

Perform this procedure to load a configuration file to the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Load a specific configuration file to the VM :

```
load WORD <1-255>
```

Example

Loading a configuration file to the VM.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> load coupled.cfg
```

Variable Definitions

The following table defines the variable for **load** command.

Variable	Value
<i>WORD</i> <1-255>	Specifies the configuration file name.

Ping an IP Address on Fabric IPsec Gateway VM

About This Task

Perform this procedure to ping an IP Address on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
enable

virtual-service WORD<1-128> console

**Note**

Type **CTRL+Y** to exit the console.

2. Ping an IP Address:
ping {A.B.C.D}

Example

Pinging an IP Address on the VM.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> ping 192.0.2.35
```

Variable Definitions

The following table defines parameters for the **ping** command.

Variable	Value
{A.B.C.D}	Specifies the IP address.

Configure Global Parameters on Fabric IPsec Gateway VM

About This Task

Perform this procedure to configure IPsec source IP address, Local Area Network (LAN) interface IP and gateway IP address, maximum transmission unit (MTU) value, and so on globally, on the Fabric IPsec Gateway Virtual Machine (VM).

**Note**

You must perform this procedure only after the VM boots up.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
enable

virtual-service WORD<1-128> console

**Note**

Type **CTRL+Y** to exit the console.

2. Configure IPsec source IP address for a Fabric Extend (FE) tunnel for IPsec in decoupled mode:
`set global ipsec-tunnel-src-ip {A.B.C.D/X}`
3. Assign VLAN ID to the configured IPsec source IP address:
`set global ipsec-tunnel-src-vlan <2-4059>`
4. Configure the LAN interface IP address on the first Ethernet interface (eth0) of Fabric IPsec Gateway VM:
`set global lan-intf-ip {A.B.C.D/X}`
5. Assign VLAN ID to the configured LAN interface IP address:
`set global lan-intf-vlan <2-4059>`
6. Configure the LAN interface gateway IP address on the VOSS switch:
`set global lan-intf-gw-ip {A.B.C.D}`
7. Configure the logical interface gateway IP address, to add routes for FE tunnels that need Fragmentation:
`set global fe-tunnel-gw-ip {A.B.C.D}`
8. Configure the logical interface source IP address for the FE tunnel:
`set global fe-tunnel-src-ip {A.B.C.D}`

**Note**

The logical interface source IP address must be same as the source IP address configured on the VOSS switch.

9. Configure the global MTU value:
`set global mtu <mtu-value>`

**Note**

- The switch applies the global MTU value, if you do not configure MTU during the IPsec tunnel configuration.
- If an IPsec tunnel is not using the fragmentation and reassembly capabilities, the default MTU value is 1950.

10. Configure the Wide Area Network (WAN) interface gateway IP address, which is the next hop for IPsec tunnels.

```
set global wan-intf-gw-ip {A.B.C.D}
```

11. Configure the virtual reassembly interface IP address:

```
set global virtual-reassembly-intf-ip {A.B.C.D/X}
```

**Note**

You must configure the virtual reassembly interface IP address to use the fragmentation and reassembly service.

12. Assign VLAN ID to the configured virtual reassembly interface IP address:

```
set global virtual-reassembly-intf-vlan <2-4059>
```

13. Disable IPsec on all configured tunnels:

```
set global ipsec-disable
```

14. Set IPsec log level:

```
set global ipsec-log-level <-1-5>
```

Example

Configuring global parameters on Fabric IPsec Gateway VM to configure an IPsec tunnel between two switches:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> set global ipsec-tunnel-src-ip 192.0.2.10/24
FIGW> set global ipsec-tunnel-src-vlan 101
FIGW> set global lan-intf-ip 192.0.2.20/24
FIGW> set global lan-intf-vlan 30
FIGW> set global lan-intf-gw-ip 192.0.2.30
FIGW> set global fe-tunnel-src-ip 192.0.2.40
FIGW> set global wan-intf-gw-ip 192.0.2.50
FIGW> set global mtu 1950
```

Variable Definitions

The following table defines parameters for the **set global** command.

Variable	Value
<i>ipsec-tunnel-src-ip</i> {A.B.C.D/X}	Specifies the source IP address and subnet mask for IPsec tunnel.
<i>ipsec-tunnel-src-vlan</i> <2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
<i>lan-intf-ip</i> {A.B.C.D/X}	Specifies the IP address and subnet mask for Local Area Network (LAN) interface.
<i>lan-intf-vlan</i> <2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
<i>lan-intf-gw-ip</i> {A.B.C.D}	Specifies the gateway IP address for LAN interface.
<i>fe-tunnel-gw-ip</i> {A.B.C.D}	Specifies the gateway IP address for Fabric Extend (FE) tunnel.
<i>fe-tunnel-src-ip</i> {A.B.C.D}	Specifies the source IP address for FE tunnel.

Variable	Value
<code>mtu <750-9000></code>	Specifies the Maximum Transmission Unit (MTU) value. Note: If an IPsec tunnel is not using the fragmentation and reassembly capabilities, the default MTU value is 1950.
<code>wan-intf-gw-ip {A.B.C.D}</code>	Specifies the Wide Area Network (WAN) interface gateway IP address.
<code>virtual-reassembly-intf-ip {A.B.C.D/X}</code>	Specifies the virtual-reassembly interface IP address and subnet mask on the Fabric IPsec Gateway (VM). Note: You must configure the virtual reassembly interface IP address to use the fragmentation and reassembly service.
<code>virtual-reassembly-intf-vlan <2-4059></code>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
<code>ipsec-disable</code>	Disables IPsec operationally on all tunnels in the Fabric IPsec Gateway VM.
<code>ipsec-log-level <-1-5></code>	Specifies the IPsec log levels on Fabric IPsec Gateway VM. Following are the three levels: <ul style="list-style-type: none"> • -1: Absolutely Silent • 0-4: Log levels • 5: Clear Logs

Configure IPsec Tunnels on Fabric IPsec Gateway VM

About This Task

Perform this procedure to configure IPsec tunnels on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Configure the Maximum Transmission Unit (MTU) value for the specific IPsec tunnel:

```
set ipsec <1-255> mtu <1300 - 9000>
```

Note

The MTU range <1300-9000> is applicable for FE tunnels with IPsec and fragmentation and reassembly capabilities.

3. Configure the ESP cipher suite for the IPsec tunnel:

```
set ipsec <1-255> esp <aes128gcm16-sha256 | aes256-sha256 |  
aes256gcm16-sha256>
```

4. Configure the authentication key for specific IPsec tunnel:

```
set ipsec <1-255> auth-key WORD <1-32>
```

Note

Do not use special characters ?, \, &, <, >, #.

5. Configure VXLAN destination IP address for IPsec tunnel:

```
set ipsec <1-255> fe-tunnel-dest-ip {A.B.C.D}
```

Note

The VXLAN destination IP address for IPsec tunnel must be the same as the VXLAN destination IP address for FE tunnel.

6. Configure the IPsec destination IP address for the specific tunnel deployed in decoupled mode:

```
set ipsec <1-255> ipsec-dest-ip {A.B.C.D}
```

7. Configure a name for the IPsec tunnel:

```
set ipsec <1-255> tunnel-name WORD <1-64>
```

8. Identify if the specific tunnel is a responder or initiator in Network Address Translation (NAT) cases:

```
set ipsec <1-255> responder-only <true | false>
```

9. Enable the IPsec on a specific tunnel:

```
set ipsec <1-255> admin-state enable
```

Example

Configure parameters for IPsec tunnel on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> set ipsec 1 ipsec-dest-ip 192.0.2.5
FIGW> set ipsec 1 mtu 1950
FIGW> set ipsec 1 auth-key abcd
FIGW> set ipsec 1 tunnel-name Tunnel-to-BEB2
FIGW> set ipsec 1 fe-tunnel-dest-ip 192.0.2.15
FIGW> set ipsec 1 esp aes256gcm16-sha256
FIGW> set ipsec 1 admin-state enable
```

Variable Definitions

The following table defines parameters for the **set ipsec** command.

Variable	Value
<1-255>	Specifies the unique ID for the IPsec tunnel.
<i>admin-state</i> <enable disable>	Enables or disables IPsec on the specific IPsec tunnel.
<i>auth-key</i> WORD <1-32>	Specifies the pre-shared authentication key. Note: Do not use special characters ?, \, &, <, >, #.
<i>encryption-key-length</i> <128 256>	Specifies the encryption key length for the IPsec tunnel. The default encryption key length is 128. As a best practice, use the newer <i>esp</i> parameter instead; the <i>encryption-key-length</i> parameter remains for backward compatibility.
<i>esp</i> <aes128gcm16-sha256 aes256-sha256 aes256gcm16-sha256>	Specifies the ESP cipher suites for the IPsec tunnel. The default is aes128gcm16-sha256. aes256-sha256 is not supported in the current release.
<i>fe-tunnel-dest-ip</i> {A.B.C.D}	Specifies the destination IP address for Fabric Extend (FE) tunnel.
<i>ipsec-dest-ip</i> {A.B.C.D}	Specifies the destination IP address for IPsec tunnel.
<i>mtu</i> <1300-9000	Specifies the Maximum Transmission Unit (MTU) value for the FE tunnel with both IPsec and fragmentation and assembly capabilities.
<i>responder-only</i> <true false>	Specifies if the IPsec session in the FE tunnel will be in responder only mode or initiator mode. When in responder mode the FE tunnel will only respond to the incoming request and not initiate the IPsec connection. By default both sides of IPsec connection will be initiators in the FE tunnel. Configure the IPsec tunnel to be in responder only mode when there is Network Address Translation (NAT) between the IPsec connection. For more information about NAT, see IPsec NAT-T on page 1775.
<i>tunnel-name</i> WORD <1-64>	Specifies a name for the IPsec tunnel.
<i>egress-shaping-rate</i> <1-1000>	Specifies the egress shaper rate for the IPsec tunnel.

Enable Fragmentation Before Encryption on Fabric IPsec Gateway VM

Perform this procedure to fragment packets larger than the IPsec tunnel maximum transmission unit (MTU) before the packets are sent for encryption.

Before You Begin

- Ensure IPsec is disabled on the tunnel. The administrative state must be disabled before you can enable or disable fragmentation before encryption.
- Configure the IPsec destination IP address or enable responder mode.

About This Task

By default, fragmentation before encryption is disabled.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Enable fragmentation before IPsec encryption:

```
set ipsec <1-255> fragment-before-encrypt enable
```

Configure the Subject Identity on Fabric IPsec Gateway VM

About This Task

Use this procedure to configure the subject parameters to identify the device.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Configure the distinguished name of the device:

```
set certificate subject <subject-label> DN <name>
```

3. (Optional) Configure the name of the generated key-pair:

```
set certificate subject <subject-label> key-label <key-label>
```

Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>set certificate subject ExtremeLab DN "CN=subca5, OU=Test, O=Extreme, L=Town,
ST=State, E=email@extremenetworks.com"
FIGW>set certificate subject ExtremeLab key-label key1
```

Variable Definitions

The following table defines parameters for the **set certificate subject** command.

Variable	Value
<i>DN</i> <name>	Specifies the distinguished name. You can create a comma-separated list.
<i>key-label</i> <key-label>	Specifies the key name of the generated key pair. This parameter is optional. If you do not configure one, the switch generates one the same as the subject-label.
<subject-label>	Specifies the subject identity. You cannot use the following special characters: <ul style="list-style-type: none"> • question mark (?) • backslash (\) • ampersand (&) • less than (<) • greater than (>) • pound (#)

Generate the Key Pair on Fabric IPsec Gateway VM

About This Task

Use the following procedure to generate the private and public key pair. By default, VOSS generates a 2,048 RSA key when the system starts. You can use this procedure to generate a new key.

Before You Begin

- Configure an EJBCA CA server.
- Configure a route from Fabric IPsec Gateway to the EJBCA CA server.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Generate the key:

```
certificate generate key <type> <size> <key-label>
```

Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>certificate generate key rsa 2048 key_rsa
fingerprint: 09ac0c64b9bf3ad04dc67f20942c674e
```

Variable Definitions

The following table defines parameters for the **certificate generate key** command.

Variable	Value
<i>key-label</i>	Specifies the key name of the generated key pair.
<i>size</i>	Specifies the size of key-pair to be generated. The switch supports 2048.
<i>type</i>	Specifies the type of cryptography algorithm used to generate the key-pair. The switch uses only rsa as the cryptography algorithm type.

Configure a Trustpoint CA on Fabric IPsec Gateway VM

About This Task

Use this procedure to configure the certificate authority (CA) to use Simple Certificate Enrollment Protocol (SCEP) with a CA server for online certificate provisioning.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Configure the trusted CA URL:

```
set certificate ca-trustpoint <ca-label> ca-url <ca-url>
```

3. Configure the common name of the CA:

```
set certificate ca-trustpoint <ca-label> caname <caname>
```

4. Configure the HTTP request type to support the type of CA:

```
set certificate ca-trustpoint <ca-label> get-method <post | get>
```

5. Configure the appropriate action:

- Configure the trustpoint, authenticate the trustpoint CA by getting the certificate of the CA, and store the CA certificate locally:

```
certificate ca <ca-trustpoint> caAuth
```

- Generate the certificate enrollment request, get the digital certificate, and store it locally, associating with the trustpoint CA:

```
certificate ca <ca-trustpoint> enroll <subject-label>
```

- Get the Certificate Revocation List (CRL) from the CDP and store into a file:

```
certificate get crl-from <A.B.C.D> <user> <file-path> <cacert-  
filename>
```

- Get the CA certificate obtained from the trustpoint CA:

```
certificate get cacert-from <A.B.C.D> <user> <file-path>
```
- Get the subject certificate obtained from the trustpoint CA:

```
certificate get signedcert-from <A.B.C.D> <user> <file-path>
<subject-label>
```
- Release the locally stored certificate associated with the trustpoint CA after revocation:

```
certificate ca <ca-trustpoint> remove <subject-label>
```
- Remove all certificates from the CA trustpoint:

**Note**

You can clean the CA trustpoint only if the subject-label is not configured on an IPsec tunnel.

```
certificate ca <ca-trustpoint> clean
```

Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>set certificate ca-trustpoint caExtremeEJBCA ca-url http://192.0.2.9:8080/ejbca/
publicweb/apply/scep/test/pkiclient.exe
FIGW>set certificate ca-trustpoint caExtremeEJBCA caname subca5
FIGW>set certificate ca-trustpoint caExtremeEJBCA get-method post
```

Variable Definitions

The following table defines parameters for the **set certificate ca-trustpoint** command.

Variable	Value
<i><ca-label></i>	Specifies the name of the certificate authority (CA). The name can use alphanumeric characters and is case-sensitive. The maximum length is 45 characters.
<i>ca-url <ca-url></i>	Specifies the trusted CA URL.
<i>caname <caname></i>	Specifies the name of the owner of the device or user.
<i>get-method <post get></i>	Specifies the HTTP request style. You can use post for EJBCA or get for Win2012 CA. The default value is post.

The following table defines parameters for the **certificate ca** command.

Variable	Value
<i><ca-trustpoint></i>	Specifies the name of the certificate authority. The name can be alphanumeric and is case-sensitive. The maximum length is 45 characters.
<i><subject-label></i>	Specifies the subject identity.

The following table defines parameters for the **certificate get** command.

Variable	Value
<code>cacert-from <A.B.C.D> <user> <file-path></code>	Specifies where to obtain the CA certificate. Specify the IP address, username, and remote file path.
<code>crl-from <A.B.C.D> <user> <file-path> <cacert-filename></code>	Specifies where to obtain the Certificate Revocation List. Specify the IP address, username, remote file path, and the CA certificate file to verify the CRL.
<code>signedcert-from <A.B.C.D> <user> <file-path> <subject-label></code>	Specifies where to obtain the subject certificate. Specify the IP address, username, remote file path, and subject label.

Generate the Certificate Signing Request on Fabric IPsec Gateway VM

About This Task

Use this procedure to generate a certificate signing request (CSR) and store it into a file. This CSR is required to obtain the offline subject certificate.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Generate the CSR:

```
certificate generate csr <subject-label>
```

3. Configure where to send the CSR for signing:

```
certificate send-csr-to <A.B.C.D> <user> <remote-path> <subject-label>
```

Variable Definitions

The following table defines parameters for the **certificate generate csr** command.

Variable	Value
<code><subject-label></code>	Specifies the subject identity.

The following table defines parameters for the **certificate send-csr-to** command.

Variable	Value
<A.B.C.D>	Specifies the IP address for the certificate authority.
<remote-path>	Specifies the file path on the certificate authority.
<subject-label>	Specifies the subject identity.
<user>	Specifies the username for the certificate authority.

Remove Keys and Certificates on Fabric IPsec Gateway VM

Before You Begin

You can remove subject certificates from the certificate authority (CA) trustpoint only if the subject-label is not configured on an IPsec tunnel.

About This Task

Use this procedure to remove keys or certificates from the certificate store.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
enable

virtual-service WORD<1-128> console

Note

Type **CTRL+Y** to exit the console.

2. Remove a key:
certificate remove key <key-label>
3. Remove a specific certificate from the store:
certificate remove offline-cacert <filename>
4. Remove a Certificate Revocation List (CRL) certificate from the store:
certificate remove offline-crl <filename>
5. Remove signed certificates for a specific subject label:
certificate remove offline-subject-certs <subject-label>
6. Remove a specific identity certificate from the CA trustpoint:
certificate ca <ca-trustpoint> remove <subject-label>
7. Remove all certificates from the CA trustPoint:
certificate ca <ca-trustpoint> clean

Variable Definitions

The following table defines parameters for the **certificate remove** command.

Variable	Value
<code>key <key-label></code>	Specifies the key name to remove.
<code>offline-cacert <filename></code>	Specifies the certificate filename to remove.
<code>offline-crl <filename></code>	Specifies the Certificate Revocation List (CRL) certificate filename to remove.
<code>offline-subject-certs <subject-label></code>	Specifies the subject label for which to remove signed certificates.

The following table defines parameters for the **certificate ca** command.

Variable	Value
<code><ca-trustpoint></code>	Specifies the name of the certificate authority. The name can be alphanumeric and is case-sensitive. The maximum length is 45 characters.
<code><subject-label></code>	Specifies the subject identity.

View the Certificate Details on Fabric IPsec Gateway VM

About This Task

Use this procedure for the following tasks:

- Display the digital certificate for a certificate type or list all the certificate details from the local store.
- Display the certificate authority (CA) details for a trustpoint CA name or list all the CA details from the local store if the CA name is not specified.
- Display the configured key details for a key name.
- Display the configured subject details.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Display all digital certificates:

```
show certificates all
```

3. Display the CA details:

```
show certificates cacert [<ca-label>]
```

4. Display Certificate Revocation List (CRL) certificate details:

```
show certificates crl [<ca-label>]
```

5. Display the certificate signing request (CSR) details:
`show certificates csr [<ca-label>]`
6. Display the name and public key of all the key-pairs:
`show certificate keys`
7. Display the details of signed certificates:
`show certificate signed [<ca-label>]`

Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>show certificates keys key_rsa
Key Label:      key_rsa
private key with:
pubkey:        RSA 2048 bits
keyid:         ef:4c:1d:a7:cc:84:6f:87:da:e4:de:99:07:3d:96:fc:9a:d1:c9:f4
subjkey:       cb:d1:67:a0:da:9c:05:ce:c0:0d:a3:5c:1b:ba:ce:3f:ff:af:8f:77
```

Variable Definitions

The following table defines parameters for the **show certificates** command.

Variable	Value
ca <ca-label>	Specifies the name of the certificate authority (CA). If you do not specify the name, the command displays the details of all configured CAs.

View the Certificate Configuration on Fabric IPsec Gateway VM

About This Task

Use this procedure to view the certificate configuration for the VM.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
`enable`
`virtual-service WORD<1-128> console`

**Note**

Type **CTRL+Y** to exit the console.

2. Display all configured entries:
`show running-config`
3. Display the CA trustpoint configuration:
`show certificate-config ca-trustpoint [<ca-label>]`
4. Display the subject-related configuration:
`show certificate-config subject [<subject-label>]`

Examples

```

Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>show certificate-config ca-trustpoint
certificate {
  ca-trustpoint {
    ca-label a;
    caname subCaVpn;
    ca-url http://10.2.38.35:8080/ejbca/publicweb/apply/scep/test/pkiclient.exe;
    get-method post;
  }
}

Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>show certificate-config subject
certificate {
  subject {
    subject-label fig;
    DN CN=FIGW;
    key-label gigi;
  }
  subject {
    subject-label figv;
    DN CN=figvpn;
  }
}

```

Configure Egress Shaping Rate for IPsec Tunnels on Fabric IPsec Gateway VM

Before You Begin

Before you can configure the egress shaping rate for the IPsec tunnel on the VM, you must first disable the IPsec tunnel.

About This Task

Perform this procedure to configure the egress shaping rate for IPsec tunnels on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**

Type **CTRL+Y** to exit the console.

2. Disable the IPsec tunnel:

```
delete ipsec <1-255> admin-state enable
```

3. Configure the egress shaping rate for the IPsec tunnel:

```
set ipsec <1-255> egress-shaping-rate <1-1000>
```

4. Enable the IPsec tunnel:

```
set ipsec <1-255> admin-state-enable
```

Example

Configuring egress-shaping-rate for the IPsec tunnel on the Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> delete ipsec 1 admin-state enable
FIGW> set ipsec 1 egress-shaping-rate 200
FIGW> set ipsec 1 admin-state enable
```

Variable Definitions

The following table defines parameters for the **set ipsec** command.

Variable	Value
<1-255>	Specifies the unique ID for the IPsec tunnel.
admin-state <enable disable>	Enables or disables IPsec on the specific IPsec tunnel.
egress-shaping-rate <1-1000>	Specifies the egress shaping rate for the IPsec tunnel.

Configure Logical Interface Tunnel on Fabric IPsec Gateway VM

About This Task

Perform this procedure to configure a Fabric Extend (FE) tunnel with only fragmentation and reassembly capabilities, on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
enable

virtual-service WORD<1-128> console

Note
Type **CTRL+Y** to exit the console.

2. Configure the logical interface destination IP address for the specific tunnel:
set logical-intf-tunnel <1-255> fe-tunnel-dest-ip {A.B.C.D}
3. Configure the Maximum Transmission Unit (MTU) value for the specific tunnel:
set logical-intf-tunnel <1-255> mtu <750-9000>

Note
The MTU range <750-9000> is applicable for FE tunnels with only fragmentation and reassembly capabilities.

4. Configure tunnel name:
set logical-intf-tunnel <1-255> tunnel-name WORD <1-64>

- Configure the egress shaping rate for a specific tunnel:

```
set logical-intf-tunnel <1-255> egress-shaping-rate <1-1000>
```

Example

Configuring logical interface tunnel on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> set logical-intf-tunnel 2 fe-tunnel-dest-ip 192.0.2.50
FIGW> set logical-intf-tunnel 2 mtu 1300
FIGW> set logical-intf-tunnel 2 egress-shaping-rate 5
FIGW> set logical-intf-tunnel 2 tunnel-name Tunnel-to-BEB2
```

Variable Definitions

The following table defines parameters for the **set logical-intf-tunnel** command.

Variable	Value
<1-255>	Specifies the unique ID for the logical interface tunnel.
<i>fe-tunnel-dest-ip</i> {A.B.C.D}	Specifies the FE tunnel destination IP address for the logical interface.
<i>mtu</i> <750-9000>	Specifies the Maximum Transmission Unit (MTU) value for the FE tunnel with only fragmentation and assembly capabilities.
<i>tunnel-name</i> WORD <1-64>	Specifies a name for the the logical interface tunnel.
<i>egress-shaping-rate</i> <1-1000>	Specifies the egress shaping rate for the logical interface tunnel.

Save Running Configuration to a File

About This Task

Perform this procedure to save the current configuration on Fabric IPsec Gateway Virtual Machine (VM) to a specific file.

Procedure

- Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

- Save configuration to the default configuration file:

```
save config [-y]
```

3. Save configuration to a specific file in the Fabric IPsec Gateway VM.

```
save config file WORD <1-255> [-y]
```

Example

Save the Fabric IPsec Gateway configuration to file "test":

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW>save config file test.txt
File already exists, do you want to overwrite [y/n]: y
```

Save the Fabric IPsec Gateway configuration to file "test", forcing the switch to overwrite the file without confirmation:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> save config file test.txt -y
```

Variable Definitions

The following table defines parameters for the **save config** command.

Variable	Value
<i>file</i> WORD <1-255>	Specifies the name of file to save the configuration of the Fabric IPsec Gateway VM.
-y	Forces the switch to overwrite the configuration file without confirmation.

Remove Configuration File from Fabric IPsec Gateway VM

About This Task

Perform this procedure to remove a specific configuration file from Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable

virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Remove the configuration file:

```
remove WORD <1-255>
```

Example

Remove configuration file "test" from Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> remove test
```

Variable Definitions

The following table defines parameters for the **remove** command.

Variable	Value
<i>WORD</i> <1-255>	Specifies the configuration file name that the system removes from Fabric IPsec Gateway VM.

Delete Global Configuration on Fabric IPsec Gateway VM

About This Task

Perform this procedure to delete the global parameters that you configure on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable

virtual-service WORD<1-128> console
```

Note
Type **CTRL+Y** to exit the console.

2. Delete configuration of specific global parameters:

```
delete global <fe-tunnel-gw-ip | fe-tunnel-src-ip | ipsec-disable |
ipsec-tunnel-src-ip | ipsec-tunnel-src-vlan | lan-intf-gw-ip | lan-
intf-ip | lan-intf-vlan | mtu | virtual-reassembly-intf-ip | virtual-
reassembly-intf-vlan | wan-intf-gw-ip>
```

Example

Deleting the global Maximum Transmission Unit (MTU) configuration on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> delete global mtu
```

Variable Definitions

The following table defines parameters for the **delete global** command.

Variable	Value
<i>fe-tunnel-gw-ip</i>	Deletes the global gateway IP address for Fabric Extend (FE) tunnel.
<i>fe-tunnel-src-ip</i>	Deletes the global source IP address for FE tunnel.
<i>ipsec-disable</i>	Deletes the global IPsec configuration.
<i>ipsec-tunnel-src-ip</i>	Deletes the global source IP address and subnet mask for IPsec tunnel.
<i>ipsec-tunnel-src-vlan</i>	Deletes the global source VLAN configuration for IPsec tunnel.
<i>lan-intf-gw-ip</i>	Deletes the global gateway IP address on the Local Area Network (LAN) interface.
<i>lan-intf-ip</i>	Deletes the global IP address and subnet mask on LAN interface.
<i>lan-intf-vlan</i>	Deletes the global VLAN configuration on LAN interface.
<i>mtu</i>	Resets the Maximum Transmission Unit (MTU) value to its default, that is 1950 bytes.
<i>virtual-reassembly-intf-ip</i>	Deletes the global virtual-reassembly interface IP address and subnet mask.
<i>virtual-reassembly-intf-vlan</i>	Deletes the global virtual-reassembly interface VLAN configuration.
<i>wan-intf-gw-ip</i>	Deletes the global gateway IP address on the Wide Area Network (WAN) interface.

Delete IPsec Tunnel Configuration on Fabric IPsec Gateway VM

Before You Begin

You must disable the IPsec administrative state on the tunnel before you can remove IPsec configuration.

About This Task

Perform this procedure to delete the configuration of a specific IPsec tunnel on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Delete the configuration of a specific tunnel:

```
delete ipsec <1-255> <admin-state enable | auth-key | encryption-key-length | fe-tunnel-dest-ip | fragment-before-encrypt enable | ipsec-dest-ip | mtu | responder-only | tunnel-name | egress-shaping-rate>
```

Example

Delete configuration on IPsec tunnel ID 2:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW>delete ipsec 2 admin-state enable
FIGW>delete ipsec 2 auth-key
FIGW>delete ipsec 2 tunnel-name
FIGW>delete ipsec 2 fragment-before-encrypt enable
```

Variable Definitions

The following table defines parameters for the **delete ipsec** command.

Variable	Value
<1-255>	Specifies the unique ID of the configured IPsec tunnel.
<i>admin-state enable</i>	Disables the IPsec status on the specific IPsec tunnel.
<i>auth-key</i>	Deletes the authentication key that you configure on the specific IPsec tunnel.
<i>encryption-key-length</i>	Resets the encryption key length for the specific IPsec tunnel to its default value, that is 128 bit.
<i>fe-tunnel-dest-ip</i>	Deletes the destination IP address that you configure on the Fabric Extend (FE) tunnel.
<i>fragment-before-encrypt enable</i>	Disables the fragmentation of packets before IPsec encryption on the tunnel. By default, fragmentation before encryption is disabled.
<i>ipsec-dest-ip</i>	Deletes the destination IP address that you configure on the IPsec tunnel.
<i>mtu</i>	Resets the Maximum Transmission Unit (MTU) value for the specific IPsec tunnel to the MTU value configured globally.
<i>responder-only</i>	Deletes the mode that you configure for the IPsec session in FE tunnel.
<i>tunnel-name</i>	Deletes the name that you configure for the IPsec tunnel.
<i>egress-shaping-rate</i>	Deletes the egress shaping rate for the IPsec tunnel.

Delete Logical Interface Tunnel Configuration on Fabric IPsec Gateway VM

About This Task

Perform this procedure to delete configuration of a specific logical interface tunnel on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**

Type **CTRL+Y** to exit the console.

2. Delete configuration of specific logical interface tunnel:

```
delete logical-intf-tunnel <1-255> < fe-tunnel-dest-ip | mtu | egress-
shaping-rate>
```

Example

Deleting the destination IP address for Fabric Extend (FE) tunnel configured on the logical interface tunnel with ID 3.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> delete logical-intf-tunnel 3 fe-tunnel-dest-ip
```

Variable Definitions

The following table defines parameters for the **delete logical-intf-tunnel** command.

Variable	Value
<i><1-255></i>	Specifies the unique ID of the logical interface tunnel.
<i>fe-tunnel-dest-ip</i>	Deletes the destination IP address that you configure on the logical interface tunnel.
<i>mtu</i>	Resets the Maximum Transmission Unit (MTU) value for the specific logical interface tunnel to the MTU value configured globally.
<i>egress-shaping-rate</i>	Deletes the egress shaping rate on the logical interface tunnel.

Display Data in a File on Fabric IPsec Gateway VM**About This Task**

Perform this procedure to display the data in a specific file on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
enable

virtual-service WORD<1-128> console

Note

Type **CTRL+Y** to exit the console.

2. Display data in a file:
more WORD <1-255>

Example

Display the data from coupled.cfg file:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> more coupled.cfg
set global ipsec-tunnel-src-vlan 125
set global ipsec-tunnel-src-ip 192.0.2.10/24
set global lan-intf-vlan 30
set global lan-intf-ip 192.0.2.20/24
set global lan-intf-gw-ip 192.0.2.25
set global fe-tunnel-src-ip 192.0.2.45
set global wan-intf-gw-ip 192.0.2.11
set global mtu 1950
set ipsec 1 auth-key *****
set ipsec 1 fe-tunnel-dest-ip 192.0.2.50
set ipsec 1 encryption-key-length 128
set ipsec 1 admin-state enable
```

Reboot Fabric IPsec Gateway VM

About This Task

Perform this procedure to reboot the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
enable

virtual-service WORD<1-128> console

Note

Type **CTRL+Y** to exit the console.

2. Reboot the VM:
reboot

Example

Rebooting Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> reboot
```

Reset Current Configuration on Fabric IPsec Gateway VM

About This Task

Perform this procedure to reset the current configuration on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**

Type **CTRL+Y** to exit the console.

2. Reset current configuration:

```
reset-config
```

**Note**

Reboot the Fabric IPsec Gateway VM after you reset the configuration.

Example

Resetting current configuration on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> reset-config
```

Traceroute to an IP address on Fabric IPsec Gateway VM

About This Task

Perform this procedure to traceroute to an IP address on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
enable

virtual-service WORD<1-128> console

**Note**

Type **CTRL+Y** to exit the console.

2. Traceroute to an IP address:
traceroute {A.B.C.D}

Example

Traceroute to IP address.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> traceroute 192.0.2.100
```

Variable Definitions

The following table defines parameters for the **traceroute** command.

Variable	Value
{A.B.C.D}	Specifies the IP address to initiate traceroute to.

Display the Default Configuration File on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the default configuration file on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
enable

virtual-service WORD<1-128> console

**Note**

Type **CTRL+Y** to exit the console.

2. Display default configuration file:
show default-config-file

Example

Displaying default configuration file on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show default-config-file
coupled.cfg
```

Display IPsec Logs on Fabric IPsec Gateway

About This Task

Perform this procedure to display IPsec session logs on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**

Type **CTRL+Y** to exit the console.

2. Display IPsec session logs:

```
show ipsec-logs
```

Example

Displaying IPsec session logs on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show ipsec-logs
<<Month dd>> <<hh:mm:ss>> 15[IKE] <ipsec0-192.0.2.10|29> sending DPD request
<<Month dd>> <<hh:mm:ss>> 15[ENC] <ipsec0-192.0.2.10|29> generating INFORMATIONAL request

--More-- (q = quit)
```

Display IPsec Routes on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the IPsec routes configured on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Display IPsec routes installed:

```
show ipsec-routes
```

Example

Displaying the IPsec routes configured on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show ipsec-routes
192.0.2.30 via 192.0.2.20 dev eth0.125 mtu lock 1950
192.0.2.1/24 dev eth0.30 proto kernel scope link src 192.0.2.2
192.0.2.10 via 192.0.2.45 dev eth0.30
192.0.2.100/24 dev eth0.125 proto kernel scope link src 192.0.2.60
192.0.2.11/16 dev docker0 proto kernel scope link src 192.0.2.12 linkdown
```

Display IPsec Encryption Statistics on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the IPsec encryption statistics on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Display IPsec encryption statistics:

```
show ipsec-stats
```

Example

Displaying IPsec encryption statistics on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show ipsec-stats

Display the Status of IPsec Tunnels on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the status of configured IPsec tunnel on the Fabric IPsec Gateway Virtual Machine (VM):

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Display the status of IPsec tunnels configured on the VM:

```
show ipsec-status
```

Example

Displaying the status of configured IPsec tunnel on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show ipsec-status
Status of IKE charon daemon (strongSwan 5.3.5, Linux 4.4.0-128-generic, x86_64):

Displays the IPsec Configuration on the Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the IPsec configuration on the Fabric IPsec Gateway Virtual Machine (VM):

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
enable

virtual-service WORD<1-128> console

Note

Type **CTRL+Y** to exit the console.

2. Display the IPsec configuration on the configured on the VM:
show ipsec-config <1-255>

Example

Displaying the IPsec configuration on the configured on the VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

FIGW> show ipsec-config 2
ipsec {
    tunnel_id 2;
    encryption-key-length 128;
    fe-tunnel-dest-ip 10.10.10.10;
    ipsec-dest-ip 70.70.70.73;
    mtu 1950;
    responder-only false;
    tunnel-name ----;
    auth-method psk;
    cert-subject;
    auth-key *****;
    egress-shaping-rate 110;
    fragment-before-encrypt enable;
    admin-state enable
```

Display the Logical Interface IPsec Configurations on the Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the logical interface IPsec configurations on the Fabric IPsec Gateway Virtual Machine (VM):

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
enable

virtual-service WORD<1-128> console

**Note**

Type **CTRL+Y** to exit the console.

2. Display the logical interface IPsec configurations on the VM:
show logical-intf-config <1-255>

Example

Displaying the logical interface IPsec configurations on the on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW>
FIGW> show logical-intf-config 1
logical-intf-tunnel {
    tunnel_id 1;
    tunnel-name ----;
    fe-tunnel-dest-ip 20.20.20.20;
    mtu 1950;
    egress-shaping-rate 110;
```

Display Current Configuration on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the parameters configured currently on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
enable

virtual-service WORD<1-128> console

**Note**

Type **CTRL+Y** to exit the console.

2. Display the parameters currently configured on the VM:
show running-config

Example

Displaying the parameters configured on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show running-config
set global ipsec-tunnel-src-vlan 125
set global ipsec-tunnel-src-ip 192.0.2.1/24
set global lan-intf-vlan 30
set global lan-intf-ip 192.0.2.10/24
set global lan-intf-gw-ip 192.0.2.25
set global fe-tunnel-src-ip 192.0.2.55
set global wan-intf-gw-ip 192.0.2.11
set global mtu 1950
set ipsec 1 auth-key *****
set ipsec 1 fe-tunnel-dest-ip 192.0.2.70
set ipsec 1 encryption-key-length 128
set ipsec 1 admin-state enable
```

Display Current Version of Fabric IPsec Gateway VM

About This Task

Display current version of the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**

Type **CTRL+Y** to exit the console.

2. Display current version of the VM:

```
show version
```

Example

Displaying current version of the Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW>show version
FabricIPSecGW_VM_4.0.0.0
```

Log Out of Fabric IPsec Gateway VM

About This Task

Perform this procedure to log out of the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

Note

Type **CTRL+Y** to exit the console.

2. Log out of VM:

```
exit
```

Example

Logging out of the Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> exit
```

Fabric Configuration Work Flow

This section describes the generic work flow to configure SPBM and IS-IS infrastructure and services on your network.

Note

This section is an overview. For further details on the SPBM and IS-IS infrastructure and configuration, see the sections described in the Documentation Sources section that follows.

1. Infrastructure configuration

As a first step, you must configure your basic infrastructure for Shortest Path Bridging MAC (SPBM).

2. Services configuration

After you complete the infrastructure configuration, you configure the appropriate services for your network to run on top of your base architecture. This includes:

- Layer 2 and Layer 3 VSNs
- IP Shortcuts
- Inter-VSN routing

3. Fabric interoperations

You can also configure Fabric gateway functionality like SPB-PIM Gateway and VXLAN Gateway.

4. Operations and Management

To debug connectivity issues and isolate network faults in the SPBM network, you can use Connectivity Fault Management (CFM).

Documentation Sources

See the following documentation sources:

- For information on basic SPBM infrastructure and IS-IS configuration and Layer 2 services, see [Fabric Basics and Layer 2 Services](#) on page 914.

This section also contains information on configuring Fabric Extend, which enables your enterprise to extend Fabric Connect technology over Layer 2 or Layer 3 core networks.

- For information on Fabric Layer 3 services configuration, see [Fabric Layer 3 Services](#) on page 1340.
- For information on IP Multicast over Fabric Connect configuration and services, see [IP Multicast over Fabric Connect](#) on page 1681. [SPB-PIM Gateway configuration](#) on page 3185 also contains information about configuring the SPB-PIM Gateway (SPB-PIM GW), which provides multicast inter-domain communication between an SPB network and a PIM network. The SPB-PIM GW can also connect two independent SPB domains.

- For information on CFM, see [Connectivity Fault Management](#) on page 3504.
- For information on VXLAN Gateway configuration, see [VXLAN Gateway](#) on page 3915.

SPBM and IS-IS Infrastructure Configuration

SPBM and IS-IS Infrastructure Fundamentals

Shortest Path Bridging MAC (SPBM) is a next generation virtualization technology that revolutionizes the design, deployment, and operations of carriers and service providers, along with enterprise campus core networks and the enterprise data center. SPBM provides massive scalability while at the same time reducing the complexity of the network.

SPBM eliminates the need for multiple overlay protocols in the core of the network by reducing the core to a single Ethernet based link-state protocol that provides all virtualization services in an integrated model. In addition, by relying on endpoint service provisioning only, the idea of building your network once and not touching it again becomes a true reality. This technology provides all the features and benefits required by carrier-grade, enterprise and service provider deployments without the complexity of alternative technologies, for example, Multiprotocol Label Switching (MPLS).

SPBM simplifies deployments by eliminating the need to configure multiple points throughout the network. When you add new connectivity services to an SPBM network you do not need intrusive core provisioning. The simple endpoint provisioning is done where the application meets the network, with all points in between automatically provisioned through the robust link-state protocol, Intermediate-System-to-Intermediate-System (IS-IS).

Most Ethernet based networks use 802.1Q tagged interfaces between the routing switches. SPBM uses two Backbone VLANs (B-VLANs) that are used as the transport instance. A B-VLAN is not a traditional VLAN in the sense that it does not flood unknown, broadcast or multicast traffic, but only forwards based on IS-IS provisioned backbone MAC (B-MAC) tables. After you configure the B-VLANs and the IS-IS protocol is operational, you can map the services to service instances.

SPBM uses IS-IS to discover and advertise the network topology, which enables it to compute the shortest path to all nodes in the SPBM network. SPBM uses IS-IS shortest path trees to populate forwarding tables for the individual B-MAC addresses of each participating node.

To forward customer traffic across the core network backbone, SPBM uses IEEE 802.1ah Provider Backbone Bridging (PBB) MAC-in-MAC encapsulation, which hides the customer MAC (C-MAC) addresses in a backbone MAC (B-MAC) address pair. MAC-in-MAC encapsulation defines a B-MAC destination address (BMAC-DA) and a B-MAC source address (BMAC-SA). Encapsulating customer MAC addresses in B-MAC addresses improves network scalability (no end-user C-MAC learning is required in the core) and also significantly improves network robustness (loops have no effect on the backbone infrastructure.)

The SPBM B-MAC header includes a Service Instance Identifier (I-SID) with a length of 32 bits with a 24-bit ID. I-SIDs identify and transmit virtualized traffic in an encapsulated SPBM frame. You can use I-SIDs in a Virtual Services Network (VSN) for VLANs or VRFs across the MAC-in-MAC backbone:

- **Unicast**

- For a Layer 2 VSN, the device associates the I-SID with a customer VLAN, which the device then virtualizes across the backbone. Layer 2 VSNs associate one VLAN per I-SID.
- With Layer 3 VSN, the device associates the I-SID with a customer VRF, which the device virtualizes across the backbone. Layer 3 VSNs associate one VRF per I-SID.
- With Inter-VSN routing, Layer 3 devices, routers, or hosts connect to the SPBM cloud using the SPBM Layer 2 VSN service. The Backbone Core Bridge can transmit traffic between different VLANs with different I-SIDs.
- With IP shortcuts, no I-SID is required, forwarding for the Global Routing Table (GRT) is done using IS-IS based shortest path BMAC reachability.

For more information on Fabric Layer 3 services, see [Fabric Layer 3 Services](#) on page 1340.

- **Multicast**

- With Layer 2 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and the scope I-SID is based on the Layer 2 VSN I-SID.
- With Layer 3 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and the scope I-SID is based on the Layer 3 VSN I-SID.
- With IP Shortcuts with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream, but there is no I-SID for the scope, which is the Global Routing Table (GRT).

For more information on IP multicast over Fabric Connect, see [IP Multicast over Fabric Connect](#) on page 1681.

**Note**

Inter-VSN routing for IP multicast over Fabric Connect is not supported.

The switch supports the IEEE 802.1aq standard of SPBM, which allows for larger Layer 2 topologies and permits faster convergence.

Multiple tenants using different SPBM services

The following figure shows multiple tenants using different services within an SPBM metro network. In this network, you can use some or all of the SPBM implementation options to meet the needs of the community while maintaining the security of information within VLAN members.

Figure 55: Multi-tenant SPBM metro network

To illustrate the versatility and robustness of SPBM even further, the following figure shows a logical view of multiple tenants in a ring topology. In this architecture, each tenant has its own domain where some users have VLAN requirements and are using Layer 2 VSNs and others have VRF requirements and are using Layer 3 VSNs. In all three domains, they can share data center resources across the SPBM network.

Figure 56: SPBM ring topology with shared data centers

spbm-config-mode boot flag

Shortest Path Bridging (SPB) and Protocol Independent Multicast (PIM) cannot interoperate with each other on the switch at the same time. The boot flag called **spbm-config-mode** ensures that SPB and PIM stay mutually exclusive.

- The **spbm-config-mode** boot flag is enabled by default. This enables you to configure SPB and IS-IS, but you cannot configure PIM either globally or on an interface.
- If you disable the boot flag, save the configuration and reboot with the saved configuration. After you enable the flag, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

**Important**

- Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.
- If you disable the boot flag, save the configuration and reboot with the saved configuration. After you disable the flag, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

For more information, see [IP Multicast](#) on page 1456.

vxlan-gw-full-interworking-mode Boot Configuration Flag

The VXLAN Gateway implementation is available in the following modes:

- **Base Interworking Mode** – This is the default mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments.
- **Full Interworking Mode** – This mode supports the Base mode communication between VXLAN and traditional VLAN environments as well as VXLAN-to-VXLAN communication and all SPB functionality including vIST and SMLT. To enter this mode, you must enable the **vxlan-gw-full-interworking-mode** boot configuration flag.

**Note**

Changing the mode requires a reboot for the change to take effect.

MAC-in-MAC encapsulation

To forward customer traffic across the core network backbone, SPBM uses IEEE 802.1ah Provider Backbone Bridging (PBB) MAC-in-MAC encapsulation, which hides the customer MAC (C-MAC) addresses in a backbone MAC (B-MAC) address pair. MAC-in-MAC encapsulation defines a B-MAC source address (BMAC-SA) and a B-MAC destination address (BMAC-DA) to identify the backbone source and destination addresses.

The originating node creates a MAC header that is used for delivery from end to end. As the MAC header stays the same across the network, there is no need to swap a label or do a route lookup at each node, allowing the frame to follow the most efficient forwarding path end to end.

Encapsulating customer MAC addresses in B-MAC addresses improves network scalability (no end-user C-MAC learning is required in the core) and also significantly improves network robustness (loops in access networks do not impact forwarding results in the backbone infrastructure.)

I-SID

SPBM introduces a service instance identifier called I-SID. SPBM uses I-SIDs to separate services from the infrastructure. After you create an SPBM infrastructure, you can add additional services (such as VLAN extensions or VRF extensions) by provisioning the endpoints only. The SPBM endpoints are Backbone Edge Bridges (BEBs), which mark the boundary between the core MAC-in-MAC SPBM domain and the edge customer 802.1Q domain. I-SIDs are provisioned on the BEBs to be associated with a particular service instance. In the SPBM core, the bridges are Backbone Core Bridges (BCBs). BCBs forward encapsulated traffic based on the B-MAC-DA.

The SPBM B-MAC header includes a Service Instance Identifier (I-SID) with a length of 32 bits with a 24-bit ID. I-SIDs identify a service instance for virtualized traffic in an encapsulated SPBM frame. You can use I-SIDs in a Virtual Services Network (VSN) for VLANs or VRFs across the MAC-in-MAC backbone:

- For a Layer 2 VSN, the I-SID is associated with a customer VLAN, which is then virtualized across the backbone. Layer 2 VSNs offer an any-any LAN service type. Layer 2 VSNs associate one VLAN per I-SID.
- For a Layer 2 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and a scope I-SID that defines the scope as Layer 2 VSN. A multicast stream with a scope of Layer 2 VSN can only transmit a multicast stream for the same Layer 2 VSN.
- For a *Transparent Port UNI*, the I-SID is associated with a port or MLT, which is then virtualized across the backbone. *Transparent Port UNI* associates multiple ports or MLT to an I-SID.
- For a Layer 3 VSN, the I-SID is associated with a customer VRF, which is also virtualized across the backbone. Layer 3 VSNs are always full-mesh topologies. Layer 3 VSNs associate one VRF per I-SID.
- For a Layer 3 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and a scope I-SID that defines the scope as Layer 3 VSN. A multicast stream with a scope of Layer 3 VSN can only transmit a multicast stream for the same Layer 3 VSN.
- For IP Shortcuts with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and defines the scope as Layer 3 GRT. A multicast stream with a scope of Layer 3 GRT can only transmit a multicast stream for a Layer 3 GRT.

Note

I-SID configuration is required only for virtual services such as Layer 2 VSN and Layer 3 VSN. With IP Shortcuts with unicast, no I-SID is required, forwarding for the Global Routing table is done using IS-IS based shortest path B-MAC reachability.

Note

I-SID to VLAN binding is used to automatically determine the path between client and server in order to attach network devices to FA Zero touch services.

*BCBs and BEBs***Table 85: Fabric Mode product support**

	VSP 8600 Series	VSP 8600 6.1
	XA1400 Series	VOSS 8.0.50

The boundary between the core MAC-in-MAC SPBM domain and the edge customer 802.1Q domain is handled by Backbone Edge Bridges (BEBs). I-SIDs are provisioned on the BEBs to be associated with a particular service instance.

In the SPBM core, the bridges are referred to as Backbone Core Bridges (BCBs). BCBs forward encapsulated traffic based on the BMAC-DA.

**Important**

SPBM separates the payload from the transport over the SPBM infrastructure. Configure all virtualization services on the BEBs at the edge of the network. There is no provisioning required on the core SPBM switches. This provides a robust carrier grade architecture where configuration on the core switches never needs to be touched when adding new services.

A BEB performs the same functionality as a BCB, but it also terminates one or more Virtual Service Networks (VSN). A BCB does not terminate any VSNs and is unaware of the VSN traffic it transports. A BCB simply knows how to reach any other BEB in the SPBM backbone.

VLANs without member ports

If a VLAN is attached to an I-SID there must be another instance of that same I-SID in the SPBM network.

- If another instance of that I-SID exists, the device designates that VLAN as operationally up regardless of whether it has a member port or not.

When the VLAN is operationally up, the IP address of the VLAN will be in the routing table.

- If no matching instance of the I-SID exists in the SPBM network, then that VLAN has no reachable members and does not act as an NNI interface.

The VLAN does not act as a UNI interface because it does not have a member port.

Therefore, the device does not designate the VLAN as operationally up because the VLAN does not act as a UNI or an NNI interface.

If the device acts as a BCB with two VLANs configured and two I-SIDs, there must be a UNI side with the corresponding I-SID existing in the network.

If the device acts as both BEB and BCB, then there must be a member port in that VLAN to push out the UNI traffic.

Basic SPBM network topology

The following figure shows a basic SPBM network topology, specifically a Layer 2 VSN. Switches A and D are the Backbone Edge Bridges (BEB) that provide the boundary between the customer VLANs (C-VLAN) and the Backbone. Switches B and C are the Backbone Core Bridges (BCB) that form the core of the SPBM network.

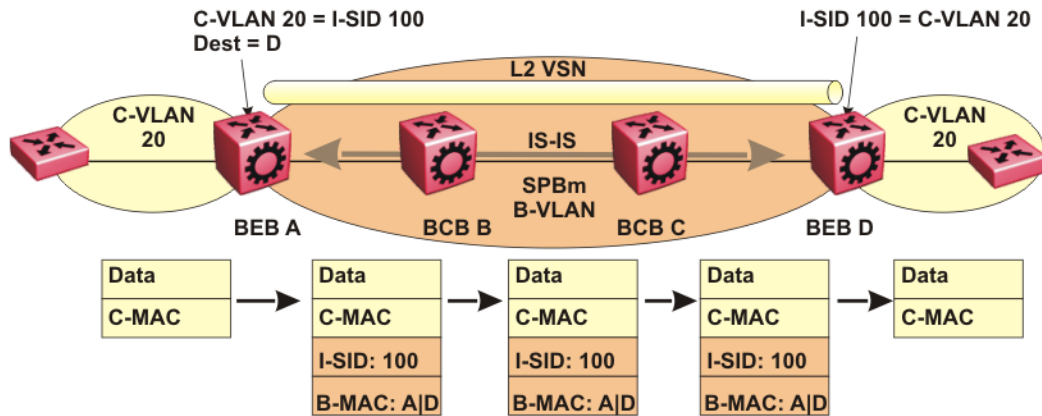

Figure 57: SPBM L2 VSN

SPBM uses IS-IS in the core so that all BEBs and BCBS learn the IS-IS System-ID (B-MAC) of every other switch in the network. For example, BEB-A uses IS-IS to build an SPBM unicast forwarding table containing the B-MAC of switches BCB-B, BCB-C, and BEB-D.

The BEBs provide the boundary between the SPBM domain and the virtualized services domain. For a Layer 2 VSN service, the BEBs map a C-VLAN to an I-SID based on local service provisioning. Any BEB in the network that has the same I-SID configured can participate in the same Layer 2 VSN.

In this example, BEB A and BEB D are provisioned to associate C-VLAN 20 with I-SID 100. When BEB A receives traffic from C-VLAN 20 that must be forwarded to the far-end location, it performs a lookup and determines that C-VLAN 20 is associated with I-SID 100 and that BEB D is the destination for I-SID 100. BEB A then encapsulates the data and C-MAC header into a new B-MAC header, using its own nodal B-MAC: A as the source address and B-MAC: D as the destination address. BEB A then forwards the encapsulated traffic to BCB B.

To forward traffic in the core toward the destination node D, BCB B and BCB C perform Ethernet switching using the B-MAC information only.

At BEB D, the node strips off the B-MAC encapsulation, and performs a lookup to determine the destination for traffic with I-SID 100. BEB D identifies the destination on the C-VLAN header as C-VLAN 20 and forwards the packet to the appropriate destination VLAN and port.

Ethernet Private Tree (E-Tree) extends Shortest Path Bridging MAC (SPBM) to Private VLANs (PVLAN).

Transport within the SPBM network is achieved by associating the private VLAN with an I-SID. Flooded traffic from both promiscuous and isolated devices is transported over the same I-SID multicast tree

and suppression for spoke-to-spoke traffic is done on the egress SPB Backbone Edge Bridge (BEB). This means the Private VLAN IDs are globally significant and must be the same on all BEBs

The following list provides details for E-Tree and Private VLAN topology:

- E-Tree associates a Private VLAN with an I-SID.

Note

The same I-SID could be attached to a regular VLAN. In that case, all ports on the regular VLAN behave like Promiscuous ports on the PVLAN.

- Other SPB BEBs can associate a regular CVLAN to the same I-SID that E-Tree uses.

Note

The CVLAN ID must match the primary PVLAN ID.

- CVLAN devices assigned to the same I-SID that E-Tree uses have Promiscuous connectivity within the segment.

The following figure shows a basic E-Tree network topology consisting of groups of private VLANs connected by the SPBM core network.

Figure 58: Sample E-Tree configuration

Private VLAN port types

The private VLAN port type is isolated, promiscuous, or trunk. If the port is a member of an MLT, then the port inherits the private VLAN type of the MLT.

In terms of network topology, the isolated port is considered a spoke. The isolated port, or spoke, does not communicate with any other isolated port in the network. The isolated port only communicates with the promiscuous ports, or hubs.

E-Tree and Private VLAN limitations

The following limitations apply to E-Tree and Private VLAN topology:

- A port that is of Private VLAN type trunk must be tagged. Isolated and Promiscuous Private VLAN ports can be either tagged or untagged.
- When a port or MLT that has a Private VLAN type set to Isolated or Promiscuous is added to a private VLAN, if that port is used by other non private VLANs, then those non private VLANs are removed.
- A port which is Private VLAN type Isolated and is tagged can belong to only one Private VLAN.

IS-IS

SPBM eliminates the need for multiple overlay protocols in the core of the network by reducing the core to a single Ethernet-based, link-state protocol (IS-IS). IS-IS provides virtualization services using a pure Ethernet technology base. SPBM also uses IS-IS to discover and advertise the network topology, which enables it to compute the shortest path to all nodes in the SPBM network.

IS-IS is a link-state, interior gateway protocol that was developed for the International Organization for Standardization (ISO). ISO terminology refers to routers as Intermediate Systems (IS), hence the name Intermediate System-to-Intermediate System (IS-IS).

To provide a loop-free network and to learn and distribute network information, SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol. IS-IS is designed to find the shortest path from any one destination to any other in a dynamic fashion. IS-IS creates any-to-any connectivity in a network in an optimized, loop-free manner, without the long convergence delay experienced with the Spanning Tree Protocol. IS-IS does not block ports from use, but rather employs a specific path. As such, all links are available for use.

IS-IS dynamically learns the topology of a network and constructs unicast and multicast mesh connectivity. IS-IS parallel adjacency support allows you to configure multiple IS-IS links between the two nodes. Each node in the network calculates a shortest-path tree to every other network node based on System-IDs (B-MAC addresses). Only one adjacency with the shortest path is selected as an active adjacency.

**Note**

Only an active interface with an active adjacency is added into local SPF calculations. This mechanism ensures the local node selects the shortest path and has the same view as the rest of the SPB network.

In the SPBM environment for Layer 2 VSNs, IS-IS carries only pure Layer 2 information with no requirement for an underlying IP control plane or forwarding path. IS-IS runs directly over Layer 2.

**Note**

SPBM carries Layer 3 information for Layer 3 VSNs.

In SPBM networks, IS-IS performs the following functions:

- Discovers the network topology
- Builds shortest path trees between the network nodes:
 - Forwards unicast traffic
 - Determines the forwarding table for multicast traffic
- Communicates network information in the control plane:
 - Service Instance Identifier (I-SID) information

SPBM can distribute I-SID service information to all SPBM nodes, as the I-SIDs are created. SPBM includes I-SID information in the IS-IS Link State protocol data units (PDUs). When a new service instance is provisioned on a node, its membership is flooded throughout the topology using an IS-IS advertisement.

Standard TLVs

IS-IS uses Type-Length-Value (TLV) encoding. SPBM employs IS-IS as the interior gateway protocol and implements additional TLVs to support additional functionality. The switch also supports Sub-TLVs. TLVs exist inside IS-IS packets and Sub-TLVs exist as additional information in TLVs.

The switch supports and is in full compliance with standard 802.1aq TLVs. The IEEE ratified the 802.1aq standard that defines SPBM and the Type-Length-Value (TLV) encoding that IS-IS uses to support SPBM services. The following table lists all the TLVs that the switch supports.

Table 88: Standard TLVs

TLV	Description	Usage
1	Area addresses — The Area Addresses TLV contains the area addresses to which the IS-IS is connected.	IS-IS area
22	Extended IS reachability — The Extended IS Reachability TLV contains information about adjacent neighbors.	IS-IS adjacencies Sub-TLV 29: SPBM link metric is carried within this TLV.
129	Protocols supported — The Protocol supported TLV carries the Network Layer Protocol Identifiers (NLPID) for the Network Layer protocols where the IS-IS can be used.	SPBM in addition to existing NLPID (IPV4 0xCC, IPV6 0xE..), IEEE 802.1aq defined SPBM NLPID as 0xC1.
135	Extended IP reachability — The Extended IP Reachability TLV 135 is used to distribution IP reachability between IS-IS peers.	SPBM uses this existing IS-IS TLV to carry IP Shortcut routes in the Global Routing Table (GRT).

Table 88: Standard TLVs (continued)

TLV	Description	Usage
143	<p>Multi-topology port aware capability (MT-Port-Capability) TLV This TLV carries the SPB instance ID in a multiple SPB instances environment. This TLV is carried within IS-IS Hello Packets (IIH), only when parallel links exist.</p>	<p>This TLV carries the following SPBM Sub TLV:</p> <ul style="list-style-type: none"> Sub-TLV 6: SPB B-VLAN Sub TLV indicates the mapping between a VLAN and its equal cost tree (ECT) algorithm. To form an adjacency, both nodes must have a matching primary (B-VLAN, ECT) pair, and secondary (B-VLAN, ECT) pair, the number of B-VLANs must be equal, B-VLAN values must match, ECT values for the B-VLANs must match. Used in IS-IS Hellos only. MCID Sub TLV: The MCID is a digest of the VLANs and MSTI. Neighboring SPBM nodes must agree on the MCID to form an adjacency. The MCID is set to all zeros (0). <p>After the switch receives a non-zero MCID Sub TLV, it reflects content back to the neighbor.</p> <ul style="list-style-type: none"> Link L1 Metric Sub-TLV 7: Contains L1 metric of the link
144	<p>Multi-topology Capability (MT-Capability) TLV. This TLV carries the SPB instance ID in a multiple SPB instance environment. This TLV is carried within LSPs. In multicast over Fabric Connect, TLV 144 on the BEB bridge, where the sender is located, has the transmit (Tx) bit set. On the BEB bridge, where the receiver is located the receive (Rx) bit is set.</p>	<p>TLV 144 is the service identifier TLV. TLV 144 advertizes B-MAC and I-SID information. This TLV carries the following Sub TLVs: Sub-TLV 1: SPB instance Sub TLV contains a unique SPSourceID (nickname) to identify the SPBM node within this SPB topology. Sub-TLV 3: SPB Service ID (I-SID) is stored in TLV 144 sub-TLV 3. Sub-TLV 3 carries service group membership (I-SIDs) for a particular SPBM B-VLAN.</p>
184	<p>SPBM IP VPN reachability — IS-IS TLV 184 is used to advertise SPBM L3 VSN route information across the SPBM cloud.</p>	<p>IP reachability for Layer 3 VSNs</p>

Table 88: Standard TLVs (continued)

TLV	Description	Usage
185	IPVPN multicast TLV with IPMC sub TLV — The IPVPN multicast TLV contains information about the scope I-SID.	TLV 185 on the BEB bridge, where the source is located, displays the multicast source and group addresses and has the transmit (Tx) bit set. Each multicast group has its own data I-SID that maps to the source and group addresses. As part of the IPVPN TLV, sub-TLVs define IPv4 unicast, IPv6 unicast and IPv4 multicast information. Layer 2 VSN IP multicast over Fabric Connect and Layer 3 VSN IP multicast over Fabric Connect (using VRF) use TLV 185.
186	IP multicast TLV (GRT) — TLV 186 on the BEB bridge, where the source is located, displays the multicast source and group addresses and has the transmit (Tx) bit set. Each multicast group has its own data I-SID that maps to the source and group addresses.	IP Shortcuts with IP multicast over Fabric Connect use TLV 186. All multicast streams are constrained within the level in which they originate, which is called the scope level.
236	IPv6 Reachability — The IPv6 reachability TLV 236 is used to distribute IPv6 network reachability between IS-IS peers.	SPBM uses the existing IS-IS TLV to carry IPv6 shortcut routes through the SPBM core.

For more information on IP multicast over Fabric Connect, see [IP Multicast over Fabric Connect](#) on page 1681.

IS-IS hierarchies

IS-IS is a dynamic routing protocol that operates within an autonomous system (or domain). IS-IS provides support for hierarchical routing, which enables you to partition large routing domains into smaller areas. When used separately from SPBM, IS-IS uses a two-level hierarchy, dividing the domain into multiple Level 1 areas and one Level 2 area. When used separately from SPBM, the Level 2 area serves as backbone of the domain, connecting to all the Level 1 areas. SPBM currently uses only Level 1 areas.

Important

The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled.

IS-IS PDUs

Intermediate System to Intermediate System Hello (IIH) packets discover IS-IS neighbors and establish and maintain IS-IS adjacencies. An IIH is sent in every Hello-interval to maintain the established

adjacency. If a node has not heard IIHs from its neighbor for (hello-interval x hello-multiple) seconds, the node tears down the adjacency. IIH carries TLV 143 and SPB B-VLAN Sub-TLV (among other sub-TLVs). For two nodes to form an adjacency the B-VLAN pairs for primary B-VLAN and secondary B-VLAN must match.

Link State Packets (LSP) advertise link state information. The system uses the link state information to compute the shortest path. LSP also advertises MT-capability TLV 144 and SPB instance Sub-TLV, and SPB I-SIDs Sub-TLV.

Complete Sequence Number Packets (CSNP) contain the most recent sequence numbers of all LSPs in the database. CSNP notifies neighbors about the local LSDB. After a neighbor receives a CSNP, it compares the LSPs in the CSNP with the LSP in the local LSDB. If the neighbor is missing LSPs, it sends a Partial Sequence Number Packets (PSNP) to request the missing LSPs. This process synchronizes the LSDBs among neighbors. A synchronized LSDB among all nodes in the network is crucial to producing a loop-free shortest path.

IS-IS configuration parameters

IS-IS system identifiers

The IS-IS system identifiers consist of three parts:

- System ID — The system ID is any 6 bytes that are unique in a given area or level. The system ID defaults to the baseMacAddress of the chassis but you can configure a non-default value. The system ID must use a unicast MAC address; do not use a multicast MAC address. A MAC address that has the low order bit 1 set in the highest byte is a multicast MAC address. For example, the following are multicast MAC addresses: x1xx.xxxx.xxxx, x3xx.xxxx.xxxx, x5xx.xxxx.xxxx, x7xx.xxxx.xxxx, x9xx.xxxx.xxxx, xBxx.xxxx.xxxx, xDxx.xxxx.xxxx, and xFxx.xxxx.xxxx.
- Manual area — The manual area or area ID is up to 13 bytes long. The first byte of the area number (for example, 49) is the Authority and Format Indicator (AFI). The next bytes are the assigned domain (area) identifier, which is up to 12 bytes (for example, 49.0102.0304.0506.0708.0910.1112). IS-IS supports a maximum of three manual areas, but the switch software only supports one manual area.
- NSEL — The last byte (00) is the n-selector. In this implementation, this part is automatically attached. There is no user input accepted.

The Network Entity Title (NET) is the combination of all three global parameters.

All routers have at least one manual area. Typically, a Level 1 router does not participate in more than one area.

The following are the requirements for system IDs:

- All IS-IS enabled routers must have one manual area and a unique system ID.
- All routers in the same area must have the same area ID.
- All routers must have system IDs of the same length (6 bytes).
- All IS-IS enabled routers must have a unique nickname.

PSNP interval

You can change the PSNP interval rate. A longer interval reduces overhead, while a shorter interval speeds up convergence.

CSNP periodic and interval rate

You can configure the CSNP periodic and interval rate. A longer interval reduces overhead, while a shorter interval speeds up convergence.

Parameters for the link state packet

Link state packets (LSPs) contain vital information about the state of adjacencies, which must be exchanged with neighboring IS-IS systems. Routers periodically flood LSPs throughout an area to maintain synchronization. You can configure the LSP to reduce overhead or speed up convergence.

The following list describes IS-IS parameters related to LSPs:

- The **max-lsp-gen-interval** is the time interval at which the generated LSP is refreshed. The default is 900 seconds with a range of 30 to 900.
- The **retransmit-lsp-interval** is the minimum amount of time between retransmission of an LSP. When transmitting or flooding an LSP an acknowledgement (ACK) is expected. If the ack is not received within **retransmit-lsp-interval**, the LSP is re-transmitted. The default is 5 seconds with a range of 1 to 300.

Point-to-point mode

All SPBM links are point-to-point links. The switch does not support broadcast links.

IS-IS interface authentication

Configure IS-IS interface authentication to improve security and to guarantee that only trusted routers are included in the IS-IS network. Interface level authentication only checks the IIH PDUs. If the authentication type or key in a received IIH does not match the locally-configured type and key, the IIH is rejected. By default, authentication is disabled.

You can use either one of the following authentication methods:

- Simple password authentication — Uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet.
- MD5 authentication — Creates a Message Digest (MD5) key.
- SHA-256 — Adds a Hash-based Message Authentication Code (HMAC) digest to each IS-IS Hello packet.

Important

If the `.isis_md5key.txt` and `.isis_simplekey.txt` are missing, IS-IS adjacencies cannot be established.

Password considerations

To reset the authentication password type, you must set the type to none.

The switch software supports only interface level authentication. The switch software does not support area level or domain level authentication.

SHA-256 considerations

IS-IS Hello packets are sent periodically to discover IS-IS neighbors, and to establish and maintain IS-IS adjacencies. If you enable SHA-256 authentication, the switch adds an HMAC-SHA256 digest to each Hello packet.

**Note**

The interfaces used to make the adjacencies must have SPBM configured.

The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet.

Directly connected switches must share the same key (secret), which can have a maximum length of 16 characters.

Hellos

To update the identities of neighboring routers, you can configure the:

- IS-IS Interface Level 1 Hello interval
- IS-IS Interface Level 1 Hello multiplier

IS-IS Interface Level 1 Hello interval

IS-IS uses level 1 Hello packets to initialize and maintain adjacencies between neighboring routers.

You can configure the IS-IS interface level 1 Hello interval to change how often Hello packets are sent out from an interface level.

IS-IS Interface Level 1 Hello multiplier

You can configure the IS-IS interface level 1 Hello multiplier to specify how many Hellos the switch must miss before it considers the adjacency with a neighboring switch down. By default, the hold (wait) time is the Hello interval multiplied by the Hello multiplier. By default, if the Hello interval is 9 and the Hello multiplier is 3, the hold time is 27. If the Hello multiplier is increased to 10, the hold time is increased to 90.

IS-IS Interface Level 1 Link metric

You can configure the IS-IS interface level 1 link metric to overwrite the default metric value. By configuring the metric, you can specify a preferred path. Low cost reflects high-speed media, and high cost reflects slower media. For the wide metric, the value ranges from 1 to 16,777,215.

- The switch only supports the wide metric.
- The total cost of a path equals the sum of the cost of each link.

- The default value for wide metrics is 10.

**Note**

When multiple paths exist to reach a node, the path with the lowest sum of metrics of the individual links is chosen. If the sum of the paths are the same, the one with the lowest number of hops is chosen. If the number of hops is the same as well, then the tie-breaking is done by the system ID.

For the primary B-VLAN, the path that has a node with the lowest system ID is chosen.

Whereas, for the secondary B-VLAN, the path that has a node with the highest system ID is chosen.

Disabling IS-IS

You can disable IS-IS globally or at the interface level. If IS-IS is globally disabled, then all IS-IS functions stop. If IS-IS is enabled at the global level and disabled at one of the interface levels, then IS-IS continues on all other interfaces.

Overload Bit

A node sends the overload bit in LSP updates to inform other devices whether to use that node to pass transit traffic. For example, when a device receives an LSP with an overload bit, the device ignores that LSP in its Shortest Path First (SPF) calculation to avoid sending transit traffic through the overloaded node; however, the overloaded node can still receive traffic destined to itself.

The system activates the overload bit on bootup and clears it after 20 seconds. You can use the **overload-on-startup** parameter to control the time before the overload bit is cleared after bootup.

You can permanently configure the overload bit using the **overload** parameter. If you use this parameter, the system does not clear the overload bit after bootup and sends it in all LSP updates. If the overload bit is configured, other devices do not include this node for use as a transit node in IS-IS computations. By default, the **overload** parameter is set to false.

The **overload** and **overload-on-startup** parameters are configured under the `router isis` configuration mode in the CLI.

When IS-IS is enabled on a switch, the switch delays a reset by two seconds so that LSPs with the overload bit can be sent to all Backbone Edge Bridges (BEB) and Backbone Core Bridges (BCB) in the SPB domain.

SPBM B-VLAN

Each SPBM network instance is associated with at least one backbone VLAN (B-VLAN) in the core SPBM network.

**Note**

SPB internally uses spanning tree group (STG) 63 or Multiple Spanning Tree Instance (MSTI) 62. STG 63 or MSTI 62 cannot be used by another VLAN or MSTI. For non-SPB customer networks, if you use STG 63 or MSTI 62 in the configuration, you must delete STG 63 or MSTI 62 before you can configure SPBM.

This VLAN is used for both control plane traffic and dataplane traffic.

**Note**

Always configure two B-VLANs in the core to allow load distribution over both B-VLANs.

SPBM alters the behavior of the VLAN. When a B-VLAN is associated with an SPBM network the following VLAN attributes and behaviors are modified for the B-VLAN:

- Flooding is disabled
- Broadcasting is disabled
- Source address learning is disabled
- Unknown MAC discard is disabled

You cannot add ports to a B-VLAN manually, IS-IS enabled ports are automatically added to the B-VLAN.

Essentially the B-MAC addresses are programmed into the B-VLAN Forwarding Information Bases (FIBs) by IS-IS instead of the traditional VLANs flooding and learning approach.

Modification of the VLAN behavior is necessary to ensure proper control over the SPBM traffic.

Pre-populated FIB

An Ethernet network usually learns MAC addresses as frames are sent through the switch. This process is called reverse learning and is accomplished through broadcast.

SPBM does not allow any broadcast flooding of traffic on the B-VLAN in order to prevent looping accomplished through flooding packets with unknown destinations (although multicast traffic is supported). As such, MAC addresses must be distributed within SPBM. This is accomplished by carrying the necessary B-MAC addresses inside the IS-IS link state database. To that end, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. This functionality enables the powerful end-point-provisioning of SPBM.

These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB) to maximize efficiency and to allow Reverse Path Forwarding Check (RPFC) to operate properly.

RPFC

A loop prevention mechanism is required at Layer 2 to stop wayward traffic from crippling the network. Reverse Path Forwarding Check (RPFC) is the chosen method of suppressing loop traffic with SPBM. RPFC was originally designed for IP traffic at Layer 3 where it checks the source address of the packet against the routing entry in the routing table. The source address must match the route for the port it came in on otherwise the packet is illegitimate and therefore dropped.

With SPBM, the node matches the source B-MAC address against the ingress port to establish validity. If the frame is not supposed to come in that port, it is immediately suppressed imposing a guaranteed loop control. If there is no VLAN FDB entry to the source MAC address with the outgoing port as the ingress port, the frame will be dropped.

SPBM Unicast FIB

Unicast FIB

The unicast computation runs a single Dijkstra (unlike all pair Dijkstras for multicast). SPBM produces only one Shortest Path First (SPF) tree and the tree is rooted on the computing node.

The unicast computation generates an entry for each node in the network. The Destination Address (DA) for that entry is the system-id of the node. In addition, if a node advertises MAC addresses other than the system-id, each MAC address has an entry in the unicast FIB table, and the shortest path to that MAC should be exactly the same as the path to the node.

Unicast FIB entries are installed to the vlan-fdb table.

The following text shows an example of the unicast FIB.

```

SPBM Restrictions

RSTP and MSTP

The following list identifies restrictions and limitations associated with RSTP and MSTP:

- RSTP mode does not support SPBM.
- A C-VLAN-level loop across SPBM NNI ports cannot be detected and needs to be resolved at the provisional level.
- SPBM NNI ports are not part of the Layer 2 VSN C-VLAN, and BPDUs are not transmitted over the SPBM tunnel. SPBM can only guarantee loop-free topologies consisting of the NNI ports. You should always use Simple Loop Prevention Protocol (SLPP) in an SMLT environment.

Note

Deploy SLPP on C-VLANs to detect loops created by customers in their access networks. However, SLPP is not required on B-VLANs, and it is not supported. The B-VLAN active topology is controlled by IS-IS that has loop mitigation and prevention capabilities built into the protocol.

- SPB internally uses spanning tree group (STG) 63 or Multiple Spanning Tree Instance (MSTI) 62. STG 63 or MSTI 62 cannot be used by another VLAN or MSTI. For non-SPB customer networks, if you use

STG 63 or MSTI 62 in the configuration, you must delete STG 63 or MSTI 62 before you can configure SPBM.

- You must configure SPBM B-VLANs on all devices in the same MSTP region. MSTP requires this configuration to generate the correct digest.
- Configure the SPBM B-VLANs to use matching VLAN IDs.

Best Practices for SPB Regarding MSTP

Use NNI ports exclusively to transport traffic for SPB-based services and not be configured as members of any VLANs other than SPB B-VLANs. In releases that do not support `nmi-mstp`, when an SPBM IS-IS interface is created on an NNI port or an MLT, MSTP is automatically disabled for MSTI-62 on the port/MLT. However, MSTP is not automatically disabled on NNI ports for the CIST (default MSTI). In releases that support the `boot config flags nmi-mstp` command, the default behavior of the MSTP NNI ports is that CIST is disabled automatically on the NNI and the NNI ports cannot be members of any VLANs other than B-VLANs. The default `boot config flags nmi-mstp` must be set to false (which is the default). The following example shows the command to disable the MSTP on the NNI ports.

```
Switch:1(config)#interface gigabitEthernet 1/8
Switch:1(config-if)#no spanning-tree mstp
```

Coexistence of MSTP and SPB-Based Services on NNI Ports

In releases that do not support `nmi-mstp` boot configuration, you can support the coexistence of non-SPB based services on the NNI ports, by adding NNI ports as members of VLANs, except for B-VLANs. These other VLANs rely on the use of MSTP for Loop prevention. The network operator must carefully consider the implications of keeping MSTP enabled on the NNI ports because any MSTP topology changes detected on the NNI ports impacts all services and causes most dynamically learned information on the UNI side to be flushed and relearned. This includes, but is not limited to, all customer MAC and ARP records. This can also cause all the UNI ports on a BEB to be temporarily put into a spanning-tree blocking state before transitioning to a forwarding state again. The net result is that MSTP topology changes on the NNI ports adversely impact traffic for SPB-based services. Therefore, the NNI ports be used exclusively for SPB traffic.

SPBM IS-IS

The following list identifies restrictions and limitations associated with SPBM IS-IS:

- The switch does not support IP over IS-IS as defined by RFC 1195. IS-IS protocol is only to facilitate SPBM.
- The switch uses level 1 IS-IS. The switch does not support level 2 IS-IS. The CLI command `show isis int-l2-contl-pkts` is not supported because the IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1.
- The IS-IS standard defines wide (32bit) metrics and narrow (8 bits) metrics. The switch supports the wide metric.
- To run IS-IS on an MLT, add the ports to the MLT, and then enable IS-IS on the MLT.

SPBM NNI SMLT

The switch does not support NNI on SMLT links.

VLACP

VLACP is generally used when a repeater or switch exists between connected switches to detect when a connection is down even when the link LED is lit. You can enable VLACP on Ethernet ports that are NNI interfaces, as well as Ethernet ports that are part of an NNI MLT.

SNMP Traps

On each SPBM peer, if you configure the SPBM B-VLANs to use different VLAN IDs, for example, VLAN 10 and 20 on one switch, and VLAN 30 and 40 on the second, the system does not generate a trap message to alert of the mismatch because the two switches cannot receive control packets from one another. Configure the SPBM B-VLANs to use matching VLAN IDs.

System MTU

Do not change the system MTU to less than the default value of 1950 bytes. The system MTU must be 1950 or jumbo because of the header size increase when transmitting packets over the SPBM cloud.

IP Multicast over Fabric Connect

IP multicast over Fabric Connect cannot connect to existing Protocol Independent Multicast (PIM) networks that connect to SPB originated streams or that add PIM network streams into the SPB network. SPB-PIM Gateway (SPB-PIM GW), however, provides multicast interdomain communication between an SPB network and a PIM network. SPB-PIM GW accomplishes this interdomain communication across a special Gateway VLAN. The Gateway VLAN communicates with the PIM network through the PIM protocol messaging and translates the PIM network requirements into SPB language, and vice versa. For more information about SPB-PIM GW, see [SPB-PIM Gateway configuration](#) on page 3185.

Other

The following list identifies other restrictions or considerations:

- You cannot use 3.33.33 as the SPB nickname because of a conflict with reserved IPv6 Ethernet multicast address 33:33:xx:xx:xx:xx.
- The software does not support I-SID filters.
- You cannot enable C-VLAN and B-VLAN on the same port.
- To ensure proper cleanup of MAC tables after you run the **no spbm** command, save the configuration, and then reboot the switch.

Network Load Balancing (NLB) - unicast operation	VSP 4450 Series	Not Supported
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	Not Supported

SPBM supports Network Load Balancing (NLB) Unicast and Multicast modes.

NLB is a clustering technology available with Microsoft Windows 2000, Microsoft Windows 2003, Microsoft Windows 2008, and Microsoft Windows 2012 server family of operating systems. You can use NLB to share the workload among multiple clustering servers. NLB uses a distributed algorithm to load balance TCP/IP network traffic across a number of hosts, enhancing the scalability and availability of mission critical, IP based services, such as web, VPN, streaming media, and firewalls. NLB also provides high availability by detecting host failures and automatically redistributing traffic to remaining operational hosts.

*SPBM Script***Table 90: run spbm installation script product support**

Feature	Product	Release introduced
run spbm installation script	VSP 4450 Series	VOSS 4.1
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 4.1
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 8.0
	XA1400 Series	Not Supported

You can use a CLI script to quickly configure the SPB and IS-IS infrastructure to enable Fabric Connect on a switch. You can use the SPB script, rather than manually configure the minimum SPBM and IS-IS parameters.

You can use the command **run spbm** to quickly configure the following:

- Configure the SPB Ethertype.
- Create an SPB instance.
- Create an SPBM backbone VLAN and associate it to the SPB instance.
- Create an SPBM secondary backbone VLAN and associate it to the SPB instance.
- Add an SPB nickname.
- Create a manual area.
- Enable IS-IS on one of the switch interfaces.
- Enable IS-IS globally.
- Configure the IS-IS system name.
- Configure the IS-IS system ID.
- Configure SPBM port and MLT interfaces.
- Clean up any SPBM configuration.

The following table displays the default values applied if you use the **run spbm** command. The SPB script creates some of the default values based on the MAC address of the switch, including the nickname and System ID value.

Parameter	Default values
Ethertype	0x8100
Primary B-VLAN	4051
Secondary B-VLAN	4052
Manual area	49.0000
Nickname	Derived from the chassis MAC

Parameter	Default values
System name	Derived from the command line prompt
System ID value	Derived from the chassis MAC, using a different algorithm from that for the Nickname

Note

The SPB script only creates the SPBM instance, VLAN, or other parameters if they do not already exist. For example, if the SPBM instance and VLAN already exist, the SPB script does not create them. If the SPB script cannot create one of the parameters because the parameter is already configured, the script stops and an error message displays.

Layer 2 Video Surveillance install script

Table 91: Layer 2 Video Surveillance install script product support

Feature	Product	Release introduced
Layer 2 Video Surveillance install script	VSP 4450 Series	VOSS 6.1
	VSP 4900 Series	VOSS 8.1 To support this feature, VIM installation is mandatory in VSP4900-48P.
	VSP 7200 Series	Not Supported
	VSP 7400 Series	Not Supported
	VSP 8200 Series	Not Supported
	VSP 8400 Series	Not Supported
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

The Layer 2 Video Surveillance install script pre-configures configuration parameters for video surveillance solutions. With this script, a technician can quickly and easily deploy a typical video surveillance network that supports up to 2000 IP cameras, a recording solution, systems management, and viewing stations.

The install script uses best practices for converged solutions and provides redundant paths for all video traffic. The script configures the basic deployment of Shortest Path Bridging (SPB) and uses Layer 2 VSNs to enable full multicast capabilities between all IP subnets and VLANs.

Configuration Parameters

The syntax of the install script command is `run vms layer-2 switch <5-99>` where the switch value (between 5 and 99) is a user-defined variable. The install script uses this switch value to configure the camera IP zone for the switch and to specify a unique SPB nickname, system-id, and IP source value.

The install script configures the following major parameters and populates the `xx` with the user-defined variable for the switch value:

- IP Loopback Interface Address: 192.168.0.xx (Management IP address on the switch.)
- IP-Source Address: 192.168.0.xx (IS-IS source IP address for the switch.)
- VLAN ID: 200 (On hardware platforms that only have NNI links, there is no need to create a surveillance VLAN.)
- System ID: 0011.0011.07xx (SPB system-id of switch)
- Nickname: 0.07.xx (SPB Nickname for switch)
- SPB Manual Area ID: 49.0001
- Backbone VLAN IDs: 4051 and 4052 (with 4051 as Primary)
- SPB Multicast: enabled
- SFP and SFP+ ports: (Define all ports as NNI links.)

Note

The install script does not configure DHCP Relay parameters.

Optional `syntax` Parameter

The install script requires that the switch be in the factory default state. The script prompts you to confirm this, but it does not check if you did so. The script continues running commands even if some of the commands in the script fail, and the failure of script commands is not evident by the script completion message.

The syntax of the install script command is: `run vms layer-2 switch <5-99> [syntax]`. The optional `syntax` parameter prints out all the commands run by the script onto the console. If you do not use the `syntax` parameter, you will not see an error message when a command fails to run.

Important

Use the `syntax` parameter to display all the commands run by the script and show any errors that the script encounters. This is the only way to ensure that all configurations are configured without error.

Configuration Filename

Upon successful completion of the install script, the switch configuration is saved with a filename based on the switch value used when the script was run. The switch primary boot config file flags are updated with the new filename.

For example, if you use 6 as the switch value, the command `run vms layer-2 switch 6` results in a switch configuration filename of `vms-layer2-switch-6.cfg`.

If you run the install script with the `syntax` parameter, you will see the pre-install command output:

- `save config file pre_vms_layer2_install.cfg`
- `Save config to file /intflash/pre_vms_layer2_install.cfg successful.`

and the completed install script output:

- `save config file vms-layer2-switch-6.cfg`

- Save config to file `/intflash/vms-layer2-switch-6.cfg` successful.

IS-IS external metric

The software supports the IS-IS external metric to differentiate between internal and external routes with Accept Policies.

With this feature you can use IS-IS to:

- change the external metric-type of a route when redistributing it from another protocol to IS-IS through route redistribution using a route-map.
- change the external metric-type of a route when accepting a remote IS-IS route with the help of IS-IS accept policies using a route-map.
- match the external metric-type when redistributing IS-IS routes into other protocols using the match option in the route-map.
- match the external metric-type when accepting a remote IS-IS route with the help of IS-IS accept policies by using a route-map
- process the external metric-type in the route selection process.

The IS-IS metric type can also be set using the base redistribute command without using the route-map.

SPB Ethertype

The switch aligns the SPB ethertype to BCB's locally configured SPB ethertype. The BCBs mark the BTAG Ethertype of a transit MAC-in-MAC packet to match its locally configured value when it exits on a different NNI port, even if the BTAG Ethertype on the incoming packet (CFM or SPB) does not match its configured value.

Note

ISIS Hello packets are always marked with 0x8100 ethertype, and do not change according to the BCB's locally configured values.

Equal Cost Multipath Pathlist with Fabric Connect

Table 92: ECMP Pathlist with Fabric Connect product support

Feature	Product	Release introduced
ECMP Pathlist with Fabric Connect (IS-IS routes)	VSP 4450 Series	VOSS 8.1.5
	VSP 4900 Series	VOSS 8.1.5
	VSP 7200 Series	VOSS 8.1.5
	VSP 7400 Series	VOSS 8.1.5
	VSP 8200 Series	VOSS 8.1.5
	VSP 8400 Series	VOSS 8.1.5
	VSP 8600 Series	Not Supported
	XA1400 Series	VOSS 8.1.5

If you use Equal Cost Multipath (ECMP) in a Shortest Path Bridging (SPB) scenario, the Intermediate System-to-Intermediate System (IS-IS) protocol sends multiple routes with the same destination to the routing manager. IS-IS can add up to eight equal cost routes with the same destination to the routing table and the router uses one route for traffic forwarding based on load management. Use the ECMP Pathlist feature to control how many equal-cost paths to add to the routing manager for the same destination.

Note

Different hardware platforms can support a different number of ECMP paths. For more information about the maximum number of ECMP paths supported on the switch, see the scaling information in [VOSS Release Notes](#).

For information about how to configure ECMP Pathlist, see [Configure ECMP](#) on page 1858 and [Configure ECMP](#) on page 1885.

FAN Transit

Fabric Area Network (FAN) transit refers to the ability of a switch to forward traffic between SPB nodes participating in a FAN. The switch is neither a part of the FAN nor does it originate or sink FAN traffic. It only forwards the traffic between the FAN end-points.

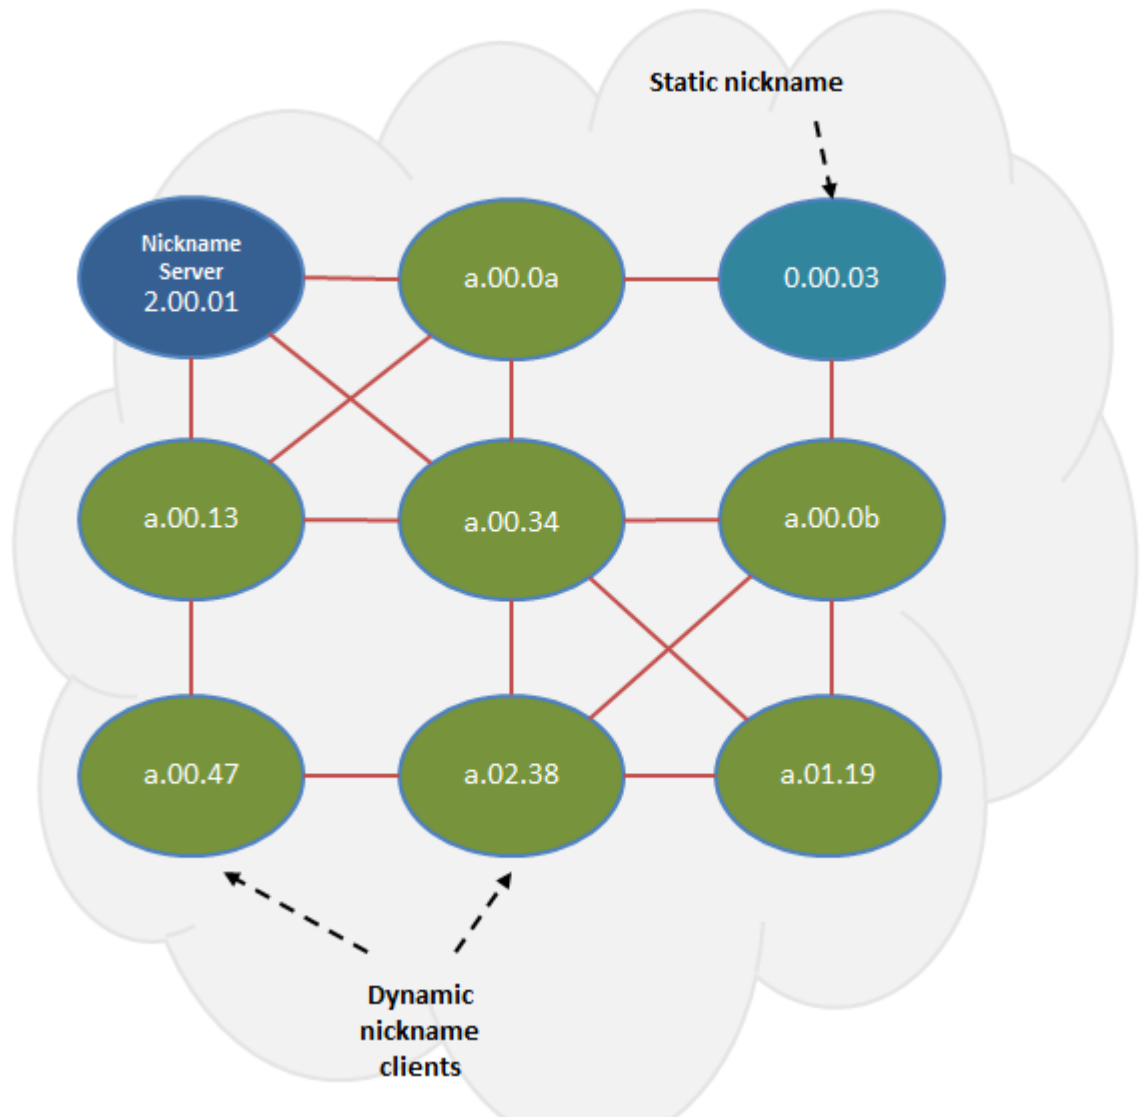

For information on how to verify the functioning of a transit switch within a FAN, see [Troubleshooting FAN Transit](#) on page 3692.

Dynamic Nickname Assignment

	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

Dynamic Nickname Assignment is a service that provides unique nicknames to compatible switches across a Fabric Area Network (FAN).

You can configure a node in a FAN as a nickname server. The nickname server cannot be started until you configure it with a static nickname. As a best practice, configure at least two nickname servers in a FAN to provide redundancy.

Note

Configure the nickname server with a static nickname that is outside any configured dynamic nickname server range in the network, or you can configure the nickname server with a static nickname from the first 10 values of the configured dynamic nickname server range in the network.

The nickname server interrogates FAN nodes that have been assigned a dynamic nickname to avoid nickname duplication.

A client joining the dynamic FAN in factory default mode initially does not have a nickname, and issues a broadcast soliciting a valid nickname assignment. The nickname server receives the request and responds with a nickname assignment offer. The client then explicitly requests the particular nickname offered and the nickname server sends an acknowledgment.

The client maintains the nickname in persistent memory regardless of whether the active nickname server is the same server that originally provided the nickname. The client generates a trap and notifies the user if it is unable to receive a nickname from the server. When IS-IS starts, it issues a trap if a client does not have a nickname and clears the trap when the client receives a nickname from the nickname server.

A client rebooting or reconnecting to the FAN requests the same nickname assignment it had before reboot. If the requested nickname is within the nickname server's configured range of nicknames and is still available, the server acknowledges the nickname. If the requested nickname is outside of the nickname server's configured range or if the nickname has been assigned to another client, the request is denied by the nickname server and the client must request a new nickname.

Static and Dynamic Nickname Servers

You can use static nickname assignment and Dynamic Nickname Assignment in the same FAN.

You can configure Dynamic Nickname Assignment using a range prefix that can use a range from 0.00.00 to F.FF.FF. This method provides 256 groups that cover the range of 0.00.00 to F.FF.FF.

Note

You can configure the nickname server with a static nickname from the first 10 values of the configured dynamic nickname server range in the network.

Do not use nicknames from the dynamic nickname range when you assign nicknames statically to non-server nodes. However, if there are existing nodes in the network with static nicknames in the dynamic nickname range, it is not a requirement to change their nickname assignment. If a node is assigned a dynamic nickname that is being used in the network, duplicate nickname protection is initiated. If the node that has the dynamic nickname loses the nickname election, it requests a different nickname from the nickname server. If a node with a static nickname loses the nickname election, IS-IS is disabled on that node and you must manually re-assign the nickname and re-enable IS-IS.

You can configure nicknames from a dynamic range if the nickname server is not started.

Note

You must disable Dynamic Nickname Assignment before you can change the nickname prefix.

Debugging

A node must be a member of a FAN to host Dynamic Nickname Assignment applications. FAN connectivity enables the exchange of information between nickname clients and servers, such as nickname requests or nickname assignments. You can use Connectivity Fault Management (CFM) to debug connectivity issues or isolate faults. For more information about CFM, see [Connectivity Fault Management](#) on page 3504.

Dynamic Nickname Assignment Considerations

Consider the following information when implementing this feature:

- You must configure a nickname server to assign unique nicknames to clients based on established policies.
- You can configure multiple nickname servers in a FAN to provide resiliency. If you configure multiple nickname servers, you must ensure that the ranges for nickname allocation do not overlap.
- Dynamic Nickname Assignment is not supported in a FAN that contains ERS 4900 or ERS 5900 products, or on products running VOSS releases prior to 7.0.

MSTP-Fabric Connect Multi Homing

Table 94: MSTP-Fabric Connect Multi Homing product support

Feature	Product	Release introduced
MSTP-Fabric Connect Multi Homing	VSP 4450 Series	VOSS 7.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 7.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 7.0
	VSP 8400 Series	VOSS 7.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

The MSTP-Fabric Connect Multi Homing feature allows MSTP or RSTP network to be multi-homed into a Fabric Connect network, providing a loop-free topology. MSTP-Fabric Connect Multi Homing enables an MSTP network to be multihomed into the SPB Fabric network through single node-to-multiple nodes or multiple nodes-to-multiple nodes.

Important

You must enable MSTP-Fabric Connect Multi Homing before you establish multihoming with an MSTP network.

MSTP-Fabric Connect Multi Homing uses I-SID 16777003. The switch creates this I-SID automatically and it cannot be modified.

MSTP-Fabric Connect Multi Homing is supported on SPBM mode only.

Some hardware platforms support Fabric Extend natively. You can use these switches in a main office of a hub and spoke deployment or to connect one Data Center to another Data Center.

The VSP 4450 Series also supports Fabric Extend, but the switch must be connected to an Open Networking Adapter (ONA) because the VSP 4450 Series does not support Fabric Extend natively. The ONA enables the VSP 4450 Series to support Fabric Extend. The VSP 4450 Series uses the ONA to encapsulate Fabric Connect traffic. For example, you can use the VSP 4450 Series in a branch office of a hub and spoke deployment.

**Note**

In a Layer 2 core Fabric Extend solution, the VSP 4450 Series does not require an ONA because the tunnels are point-to-point VLAN connections, not VXLAN connections. Therefore, there is no need for an ONA to encapsulate a VXLAN header to SPB packets.

Fabric Extend enables Enterprises to extend the Fabric Connect technology over Layer 2 or Layer 3 core networks. The *logical IS-IS interface* is the mechanism that enables Fabric Extend to connect SPB fabric nodes. Logical IS-IS interfaces create virtual tunnels and encapsulate SPB traffic by adding a VXLAN header to SPB packets.

The following figure illustrates two Fabric Connect “islands” separated by a third-party core IP network. The IP network could be third-party equipment in an enterprise or a service provider’s infrastructure such as an MPLS VPN service.

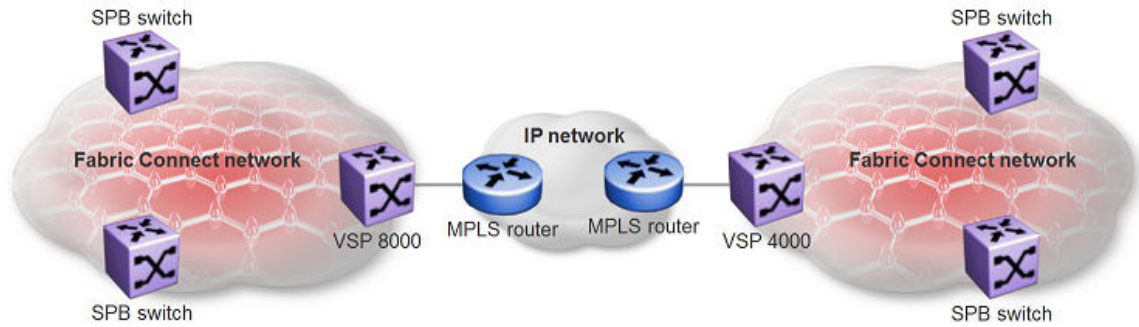

Figure 59: Fabric Connect networks connected by an IP network

The following figure illustrates how Fabric Extend enables you to connect the fabric islands to create ONE Fabric Connect network. This figure shows a Layer 3 core network where Fabric Extend uses IP tunneling by adding a VXLAN header to the SPBM packets. This can be over a third party IPv4 transport network such as MPLS IP-VPN or in a Campus IP backbones.

Figure 60: Single Fabric Connect Domain realized using Fabric Extend

The following figure shows a Layer 2 core network where Fabric Extend can transport SPBM packets over a Layer 2 MPLS VPLS or PBB E-LINE service by creating layer 3 tunnels over a Layer 2 third party network.

Figure 61: Fabric Extend over VLAN tunnels

Advantages of Fabric Extend

Fabric Connect is an Ethernet-based, industry-standard (IEEE 802.1aq) networking virtualization solution. With Fabric Connect, you can have thousands of virtualized service instances at any point in

the network. Other Fabric Connect advantages include rapid time to service, Layer 2 and Layer 3 Unicast and IP Multicast virtualization, and scalable IP multicast. But the most significant advantage of Fabric Connect is that you provision services at the network edge only, not the core.

The Fabric Extend feature enables you to extend the Fabric Connect model over Layer 2 and Layer 3 core networks. The interconnection of Fabric Connect deployments can be over any IP-based network whether it's a campus backbone, Data Center, or a MAN/WAN IP MPLS network.

Fabric Extend and ONA

Some hardware platforms support Fabric Extend natively on any of its physical ports. However, the VSP 4450 Series requires an Open Networking Adapter (ONA) to enable this functionality. The ONA is the Fabric Extend packet encapsulation engine for the VSP 4450 Series. The ONA / VSP 4450 Series combination can also provide enhanced features such as IP fragmentation and reassembly on Fabric Extend tunnels.

Note

In a Layer 2 core Fabric Extend solution, the VSP 4450 Series does not require an ONA because the tunnels are point-to-point VLAN connections, not VXLAN. Therefore, there is no need for an ONA to encapsulate a VXLAN header to SPB packets.

The VSP 4450 Series manages the ONA in the following ways:

- Controls and provisions the ONA.
- If PoE capable, the VSP 4450 Series supplies power to the ONA. (The ONA also supports an optional wall unit power adapter.)
- Transports traffic to and from the ONA over 1 GbE ports and sets QoS appropriately to the ONA's.
 - The ONA 1101GT can support basic Fabric Extend at line rate 1G traffic from the VSP 4450 Series at 1500 byte packet sizes.
 - Oversubscription of the ONA's packet engine may result if packets are smaller than 1500 bytes or if you enable enhanced features such as fragmentation and reassembly of packets. This results in packet drop starting with lower QoS queued packets consistent with PCP and DSCP markings on packets received from the VSP 4450 Series. For more details on the ONA 1101GT forwarding performance, see [ONA Considerations](#) on page 964.

The ONA can operate in different modes. Fabric Extend is Operational Mode 1. To enable Fabric Extend, use the ONA's Manual Configuration menu to change the Operational Mode parameter to 1. For more information, refer to the manual that ships with the ONA.

In the following figure, the VSP 8200 Series is in a Fabric Connect network and is configured with Fabric Extend (FE). The VSP 4450 Series is also in a Fabric Connect network and is configured with SPB. The VSP 8200 Series and the VSP 4450 Series use industry-standard VXLAN tunnels to create a flow for FE traffic between the VSP 8200 Series and the ONA attached to the VSP 4450 Series.

Figure 62: Fabric Extend traffic flow

The following flow occurs when User A sends a packet to User B:

- The VSP 8200 Series receives the packet and encapsulates it with a MAC-in-MAC header.
- The VSP 8200 Series sends the MAC-in-MAC-encapsulated packet over the VXLAN tunnel to the VSP 4450 Series.
- The VSP 4450 Series receives the packet and sends it to the ONA network port.
- The ONA decapsulates the packet by removing the VXLAN header and sends the MAC-in-MAC packet header out the ONA device port back to the VSP 4450 Series.
- The VSP 4450 Series decapsulates the MAC-in-MAC header and forwards the packet to User B.

The following flow occurs when User B sends a packet to User A:

- The VSP 4450 Series receives the packet and sends it to the ONA over the ONA device port with MAC-in-MAC encapsulation.
- The ONA encapsulates the packet with a VXLAN header.
- The ONA then sends the packet out the ONA network port and back to the VSP 4450 Series.
- The VSP 4450 Series sends the VXLAN-encapsulated packet over the Routed IP network to the VSP 8200 Series.

Note

To interoperate with the VSP 8200 Series, you must set the MTU on the VSP 4450 Series/ONA combination to 1950 bytes.

- The VSP 8200 Series decapsulates the packet by removing the VXLAN header and the MAC-in-MAC header, and then forwards it to User A.

Note

Connect the ONA as shown with two ports to the VSP 4450 Series. You cannot connect the ONA directly to the IP core infrastructure.

Logical IS-IS interface

The logical IS-IS interface is the mechanism that enables Fabric Extend to connect SPB fabric nodes.

Logical IS-IS interfaces perform the following functions depending on the type of core network:

- In a Layer 3 core network, logical IS-IS interfaces create virtual IP tunnels and encapsulate SPB traffic by adding a Virtual Extensible LAN (VXLAN) header to SPB packets.

- In a Layer 2 core network, logical IS-IS interfaces do not use VXLAN. The tunnels are point-to-point VLAN connections so there is no need to encapsulate a VXLAN header to SPB packets. The logical IS-IS interfaces translate the Backbone VLAN IDs (B-VIDs) and maps them to each of the branch provider VIDs.

Fabric Extend uses virtual tunnels in Layer 3 core solutions to connect SPB fabric nodes. These nodes can stretch over IP routed campus networks, service provider Layer 2 core networks, or service provider Layer 3 core networks such as IP MPLS VPNs.

Note

VLACP cannot be used on logical IS-IS interface connections.

Layer 2 core network

If the service provider has a Layer 2 core network, note the following points:

- The syntax for configuring a logical interface is:

```
logical-intf isis <id> vid <list of vlans> primary-vid <vlanId> port
<slot/port> Mlt <mltId> [name <name>]
```

- `vid <list of vlans>` should have two VLANs, not more than two or less than two. The VID range is <2-4059>. You do not have to configure the VIDs as platform VLANs.
- `primary-vid` should be included in `vid <list of vlans>`.
- Each logical interface must have a unique set of VIDs for each port or MLT. The same VIDs however, can be reused across a different set of ports or MLTs.
- Logical interface VIDs and B-VLANs cannot be the same.
- Configuring the same VIDs as primary and secondary is not allowed.
- The `port/MLT` on which the Layer 2 core IS-IS logical interface is configured cannot be part of any other user configured VLANs.
- Cannot delete an MLT that is configured as a logical interface tunnel MLT.
- A logical interface consists of a port/MLT and a list of VLANs, where port/MLT is the physical connectivity to the Layer 2 core network and VLANs are the list of VLANs used to transport/bridge IS-IS control packets and Mac-in-Mac data traffic.
- VXLAN headers are not used in Layer 2 core Fabric Extend solutions.
- IS-IS control packets are not encapsulated before they are sent over a logical interface. Instead, the VLAN in the outer Ethernet header (SPB primary bvid) is replaced by the user configured logical interface VLAN.
- Spanning tree is disabled by default on **port/MLT** on which a Layer 2 core logical IS-IS interface is configured.

Layer 3 core network

If the service provider has a Layer 3 core network, note the following points:

- The syntax for configuring a logical interface is:

```
logical-intf isis <id> dest-ip <destIpAddress> [name <name>]
```

- A logical IS-IS interface points to a remote BEB destination IP address.

- Port and VlanId are not needed to create a logical IS-IS interface, instead they can be retrieved from the next hop of destination IP address.
- IS-IS control packets (IS-IS hello, LSDB, CSNP, PSNP) are encapsulated with a VXLAN header and sent over a logical IS-IS interface.

IPsec Compression

IPsec compression reduces the size of the IP datagram to improve the communication performance between hosts connected behind XA1400 Series Backbone Edge Bridges (BEB).

Tip

As a best practice, use IPsec compression only for Fabric Extend tunnels where latency is greater than 70ms.

The following list identifies how you can implement IPsec compression:

- You can configure IPsec compression for each logical-interface.
- You can configure multiple IPsec Fabric Extend (FE) adjacencies with or without compression simultaneously.
- You must enable IPsec compression on both BEBs to use IPsec compression for an FE adjacency.
- You cannot configure IPsec compression if fragmentation before encryption is already enabled on the logical interface.
- You can change the IPsec compression configuration for a logical interface only if IPsec is disabled on the logical interface.

For configuration information, see the following tasks:

- [Configure Fabric Extend Over IPsec](#) on page 1045 (using CLI)
- [Configure Fabric Extend Logical Interfaces for Native Support](#) on page 1166 (using EDM)

IS-IS Hello Padding

To detect maximum transmission unit (MTU) mismatches, Intermediate System-to-Intermediate System (IS-IS) pads hello packets to the full interface MTU. All hello packets on Fabric Extend NNI links are padded. On non-Fabric Extend point-to-point NNI links, hello packets are padded until a hello packet is received from the other side.

Note

If you downgrade to a release that does not support this feature, you must disable the feature and save the configuration before you downgrade. You must have a compatible configuration file if you downgrade to an earlier release.

IPsec Fragmentation Before Encryption

XA1400 Series, VSP 4900 Series, and VSP 7400 Series switches support IPsec fragmentation before encryption of Fabric Extend tunnels; VSP 4900 Series and VSP 7400 Series provide that support using Fabric IPsec Gateway.

The best practice is to enable fragmentation before encryption only for an IPsec adjacency over a WAN.

Configure IPsec fragmentation of the packets to occur before encryption and IPsec encapsulation. Packets are fragmented based on the tunnel maximum transmission unit (MTU) without the IPsec header so that the final packet does not exceed the tunnel MTU. The MTU value is a per tunnel configuration, which means packet fragmentation occurs per tunnel. For a tunnel with this functionality enabled, packets that egress the specific NNI port are encapsulating security payload (ESP) packets only.

The following list identifies how you can implement IPsec fragmentation before encryption:

- You can configure IPsec fragmentation before encryption for each logical-interface.
- You must configure IPsec over Fabric Extend in IPsec decoupled mode, which means the IPsec source and destination IP addresses are different than the Fabric Extend addresses.
- You cannot configure IPsec compression if fragmentation before encryption is already enabled on the logical interface.

IPsec Coupled and Decoupled Mode

A device is in IPsec decoupled mode when IPsec and Fabric Extend (FE) termination takes place on two different IP addresses. A device is in IPsec coupled mode when IPsec and Fabric Extend (FE) termination takes place on the same IP address.

The XA1400 Series devices, which use VOSS for Fabric Extend over IPsec, support both IPsec decoupled and coupled modes. The VSP 4900 Series and VSP 7400 Series devices, which use Fabric IPsec Gateway for Fabric Extend over IPsec, support IPsec in decoupled mode only. You must configure the IPsec tunnel in decoupled mode to enable IPsec termination in the Fabric IPsec Gateway VM. For more information about how to configure IPsec tunnels on the VM, see [Configure IPsec Tunnels on Fabric IPsec Gateway VM](#) on page 882.

For more information, see the following tasks:

- For XA1400 Series configuration using VOSS:
 - [Enable IPsec Fragmentation Before Encryption](#) on page 1053
 - [Disable IPsec Fragmentation Before Encryption](#) on page 1055
- For VSP 4900 Series and VSP 7400 Series configuration using Fabric IPsec Gateway, see [Enable Fragmentation Before Encryption on Fabric IPsec Gateway VM](#) on page 884.

Adjusting the TCP Maximum Segment Size

You can adjust the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency.

TCP MSS Overview

When a client initiates a connection with a server, it uses TCP SYN packets to negotiate the MSS to avoid fragmentation. The client and server use the outgoing maximum transmission unit (MTU) to advertise the MSS.

If a tunnel exists between the client and server, the encapsulation consumes more room in the outer IP header. As a result, the router that performs the tunnel encapsulation fragments the packet to fit over the tunnel. Adjust the MSS to modify the value in the TCP SYN packet so the client and server negotiate a lower number and leave headroom for tunnel encapsulation.

This adjustment functionality applies to IPv4 only.

**Important**

If you enable this functionality and port mirroring simultaneously, the switch does not mirror CP-generated packets.

VSP 4900 Series Support

TCP MSS adjustment applies unidirectionally when a packet is forwarded from a UNI interface to any other interface. To use this functionality, you must enable TCP MSS adjustment on both sides of the FE tunnel.

VSP 7400 Series Support

TCP MSS adjustment applies unidirectionally when a packet is forwarded into an FE tunnel. To use this functionality, you must enable TCP MSS adjustment on both sides of the FE tunnel.

XA1400 Series Support

The MSS adjustment functionality only activates when at least one Fabric Extend (FE) tunnel with a MTU less than or equal to 1500 is configured. The functionality is inactive if no FE tunnels with MTU less than or equal to 1500 are configured. Deleting the last tunnel with MTU less than or equal to 1500 results in the functionality becoming inactive.

The switch can auto-derive the MSS value based on the tunnel MTUs or you can manually configure the MSS value. The formula for the auto-derived value is

$\text{min}(\text{Tunnels MTUs}) - 200\text{B}$ (size for VXLAN + MIM + IPSEC + IP+TCP headers)

If you configure multiple FE tunnels with MTU less than or equal to 1500, then the switch uses the lowest of all tunnel MTUs to auto-derive the TCP MSS adjust value. The same value applies bidirectionally, to all TCP syn packets that transmit NNI to UNI and UNI to NNI.

**Tip**

As a best practice, disable this enhancement on the head-end side and enable only at the branch side.

The switch does not support different TCP adjust MSS values if you configure different FE tunnel MTUs on different tunnels.

If you configure FE tunnels and regular NNIs on the same adjacency, then the TCP adjust MSS value applies to all TCP packets traversing across regular NNIs and FE tunnels.

Types of Fabric Extend Deployments

As the number of Fabric Connect networks increased, the need to connect those networks became more and more desirable. Fabric Extend solves the problem of going beyond the Ethernet Fabric Connect connections to include the following IP routed wide area network (WAN) and campus solutions:

1. Fabric Extend over an MPLS IP-VPN provider WAN
2. Fabric Extend over an MPLS Virtual Private LAN Service (VPLS) or Provider Backbone Bridging (PBB) Ethernet LAN (ELAN) provider network

3. Fabric Extend over an IP campus network
4. Fabric Extend over an MPLS Pseudo-Wire or Ethernet Virtual Private Line (E-Line) provider network
5. Fabric Extend over IPsec

Fabric Extend over an MPLS IP-VPN Provider WAN

The most common Fabric Extend deployment is a hub and spoke topology that connects the Main office over a service provider's MPLS IP VPN to multiple Branch offices. The following figure illustrates how the hub device on the main site establishes virtual tunnels with all of the spoke devices in the same domain. In this scenario, the traffic flows are bidirectional: from hub-to-spoke and spoke-to-hub.

Figure 63: Fabric Extend IP VPN Deployment Option

Note

If Fabric Extend with IPsec or fragmentation and reassembly is a requirement, depending on your requirements, you can use a mix of VSP 7400 Series or VSP 4900 Series with Fabric IPsec Gateway and XA1400 Series at the main and branch sites.

Fabric Extend over an MPLS VPLS/P2P-VPLS/E-LINE/P2P-VLAN Provider Network

Where the preceding hub and spoke deployment is over a Layer 3 MPLS IP-VPN, the following VPLS deployment is over a Layer 2 segment. This type of hub and spoke deployment extends the fabric over an MPLS Virtual Private LAN Service (VPLS) or Provider Backbone Bridging (PBB) Ethernet LAN (E-LINE) network. In this scenario, the SPB nodes are connected with a point-to-point Ethernet link.

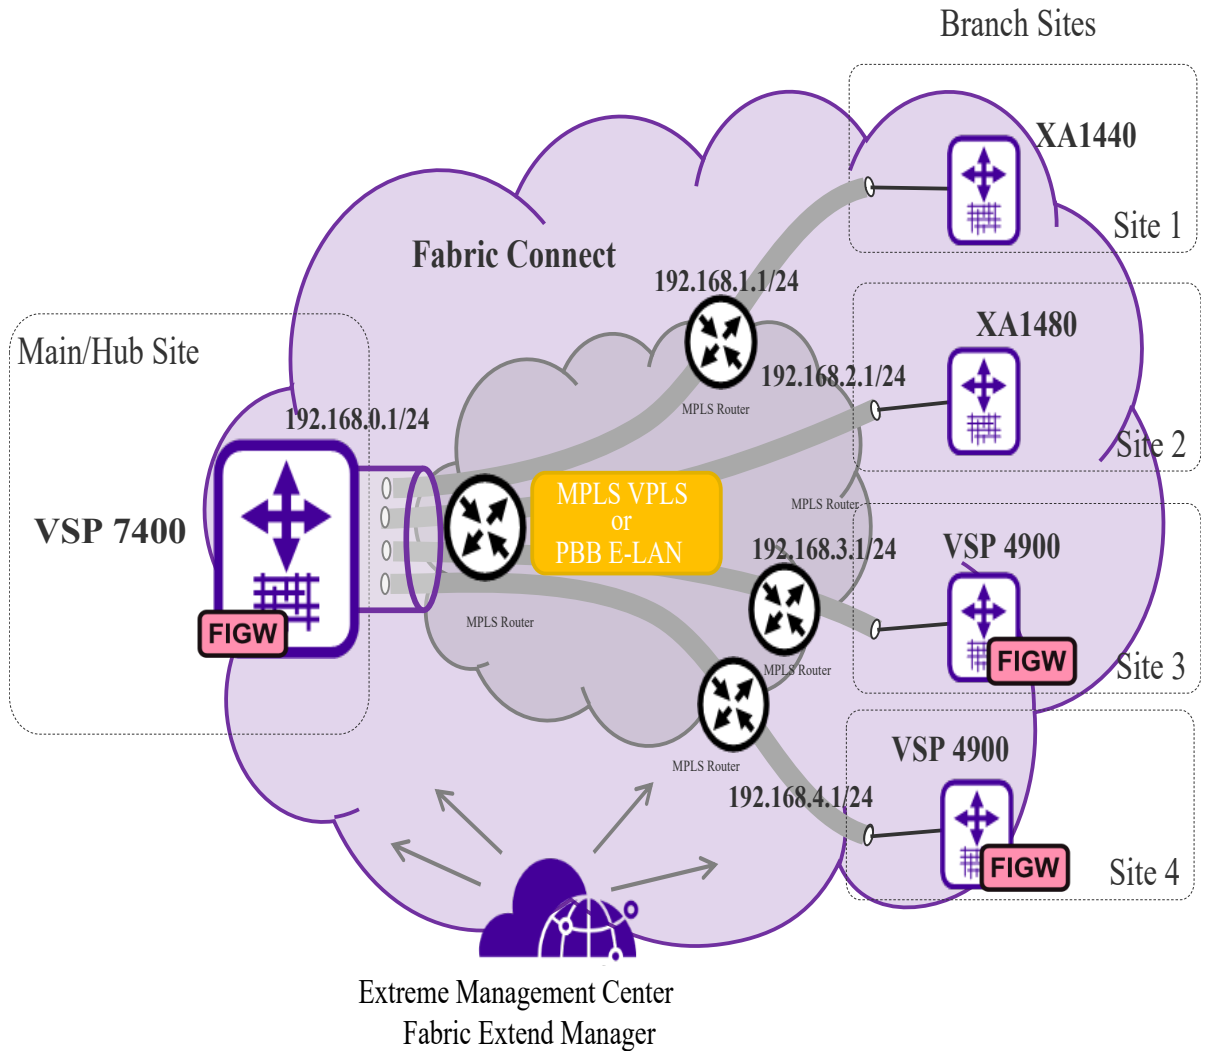

Figure 64: Fabric Extend VPLS Deployment Option

Fabric Extend over an IP Campus Network

Some customers do not want to migrate their infrastructures to SPB immediately. They want to keep their existing IP core network and deploy SPB on the edge. In this scenario, Fabric Extend supports a fabric overlay on top of the existing campus infrastructure.

The following figure illustrates how this deployment supports any-to-any traffic with full-mesh tunnels between fabric nodes. The fabric nodes serve as campus switches, support routing into the IP infrastructure, and provide an overlay fabric that enables all fabric benefits.

Figure 65: Fabric Extend Full Mesh Campus Deployment Option

Fabric Extend over an MPLS PWE3/E-Line Provider Network

The following hub and spoke deployment over an MPLS Pseudowire or Ethernet Virtual Private Line (E-Line) uses service provider VLAN tunnels. Because you can map many (VID, port/mlt list) sets to an I-SID, this gives Service Providers the flexibility to let more than one customer use the same VLAN with different I-SIDs.

Note

The VSP 4450 Series switches in this type of deployment do not require an ONA because the tunnels are point-to-point VLAN connections, not VXLAN. Therefore, there is no need for an ONA to encapsulate a VXLAN header to SPB packets.

The following figure illustrates how two dedicated Backbone VLAN IDs (B-VIDs) are mapped from the hub to spoke sites. Logical IS-IS interfaces translate the B-VIDs and maps them to each of the branch provider VLANs.

For a detailed configuration example showing logical interfaces using B-VID translation to two different logical VLAN IDs, see *Shortest Path Bridging (802.1aq) Technical Configuration Guide*.

Figure 66: Fabric Extend Pseudowire Deployment Option

Fabric Extend over IPsec

The Fabric Extend over IPsec hub and remote deployment uses service provider VLAN tunnels and IPsec to provide permanent connections between locations. It is best used for site-to-site connections, such as connecting remote sites to the core network. Since IPsec works at the network layer, this type of configuration is not limited or dedicated to a particular application.

Note FE over IPsec connectivity requires an XA1400 Series device on each end of the FE tunnel.

The following figure illustrates how the FE over IPsec deployment supports the site-to-site connections. It shows a Layer 3 core network where Fabric Extend uses IP tunneling by adding a VXLAN header to the SPBM packets. This can be over a third party IPv4 transport network such as MPLS IP-VPN or in a Campus IP backbone.

Figure 67: Fabric Extend over IPsec Deployment Option

Fabric Extend Tunnel MTU

You can configure a unique MTU value for each Fabric Extend (FE) tunnel on a XA1400 Series device. You can configure each ISIS logical interface with a unique MTU value for each FE tunnel in the VXLAN interface to improve fragmentation and reassembly in WAN connectivity over MPLS IP VPN and internet-based connections through a NAT router.

Fragmentation and reassembly is based on the MTU value configured for each FE tunnel. You can change the MTU configuration at any time for each FE tunnel. The supported MTU range is 750 to 9000, and the default MTU value is 1950.

**Note**

FE Tunnel MTU is an optional configuration.

For example, if you configure an FE tunnel with an MTU of 900, and a packet size of 1950 is received on UNI with the destination on the FE tunnel, the system fragments the original 1950-sized packet into the three packets (900, 900, 150) with a packet size equal to or less than 900. The system transmits the three fragmented packets over the ISIS logical interface of the FE tunnel. After the packets are received at the destination, the system performs the packet reassembly (900, 900, 150) into the 1950-sized packet.

Fabric Extend Tunnel MTU Considerations

Consider the following interactions between route MTU and FE Tunnel MTU configurations:

- If route MTU is not configured, the MTU value for each FE tunnel is applicable to ingress and egress traffic on the tunnel.
- If route MTU is configured, the MTU value for each FE tunnel is applicable for ingress traffic on the tunnel. The route MTU value applies to all egress traffic.

**Note**

System MTU maximum is a separate configuration. You can configure a system maximum MTU size of 1522, 1950, or 9022. The default value is 1950.

IPsec Source IP Address Per Tunnel Interface

To deploy the XA1400 Series in an environment that includes more than one provider connection with IPsec, you require a source IP address for each IPsec tunnel.

When you connect to a broadband provider such as cable modem, DSL, or LTE, the only routable IP interface is the one that is assigned by the provider (either through DHCP or statically). As a result, the Internet can only route the assigned subnet. You cannot deploy a routing protocol between the branch device and the provider modem.

When you connect two different providers to a branch device, each provider uses a different subnet. The XA1400 Series must apply a different source IP address for each IPsec tunnel.

The following options are available to configure a specific source IP address for each IPsec tunnel:

- Statically configure a source IP address for each IPsec tunnel:
 - You must configure a VLAN, brouter, or CLIP IP address for the IPsec tunnel to use; this address must be in the same VRF as the tunnel.
 - You cannot delete the VLAN, brouter, or CLIP IP address if it is used as the static IPsec source IP.
 - You must disable IPsec on the logical interface before you configure an IPsec source IP.
 - The specified IP must be different than the global IPsec IP source address.
 - The specified IP can be the same as the management IP if you do not configure other logical IPsec interfaces with a source IP type of DHCP.
 - Multiple logical interfaces can use the same statically configured IPsec source IP.
- Dynamically obtain the source IP address for each IPsec tunnel from the management VLAN IP address assigned through DHCP:
 - You must enable DHCP on the management VLAN.
 - The co-existence mode, where both the management IP stack and the routing IP stack share the same IP address and default routes, must be present. For more information, see [VLAN](#) on page 76.
 - After you run the **ipsec tunnel-source-address type dhcp** command, the system imports the IP and VRF used by the management VLAN as the IPsec source IP on the logical interface.
 - The VRF can be different than the tunnel VRF.
 - You cannot delete the VLAN or modify its IP address if the IP address is used as the IPsec source IP.
 - The IPsec source IP type DHCP cannot be the same as the global IPsec source IP address or statically configured IP address.
 - After the system imports the DHCP IP address for use by IPsec, you can modify the management VLAN. For example, you can disable DHCP on the management VLAN, change the management VLAN ID, or delete the management VLAN.
 - After you save the configuration, the IP and VRF that the system imported for use by IPsec is saved to the configuration file using **ipsec tunnel-source-ip type dhcp <IP_address> vrf <vrf_name>**. After you reboot the switch, it loads the information from the configuration file and the IPsec tunnel IP address is no longer imported from the management VLAN.

Fabric Extend Considerations

Review the following restrictions, limitations, and behavioral characteristics that are associated with Fabric Extend.

Note

If your Fabric Extend configuration includes a VSP 4450 Series/ONA combination, see [ONA Considerations](#) on page 964 for more information.

Tunnel Source IP

Fabric Extend supports the tunnel source IP address using a brouter port interface, a CLIP IP, or a VLAN IP.

The following table shows the product support.

Product	Tunnel source IP		
	Brouter port	CLIP IP	VLAN IP
VSP 4450 Series	Yes	Yes	Yes
VSP 4900 Series	Yes	Yes	Yes
VSP 7200 Series	Yes	Yes	Yes
VSP 7400 Series	Yes	Yes	Yes
VSP 8200 Series	Yes	Yes	Yes
VSP 8400 Series	Yes	Yes	Yes
VSP 8600 Series	Not supported	Not supported	Not supported
XA1400 Series	Yes	Yes	Yes

- Configure route-maps to not permit redistribution of the local route used as the tunnel source address (**ip-tunnel-source-address** command).
- Configure an accept policy to deny IS-IS routes that overlap with the destination tunnel IP address.

Tunnel Failover Time

With IS-IS interface default values, tunnel failure detection can take up to 27 seconds. You can reduce the IS-IS interface hello timers to speed up logical link failure detection, but be careful to avoid link flapping due to values that are too low.

Note

If the number of IS-IS interfaces on a node is greater than 100, it is a good practice to set the hello timer not lower than 5 seconds.

ACL Filters over VXLAN

IP filters configured to match IP header fields in the headers of VXLAN encapsulated packets, work only when the switch acts as a transit router and does not participate in the initiation or termination of VXLAN traffic.

VLACP

VLACP is not supported over logical IS-IS interfaces.

CFM CCM

CFM Continuity Check Messages are not supported over logical IS-IS interfaces.

CFM traceroute and tracemroute

If CFM packets transit over a layer 3 tunnel (that is the CFM packets ingress a Fabric Extend layer 3 core tunnel and egress through another layer 3 core tunnel), the transit SPBM nodes do not display as intermediate hops in the output for CFM **12 traceroute** and **12 tracemroute**.

This is because the CFM packets are encapsulated in the outer layer 3 header as part of VXLAN encapsulation, and the transit SPBM nodes cannot look into the payload of the VXLAN packet and send a copy of the CFM packet to local CPU for processing.

CFM L2 Ping

CFM Layer 2 ping to MCoSPB source mac is not supported and can fail if they are reachable via Fabric Extend tunnel.

MACsec

Switch-based MAC Security (MACsec) encryption is Layer 2 so it cannot be used with Fabric Extend IP, which is Layer 3.

MTU Minimum in Layer 2 Pseudowire Core Networks

Service provider Layer 2 connections must be at least 1544 bytes. In this type of deployment the tunnels are point-to-point VLAN connections that do not require VXLAN encapsulation. The default MTU value is 1950.

Logical IS-IS Interfaces

Layer 2 core and Layer 3 core logical IS-IS interfaces are not supported on the same switch at the same time.

Fragmentation and Reassembly

There is no fragmentation and reassembly support in Layer 2 core solutions.

If a tunnel was initially UP between a VSP 4450 Series and another switch with MTU 1950 and then the VSP 4450 Series was later configured for fragmentation, the following behavior occurs:

- If the ONA MTU is less than 1594, the tunnel to the other switch will go DOWN.
- If the ONA MTU is 1594 and above, the tunnel will stay UP, but any fragmented packets received from the VSP 4450 Series will be lost at the other switch site.

RFC4963 and RFC4459 Considerations

The ONA 1101GT provides for the IP MTU of the Network port to be reduced from the default setting of 1950 bytes to 1500 bytes or lower. The MTU reduction feature with Fabric Extend is provided to facilitate the connection of two Fabric Connect networks over an IP network with any MTU without requiring end stations on the networks to reduce their MTU. The ONA 1101GT with the IP MTU of the network port set to 1500 bytes will fragment Fabric Extend VXLAN tunnel packets exceeding 1500 bytes. The ONA 1101GT will also reassemble fragmented Fabric Extend VXLAN tunnel packets at the tunnel termination point. The IP fragmentation and reassembly RFC 791 describes the procedure for IP fragmentation, and transmission and reassembly of datagrams and RFC4963 and RFC4459 detail limitations and network design considerations when using fragmentation to avoid out of order packets and performance degradation.

The following list identifies factors that can impact performance:

- The link speed per VXLAN IP address should be slower than 1G to avoid reassembly context exhaustion.

- ECMP and link aggregation algorithms in the IP core should be configured not to use UDP port hashing that could send IP fragments after the first fragment on different paths causing out of order packets. This is due to the fact that subsequent fragments do not have UDP port information.

**Important**

Different MTU sizes on each end can result in traffic drops.

Layer 2 Logical IS-IS Interfaces

Layer 2 logical IS-IS interfaces are created using VLANs. Different Layer 2 network Service Providers can share the same VLAN as long as they use different ports or MLT IDs.

**Note**

Exception: Layer 2 logical IS-IS interfaces are not supported on XA1400 Series.

MTU Minimum in Layer 3 Core Networks

Service provider IP connections must be at least 1594 bytes to establish IS-IS adjacency over FE tunnels. The 1594 bytes includes the actual maximum frame size with MAC-in-MAC and VXLAN headers. If this required MTU size is not available, a log message reports that the IS-IS adjacency was not established. MTU cannot be auto-discovered over an IP tunnel so the tunnel MTU will not be automatically set. The default MTU value is 1950.

If the maximum MTU size has to be fewer than 1594 bytes, then you require fragmentation and reassembly of packets. The XA1400 Series and VSP 4450 Series/ONA combination supports fragmentation and reassembly, but you must have either an XA1400 Series or VSP 4450 Series with ONAs at BOTH ends of the IP WAN connection.

IP Shortcuts

The tunnel destination IP cannot be reachable through an IP Shortcuts route.

**Important**

If you enable IP Shortcuts and you are using the GRT as the tunnel source VRF, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.

If you enable IP Shortcuts and you are using a VRF as the tunnel source VRF, this is not an issue.

Layer 3 over Layer 2 Limitation

- The switch requires a single next hop (default gateway) for all tunnels.
 - Over a Layer 3 core network, on a given outgoing port or MLT, there is no issue as the one router next hop can support multiple VXLAN tunnels to one or more remote sites.
 - For Layer 3 tunneling over a Layer 2 core, the switch without any specific configuration supports only one Fabric Extend tunnel to one remote site. The workaround for this single next hop issue is to create an additional VRF, VLAN, and loopback interface.

**Note**

This limitation does not apply to VSP 4450 Series.

- You cannot establish a Virtual IST (vIST) session over a logical IS-IS interface. IST hellos cannot be processed or sent over a logical IS-IS interface if that is the only interface to reach BEBs in vIST pairs.

Assume that vIST is established over a regular NNI interface and the NNI interface goes down. If the vIST pairs are reachable through a logical IS-IS interface, then the vIST session goes down in up to 240 seconds (based on the IST hold down timer). During this time, the error message `IST packets cannot be sent over Fabric Extend tunnels, vist session may go down` is logged.

**Caution**

Expect traffic loss when the vIST session is down or when the error message is being logged.

Port Mirroring Resources

Port mirroring resources are limited to four ports simultaneously (where each mirroring direction counts as one). For example, if two mirroring ports are designated to mirror both ingress and egress traffic then all four mirroring ports are consumed.

Port mirroring shares these four resources with other applications such as port mirroring RSPAN, Fabric Extend, Application Telemetry, IPFIX, and ACL with mirror action. Each one of these applications consumes at least one port mirroring resource. (port mirroring RSPAN consumes two if you configure both Ingress and Egress modes.)

**Important**

To enable any one of the preceding applications, you must have at least one free mirroring resource. If all four port mirroring resources are already in use, the switch displays a `Resource not available` error message when you try to enable the application.

The VSP 8600 Series uses the four reserved resources for port mirroring and ACLs that have a mirroring action. For the other applications, this restriction does not apply because the VSP 8600 Series uses mirroring resources that do not come out of the four reserved port mirroring resources.

Fabric Extend over IPsec Limitations

- Fabric Extend over IPsec is only supported on XA1400 Series devices or on VSP 4900 Series and VSP 7400 Series using Fabric IPsec Gateway.
- Only pre-shared authentication key IPsec parameters are user configurable. Other, third-party solutions are not configurable.
- IKEv2 protocol key exchange only.
- IPsec support is only added for Fabric Extend tunnels.
- IPsec is not supported for regular Layer 3 routed packets.

ONA Considerations

Review the following restrictions, limitations, and behavioral characteristics that are associated with the ONA.

ONA Network port requirements

The following are **Network** port mandatory requirements for configuring Fabric Extend on the VSP 4450 Series:

- The ONA Network port should not be part of any static/LACP MLT configurations.
- The ONA Network port should be part of a VLAN that belongs to the GRT.
- The ONA Network port that is configured on the switch cannot be tagged. It must be an Access port.

ONA Device port requirements

The following are **Device** port mandatory requirements for configuring Fabric Extend on the VSP 4450 Series:

- The ONA Device port should not be part of any static/LACP MLT, VLAN, or brouter configurations.
- The ONA Device port should not be configured as an access port. It is automatically configured as a trunk port when the **ip-tunnel-source-address** command is configured.
- The ONA Device port has to be connected directly to the VSP 4450 Series node where the FE tunnels originate.

Layer 3 and Layer 2 ONA requirements

An ONA is required for Fabric Extend Layer 3 core solutions. An ONA is *not* required in Layer 2 core solutions because the tunnels are point-to-point VLAN connections, not VXLAN. Therefore, there is no need for an ONA to encapsulate a VXLAN header to SPB packets.

DHCP server

ONAs require access to a local DHCP server to automatically configure IP addresses. Configure an untagged ONA management VLAN to where the ONA is connected with its network side interface. If DHCP is used, a DHCP relay configuration needs to be added to the ONA network side port in order for the ONA to get an IP address assigned from a DHCP server. Alternatively, you can manually configure its IP address and other required settings with the ONA Manual Configuration menu.

IP tunnel source address

Before the ONA can get an IP tunnel source address from the VSP 4450 Series, the following steps must be taken:

- Connect the Device and Network ports on the ONA to the VSP 4450 Series.
- Make sure that the ONA is connected to a DHCP server. If a DHCP server is unavailable, statically configure an IP tunnel source address on the ONA.
- Create a Management VLAN on the ONA that includes the Network port.
- Designate the Device port for the IP tunnel source address in the configuration file.

The syntax for the IP tunnel source address is: **ip-tunnel-source-address <A.B.C.D> port <slot/port> [mtu <mtu_value>] [vrf WORD<1-16>]**.

Automatic routing of VXLAN packets on the VSP 4450 Series

If you configure an IP tunnel source address in a VRF instead of a GRT, then the VSP 4450 Series automatically routes VXLAN packets from the ONA network port into the VRF configured as part of the IP tunnel source. Although the ONA network port is a part of the management VLAN that is in the GRT,

for VXLAN encapsulated packets, the VSP 4450 Series automatically routes the packets into the VRF in which the tunnel source IP address is configured. This is done using a filter rule that the VSP 4450 Series software automatically sets up that filters based on whether the incoming port is equal to the ONA network port and the packet has a VXLAN header.

The Management VLAN on the VSP 4450 Series that is used to communicate with the ONA must always be in a GRT and must not be a part of the IP tunnel source VRF.

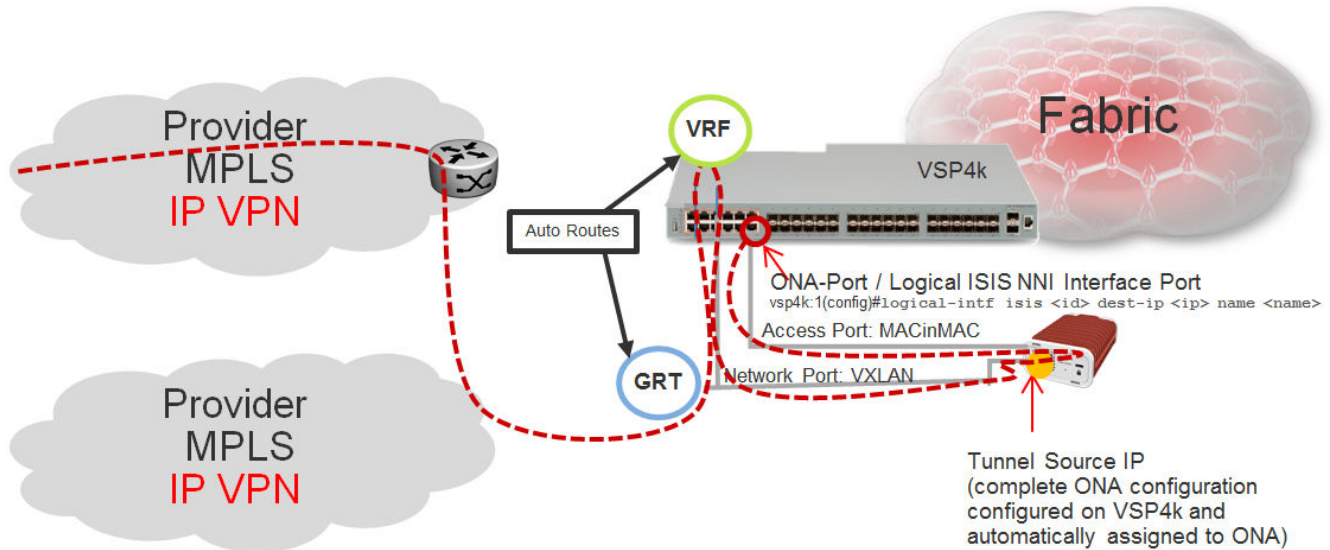

Figure 68: Autorouting between GRT and VRF

ONA Gateway

The ONA gateway has to be a local IP address on the ONA Management VLAN. The ONA gateway IP address must be the same as the local IP address of the VSP 4000 connected to the ONA.

Note

Extreme does not support ONA gateway IP addresses that are not local to the VSP 4450 Series. For example, you cannot use a VRRP IP address configured in a switch cluster for the ONA gateway.

Maximum MTU

The ONA supports a maximum transmission unit (MTU) size of 1950 bytes. For the VSP 4450 Series to work with a switch that supports Fabric Extend natively, the MTU size must be left at the default setting of 1950. If the core network does not support jumbo frames, the VSP 4450 Series with ONA must be used on all sites.

Fragmentation and reassembly

If the maximum MTU size has to be fewer than 1594 bytes, then you require fragmentation and reassembly of packets. The VSP 4450 Series with ONAs support fragmentation and reassembly, but you must have VSP 4450 Series switches with ONAs at BOTH ends of the IP WAN connection.

QoS priority queues

The ONA 1101GT implements both Layer 2 and Layer 3 QoS. Specifically, it implements IEEE 802.1Q VLAN TCI PCP (Priority Code Point) and IETF IPv4 DSCP (Differentiated Services Code Point). These are implemented in hardware with the limitation that there are four Weighted Random Early Detection (WRED) priority queues, numbered 4 (highest) to 7 (lowest). The following tables show the mappings from the PCP and DSCP values in the packet to the priority queue.

The hardware puts each packet in 1 of the 4 HW queues in the following order:

1. If a packet is a tagged VLAN packet, the PCP field determines the priority queue. (Ethertypes 0x8100 and 0x88a8 identify tagged VLAN packets.)
2. If the packet is an IPv4 packet, the DSCP field determines the priority queue.
3. Use the highest priority queue (4).

The HW QoS is always enabled, and the CP to priority queue mappings are static.

The following table defines the 3 bit VLAN PCP value to queue number mapping. The queues are numbered 4..7 with 4 being the highest priority and 7 the lowest priority.

Table 96: VLAN PCP to queue mapping

VLAN PCP	Queue Number
0	7
1	7
2	6
3	6
4	5
5	5
6	4
7	4

The following table defines the 6 bit IPv4 DSCP value to queue number mapping. The queues are numbered 4..7 with 4 being the highest priority and 7 the lowest.

Table 97: IPv4 DSCP to queue mapping

IPv4 DSCP	VLAN PCP	Queue Number
0	1	7
1	1	7
2	1	7
3	1	7
4	1	7
5	1	7
6	1	7

Fabric Attach

Table 98: Fabric Attach product support

Feature	Product	Release introduced
Fabric Attach Server	VSP 4450 Series	VOSS 5.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.0
	VSP 8400 Series	VOSS 5.0
	VSP 8600 Series	VSP 8600 6.3
	XA1400 Series	Not Supported

With Fabric Attach, network edge devices that do not support Shortest Path Bridging (SPB), MAC-in-MAC encapsulation (802.1ah) or service identifiers (I-SIDs) can take advantage of SPB infrastructure. To attach to an SPB network, edge devices signal an SPB-aware FA Server to automatically configure the I-SIDs. The edge devices can then utilize existing SPB features across the fabric and leverage SPB infrastructure capabilities without manual configuration. Fabric Attach uses the IEEE 802.1AB Logical Link Discovery Protocol (LLDP) to signal a desire to join the SPB network.

FA uses the client-server model. An initial handshake occurs between the FA Server and the FA Client. After the discovery phase is complete, the FA Server accepts requests (from FA Clients) to add the C-VID (VLAN ID) and I-SID elements in the SPB network, and also automatically configures the necessary C-VID and I-SID. The FA Server then responds with an acknowledgement of whether the request succeeded. FA Clients can also be aggregated into a proxy device that handles the handshakes and requests on behalf of many clients, to the server. All of the discovery handshakes and I-SID mapping requests are then transferred using LLDP Type, Length, Value (TLV) fields.

FA leverages LLDP to discover directly connected FA peers and to exchange information associated with FA between those peers. Based on the LLDP standard, FA information is transmitted using organizational TLVs within LLDP Protocol Data Units (PDU).

*FA Zero Touch Client Attachment***Table 99: Fabric Attach Zero Touch Client Attachment product support**

FA Zero Touch Client Attachment eases the configuration process on FA-capable devices by automating specific configuration tasks required for FA functionality.

**Note**

Only the base functionality of Zero Touch Client Attachment is supported.

After you initially configure Zero Touch Client Attachment on the FA Server, the settings are exported to receiving FA devices, where the required configuration tasks are automatically performed.

Base Zero Touch Client Attachment operation is tightly coupled with FA operation. Although you can enable or disable Zero Touch Client Attachment separately from FA, the feature is dependant on data that is only available during exchanges between the FA Server and FA Proxies, after a primary FA Server has been selected. By default, base Zero Touch Client Attachment support is enabled.

Base Zero Touch Client Attachment operation, when enabled, extracts management VLAN data from the primary FA Server advertisements and uses this data to update the in-use management VLAN if applicable. An FA Client can also utilize FA-provided management VLAN data after the FA Proxy or Server is discovered.

Zero Touch is active when the following criteria are met:

- On an FA Proxy:
 - Zero Touch Client Attachment is enabled
 - Fabric Attach is enabled
 - A primary FA Server is discovered and selected
- On an FA Server:
 - Zero Touch Client Attachment is enabled
 - FA is enabled
 - FA Proxies or FA Clients are discovered

The switch supports configurable VLANs in the range of 1 to 4059. VLAN 0 is invalid. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs on the switch range from 2 to 4094 but, by default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support

the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.

**Note**

You must enable Base Zero Touch **auto-client attach** and define the target Fabric Attach client in order to initiate Zero Touch Client Attachment processing.

FA Signaling generated by an FA Proxy or Server contains management VLAN data. If the management VLAN advertised by the primary FA Server differs from the management VLAN currently configured on the FA Proxy, Zero Touch Client Attachment initiates the following:

- VLAN creation — If the FA Server-specified management VLAN does not exist on the FA Proxy, Zero Touch Client Attachment creates a port-based VLAN.
- Management VLAN update — The created port-based VLAN becomes the designated management VLAN for the FA Proxy. No operations related to the previous management VLAN, such as port membership updates or VLAN deletion, are performed.
- Port VLAN membership update (FA Proxy/Server) — If required, Zero Touch Client Attachment updates the port VLAN membership to ensure that the uplink port through which the primary FA Server is accessed is a member of the management VLAN, for network accessibility.
- Port Default VLAN (PVID) update — The port-based PVID is automatically updated based on the VLAN ID value.
- Port Default Priority update — The default 802.1p user priority for the port is updated based on the specified port priority value of the Zero Touch client (range is 0–7).
- Zero Touch Client Specification removal — All Zero Touch client-related settings are updated based on the FA client discovery. Deleting a Zero Touch client specification or disabling any related Zero Touch option does not result in the immediate removal of any previously applied settings.

**Note**

The FA Proxy does not update the acquired management VLAN if the primary FA Server is lost. This data is updated if the management VLAN advertised by the current primary FA Server changes or if another primary FA Server is selected and new management VLAN data is advertised by the server.

Management VLAN and port membership updates performed by Zero Touch are maintained in non-volatile storage and are restored following a system reset. You must remove or update these configuration settings if they are deemed unnecessary at a later time.

- IP Address Source Mode Update — Updates the IP address source mode of the receiving device to DHCP-When-Needed, to initiate DHCP-based IP address acquisition if necessary.
- Automation of the FA Client Port Mode — Automates the configuration of EAP port modes based on the type of discovered FA Clients. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports.
- ZTC Installation — Initiates ZTC installation on applicable ports on the receiving device. Applies to FA Proxy and, in a limited manner, to FA Server devices. Automated configuration is applied only to FA-enabled ports.

- Auto Trusted FA Client Port Mode — Initiates automatic QoS interface class update based on the type of discovered FA clients. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports.
- Auto PVID FA Client Port Mode — Initiates automatic port PVID, port management VLAN membership and port tagging mode based on the type of discovered FA device. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports. This configuration is incompatible with the automatic FA Client Port Mode and ZTC Automatic attach options.

Fabric Attach Components

FA components dynamically communicate with each other using FA signaling.

FA Signaling

FA has defined organizational specific TLVs within the standard LLDP protocol, to exchange messages and data amongst components of an FA solution. The FA TLVs facilitate handshaking and authentication, processing of requests for the creation of services, and providing responses on whether the requests succeeded. In addition, these services are deleted when the service requests are terminated, or when the authentication criteria are no longer valid. All components that participate in FA must be able to send, receive, and interpret the FA TLVs.

FA Components

FA includes the following network elements as components:

- FA Server:

An SPB-capable switch at the edge of a Fabric Connect cloud.

An FA Server receives requests from FA Clients or FA Proxies to create services with specific I-SID-to-VLAN bindings. The FA Server completes the association between conventional networks and fabric-based virtual service networks. For more details on the operation of an FA Server, see [Fabric Attach Server](#) on page 973.

- FA Proxy:

A network switch that supports the definition of I-SID-to-VLAN assignments and has the ability to advertise these assignments for possible use by an FA Server. FA Proxy switches also support the client mode for directly attached users or end devices. Typically, FA Proxies support downstream FA Client devices, while being directly connected to an upstream FA Server device.

- FA Client:

A network attached end-point device that advertises I-SID-to-VLAN binding requests for service creation, to an FA Proxy or an FA Server. FA Clients use FA signaling to automatically attach to fabric services.

Fabric Attach Server

FA Server operation

In an FA solution, the FA Server performs the role of connecting FA Clients and FA Proxies to the SPB fabric, with minimal configuration. As part of the discovery handshake between the FA Server and client or proxy devices, LLDP PDUs are exchanged. Using standard LLDP, the FA Server learns neighbors, that

include the proxy and client devices. In addition, the FA Server transmits organizational-specific element-discovery TLVs that are used by the client or proxy device to recognize its attachment to the FA Server.

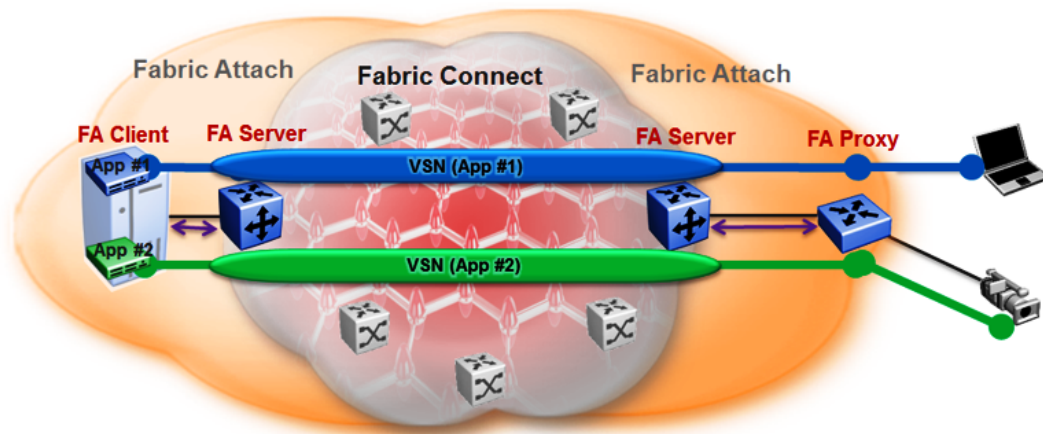

Figure 69: Fabric Attach Server connecting client or proxy devices to the Fabric network

After the initial discovery handshake is complete, the client or proxy device transmits I-SID-to-VLAN assignment mapping requests to the FA Server to join the SPB fabric. These requests include the C-VID (VLAN ID) and the I-SID that the client or proxy device needs to join. The FA Server then creates the requested C-VID and I-SID on its device. It then responds with a PDU (containing the FA-specific TLV) to indicate whether the request succeeded. The I-SID thus created is a ELAN I-SID with endpoints of type Switched UNI. After I-SID creation, the I-SID is also advertised to the SPB network by IS-IS.

The traffic that is sent to or received from the SPB cloud is MAC-in-MAC (MiM) encapsulated. The FA Server, being SPB-capable, decapsulates the MiM traffic. If the I-SID matches the I-SID created on behalf of the client or proxy, the FA Server sends the traffic to that client or proxy and passes it on the C-VID that it expects.

FA Server configuration

An FA Server can be configured at two levels—global and interface.

Configuration at the global level enables or disables FA on the entire switch. However, for attachment of clients or proxy devices, you must also configure FA at the interface level. Interfaces can be ports (including channelized ports), MLTs, SMLT or LACP MLTs. Enabling FA on an interface also enables transmission of LLDP packets that contain the FA-specific TLVs.

When you disable FA on an interface, LLDP transmission automatically stops on that interface.

Caution

Disabling FA or IS-IS triggers a flush of FA information on the switch. Disabling FA at the global level flushes all FA element-discovery information and mappings. Disabling at the interface level flushes element-discovery information and mappings associated with that interface.

Important

The only provisioning mode supported on the FA Server is SPB.

FA Proxies and FA Clients

The configuration mode of FA Proxies and FA Clients is not supported. However, in an FA solution, the FA Server interacts with FA Proxies and FA Clients by accepting LLDP PDUs (containing FA TLVs) and using them to automatically create Switched UNI I-SIDs and endpoints, based on the mapping requests contained in those TLVs. For more information, see [FA TLVs](#) on page 975.

Fabric Attach operation

The following sections detail FA operation.

FA TLVs

FA leverages LLDP to discover directly connected FA peers and to exchange information associated with FA amongst those peers. FA information is transmitted using company-specific proprietary organizational Type, Length, Value (TLV) fields within LLDP Protocol Data Units (PDU). The following section describes the TLVs for FA.

FA uses two TLVs:

- FA Element TLV
- FA Assignment TLV

FA Element TLV

The FA Element TLV is used by FA elements to advertise Fabric Attach capabilities. This data forms the basis for FA element discovery and is used in the initial handshake between the FA Server and a client or proxy device.

TLV Type [127]	TLV Length [50 octets]	OUI [00-04-0D]	Subtype [11]	HMAC-SHA Digest	Element Type	State	Mgmt VLAN	Rsvd	System ID
7 bits	9 bits	3 octets	1 octet	32 octets	6 bits	6 bits	12 bits	1 octet	10 octets

Figure 70: FA Element TLV format

Table 100: FA Element TLV field descriptions

Field	Description
TLV Type	Indicates whether the discovered element is a client or a proxy device.
OUI and Subtype	The information in these fields is used in LLDP packet handling.

Table 100: FA Element TLV field descriptions (continued)

Field	Description
HMAC-SHA Digest	<p>Data integrity and source validation is supported through the use of the HMAC-SHA256 message authentication. This field supports a digest exchange between the source and destination devices. Symmetric private keys are used for digest generation. The HMAC-SHA256 generated digest size is 32 octets.</p> <p>The HMAC-SHA256 digest is computed starting with the Element Type data, that is, it starts at zero-based byte 38 of the TLV. The digest is then placed in the HMAC-SHA256 Digest field in the TLV prior to transmission. Upon receipt, the digest is again computed and the resulting digest is compared against the received digest. If the received digest is the same as the newly computed digest, the TLV is considered valid and processing commences. If the comparison fails, the TLV is discarded and processing is terminated.</p> <p>Caution:</p> <p>If FA communication occurs between non-secure systems, the HMAC-SHA256 Digest data must always be zero. If one system operates in secure mode and the other operates in non-secure mode, the FA Element TLV is discarded before it is processed by the system operating in secure mode.</p>
Element Type	<p>Indicates the supported element type. The primary element types are the FA Server, FA Proxy and FA Client.</p> <p>An FA Server is an SPB capable device that accepts externally generated I-SID-to-VLAN assignments. An FA Proxy is a non-SPBM device that supports I-SID-to-VLAN assignment definitions and advertises these assignments for possible use by an FA Server. An FA Client, also a non-SPBM device, advertises I-SID-to-VLAN assignments to a directly connected FA Proxy or an FA Server. Both tagged and untagged FA Client connections are supported.</p> <p>The list of supported element types and their values are:</p> <ul style="list-style-type: none"> • FA Element Type - Other (1) • FA Server (2) • FA Proxy (3) • FA Server No Authentication (4) • FA Proxy No Authentication (5) • FA Client - Wireless Access Point Type 1, which directly attaches to the SPBM network. • FA Client - Wireless Access Point Type 2, which is tunneled to a controller. • FA Client - Switch (8) • FA Client - Router (9) • FA Client - IP Phone (10) • FA Client - IP Camera (11) • FA Client - IP Video (12) • FA Client - Security Device (13) • FA Client - Virtual Switch (14) • FA Client - Server/Endpoint (15)

Table 100: FA Element TLV field descriptions (continued)

Field	Description
State	<p>Indicates the link tagging requirements in FA Client-sourced frames. This field also indicates the current provisioning mode.</p> <p>The Link VLAN Tagging bit (bit 1) has one of the following values:</p> <ul style="list-style-type: none"> 0 – indicates that all traffic on the link is tagged. In this case, all discovered FA Clients are treated as tagged. 1 – indicates that traffic on the link is either tagged or untagged. Here, all discovered FA Clients are treated as untagged. <p>The automatic provisioning mode bits (bits 2 and 3) always have the value 1 for SPB provisioning. The switch only supports the SPB provisioning mode.</p>
Mgmt VLAN	<p>When you configure a management VLAN on the FA Server, it is included in this field in FA Server or FA Proxy sourced frames, and is used to support management VLAN auto-configuration on the downstream proxy and client devices.</p>
System ID	<p>This field contains connection information that a TLV recipient can use to enforce connectivity restrictions.</p> <p>It contains the system MAC address (6 octets) for MLT configurations and the virtual BMAC address for vIST and SMLT configurations. It also contains information on the connection type such as MLT or SMLT.</p>

Limitations

- The FA Element TLV exists only once in an LLDP PDU and is included in all PDUs when the FA service is enabled.
- The maximum length of the FA Element TLV is 56 bytes.

FA I-SID-to-VLAN Assignment TLV

The FA I-SID-to-VLAN Assignment TLV is used by FA Clients to distribute I-SID-to-VLAN assignments that need to be supported by an FA Proxy or an FA Server.

TLV Type [127]	TLV Length [41-506 octets]	OUI [00-04-0D]	Subtype [12]	HMAC-SHA Digest	Assignment Status	VLAN	I-SID
7 bits	9 bits	3 octets	1 octet	32 octets	4 bits	12 bits	3 octets

Figure 71: FA Assignment TLV format

FA I-SID-to-VLAN Assignment TLV fields

Some fields are common to both the FA Element and FA Assignment TLVs. The following fields are specific only to the FA Assignment TLV.

TLV Field	Description
HMAC-SHA Digest	<p>The HMAC-SHA256 digest is computed for the series 1 to 94 of I-SID-to-VLAN assignments, that is, the data for the digest computation starts at zero-based byte 38 of the TLV. The digest is then placed in the HMAC-SHA256 Digest field in the TLV prior to transmission. Upon receipt, the digest is again computed for the series 1 to 94 of I-SID-to-VLAN assignments in the received TLV and the resulting digest is compared against the received digest. If the received digest is the same as the newly computed digest, the TLV is considered valid and processing can commence. If the comparison fails, the TLV is discarded and processing is terminated.</p> <p>Caution: If FA communication occurs between non-secure systems, the HMAC-SHA256 Digest data must always be zero. If one system operates in secure mode and the other operates in non-secure mode, the FA I-SID-to-VLAN Assignment TLV is discarded before it is processed by the system operating in secure mode.</p>
Assignment status	Indicates whether the FA Server accepted or rejected the I-SID-to-VLAN mapping request from a client or proxy device.
VLAN	Indicates the C-VID value advertised by the client or proxy device in the FA I-SID-to-VLAN mapping request.
I-SID	<p>Indicates the I-SID that is advertised by a client or proxy device in the FA I-SID-to-VLAN mapping request. This I-SID is used to create a Switched UNI (ELAN) I-SID.</p> <p>Note: This I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or Transparent Port UNI.</p>

Limitations

- The FA I-SID-to-VLAN Assignment TLV is included in an LLDP PDU only if the FA Server and proxy or client devices are directly connected to each other.
- This TLV can exist only once in an LLDP PDU.
- The size limit of this TLV is 511 bytes. This limits the maximum number of I-SID-to-VLAN assignments supported in an LLDP PDU to 94.
- For an FA I-SID-to-VLAN Assignment TLV to be processed, the FA Element TLV must also be present in the LLDP PDU.

FA Element Discovery

The first stage of establishing FA connectivity is element discovery.

On an FA Server, FA is enabled globally by default. However, you must explicitly enable FA on a desired port or MLT interface. After FA is enabled, the FA Server begins transmitting LLDP PDUs that contain the element discovery TLVs. This information is received by FA Client and FA Proxy devices which in turn also transmit their FA capabilities and settings. After the element handshake completes, the FA Server receives I-SID-to-VLAN assignment mappings from the connected client or proxy devices.

An FA Server can communicate with multiple different FA Client and FA Proxy devices.

FA data processing

In the following FA deployment, a client device (Client 1) attaches to the FA Server (FA Server 1) using a proxy device. Another client device (Client 2) attaches to the FA Server (FA Server 2) at the other edge of the network. The following section describes how data is processed when data traffic is transmitted from Client 1 to Client 2.

When Client 1 successfully attaches to FA Server 1, FA Server 1 creates a unique I-SID-to-VLAN mapping for Client 1 on its device. This mapping contains the I-SID and C-VID advertised by Client 1, using the FA Assignment TLV. For example, assume that Client 1 advertises I-SID 200 and C-VID 250.

Similarly, when Client 2 attaches to FA Server 2, FA Server 2 creates an I-SID-to-VLAN mapping for Client 2 on its device with, for example, I-SID 200 and C-VID 100. This is depicted in the following figure.

Figure 72: Learning of I-SID-to-VLAN mappings

When data traffic ingresses FA Server 1 at the FA-enabled port 1/1, it contains the C-VID of Client 1, which is, 250. The data is VLAN-encapsulated at this stage. As traffic egresses FA Server 1 into the SPB cloud, it is encapsulated with the ELAN I-SID created on FA Server 1 on behalf of Client 1, that is I-SID 200. The traffic is now MiM encapsulated with I-SID 200.

The following figure depicts VLAN encapsulation of data traffic from the FA Client to the FA Server (at either end of the SPB cloud) and its MiM encapsulation as it traverses the SPB cloud.

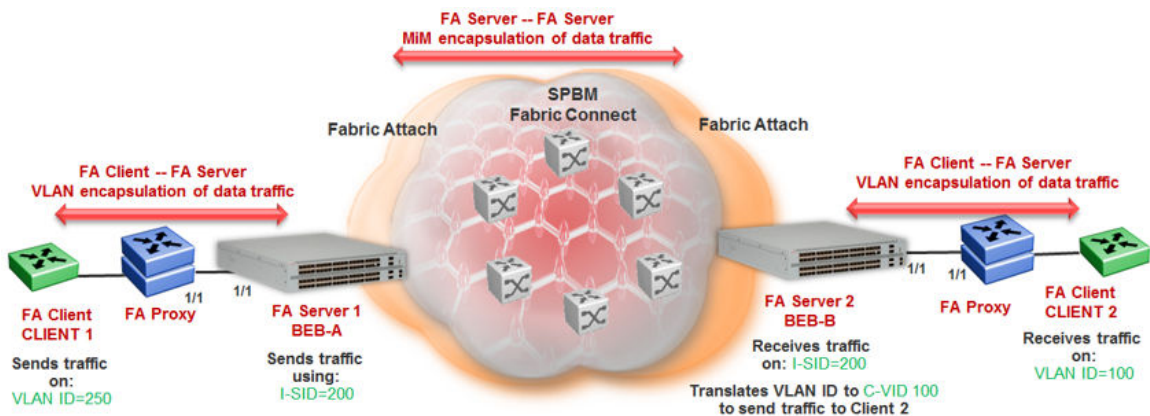

Figure 73: Data encapsulation – VLAN encapsulation and MiM encapsulation

As traffic exits the SPB cloud and ingresses the remote FA Server 2, it continues to be MiM encapsulated with I-SID 200.

At FA Server 2, the MiM traffic is decapsulated. Since the I-SID in the data packet matches the I-SID created on its device on behalf of Client 2, FA Server 2 prepares to send traffic to Client 2. At this stage, to successfully transmit the data traffic to Client 2, FA Server 2 must additionally know the C-VID that

Client 2 expects traffic on. This information is obtained from the I-SID-to-VLAN mapping on FA Server 2 created on behalf of Client 2, which is C-VID 100. Thus FA Server 2 translates the C-VID in its data packets to this VLAN ID, and then passes it on to Client 2.

The following figure depicts the typical MiM encapsulation of a data packet. The B-DA and B-SA components indicated the system ID of the FA Server running SPB.

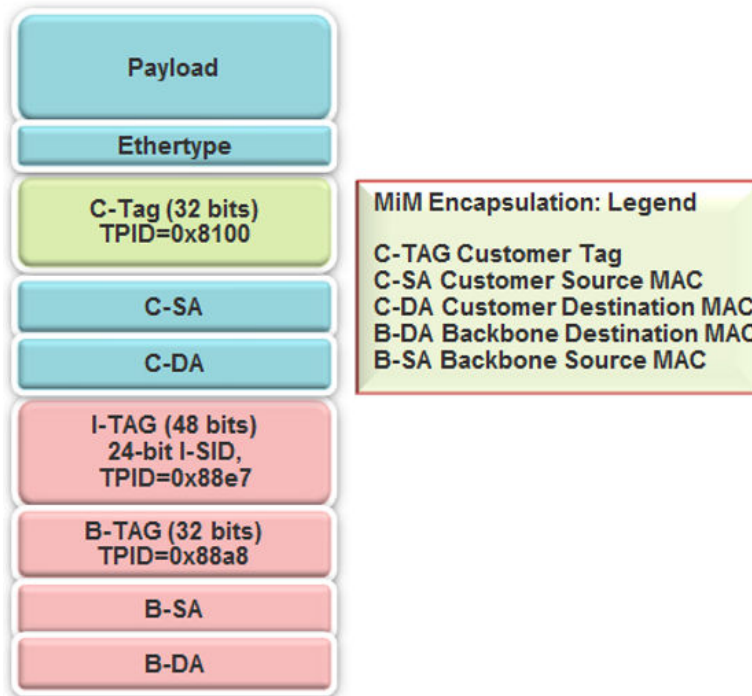

Figure 74: MiM encapsulation

FA Server and I-SID-to-VLAN Assignments

FA Client or FA Proxy devices advertise I-SID-to-VLAN assignments to be supported on the FA Server. These assignments can be accepted or rejected by the FA Server. All communication between FA Proxies or Clients and the FA Server is using LLDP. Successful assignments result in the creation of a Switched UNI I-SIDs and endpoints based on the mapping requests.

The FA Server rejects I-SID-to-VLAN assignment requests if:

- FA is not configured properly on the port or MLT.
- Router IS-IS is disabled.

Note

For Fabric Attach to operate properly and for the FA Server to accept I-SID-to-VLAN assignment requests, IS-IS must be enabled.

The following error message is logged immediately after IS-IS is disabled, and displays the error message only once in the log file. The system does not display it again when an assignment request is made from the FA Proxy.

```
CP1 [12/04/15 00:33:49.733:UTC] 0x00374589 00000000
GlobalRouter FA INFO Fabric Attach Assignments will be rejected
since ISIS is disabled.
```

- The C-VID and I-SID are not within the supported range.

Different hardware platforms support different customer C-VID ranges. The value 4095 is not supported. The value 4096 indicates that the port is untagged. An I-SID value of 0 is not supported on the FA Server.

- The I-SID is already assigned to an IP VPN.

The system displays the error message `I-SID is already assigned to an IPVPN`.

- The I-SID is already in use for SPB multicast.

The system displays the error message `SPB Multicast is enabled, ISID 16000000 and greater reserved for dynamic data-isid's used to carry Multicast traffic over SPB`.

- The I-SID has a value that is reserved for internal use.
- The I-SID cannot be used in an IS-IS accept policy.
- The I-SID is associated with a platform VLAN and that VLAN is used as a private VLAN (that is, has a secondary VLAN specified).
- The I-SID is already in use for Transparent Port UNI.
- The port that receives the I-SID-to-VLAN assignment is a member of an MLT, but FA is not successfully enabled on that MLT interface.
- There is a resource error on the FA Server system, such as lack of memory.
- The number of I-SID-to-VLAN assignments on a port exceeds the maximum limit which is 94.
- The number of I-SIDs on the switch exceeds the maximum limit.
- The same endpoint is configured on more than one I-SID.
- The port or MLT is associated with more than one C-VID in the same I-SID.

When the FA Server rejects I-SID-to-VLAN assignments, aside from viewing the log file, you can use trace to troubleshoot the cause of rejection.

For an example on troubleshooting rejection of I-SID-to-VLAN assignments on the FA Server and for more information on using trace, see [Troubleshooting Fabric Attach](#) on page 3682.

FA management

You can configure a management I-SID on an FA-enabled port or MLT. This I-SID includes an optional C-VID parameter, which is a VLAN ID that is locally significant to the port or MLT and does **not** represent a platform VLAN.

Depending on whether the C-VID value is specified, the behavior is as follows:

- If the C-VID value is specified, the FA Server transmits this VLAN ID as the management VLAN in the FA Element TLV. A client or proxy receiving this TLV uses this VLAN ID for management traffic on the FA Server uplink.

Different hardware platforms support different customer C-VID ranges.

- If the C-VID value is not specified, the FA Server transmits a management VLAN with a VLAN ID value of 4095 in the FA Element TLV. A client or proxy receiving this TLV uses **untagged** traffic for network management on the FA Server uplink.

If you do not configure a management I-SID, the FA Server transmits a management VLAN ID value of 0 in the FA Element TLV. A client/proxy that receives the FA Element TLV retains the initial management configuration (if any) on its device.

Limitations of FA management I-SIDs

- A management I-SID value of 0 is not supported on the FA Server.
- You cannot enable BPDU on a management I-SID.

FA management configuration considerations

A Switched UNI I-SID that is created when an FA assignment is learned on a port or MLT, is uniquely identified by a tuple comprising of one of the combinations of (port, I-SID and C-VID) or (MLT ID, I-SID and C-VID). When you configure FA management, similar tuples are used. You can configure FA management on an FA-enabled port or MLT on which FA assignment mappings are learned, as long as the FA management tuple exactly matches the tuple created by the learned FA mapping.

The following scenarios describe the behavior when you configure FA management on a port or MLT that also receives learned FA mappings, but the tuples do not match.

- **Scenario 1:** You attempt to configure FA management on a port or MLT where an FA assignment mapping is already learned.

For example, consider an FA-enabled port 1/1 on which an assignment mapping is learned, with I-SID 100 and C-VID 20. You can configure FA management on port 1/1 as long as the I-SID and C-VID values exactly match that of the learned FA mapping. However, if you attempt to configure FA management on the port with a different I-SID and C-VID value, the configuration is not successful and an error message displays.

- **Scenario 2:** An FA assignment mapping is learned on a port or MLT that already has FA management configured.

For example, consider that FA management is configured on port 1/1. If an FA assignment mapping is learned on the port with the same I-SID and C-VID values as that of the FA management configuration, then the mapping is accepted. Otherwise the mapping is rejected.

FA message authentication and integrity protection

For the security of FA communication in terms of data integrity and authenticity, a keyed-hash message authentication code can be transmitted within every FA TLV.

It protects the I-SID-to-VLAN assignment exchanges between the FA Server and FA Proxy. The standard HMAC-SHA256 algorithm calculates the message authentication code (digest) involving a cryptographic hash function (SHA-256) in combination with a shared secret key. The key is symmetric, that is, it is known by both the source and destination parties.

By default, on the FA Server, message authentication is enabled at the interface level and a default key is defined to provide secure communication.

You can configure a different authentication key on an interface (port or MLT) on the FA Server, to authenticate a client on that interface. The authentication key is stored in encrypted form when you save configuration on the FA Server. For an FA Client to authenticate and attach to the FA Server, the authentication key must match on both the client and the server. In general, the FA authentication key must match between two FA components exchanging FA TLVs through LLDP.

When you enable FA message authentication, the message authentication key (default or configured) generates a Hash-based Message Authentication Code (HMAC) digest that is included in FA I-SID-to-VLAN Assignment TLV. Upon receipt, the HMAC digest is recomputed for the TLV data and compared against the digest included in the TLV. If the digests are the same, the data is valid. If the digests are not the same, the data is considered invalid and is ignored.

The FA secure communication setting (enabled/disabled) and the symmetric key data are maintained across resets and restored during FA initialization.

Fabric Attach and Switched UNI

With the C-VLAN UNI feature, I-SID-to-VLAN mappings must be unique across the network. With the Transparent Port UNI (ELAN Transparent) feature, you can map an entire port or MLT to an I-SID.

With the Switched UNI feature, you can associate many different C-VID/port or C-VID/MLT list combinations to a single I-SID.

Switched UNI and FA

FA brings the capability of automatically creating Switched UNI I-SIDs on a switch, without manual intervention. The I-SIDs thus created are ELAN I-SIDs with endpoints of type Switched UNI, and are by default for Layer 2. MAC learning takes place and there is an any-to-any relationship. For Layer 3 participation, you must configure a platform VLAN with the same I-SID value as that of the I-SID in a learned FA mapping.

Note

The number of Switched UNI I-SIDs created are different for different product families. For more information, see [VOSS Release Notes](#).

Limitations of FA-created Switched UNI I-SIDs

- An FA-created Switched UNI I-SID is always ELAN.
- You cannot enable BPDU on an FA-created Switched UNI I-SID.

- The ELAN I-SIDs created are by default for Layer 2. For Layer 3 participation, you must manually configure a platform VLAN with the same I-SID value as that of the I-SID in a learned FA mapping. You can configure the platform VLAN with the same VLAN ID as that of the C-VID, or use a different value.
- The Switched UNI (ELAN) I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or a T-UNI.
- You cannot change from one UNI type to another dynamically. The I-SID must be deleted and created with the new UNI type (Customer VLAN (C-VLAN), Transparent Port user-network-interface (T-UNI), ELAN).
- If the port is a member of an MLT, you must add the entire MLT to the C-VID.
- The port is always in the forwarding state.
- You cannot associate a port or MLT with more than one C-VID in the same I-SID.
- The same C-VID, port or MLT cannot be a member of more than one I-SID. Different hardware platforms support different customer C-VID ranges. The value 4095 is not supported and cannot be configured. The value 4096 indicates that the port is untagged.
- An I-SID value of 0 is not supported on the FA Server.

Fabric Attach Deployment Scenarios

Fabric Attach is typically deployed in the access layer(s) of a Fabric Connect network.

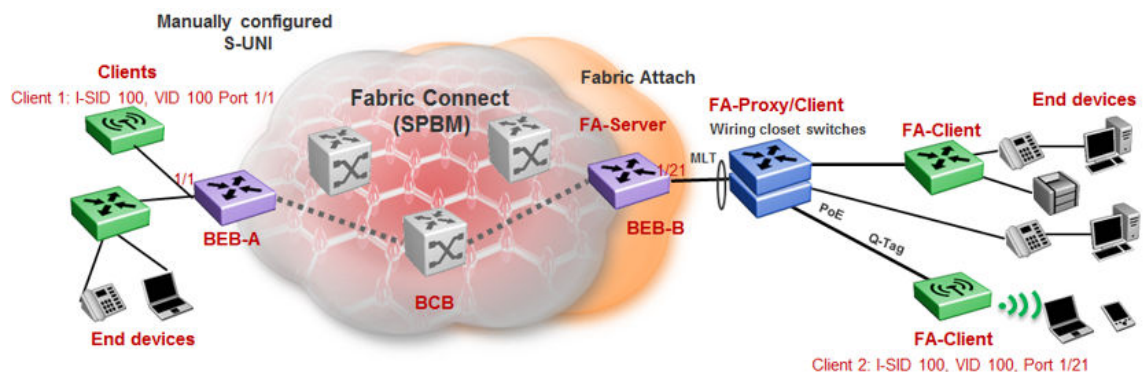

Fabric Attach, when used with a Fabric Connect solution, provides the same capabilities at the access layer, but those services and policies are now mapped across the entire network end-to-end. FA makes user and end device attachment simple and creates network configuration and sets up resources only when needed.

An FA Server can be connected to FA Client or FA Proxy devices on three types of interfaces, namely, a port, MLT or an SMLT. The following sections discuss FA in SMLT and non-SMLT deployments.

FA and Switched UNI in non-SMLT deployments

The following deployment shows an SPBM network in which one edge has manually configured Switched UNI I-SIDs and the other edge has Fabric Attach (FA). At the FA edge, the I-SIDs are learned using FA TLVs and are automatically created on the FA Server as ELAN I-SIDs with Switched UNI endpoints.

This deployment demonstrates that the FA-created I-SIDs can communicate with any other I-SID (manually created Switched UNI or a C-VLAN with an I-SID), on the local switch or across the SPBM fabric, as long as the I-SID values are the same.

BEB-B is a switch acting as the FA Server with an NNI interface to the SPBM cloud. FA Client and FA Proxy devices send I-SID-to-VLAN mapping requests to the FA Server on the respective FA-enabled ports, using LLDP TLVs. This enables the I-SID endpoints to communicate with the SPB cloud.

If several clients are aggregated in an MLT, at least one of the ports must send the mapping requests for the FA Server to create the I-SID endpoints for that MLT. For example, let Client 2 be a wireless FA Client (such as an WLAN 9100 AP device) on port 1/21, that sends an FA mapping request for I-SID 100 and C-VID (VLAN ID) 100. The FA Server (BEB-B) creates the requested I-SID 100 on its device, and advertises it to the SPB cloud.

BEB-A has manually configured Switched UNI endpoints, one of which is Client 1 (connected at port 1/1) using the same I-SID value 100.

With this setup, data traffic can freely flow between Client 1 and Client 2 through the two BEBs and the BCB.

Thus the Switched UNI I-SIDs learned using FA TLVs on one edge of the Fabric Connect (SPBM) network can communicate with the manually created I-SIDs on the other edge, as long as they both have the same value.

FA and Switched UNI in SMLT deployments

The following examples discuss FA in dual-homed and single-homed SMLT deployments.

Fabric Attach in a dual-homed SMLT deployment

The following section describes FA in a dual-homed SMLT deployment. A pair of switches that operate as IST peers act as the FA Server. An FA Proxy (typically a wiring closet switch or an access switch) is connected to FA Clients and in turn to end devices. The FA Clients or FA Proxies advertise I-SID-to-VLAN mappings namely the interface C-VID and the I-SID to the FA Server switches. Both switches receive the mapping information using LLDP TLVs. The switch that learns the mapping first from the LLDP TLV considers the I-SID endpoint to be discovered locally, and creates the I-SID on its device. It then sends the mapping information to its peer switch. When the peer switch receives the mapping across IST in a new SMLT message, it too creates the I-SID and endpoint on its device. This I-SID however, is considered to be discovered remotely, because the data was synchronized from its peer.

Note

- For the peer switches acting as the FA Server to transmit the same FA System ID (based on the virtual MAC), SMLT configuration must be the same on both peers.
- For successful FA operation, configuration of FA message authentication and the authentication key must be the same on both peers.
- For successful operation in Layer 3, a platform VLAN must be configured on both peers. This is necessary for proper MAC learning.

Figure 75: FA in a dual-homed SMLT deployment

In the above example deployment, BEB-A and BEB-B are IST peers collectively acting as the FA Server. FA TLVs sent from the clients (through the proxy) are learned on FA-enabled ports on BEB-A and BEB-B. When BEB-A learns the mapping for the first time on its port, it creates an I-SID on its device. This is considered locally discovered. In addition, it sends an SMLT message to its peer BEB-B, which also creates the I-SID on its device. This time, the I-SID is considered remotely discovered. Similarly, if BEB-B receives a mapping from a client for the first time, it creates an I-SID (locally discovered) and also sends an IST message to its peer to create an I-SID (remotely discovered).

Irrespective of whether the I-SID creation on the FA peers is triggered by a local TLV event or by messaging from the IST peer, they can both receive data traffic. Thus in a dual-homed SMLT deployment, any I-SID can be learned irrespective of whether it is discovered locally, discovered remotely or both.

Note

On the IST peers, if an FA TLV is learned on a port or normal MLT (instead of the admin SMLT), only the I-SID is sent to the peer switch.

Fabric Attach in a single-homed SMLT deployment

In the single-homed SMLT, as shown in the following deployment, the FA Server creates either a locally discovered I-SID (if received from a client using FA TLVs) or a remotely discovered I-SID (if synchronized from its IST peer), but not both.

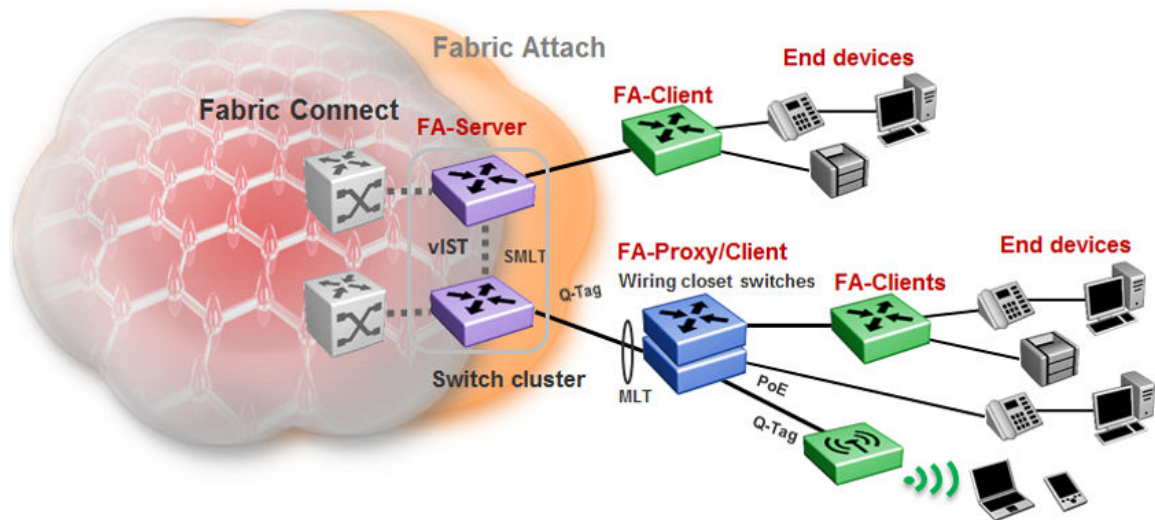

Figure 76: Fabric Attach in a single-homed SMLT deployment

Fabric Attach Considerations

Review the following restrictions, limitations, and behavioral characteristics for Fabric Attach.

- IS-IS and FA must be globally enabled on the FA Server, for FA to operate successfully.
- Static MAC, Static ARP and configuration of a static IGMP group are not supported on FA-enabled ports.
- An FA port cannot be a BROUTER port.
- You cannot enable FA on an existing Transparent Port UNI or a C-VLAN UNI port.
- On VSP 8600 Series, you cannot enable FA on an existing Switched UNI.
- FA I-SID-to-VLAN assignment mapping requests from a client or proxy device can be accepted or rejected by the FA Server.
- On an FA-enabled port or MLT, you must first disable LACP before you change the LACP key.
- You can only enable VLACP on an FA enabled MLT; VLACP is not supported on FA enabled non-MLT ports.
- On VLACP enabled ports, FA and LLDP signaling run independent of the VLACP state. Therefore, requests and responses are exchanged between the FA Server and client or proxy devices even if VLACP is operationally down. However, forwarding of data traffic is dependent on VLACP being operationally up on the port.

For example, if VLACP is enabled on the FA Server side of the link but not on the proxy or the client side, the FA Server learns the I-SID-to-VLAN assignment mappings and creates the required I-SIDs on its device. However, data traffic is not forwarded on the port until VLACP is operationally up.

- On VSP 4450 Series, you cannot use a port designated as a Fabric Extend tunnel source, configured using the command **ip-tunnel-source-address**, for Fabric Attach.
- FA uses the virtual MAC to create the FA system ID when the FA is on an SMLT. If you delete the SPBM instance, then this information is no longer available. Therefore, you must delete the FA on SMLT before deleting the SPBM instance.

- You cannot enable FA and Endpoint Tracking simultaneously on the same interface.
- On VSP 8600 Series, dynamically learned Fabric Attach announced VLAN:ISID bindings and manually configured Switched-UNI end-points are not supported on the same interface.

Endpoint Tracking

Table 101: Endpoint Tracking product support

Feature	Product	Release introduced
Endpoint Tracking	VSP 4450 Series	Not Supported
	VSP 4900 Series	Not Supported
	VSP 7200 Series	VOSS 8.1.1
	VSP 7400 Series	VOSS 8.1.1
	VSP 8200 Series	VOSS 8.1.1
	VSP 8400 Series	VOSS 8.1.1
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

Endpoint Tracking Overview

Endpoint Tracking provides dynamic assignment of virtual machines (VMs) to IP subnets as they attach to a Shortest Path Bridging (SPB) cloud. Deployment scenarios include VMs connecting to DVR Leaf nodes, or regular SPBM deployments.

Extreme Management Center or ExtremeCloud IQ - Site Engine is integral to the Endpoint Tracking solution. Extreme Management Center or ExtremeCloud IQ - Site Engine delivers automation; there is no need to manually configure server VLANs on data center access switches. Additionally, Extreme Management Center or ExtremeCloud IQ - Site Engine) provides the ability to see what VM MACs exist, and where they are located.

Extreme Management Center or ExtremeCloud IQ - Site Engine's ExtremeConnect module integrates with third-party virtualization software (such as VMware or Microsoft HyperV) and communicates with the ExtremeControl module to automatically extract all of the VM MACs (including VLAN assignment for each MAC) and then automatically create all of the necessary authentication profiles, rules and mappings.

When the switch detects a new VM on a port, it sends a RADIUS request to Extreme Management Center or ExtremeCloud IQ - Site Engine. ExtremeConnect checks with VCenter for the Port Group, VLAN ID, and I-SID information that corresponds with the VM, communicates with the ExtremeControl module for the RADIUS authentication, and sends the RADIUS response back to the switch with the VLAN:ISID binding information. Based on the binding, the switch then automatically creates a dynamic Switched UNI (S-UNI). Dynamic S-UNIs are not saved into the configuration file.

Typical Endpoint Tracking Implementation Example

The following example shows a typical implementation of Endpoint Tracking and the dynamic I-SID assignment process, as provisioned in Extreme Management Center or ExtremeCloud IQ - Site Engine.

Figure 77: Endpoint Tracking Example

The sequence within and among the four example VLANs in this configuration is as follows:

1. The RADIUS server authenticates VM1, and the switch automatically creates a Switched UNI with VLAN 10 and I-SID 10 binding, (using the outbound attributes received from the RADIUS server). Subsequently, the server authenticates VM2, which uses the same Switched UNI.
2. Similarly, on the other side of the SPB cloud, the RADIUS server authenticates VM5 and the switch automatically creates a Switched UNI with VLAN 30 and I-SID 10 binding, (using the outbound attributes received from the RADIUS server). Subsequently, the server authenticates VM6, which uses the same Switched UNI.
3. The same sequence occurs for VMs 3 and 4, and PCs 7 and 8, with the first authentication in each VLAN providing the outbound RADIUS attributes needed for the creation of a Switched UNI for that VLAN.
4. The final result is that VMs 1, 2, 5, and 6 can access each other on I-SID 10, and VMs 3, 4, 7, and 8 can access each other on I-SID 20.

Static S-UNIs and Visibility Mode

Endpoint Tracking can also be used in cases where static S-UNIs are configured on Endpoint Tracking-enabled ports. In this case, the MACs are allowed by default on the static S-UNI. However, by default, the

MACs learned on a static S-UNI are not learned at the Endpoint Tracking level. Endpoint Tracking Visibility Mode allows tracking of MACs that are learned on static S-UNIs. This implies that a binding is created for these MACs, but these bindings do not create dynamic S-UNIs, they are used for tracking purposes only.

Interface Support

Endpoint Tracking is supported on Ethernet ports, MLTs, and SMLTs.

If the switch is a Virtual IST (vIST) peer, the dynamic Switched UNI is synchronized to its vIST peer as follows:

- If the MAC is learned on an SMLT UNI interface, all Switched UNI information is synchronized to the vIST peer.
- If the MAC is learned on a non-SMLT UNI interface, only the I-SID is synchronized to the vIST peer.

VM Moves and VLAN:ISID Bindings

When a VM moves to a new switch within a network (with no change to the VLAN segment), the new switch triggers a new RADIUS authentication, which points that VM MAC to the new switch, and new bindings are applied on the new switch. The old switch detects that the VM MAC is moved and automatically deletes the old binding, if the old binding has not already aged out.

However, if a VM remains attached to the same (previously authenticated) switch, but the VLAN segment is changed, you must push a reauthentication request from Extreme Management Center or ExtremeCloud IQ - Site Engine to force the required binding updates. For more information about managing binding updates using RADIUS Change-of-Authorization (CoA) functionality, see [Extreme Management Center or ExtremeCloud IQ - Site Engine Integration](#) on page 990.

Operational Considerations

Consider the following when implementing Endpoint Tracking:

- A RADIUS server used for Endpoint Tracking provides authorization only; no accounting processes are supported. Although accounting is enabled by default for all RADIUS servers, it is not currently supported for use with Endpoint Tracking, even if left enabled.
- Fabric Attach is not supported on ports or MLT/SMLTs that have Endpoint Tracking enabled.

Extreme Management Center or ExtremeCloud IQ - Site Engine Integration

Endpoint Tracking integrates with Extreme Management Center or ExtremeCloud IQ - Site Engine ExtremeConnect and ExtremeControl modules. The ExtremeConnect module offers API integration with third party products, such as VMware or Microsoft HyperV, from which VM endpoint information is extracted and automatically converted into usable policies for use in the ExtremeControl module, which acts as a RADIUS server for authorizing Endpoint Tracking MACs.

The following diagram illustrates an example of Extreme Management Center or ExtremeCloud IQ - Site Engine interaction with a switch for Endpoint Tracking:

Figure 78: Extreme Management Center or ExtremeCloud IQ - Site Engine Endpoint Tracking Interaction Example

RADIUS Server Attributes

The RADIUS attributes to configure in either standard or custom Extreme Management Center or ExtremeCloud IQ - Site Engine RADIUS profiles for Endpoint Tracking depend on your deployment and traffic type:

- For tagged traffic, if the RADIUS server provides both the VLAN ID and I-SID value, use only the **FA-VLAN-ISID** attribute.
- For tagged traffic, if the RADIUS server provides only the VLAN ID (and you are therefore using an I-SID offset value), use only the **Tunnel-Private-Group-ID** attribute.
- For untagged traffic, if the RADIUS server provides both the VLAN ID and I-SID value, use the **FA-VLAN-ISID** and **Egress-VLANID** or **Egress-VLAN-name** attributes.
- For untagged traffic, if the RADIUS server provides only the VLAN ID (and you are therefore using an I-SID offset value), use the **Tunnel-Private-Group-ID** and **Egress-VLANID** or **Egress-VLAN-name** attributes.
- Use the **Session-Timeout** attribute to override the default timeout period of 24 hours, which is amount of time, in seconds, between a MAC address authentication and the deletion of that MAC address from the Endpoint Tracking binding table.

All other RADIUS attributes are ignored.

Managing Binding Updates using RADIUS Change-of-Authorization

Endpoint Tracking uses RADIUS RFC 5176 Change-of-Authorization (CoA) functionality to enable forced VLAN:ISID binding updates.

For example, when a VLAN segment is changed on a VM that resides on a previously authenticated switch, that VM requires a new VLAN:ISID binding to reflect the new VLAN segment. Because the switch has previously been authenticated, you must force a new authentication request to update the binding information.

Using ExtremeControl, you can manually push a reauthentication request for the VM MAC. This action sends a disconnect-request from the RADIUS server to the switch, which deletes the old binding. When the switch detects the VM again, a new RADIUS authentication request is sent from the switch to the RADIUS server, resulting in updated binding information upon successful authentication.

For more information about RADIUS Dynamic Session Change Support (RFC 5176), see [RFC 5176 – Dynamic Session Change](#) on page 2728.

Deployment Examples

Endpoint Tracking deployment scenarios include Distributed Virtual Routing (DvR) deployments, or regular SPBM deployments.

The following example illustrates a DvR deployment:

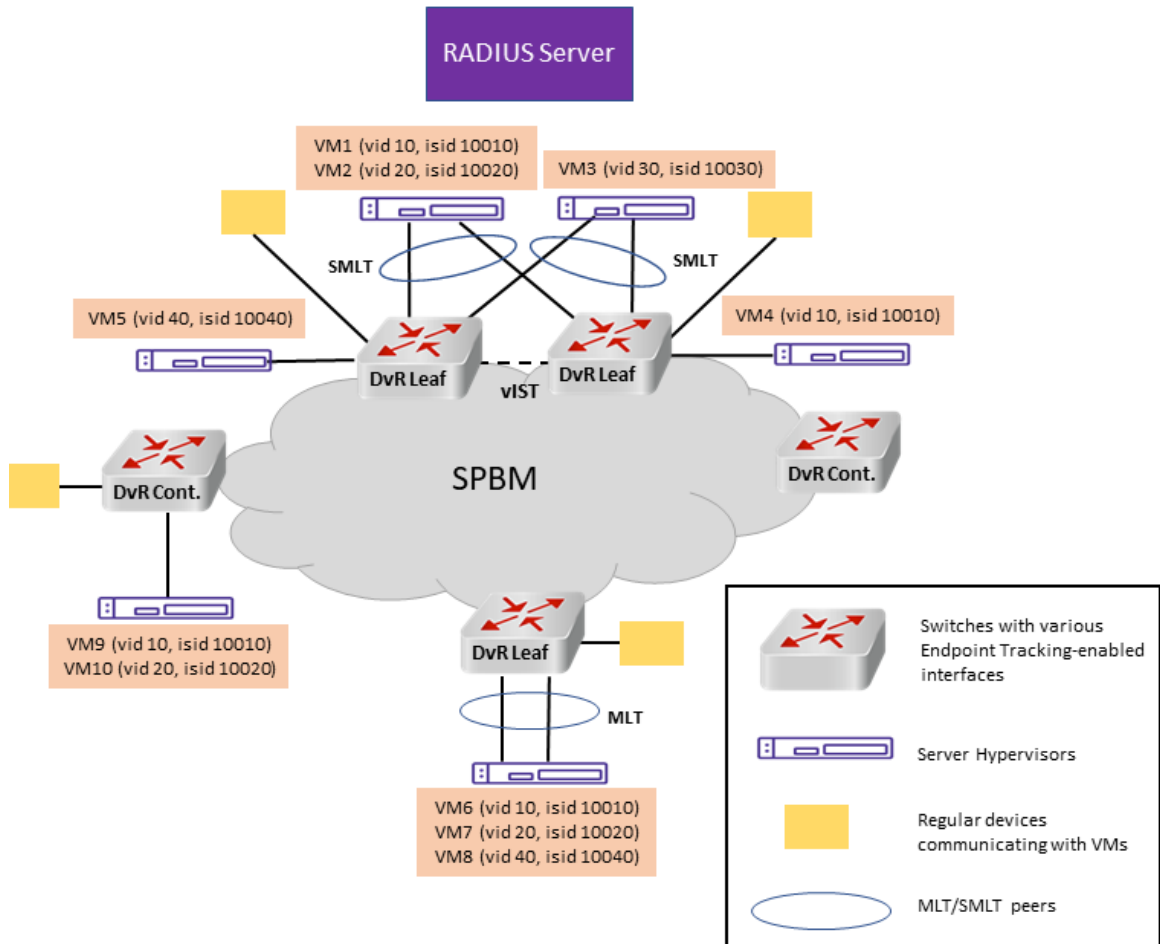

Figure 79: DvR Topology Example

The following example illustrates a regular SPBM deployment:

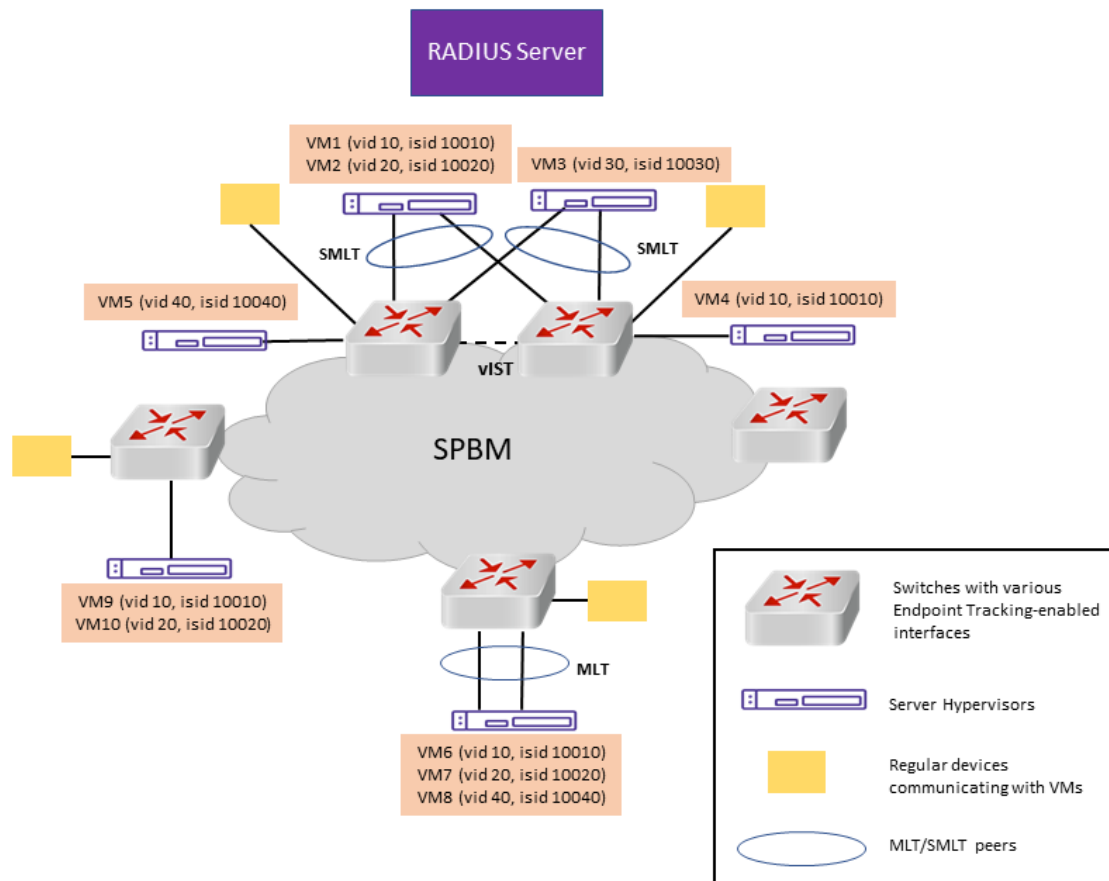

Figure 80: SPBM Cloud Example

Configuration Fundamentals

Extreme Management Center or ExtremeCloud IQ - Site Engine Configuration

To configure Endpoint Tracking, you must perform the following:

- Using the ExtremeConnect component, configure and manage your third-party virtualization platform.
- Using the ExtremeControl component, configure and manage the RADIUS server used for Endpoint Tracking authentication.

For information about configuring Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.

Switch Configuration

To configure Endpoint Tracking, you must perform the following:

- Add, configure, and enable the RADIUS server host as configured in the Extreme Management Center or ExtremeCloud IQ - Site Engine to function as the switch authentication server for Endpoint Tracking. Ensure that you select **endpoint-tracking** for the **used-by** variable. Add, configure

and enable the RADIUS dynamic-server client. For information about adding a RADIUS server host and a RADIUS dynamic-server client to the switch, see [RADIUS](#) on page 2720.

- Optionally configure a global I-SID offset value.

When you provision the Endpoint Tracking RADIUS server in Extreme Management Center or ExtremeCloud IQ - Site Engine, you choose which outbound attributes the RADIUS server includes in each authentication response. If you always include an I-SID value in those outbound attributes, you do not need to configure an I-SID offset value on the switch.

For MACs that do not receive an I-SID attribute from the RADIUS server, use Auto-ISID-Offset functionality. The configured I-SID offset value is used to calculate an I-SID value for a switched UNI when no I-SID value is provided by the RADIUS server in the outbound attributes. In that case, the I-SID value is calculated as follows:

I-SID = VLAN ID + configured I-SID offset value.

- After optionally configuring a global I-SID offset value, enable Endpoint Tracking globally on the switch.
- Create and enable Endpoint Tracking on each interface. Ensure that you have deleted any existing VLAN bindings on the interfaces, as the Endpoint Tracking bindings are dynamic.

CLI commands provide the functionality to separate the creation, deletion, enabling, and disabling of Endpoint Tracking on interfaces. For example, if you want to flush all VLAN:ISID bindings on a port, you can disable (but not delete) Endpoint Tracking on that port, keeping the port distinct from other ports where Endpoint Tracking is not yet created.

Multi-area SPB

Table 102: Multi-area SPB

Feature	Product	Release introduced
Multi-area SPB Boundary Node	VSP 4450 Series	Not Supported
	VSP 4900 Series	Not Supported
	VSP 7200 Series	Not Supported
	VSP 7400 Series	VOSS 8.4
	VSP 8200 Series	Not Supported
	VSP 8400 Series	Not Supported
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

The Multi-area SPB feature enables building a scalable Shortest Path Bridging (SPB) network, consisting of multiple Intermediate System-to-Intermediate System (IS-IS) areas that connect to each other through the boundary nodes. The Multi-area SPB feature provides flexible network design through which you can group the nodes in the areas on a need basis.

Each area in the Multi-area SPB network contains the interior nodes and the boundary nodes.

Figure 81: Boundary nodes in the Multi-area SPB network

Each boundary node runs two Intermediate-System-to-Intermediate-System (IS-IS) instances, representing the home area and the remote area. Each IS-IS instance runs the Shortest Path First (SPF) computation and uses its own Link State Database (LSDB). The boundary nodes support Backbone Edge Bridge (BEB) functionality in addition to the Backbone Control Bridge (BCB) configuration and the UNIs belong only to the home area. You can configure IS-IS interfaces on each instance.

Note

The boundary nodes do not support Auto-sense, you must manually configure all network-to-network interfaces (NNI) on the boundary nodes.

The multiple areas in the Multi-area SPB network connect in various patterns, for example, the hub and spoke topology and the daisy chain topology.

Designated and Non-designated Boundary Nodes

Among the boundary nodes in the Multi-area SPB network, the system elects the designated boundary node on basis of the unique chassis MAC value of the node. The nodes in the SPB area advertise their chassis MAC value using the link state packet (LSP) and the system elects the node with the smallest chassis MAC value as the designated boundary node. Each node in the network detects the designated boundary node on basis of the LSDB information.

The functions of the boundary nodes in the Multi-area SPB network are:

- Designated boundary node:
 - Creates the area virtual node LSPs on each IS-IS instance.
 - Configures the virtual node's adjacency with the other boundary node on basis of the reachability of the node.
 - Advertises the services on the area virtual node on basis of the redistribution policies that you configure.

- Non-designated boundary node:
 - Connects to the area virtual node and the system uses it to forward the traffic on basis of the IS-IS computation.
 - Takes over as the designated boundary node if the designated boundary node is no longer available in any area.

For more information about the area virtual node, see [Area Virtual Node](#) on page 996.

Minimum Requirements

The minimum requirements for the Multi-area SPB to function are:

- Two boundary nodes to provide redundancy.
- Multi-area SPB redistribution policies between areas, like layer 2 redistribution, layer 3 unicast redistribution, multicast redistribution, Distributed Virtual Routing (DvR) backbone redistribution and so on. For more information, see [Multi-area SPB Redistribution and Policies](#) on page 997.

Area Virtual Node

The designated boundary node in the Multi-area SPB network creates the area virtual node. The area virtual node sums up an entire network topology in a single virtual node representing all the services from the represented area.

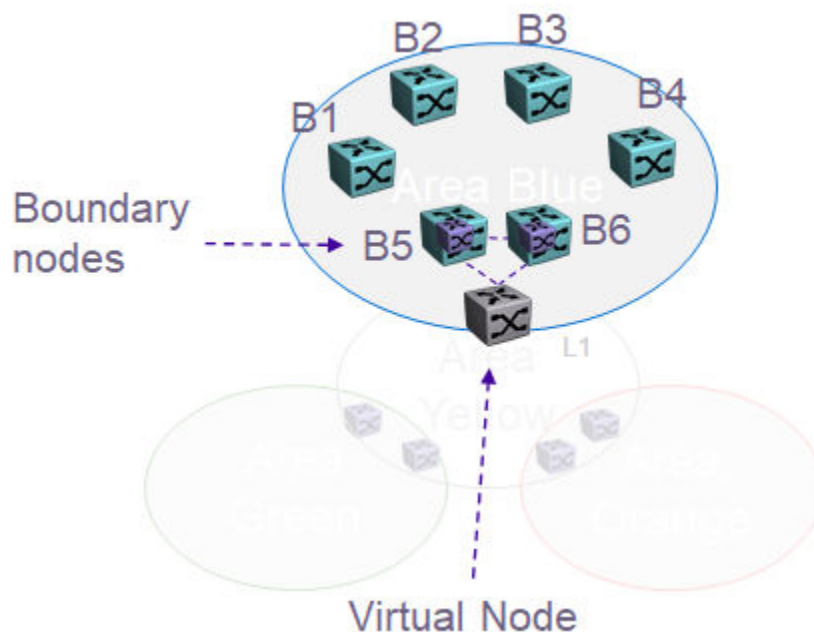

Figure 82: Representation of area virtual node

When considering the shortest path between two nodes in different areas in the Multi-area SPB network, the area virtual node logically connects the shortest path within one area to the shortest path within another area. The area virtual nodes help the Multi-area SPB network to visualize any external area as a single IS-IS entity.

The boundary nodes in the Multi-area SPB network exposes one virtual node in each of two connected areas, to represent a collection of nodes from the other area. On the basis of the policies that you configure on the boundary nodes, you can control the services that the system exports from a home

area to the remote area as the system includes the configuration in the Link State Packets (LSP) of the corresponding area virtual node.

You can configure the area virtual node parameters on both home and remote IS-IS instances. For more information about configuring the area virtual node, see [Configure IS-IS Multi-area SPB Virtual Node](#) on page 1102.

Remote IS-IS Instance

The Multi-area SPB feature introduces the remote Intermediate-System-to-Intermediate-System (IS-IS) instance. You can configure the manual area, system ID, nickname, and area virtual node parameters on the remote IS-IS instance. When enabling Remote IS-IS Instance, make sure that the physical node nickname, virtual node nickname and system ID are different. To configure the remote IS-IS instance on the switch, you must:

- Configure manual area and nickname manually on the switch.
- Enable IS-IS and remote IS-IS instances on the switch, globally.
- Configure Shortest Path Bridging MAC (SPBM) instance on both home and remote IS-IS instances.
- Configure Backbone-VLANs (B-VLANs) globally on both home and remote instances.

For more information, see [Enable Remote IS-IS Router Configuration Globally](#) on page 1110.

Multi-area SPB Redistribution and Policies

The Multi-area SPB redistribution and policies govern the process of importing routes in the Multi-area SPB network across the boundary nodes, that is from the home area to the remote area or vice versa. The traffic flow between the areas within the Multi-area SPB network is the same as the packet flow between the source and destination in a flat SPB network. If more than one boundary node connects to same two areas then the redistribution configuration on the boundary nodes must be consistent, that is the system must permit or deny the same routes to the cross area boundaries. With Multi-area SPB you can configure layer 2 redistribution, layer 3 unicast redistribution, multicast over SPB redistribution, and Distributed Virtual Routing backbone redistribution on the switch.

Layer 2 Redistribution

In the Multi-area SPB network the layer 2 redistribution identifies the services that the system transports from the home area to the remote area and the I-SIDs that the system extends across the boundary nodes in an area. The destination area permits or denies the services on basis of the layer 2 redistribution policies that you configure.

You can configure the layer 2 I-SID redistribution on the switch globally. The layer 2 redistribution policies are bidirectional, which means only one redistribution filter applies to both the home area and the remote area.

Note

Any changes in the layer 2 I-SIDs in the home area will trigger updates to the I-SIDs in the remote area or vice versa.

For more information about configuring Multi-area SPB layer 2 redistribution, see:

- [Configure Multi-area SPB Layer 2 I-SID Redistribution](#) on page 1111
- [Configure Multi-area SPB Layer 2 I-SID List](#) on page 1111

Layer 3 Unicast Redistribution

The layer 3 VSN functionality within the Multi-area SPB network is same as the layer 3 VSN functionality in the flat SPB network. In the Multi-area SPB network, for the layer 3 services to pass the area boundary, you must explicitly configure them on the boundary nodes. Inter-VRF routes on the boundary node will not be redistributed across area boundaries. You can configure redistribution unidirectionally on the boundary nodes. You can also apply different policies from home to remote and remote to home.

The configuration guidelines for the layer 3 Multi-area SPB redistribution are:

- To redistribute inter-area routes in GRT, configure IPSC on the boundary nodes.
- To redistribute inter-area routes in a specific VRF, configure IPSC and layer 3 VSN for that VRF.

Note

The system does not redistribute inter-vrf routes on the boundary nodes across the area boundaries.

For information about configuring layer 3 unicast redistribution, see:

- [Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution](#) on page 1113
- [Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution on a VRF Instance](#) on page 1116
- [Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution](#) on page 1114
- [Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution on a VRF Instance](#) on page 1117

Multicast over SPB Redistribution

Multicast over Shortest Path Bridging (SPB) redistribution manages filtering of the IP multicast streams that the system transports from one area to another. The IP multicast services pass through to the other area on the boundary node depending on the policy that you configure specific to the sender IP address, the multicast group IP address and the Virtual Router Forwarding (VRF) ID.

Multicast over SPB policy is a unidirectional solution, the system filters the IP multicast streams from the area that they originate to the other area or vice versa, independently. Each IP multicast stream that the system advertises in one area will also be advertised on the corresponding area virtual node after it passes the multicast over SPB policy.

Following are the configuration guidelines for the multicast over SPB redistribution:

- Enable multicast on the boundary nodes.
- For layer 3 VSNs, configure Multiprotocol Label Switching Virtual Private Network (MVPN) on the boundary nodes.
- For layer 2 multicast, the scope I-SID must pass the layer 2 VSN policy.
- Configure the same policies as the boundary node on the peer boundary nodes.

For information about configuring Multi-area SPB multicast redistribution, see:

- [Configure Multi-area SPB IPv4 Routed Multicast Redistribution](#) on page 1122
- [Configure IS-IS Multi-area SPB IPv4 Routed Multicast Redistribution on a VRF Instance](#) on page 1123

Distributed Virtual Routing Backbone Redistribution

The Distributed Virtual Routing (DvR) functionality within the Multi-area SPB network is same as the DvR functionality in the flat SPB network. For more information, see [Distributed Virtual Routing Fundamentals](#) on page 683. To configure Multi-area SPB DvR backbone redistribution, the boundary node must be a functional DvR controller in a domain in the home area or a non-DvR Backbone Edge Bridge.

Note

DvR domains can only be a part of one area, you must not configure the same DvR domain in multiple areas.

When you enable the Multi-area SPB DvR backbone redistribution the system extends the DvR backbone across the area boundaries. The boundary node in the Multi-area SPB network performs the DvR controller functions to receive and propagate the hosts in the DvR domain. Since the interior nodes in one area of the Multi-area SPB network are not visible to the interior nodes in other areas, the system sends the area virtual nodes representing the specific area as a gateway in the DvR route TLV. When the system sends the DvR traffic to another DvR domain in a specific destination area, the system sends the traffic to the destination area's boundary nodes and the boundary nodes perform the route lookup and forward the traffic to the correct DvR domain in the destination area.

For information about configuring Multi-area SPB DvR backbone redistribution, see [Configure Multi-area SPB DvR Backbone Redistribution](#) on page 1119.

Multi-area SPB Considerations and Restrictions

The following list identifies the restrictions and considerations that apply to the Multi-area SPB feature:

- You must not connect the same Protocol Independent Multicast (PIM) domain to the SPB-PIM Gateway nodes that are in different Intermediate-System-to-Intermediate-System (IS-IS) areas, to avoid the inter-area redistribution of the same multicast information.
- You can enable the Dynamic Nickname server on the boundary nodes in the home area, but the boundary nodes cannot be clients in any of the two areas. The boundary nodes do not support the Dynamic Nickname server in the remote area.
- The virtual node MAC address does not support CFM layer 2 ping and layer 2 traceroute.
- You must manually configure the backbone VLANs (B-VLAN) on the boundary nodes, so the system does not learn the dynamic values that it receives through the Link Layer Discovery Protocol (LLDP). However, the system sends the manually configured B-VLANs on the BN through LLDP, so that other neighbors can learn them (both in home and remote areas).
- If you enable Auto-sense on a port and it receives a Fabric Connect TLV through LLDP then the port transitions to the NNI pending state and the system logs a message. In this state the system does not enable IS-IS (including home and remote area), and no IS-IS adjacency forms. For more information, see [Auto-sense Port States](#) on page 17.
- If the system forms an adjacency between two boundary nodes that are part of the home and remote area, the hello packets in the home area will use the home manual area and the hello packets in the remote area use the remote manual area.
- If the system forms a home and a remote adjacency on the same port then the Multi-area SPB feature uses different Backbone VLAN IDs (B-VIDs) for each adjacency, the home adjacency uses the primary B-VID and the remote adjacency uses the secondary B-VID.

- If the system forms an IS-IS adjacency in both the home and remote areas on a boundary node, of the same port then the remote adjacency stays up only with another boundary node that also has IS-IS configured on both the home and remote areas of the same port.
- If a boundary node connects to a Backbone Edge Bridge (BEB) in the remote area and if you configure IS-IS in the home area on the same interface, then the remote adjacency goes down.
- On the boundary node, to install a route from a remote area in the routing table manager (RTM), the route must pass the accept policy and the Multi-area SPB redistribution policy that you configure on the specific Virtual Router Forwarding (VRF) instance.
- On the boundary node, to install an inter-VRF route from a remote area in the routing table manager (RTM), the inter-VRF route must pass the accept policy and the Multi-area SPB redistribution policy that you configure on both the source and destination VRF instances.
- Nickname for the physical node and virtual node must be different.
- When enabling Remote IS-IS Instance, make sure that the physical node nickname, virtual node nickname and system ID are different.

SPBM and IS-IS infrastructure configuration using CLI

This section provides procedures to configure SPBM and IS-IS using Command Line Interface (CLI).

Important

The **spbm-config-mode** boot flag must be enabled (default) before you can configure SPBM or IS-IS. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

Running the SPBM script

Use the following procedure to run the SPBM script to automate the minimum required SPBM and IS-IS parameters to allow Fabric Connect to operate on the switch.

Before You Begin

- Enable SPBM before running the SPBM script.
- Delete existing IS-IS interfaces before running this script. See [Removing specific IS-IS and MLT interfaces](#) on page 1004 for information on removing IS-IS interfaces.

About This Task

You can use this procedure to quickly configure the minimum SPBM and IS-IS parameters. However, a manual procedure is available instead of using this script. The default values are given in square brackets. You may input your values at the prompt or if you wish to accept the default values, press **Enter**. This command first accepts all values and then removes existing SPBM configurations before configuring the entered values.

Note

This process causes the SPBM traffic to flap temporarily.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Run the SPBM script:
run spbm

Note

If the script causes a configuration conflict or cannot execute a command, an error message displays and the script stops.

Example

Run the SPBM script:

```
Switch:1(config)# run spbm
```

```
*****
*** This script will guide you through configuring the          ***
*** switch for optimal operation SPB.                          ***
*** -----                                                  ***
*** The values in [] are the default values, you can          ***
*** input alternative values at any of the prompts.           ***
*** If you wish to terminate or exit this script              ***
*** enter ^C <control-C> at any prompt.                        ***
*** NOTE: THE COMMAND WILL TEMPORARILY FLAP IS-IS,SPBM        ***

*IS-IS on port 1/6 configured*
*IS-IS on MLT 1 configured*
```

```
*CFM SPBM configured*
****SCRIPT EXECUTION COMPLETE****
```

Remove Existing SPBM Configuration

Use the following procedure to remove existing SPBM configurations, disable CFM, and return the CFM MEP-ID and level configurations to default values.

Before You Begin

- Enable SPBM before running this script.
- If the switch uses Zero Touch Fabric Configuration, you must run the following commands before you perform this procedure:
 - **no auto-sense onboarding i-sid**
 - **no vlan i-sid <1-4059>**

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Run the script:

```
run spbm clean
```

Note

If the script causes a configuration conflict or cannot run a command, an error message displays and the script stops.

3. To ensure proper cleanup of MAC tables, save the configuration, and then reboot the switch.

Example

Run the script:

```
Switch:1(config)#no auto-sense onboarding i-sid
Switch:1(config)#no vlan i-sid
Switch:1(config)#run spbm clean
The following will delete all SPBM and interfaces and default the CFM configurations. Do
you want to continue? <y/n>[n]:y

Switch:1(config)#no router isis enable
Switch:1(config)#interface gigabitethernet 1/10
Switch:1(config-if)#no isis
Switch:1(config-if)#interface gigabitethernet 1/11
Switch:1(config-if)#no isis
Switch:1(config-if)#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no vlan 4051
Switch:1(config)#no vlan 4052
Switch:1(config)#router isis
Switch:1(config-isis)#no spbm 1
Switch:1(config-isis)#router isis
Switch:1(config-isis)#no ip-source-address
Switch:1(config-isis)#no system-id
Switch:1(config-isis)#no manual-area 49.0000
Switch:1(config-isis)#no cfm spbm enable
```

```
Switch:1(config)#cfm spbm level 4
Switch:1(config)#cfm spbm mepid 1
Switch:1(config)#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#

**SPBM configurations have been removed**
```

Configuring the IS-IS port interfaces using SPBM script

Use the following procedure to run the SPBM script to configure the IS-IS port interfaces. As this command does not flap IS-IS or SPBM, it is particularly effective to use this command when SPBM is already configured and you require to configure additional ports or MLTs. Running the run spbm interface command does not alter existing IS-IS or SPBM configurations.

About This Task

You can use this procedure to quickly configure the minimum SPBM and IS-IS parameters. However, a manual procedure is available instead of using this script.

Note

You must enable SPBM before running the SPBM script.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Run the SPBM script:

```
run spbm interface
```

Note

If the script causes a configuration conflict or cannot execute a command, an error message displays and the script stops.

Example

Run the SPBM script:

```
Switch:1(config)# run spbm interface
```

```
*****
*** This script will guide you through configuring the          ***
*** switch for optimal operation SPB.                          ***

```

Removing specific IS-IS and MLT interfaces

Use the following procedure to remove specific IS-IS ports and MLT interfaces when you get the error IS-IS SPBM interfaces have been configured. Please delete these interfaces.

About This Task

This procedure removes existing IS-IS ports and MLT interfaces. You can choose which port and MLT interfaces need to be removed. This command does not alter the other SPBM or IS-IS configurations.

Note

You must enable SPBM before running the SPBM script.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Run the script:

```
run spbm interface clean
```

Note

If the script causes a configuration conflict or cannot execute a command, an error message displays and the script stops.

Example

Run the spbm interface clean script:

```
Switch:1(config)# run spbm interface clean
```

```
*****
*** This script will guide you through deleting the interfaces. ***
*** IS-IS SPBM interfaces. ***
*** ----- ***
*** The values in [] are the default values. ***
*** If you wish to terminate or exit this script ***
*** enter ^C <control-C> at any prompt. ***
*****
ISIS port interfaces to be deleted <a/b,c/d>[:1/2,1/4,1/8]
ISIS MLT interface <MLT ID LIST> [:1]
IS-IS port 1/2 deleted
IS-IS port 1/4 deleted
IS-IS port 1/8 deleted
** 3 IS-IS port interfaces deleted **
MLT 1 deleted
** 1 IS-IS MLTs deleted **
```

Configure Minimum SPBM and IS-IS Parameters

Use the following procedure to configure the minimum required SPBM and IS-IS parameters to enable SPBM operation on the switch.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable SPBM globally:

```
spbm
```
3. Enter IS-IS Router Configuration mode:

```
router isis
```
4. Create the SPBM instance (only one SPBM instance is supported):

```
spbm <1-100>
```
5. Add the SPBM B-VLAN to the SPBM instance:

```
spbm <1-100> b-vid {<vlan-id [-vlan-id] [,...]} [primary <1-4059>]
```
6. Configure the system nickname (2.5 bytes in the format <x.xx.xx>):

```
spbm <1-100> nick-name <x.xx.xx>
```

Note

Although it is not strictly required for SPBM operation, you should change the IS-IS system ID from the default B-MAC value to a recognizable address to easily identify a switch (Log on to IS-IS Router configuration mode and use the `system-id <xxxx.xxxx.xxxx>` command). This helps to recognize source and destination addresses for troubleshooting purposes.

7. Configure an IS-IS manual area (1-13 bytes in the format <xx.xxxx.xxxx...xxx>, only one manual area is supported.):

```
manual-area <xx.xxxx.xxxx...xxx>
```
8. Exit IS-IS Router Configuration mode to Global Configuration mode:

```
exit
```
9. Create the SPBM backbone VLAN (B-VLAN):

```
vlan create <2-4059> type spbm-bvlan
```
10. Enter Interface Configuration mode, by specifying the ports or MLTs that are going to link to the SPBM network:

```
interface {GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | mlt <1-512> }
```
11. Configure an IS-IS interface on the selected ports or MLTs:
 - a. Create an IS-IS circuit and interface on the selected ports or MLTs:

```
isis
```
 - b. Enable the SPBM instance on the IS-IS interfaces:

```
isis spbm <1-100>
```

- c. Enable the IS-IS circuit/interface on the selected ports or MLTs:

```
isis enable
```

- 12. Enable interface.

- 13. Exit Interface Configuration mode:

```
exit
```

- 14. Enable IS-IS globally:

```
router isis enable
```

- 15. Display the SPBM configurations:

```
show isis spbm
```

- 16. Display the global IS-IS configuration:

```
show isis
```

- 17. Display the interface IS-IS configuration:

```
show isis interface
```

Examples

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spbm
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 b-vid 4051,4052 primary 10
Switch:1(config-isis)#spbm 1 nick-name 1.11.16
Switch:1(config-isis)#manual-area c0.2000.000.00
Switch:1(config-isis)#exit
Switch:1(config)#interface GigabitEthernet 1/21
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-if)#exit
Switch:1(config)#vlan create 4051 type spbm-vlan
Switch:1(config)#vlan create 4052 type spbm-vlan
Switch:1(config)#router isis enable
Switch:1(config)#show isis spbm
```

```

Variable definitions

The following table defines parameters for the **isis** command.

Variable	Value
<i>enable</i>	Enables or disables the IS-IS circuit/interface on the specified port or MLT. The default is disabled. Use the no option to disable IS-IS on the specified interface.
<i>spbm <1-100></i>	Enable the SPBM instance on the IS-IS interfaces.

The following table defines parameters for the **manual-area** command.

Variable	Value
<xx.xxx.xxx...xxx>	Specifies the IS-IS manual-area (1-13 bytes in the format <xx.xxx.xxx...xxx>). Only one manual area is supported. For IS-IS to operate, you must configure at least one area. Use the no option to delete the manual area.

The following table defines parameters for the **spbm** command.

Variable	Value
<1-100>	Creates the SPBM instance. Only one SPBM instance is supported.
<i>b-vid</i> {<vlan-id [-vlan-id] [,...]}>	Sets the IS-IS SPBM instance data VLANs. Use the no option to remove the specified B-VLAN from the SPBM instance.
<i>nick-name</i> <x.xx.xx>	Specifies a nickname for the SPBM instance globally. The value is 2.5 bytes in the format <x.xx.xx>. Use the no or default options to delete the configured nickname.
<i>primary</i> <1-4059>	Sets the IS-IS instance primary data B-VLAN.

The following table defines parameters for the **vlan create** command.

Variable	Value
<2-4059>	Specifies the VLAN ID. Creates an SPBM Backbone VLAN (B-VLAN). You can optionally specify a name for the SPBM B-VLAN.
<i>type</i> {port-mstp protocol-mstp spbm-bvlan}	Specifies the type of VLAN created. <ul style="list-style-type: none"> port-mstp — Create a VLAN by port. protocol-mstp — Create a VLAN by protocol. spbm-bvlan — Create an SPBM B-VLAN.

Job aid

Important

After you have configured the SPBM nickname and enabled IS-IS. To maintain the same nickname with a different system ID, perform the following steps:

1. Disable IS-IS.
2. Change the system ID.
3. Change the nickname to a temporary one.
4. Enable IS-IS.
5. Wait up to 20 minutes for the LSPs with the original system ID to age out.

Note

To check the age out time, use the **show isis lsdb sysid <original-sys-id>** command on any of the other SPB nodes in the network. When there is no output from this command, proceed to the next step. The time left (in seconds) for the LSPs to age out is shown under the column **LIFETIME**.

6. Disable IS-IS.
7. Change the nickname to the original nickname.
8. Enable IS-IS.

Configure Minimum SPBM and IS-IS Parameters using *auto-nni* Command

Use the following procedure to configure the minimum required SPBM and IS-IS parameters using the **auto-nni** command to have the node create an IS-IS interface, attach the interface to an SPBM instance, and then enable IS-IS on the port interface.

This procedure is only for the port interface. The **auto-nni** command is not supported on the MLT interface and the Fabric Extend Logical Interface.

About This Task

The **auto-nni** command provides a quick and simple way to configure the IS-IS interface. You can use the **auto-nni** command instead of the following existing IS-IS commands on the physical (port) interface:

- **isis**
- **isis spbm instance**
- **isis enable**

The existing commands are still available and you have the option to use the new command or the three existing commands. If you need to modify any of the default parameters under **isis** or **isis spbm instance**, use **isis** and **isis spbm instance** constructs even if you created the interface with the **auto-nni** command.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable SPBM globally:

```
spbm
```
3. Enter IS-IS Router Configuration mode:

```
router isis
```
4. Create the SPBM instance (only one SPBM instance is supported):

```
spbm <1-100>
```
5. Add the SPBM B-VLAN to the SPBM instance:

```
spbm <1-100> b-vid {<vlan-id [-vlan-id] [,...]} [primary <1-4059>]
```
6. Configure the system nickname (2.5 bytes in the format <x.xx.xx>):

```
spbm <1-100> nick-name <x.xx.xx>
```

Note

Although it is not strictly required for SPBM operation, you should change the IS-IS system ID from the default B-MAC value to a recognizable address to easily identify a switch (Log on to IS-IS Router configuration mode and use the `system-id <xxxx.xxxx.xxxx>` command). This helps to recognize source and destination addresses for troubleshooting purposes.

- Configure an IS-IS manual area (1-13 bytes in the format <xx.xxxx.xxxx...xxxx>. Only one manual area is supported.):

```
manual-area <xx.xxxx.xxxx...xxxx>
```

- Exit IS-IS Router Configuration mode to Global Configuration mode:

```
exit
```

- Create the SPBM backbone VLAN (B-VLAN):

```
vlan create <2-4059> type spbm-bvlan
```

- Enter Interface Configuration mode, by specifying the ports or MLTs that are going to link to the SPBM network:

```
interface {GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | mlt <1-512> }
```

- Configure an IS-IS interface on the selected ports.

```
auto-nni
```

- Enable interface.

- Exit Interface Configuration mode:

```
exit
```

- Enable IS-IS globally:

```
router isis enable
```

- Display the SPBM configurations:

```
show isis spbm
```

- Display the global IS-IS configuration:

```
show isis
```

- Display the interface IS-IS configuration:

```
show isis interface
```

Examples

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spbm
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 b-vid 10,20 primary 10
Switch:1(config-isis)#spbm 1 nick-name 1.11.16
Switch:1(config-isis)#manual-area c0.2000.000.00
Switch:1(config-isis)#exit
Switch:1(config)#interface gigabitethernet 1/21

Configure I-SIDs for Private VLANs

Before You Begin

- A private VLAN must be created. For more information about creating private VLANs, see [Create a Private VLAN](#) on page 3773.

About This Task

Assign one I-SID for each private VLAN.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Assign the I-SID to the primary and secondary VLAN.

```
vlan i-sid <1-4059> <0-16777215> [force]
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

```

Variable Definitions

The following table defines parameters for the **vlan i-sid** command.

Variable	Value
<code><1-4059></code>	Specifies the VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<code><0-16777215></code>	Specifies the service instance identifier (I-SID). You cannot use I-SID 0x00ffffff. The system reserves this I-SID to advertise the virtual BMAC in an SMLT dual-homing environment. This value is the same for the primary and secondary VLANs.
<code>force</code>	Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.

Displaying global SPBM parameters

Use the following procedure to verify the proper global SPBM configuration.

Procedure

1. Display the SPBM configuration:

```
show isis spbm
```

2. You can also use the following command to identify SPBM VLANs. For spbm-bvlan, the attribute `TYPE` displays `spbm-bvlan` instead of `byport`. For private VLANs, the attribute `TYPE` displays `private` instead of `byport`.

```
show vlan basic
```

Example

```
Switch# show isis spbm

=====
                        ISIS SPBM Info
=====

```

Configuring SMLT parameters for SPBM

Use the following procedure to configure the required Split MultiLink Trunking (SMLT) parameters to allow SPBM to interoperate with SMLT on the switch.

Note

- The assignment of primary and secondary roles to the vIST peers is automatic. The switch with the lower system ID (between the two vIST peers) is primary, and the switch with the higher system ID is secondary when default system-id values are being used.
- SMLT peer system ID is part of the required configuration. You must configure the SMLT peer system ID as the nodal MAC of the peer device. In the IS-IS network, the nodal MAC of devices should be eight apart from each other.
- When using the default hardware assigned system-id value, the SMLT Virtual B-MAC is automatically derived by comparing the system-id values of the two vIST peers. A value of 0x01 plus the lower of the two system-id values is used as the SMLT Virtual B-MAC.

When using a manually configured system-id value, the SMLT Virtual B-MAC must also be manually configured.

- An I-SID must be assigned to every VLAN that is a member of a Layer 2 VSN. Also, if a Layer 2 VSN is created on one vIST Peer, it must also be created on the other vIST peer.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Disable IS-IS on the switch:

```
no router isis enable
```
3. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
4. Specify the system ID of the vIST peer, so that if it goes down, the local peer can take over forwarding for the failed peer:

```
spbm <1-100> smlt-peer-system-id <xxxx.xxxx.xxxx>
```
5. Configure the virtual B-MAC, which is shared and advertised by both peers:

```
spbm <1-100> smlt-virtual-bmac <0x00:0x00:0x00:0x00:0x00:0x00>
```
6. Exit to Global Configuration mode:

```
exit
```

7. Enable IS-IS on the switch:

```
router isis enable
```
8. Display the SPBM SMLT configuration:

```
show isis spbm
```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Disable IS-IS on the switch:

```
Switch:1(config)#no router isis enable
```

Enter the IS-IS Router Configuration mode:

```
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 smlt-peer-system-id 0018.b0bb.b3df
Switch:1(config-isis)#spbm 1 smlt-virtual-bmac 00:14:c7:e1:33:e0
Switch:1(config-isis)#router isis enable

Switch:1(config-isis)#show isis spbm
=====
                        ISIS SPBM Info
=====

Total Num of SPBM instances: 1
=====
```

Variable definitions

The following table defines parameters for the **spbm** command.

Variable	Value
<code>smlt-peer-system-id</code> <xxxx.xxxx.xxxx>	Specifies the IS-IS SPBM peer system ID. SMLT peer system ID is part of the required configuration. You must configure the SMLT peer system ID as the nodal MAC of the peer device. In the IS-IS network, the nodal MAC of devices should be eight apart from each other.
<code>smlt-virtual-bmac</code> <0x00:0x00:0x00:0x00:0x00:0x00>	Specifies a virtual MAC address that can be used by both peers. SMLT virtual B-MAC is an optional configuration. Note: <ul style="list-style-type: none"> If SMLT virtual B-MAC is not configured, the system derives SMLT virtual B-MAC from the configured SMLT peer system ID and the nodal MAC of the device (IS-IS system ID). The system compares the nodal MAC of the device with the SMLT peer system ID configured and takes the small one, plus 0x01, as the SMLT virtual B-MAC. The system also derives SMLT split BEB from the SMLT peer system ID and nodal MAC of the device. The device with the lower system ID is primary, the device with the higher system ID is secondary.

Configuring optional SPBM parameters

Use the following procedure to configure optional SPBM parameters.

Procedure

- Enter Global Configuration mode:

```
enable
configure terminal
```
- Configure the SPBM ethertype:

```
spbm ethertype {0x8100 | 0x88a8}
```
- Configure the optional link-state database (LSDB) trap global parameter. To configure this parameter, you must globally disable IS-IS on the switch:
 - Disable IS-IS on the switch:

```
no router isis enable
```
 - Enter IS-IS Router Configuration mode:

```
router isis
```
 - Enable a trap when the SPBM LSDB changes:

```
spbm <1-100> lsdb-trap enable
```
 - Enable IS-IS on the switch:

```
router isis enable
```
 - Exit IS-IS Router Configuration mode:

```
exit
```

4. Configure the optional SPBM interface parameters. To configure these parameters, you must disable IS-IS on the interface:
 - a. Specify an SPBM interface to configure:

```
interface {GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]][,...]} | mlt <mltid> }
```
 - b. Disable IS-IS on the interface:

```
no isis enable
```
 - c. Configure SPBM instance interface-type on IS-IS interface. SPBM supports only pt-pt:

```
isis spbm <1-100> interface-type {broadcast|pt-pt}
```
 - d. Configure the IS-IS Interface level 1 metric:

```
isis spbm <1-100> ll-metric <1-16777215>
```
 - e. Enable IS-IS on the switch:

```
isis enable
```

Example

```
Switch> enable
Switch# configure terminal
Switch(config)# spbm ethertype 0x8100
Switch(config-isis)# no router isis enable
Switch(config)# router isis
Switch(config-isis)# spbm 1 lsdB-trap enable
Switch(config-isis)# router isis enable
Switch(config-isis)# exit
Switch(config)# interface gigabitEthernet 1/7
Switch(config-if)# no isis enable
Switch(config-if)# isis spbm 1 interface-type pt-pt
Switch(config-if)# isis spbm 1 ll-metric 500
Switch(config-if)# isis enable
```

Variable definitions

The following table defines parameters for the **spbm** command.

Variable	Value
<code>ethertype {0x8100 0x88a8}</code>	Configures the SPBM ethertype. The default value is 0x8100.
<code><1-100> lsdb-trap enable</code>	Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disabled. Use the no or default options to disable LSDB traps.

The following table defines parameters for the **isis spbm** command.

Variable	Value
<code><1-100> interface-type {broadcast pt-pt}</code>	Configures the SPBM instance interface-type on the IS-IS interface located on the specified port or MLT. SPBM only supports the point-to-point (pt-pt) interface type. The default is pt-pt. Use the no or default options to set this parameter to the default value of pt-pt.
<code><1-100> ll-metric <1-16777215></code>	Configures the IS-IS interface level 1 metric on the specified port or MLT. The default value is 10. Use the no or default options to set this parameter to the default.

Configuring optional IS-IS global parameters

Use the following procedure to configure optional IS-IS global parameters.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable
configure terminal
router isis
```
2. Configure optional IS-IS global parameters:
 - a. Specify the Complete Sequence Number Packet (CSNP) interval in seconds:

```
csnp-interval <1-600>
```
 - b. Configure the router type globally:

```
is-type {11|112}
```
 - c. Configure the maximum level, in seconds, between generated LSPs by this Intermediate System:

```
max-lsp-gen-interval <30-900>
```
 - d. Configure the IS-IS metric type:

```
metric {narrow|wide}
```
 - e. Set or clear the overload condition:

```
overload
```
 - f. Configure the overload-on-startup value in seconds:

```
overload-on-startup <15-3600>
```

- g. Configure the Partial Sequence Number Packet (PSNP) in seconds:
psnp-interval <1-120>
- h. Configure the minimum time between retransmission of an LSP:
retransmit-lsp-interval <1-300>
- i. Configure the SPF delay in milliseconds:
spf-delay <0-5000>
- j. Configure the name for the system:
sys-name WORD<0-255>
- k. Configure the IS-IS system ID for the switch:
system-id <xxxx.xxxx.xxxx>

Example

```
Switch> enable

Switch# configure terminal

Switch(config)# router isis

Switch(config-isis)# csnp-interval 10

Switch(config-isis)# is-type 11

Switch(config-isis)# max-lsp-gen-interval 800

Switch(config-isis)# metric wide

Switch(config-isis)# overload

Switch(config-isis)# overload-on-startup 30

Switch(config-isis)# psnp-interval 10

Switch(config-isis)# retransmit-lsp-interval 10

Switch(config-isis)# default sys-name

Switch(config-isis)# spf-delay 200

Switch(config-isis)# default system-id
```

Variable definitions

The following table defines parameters for the **csnp-interval** command.

Variable	Value
<1-600>	Specifies the CSNP interval in seconds. This is a system level parameter that applies for level 1 CSNP generation on all interfaces. A longer interval reduces overhead, while a shorter interval speeds up convergence. The default value is 10. Use the no or default options to set this parameter to the default value of 10.

The following table defines parameters for the **is-type** command.

Variable	Value
{l1 l12}	Sets the router type globally: <ul style="list-style-type: none"> • l1: Level-1 router type • l12: Not valid. The default value is l1. Use the no or default options to set this parameter to the default value of l1.

The following table defines parameters for the **max-lsp-gen-interval** command.

Variable	Value
<30-900>	Specifies the maximum interval, in seconds, between generated LSPs by this Intermediate System. The default value is 900 seconds. Use the no or default options to set this parameter to the default value of 900.

The following table defines parameters for the **metric** command.

Variable	Value
{narrow wide}	Specifies the IS-IS metric type. Only wide is supported. The default value is wide. Use the no or default options to set this parameter to the default value of wide.

The following table defines parameters for the **overload** command.

Variable	Value
overload	Sets or clears the overload condition. The default value is disabled. Use the no or default options to set this parameter to the default value of disabled.

The following table defines parameters for the **overload-on-startup** command.

Variable	Value
<15–3600>	Specifies the IS-IS overload-on-startup value in seconds. The overload-on-startup value is used as a timer to control when to send out LSPs with the overload bit cleared after IS-IS startup. The default value is 20. Use the no or default options to set this parameter to the default value of 20.

The following table defines parameters for the **psnp-interval** command.

Variable	Value
<1–120>	Specifies the PSNP interval in seconds. This is a system level parameter that applies for level 1 PSNP generation on all interfaces. A longer interval reduces overhead, while a shorter interval speeds up convergence. The default value is 2. Use the no or default options to set this parameter to the default value of 2.

The following table defines parameters for the **retransmit-lsp-interval** command.

Variable	Value
<1–300>	Specifies the minimum time between retransmission of an LSP. This defines how fast the switch resends the same LSP. This is a system level parameter that applies for Level 1 retransmission of LSPs. The default value is 5 seconds. Use the no or default options to set this parameter to the default value of 5.

The following table defines parameters for the **spf-delay** command.

Variable	Value
<0–5000>	Configures the delay, in milliseconds, to pace successive Shortest Path First (SPF) runs. The timer prevents more than two SPF runs from being scheduled back-to-back. The mechanism for pacing SPF allows two back-to-back SPF runs. The default value is 100 milliseconds. Use the no or default options to set this parameter to the default value of 100 milliseconds.

The following table defines parameters for the **sys-name** command.

Variable	Value
WORD<0–255>	Specifies a name for the system. This may be used as the host name for dynamic host name exchange in accordance with RFC 2763. By default, the system name comes from the host name configured at the system level. Use the no or default options to set this parameter to the default value (host name). Note: The system does not display any consistency checks when you edit sys-name.

The following table defines parameters for the **system-id** command.

Variable	Value
<xxxxx.xxxxx.xxxxx>	Specifies the IS-IS system ID for the switch. Use the no or default options to set this parameter to the default value (node BMAC).

Job aid

Important

After you have configured the SPBM nickname and enabled IS-IS. To maintain the same nickname with a different system ID, perform the following steps:

1. Disable IS-IS.
2. Change the system ID.
3. Change the nickname to a temporary one.
4. Enable IS-IS.
5. Wait up to 20 minutes for the LSPs with the original system ID to age out.

Note

To check the age out time, use the **show isis lsdbsysid <original-sys-id>** command on any of the other SPB nodes in the network. When there is no output from this command, proceed to the next step. The time left (in seconds) for the LSPs to age out is shown under the column **LIFETIME**.

6. Disable IS-IS.
7. Change the nickname to the original nickname.
8. Enable IS-IS.

Configuring Optional IS-IS Interface Level 1 Parameters

Use the following procedure to configure optional IS-IS interface level 1 parameters.

Important

Save your configuration using **save config** for the updates to be available after reboot. Saving the configuration also ensures that any authentication keys (passwords) specified during the configuration are properly encrypted.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure optional IS-IS interface level 1 parameters:

- a. Specify the authentication type used for IS-IS hello packets on the interface:

```
isis hello-auth type {none|simple|hmac-md5|hmac-sha-256}
```

- b. If you select `simple` as the `hello-auth` type, you must also specify a key value but the key-id is optional:

```
isis hello-auth type simple key WORD<1-16> [key-id <1-255>]
```

- c. If you select `hmac-md5` or `hmac-sha-256`, you must also specify a key value. The key-id is optional:

```
isis hello-auth type hmac-md5 key WORD<1-16> [key-id <1-255>]]
```

```
isis hello-auth type hmac-sha-256 key WORD<1-16> [key-id <1-255>]]
```

- d. Configure the IS-IS Interface level 1 designated router priority:

```
isis [l1-dr-priority <0-127>]
```

**Note**

This parameter is not used for SPBM because SPBM only runs on point-to-point interfaces. This parameter is for designated router election on a broadcast LAN segment, which is not supported.

- e. Configure the IS-IS Interface level 1 hello interval:

```
isis [l1-hello-interval <1-600>]
```

- f. Configure the IS-IS Interface level 1 hello multiplier:

```
isis [l1-hello-multiplier <1-600>]
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch(config):1# interface gigabitethernet 1/1
```

```
Switch(config-if):1# isis
```

```
Switch(config-if):1# isis hello-auth type hmac-md5 key test
```

```
Switch(config-if):1# isis l1-dr-priority 100
Switch(config-if):1# isis l1-hello-interval 20
Switch(config-if):1# isis l1-hello-multiplier 10
Switch(config):1# save config
```

Variable Definitions

The following table defines parameters for the **isis** command.

Variable	Value
<pre>hello-auth type {none simple hmac-md5 hmac- sha-256}} [key [key WORD<1- 16>] [key-id <1-255>]</pre>	<p>Specifies the authentication type used for IS-IS hello packets on the interface. type can be one of the following:</p> <ul style="list-style-type: none"> • none • simple: If selected, you must also specify a key value but the key id is optional. Simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet. • hmac-md5: If selected, you must also specify a key value but the key-id is optional. MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. There is an optional key ID. • hmac-sha-256: If selected, you must also specify a key value but the key-id is optional. With SHA-256 authentication, the switch adds an hmac-sha-256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet. There is an optional key ID. <p>Note: Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate IS-IS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key. This feature is in full compliance with RFC 5310.</p> <p>The default is none. Use the no or default options to set the hello-auth type to none.</p>
<pre>ll-dr-priority <0-127></pre>	<p>Configures the IS-IS Interface level 1 designated router priority to the specified value. The default value is 64. Use the no or default options to set this parameter to the default value of 64.</p> <p>Note: This parameter is not used for SPBM because SPBM only runs on point-to-point interfaces. This parameter is for designated router election on a broadcast LAN segment, which is not supported.</p>

Variable	Value
<code>l1-hello-interval <1-600></code>	Configures the IS-IS interface level 1 hello interval. The default value is 9 seconds. Use the no or default options to set this parameter to the default value of 9 seconds.
<code>l1-hello-multiplier <1-600></code>	Configures the IS-IS interface level 1 hello multiplier. The default value is 3 seconds. Use the no or default options to set this parameter to the default value of 3 seconds.

Display IS-IS Interface Parameters

Use the following procedure to display the IS-IS interface parameters.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Display IS-IS interface configuration and status parameters (including adjacencies):
`show isis interface [l1|l2|l12] [home|remote]`
3. Display IS-IS interface authentication configuration:
`show isis int-auth [home|remote]`
4. Display IS-IS interface timers:
`show isis int-timers [home|remote]`
5. Display IS-IS circuit level parameters:
`show isis int-ckt-level [home|remote]`

Example

```
Switch:1# show isis interface
=====

Variable Definitions

The following table defines parameters for the **show isis interface** command.

Variable	Value
<i>home</i>	Displays the IS-IS interface information that the system configures in the home area.
<i>l1</i>	Displays the interface information for Level 1.
<i>l2</i>	Displays the interface information for Level 2.
<i>l12</i>	Displays the interface information for Level 1 and Level 2.
<i>remote</i>	Displays the IS-IS interface information that the system configures in the remote area.

The following table defines parameters for the **show isis ini-auth** command.

Variable	Value
<i>home</i>	Displays the IS-IS interface authentication information that the system configures in the home area.
<i>remote</i>	Displays the IS-IS interface authentication information that the system configures in the remote area.

The following table defines parameters for the **show isis ini-timer** command.

Variable	Value
<i>home</i>	Displays the IS-IS interface timer information that the system configures in the home area.
<i>remote</i>	Displays the IS-IS interface timer information that the system configures in the remote area.

The following table defines parameters for the **show isis ini-ckt-level** command.

Variable	Value
<i>home</i>	Displays the IS-IS interface circuit level parameters that the system configures in the home area.
<i>remote</i>	Displays the IS-IS interface circuit level parameters that the system configures in the remote area.

Display the IP Unicast FIB, Unicast FIB, and Unicast Tree

About This Task

In SPBM, Backbone MAC (B-MAC) addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS Type-Length-Value (TLV) that advertises the Service Instance Identifier (I-SID) and B-MAC information across the network. Each node has a System ID, which also serves as B-MAC of the switch. These B-MAC addresses are populated into the SPBM Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are never exchanged in the network as IP Shortcuts allow Global Routing Table (GRT) IP networks to be transported across IS-IS.

The **show isis spbm ip-unicast-fib** or **show isis spbm ipv6-unicast-fib** command displays all of the IS-IS routes in the IS-IS LSDB. The IP ROUTE PREFERENCE column in the show output displays the IP route preference.

Routes within the same VSN are added to the LSDB with a default preference of 7. Inter-VSN routes are added to the LSDB with a route preference of 200. IS-IS accept policies enable you to change the route preference for incoming routes. If the same route is learned from multiple sources with different route preferences, then the routes are not considered equal cost multipath (ECMP) routes. The route with the lowest route preference is the preferred route. In Layer 2, in the event of a tie-break between routes from multiple sources, the tie-breaking is based on cost and hop count.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display the SPBM IP unicast FIB:

- For IPv4:

```
show isis spbm ip-unicast-fib [all] [id <1-16777215] [spbm-nh-as-  
mac] [home|remote]
```

- For IPv6:

```
show isis spbm ipv6-unicast-fib [all] [id <1-16777215] [spbm-nh-as-  
mac] [home|remote]
```

3. Display the SPBM unicast FIB:

```
show isis spbm unicast-fib [b-mac <0x00:0x00:0x00:0x00:0x00:0x00>]
[vlan <1-4059>] [summary] [home|remote]
```

4. Display the SPBM unicast tree:

```
show isis spbm unicast-tree <1-4059> [destination <xxxx.xxxx.xxxx>]
```

Examples

```
Switch# show isis spbm ip-unicast-fib

Variable Definitions

The following table defines parameters for the **show isis spbm ip-unicast-fib** command.

Variable	Value
<i>all</i>	Displays entries for the Global Routing Table (GRT) and all Virtual Routing and Forwarding (VRF) instances. Note: If you use the command show isis spbm ip-unicast-fib the device displays only GRT entries. The command shows IP routes from remote Backbone Edge Bridges (BEBs).
<i>home</i>	Displays the IS-IS SPBM IP unicast Forwarding Information Base (FIB) information that the system configures in the home area.
<i>id <1-16777215></i>	Displays IS-IS SPBM IP unicast FIB information by Service Instance Identifier (I-SID) ID.

Variable	Value
<i>remote</i>	Displays the IS-IS SPBM IP unicast FIB information that the system configures in the remote area.
<i>spbm-nh-as-mac</i>	Displays the next hop B-MAC of the IP unicast FIB entry.

The following table defines parameters for the **show isis spbm ipv6-unicast-fib** command.

Variable	Value
<i>all</i>	Displays entries for the Global Routing Table (GRT) and all Virtual Routing and Forwarding (VRF) instances. Note: If you use the command show isis spbm ipv6-unicast-fib the device displays only GRT entries. The command shows IPv6 routes from remote Backbone Edge Bridges (BEBs).
<i>home</i>	Displays the IS-IS SPBM IPv6 unicast Forwarding Information Base (FIB) information that the system configures in the home area.
<i>id</i> <1-16777215>	Displays IS-IS SPBM IPv6 unicast FIB information by Service Instance Identifier (I-SID) ID.
<i>remote</i>	Displays the IS-IS SPBM IPv6 unicast FIB information that the system configures in the remote area.
<i>spbm-nh-as-mac</i>	Displays the next hop as MAC of the IPv6 unicast FIB entry.

The following table defines parameters for the **show isis spbm unicast-fib** command.

Variable	Value
<i>b-mac</i> <0x00:0x00:0x00:0x00:0x00:0x00>	Displays the FIB for the specified B-MAC.
<i>home</i>	Displays the IS-IS SPBM unicast Forwarding Information Base (FIB) information that the system configures in the home area.
<i>remote</i>	Displays the IS-IS SPBM unicast FIB information that the system configures in the remote area.
<i>vlan</i> <1-4059>	Displays the FIB for the specified SPBM VLAN.
<i>summary</i>	Displays a summary of the FIB.

The following table defines parameters for the **show isis spbm unicast-tree** command.

Variable	Value
<1-4059>	Specifies the SPBM B-VLAN ID.
<i>destination</i> <xxxx.xxxx.xxxx>	Displays the unicast tree for the specified destination.

Display IS-IS LSDB and Adjacencies

Use the following procedure to display the IS-IS LSDB and adjacencies.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS LSDB:

```
show isis lsdb [level {l1|l2|l12}] [sysid <xxxx.xxxx.xxxx>] [lspid
<xxxx.xxxx.xxxx.xx-xx>] [tlv <1-236>] [detail] [home|remote]
```
3. Display IS-IS adjacencies:

```
show isis adjacencies [home|remote]
```
4. Clear IS-IS LSDB:

```
clear isis lsdb
```

Example

```
Switch:1# show isis lsdb

Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

Variable	Value
<i>detail</i>	Displays detailed information.
<i>home</i>	Displays the IS-IS LSDB information that the system configures in the home area.
<i>level {l1 l2 l12}}</i>	Displays the LSDB for the specified level: l1, l2, or l12.
<i>local</i>	Displays IS-IS local LSDB information.
<i>remote</i>	Displays the IS-IS LSDB information that the system configures in the remote area.
<i>sysid</i> <xxxx.xxxx.xxxx>	Displays the LSDB for the specified system ID.
<i>lspid</i> <xxxx.xxxx.xxxx.xx-xx>	Displays the LSDB for the specified LSP ID.
<i>tlv</i> <1-236>	Displays the LSDB by TLV type.

The following table defines parameters for the **show isis adjacencies** command.

Variable	Value
<i>home</i>	Displays the IS-IS adjacencies that the system configures in the home area.
<i>remote</i>	Displays the IS-IS adjacencies that the system configures in the remote area.

The following table defines parameters for the **clear isis** command.

Variable	Value
<i>Isdb</i>	Clears the IS-IS Link State Database (LSDB). The command clears learned LSPs only. The command does not clear local generated LSPs. As soon as the platform clears the LSDB the LSP synchronization process starts immediately and the LSDB synchronizes with its neighbors.

Display IS-IS Statistics and Counters

Use the following procedure to display the IS-IS statistics and counters.

Procedure

1. Display IS-IS system statistics:
`show isis statistics`
2. Display IS-IS interface counters:
`show isis int-counters [home|remote]`
3. Display IS-IS level 1 control packet counters:
`show isis int-l1-ctrl-pkts [home|remote]`

Note

The switch uses level 1 IS-IS. The switch does not support level 2 IS-IS. The command **show isis int-l2-ctrl-pkts** is not supported because the IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1.

4. Clear IS-IS statistics:
`clear isis stats [error-counters] [packet-counters]`

Example

```
Switch:1# show isis statistics
=====
ISIS System Stats
=====

Port1/21	Received	13335	226	1	227	HOME	area-9.00.02

Variable Definitions

The following table defines parameters for the **show isis int-counters** command.

Variable	Value
<i>home</i>	Displays the IS-IS interface counters that the system configures in the home area.
<i>remote</i>	Displays the IS-IS interface counters that the system configures in the remote area.

The following table defines parameters for the **show isis int-l1-ctrl-pkts** command.

Variable	Value
<i>home</i>	Displays the IS-IS L1 control packet counters that the system configures in the home area.
<i>remote</i>	Displays the IS-IS L1 control packet counters that the system configures in the remote area.

The following table defines parameters for the **clear isis stats** command.

Variable	Value
<i>error-counters</i>	Clears IS-IS stats error-counters.
<i>packet-counters</i>	Clears IS-IS stats packet-counters.

Run the Layer 2 Video Surveillance install script

Use the following procedure to run the Layer 2 Video Surveillance install script.

Before You Begin

The switch must be in the factory default state. When you start the install script, the switch displays a prompt to remind you to do this.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Run the install script:

```
run vms layer-2 switch <5-99> [syntax]
```

The script uses the value that you assign to the switch number (between 5 and 99) to seed unique values in the configuration script.

Examples

The following example shows the complete output of the install script without the `syntax` parameter. As you can see, there is no indication that the script encountered any errors.

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)# run vms layer-2 switch 6

Do you want to execute the run vms layer-2 script? Device needs to be in factory default
state. (y/n) ? y

**Previous configurations stored in pre_vms_layer2_install.cfg**
**New VMS configurations stored in new primary config file vms-layer2-switch-6.cfg**
*** VMS Layer-2 script execution complete ***
Switch:1(config)#boot config choice primary config-file /intflash/vms-layer2-switch-6.cfg
```

The following example displays the output of the script using the `syntax` parameter. This example is only a small sample of the output, but it shows how the script reports warnings and errors it encounters.

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)# run vms layer-2 switch 6 syntax

Do you want to execute the run vms layer-2 script? Device needs to be in factory default
state. (y/n) ? y

Switch:1(config)# save config file pre_vms_layer2_install.cfg
File [/intflash/pre_vms_layer2_install.cfg] already existing,CP-1: Save config to file /
intflash/pre_vms_layer2_install.cfg successful.
WARNING: Choice Primary Node Config file is "/intflash/vms-layer2-switch-6.cfg".

Switch:1(config)# spbm
Switch:1(config)# spbm ethertype 0x8100
Switch:1(config)# router isis
Switch:1(config-isis)# spbm 1

Error: ISIS - IS-IS is enabled, runtime change not allowed.

Switch:1(config)# exit

Switch:1(config)# save config file vms-layer2-switch-6.cfg
File [/intflash/vms-layer2-switch-6.cfg] already existing,CP-1: Save config to file /
intflash/vms-layer2-switch-6.cfg successful.

Switch:1(config)# boot config choice primary config-file /intflash/vms-layer2-switch-6.cfg
Switch:1(config)#
**Previous configurations stored in pre_vms_layer2_install.cfg**
**New VMS configurations stored in new primary config file vms-layer2-switch-6.cfg**
*** VMS Layer-2 script execution complete ***
Switch:1(config)#boot config choice primary config-file /intflash/vms-layer2-switch-6.cfg
```

Variable Definitions

The following table defines parameters for the `run vms layer-2 switch` command.

Variable	Value
<5-99>	Specifies a switch value, which is then used as a common element to configure switch parameters such as nickname, VLAN ID, SPB and IP parameters. This switch value is also used in the name of the saved configuration file. For example, 6 is the switch value in <code>vms-layer2-switch-6.cfg</code>
<i>syntax</i>	Species that the switch displays all the commands run by the script on the console. Use this parameter to see errors that the script encounters. Note: The script does not stop if it encounters errors. To verify that the script runs without errors, use the <i>syntax</i> parameter to display errors or conflicting configurations on the switch.

Suspend Duplicate System ID Detection When Replacing a Switch

When a switch is replaced and the original system ID and nickname is used, you must wait up to 20 minutes for the LSPs with the original system to age out. This is due to duplicate system ID and nickname detection. However, you can suspend duplicate detection on the replacement switch so that you can bring the switch into the network immediately.

About This Task

To temporarily disable duplicate detection on the replacement switch, perform the following steps:

Procedure

1. Copy the configuration file of the original switch to the replacement switch.
2. Power up the replacement switch while it is not connected to the SPB network, that is, NNI ports are not connected.
3. Disable IS-IS on the original switch, or remove the switch from the network.
4. On the replacement switch, enter the following Global Configuration command to suspend duplicate detection for up to 21 minutes:

```
isis dup-detection-temp-disable
```
5. To check the remaining time, use the `show isis dup-detection-temp-disable remaining time` command.
6. Remove the original switch from the network.
7. Connect the replacement switch to the network.

Configure Dynamic Nickname Assignment

About This Task

Use this procedure to specify a nickname prefix for Dynamic Nickname Assignment.

Note

You must disable Dynamic Nickname Assignment before you can change the nickname prefix.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the Dynamic Nickname Assignment nickname allocation:

```
spbm nick-name server prefix x.xx.xx
```
3. Enable Dynamic Nickname Assignment:

```
spbm nick-name server
```
4. Verify the configuration:

```
show spbm
```

Examples

Configure a nickname allocation prefix and enable Dynamic Nickname Assignment:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spbm nick-name server prefix C.30.00
Switch:1(config)#spbm nick-name server
```

Dynamic Nickname Assignment configuration values and their associated behavior are shown in the following output from the **show spbm** command:

```
Switch:1>show spbm
                    spbm : enable
                    ethertype : 0x8100
                    nick-name server : enable
                    nick-name allocation : static
                    nick-name server range : C.30.00-C.3F.FF
```

Variable Definitions

The following table defines parameters for the **spbm nick-name server** command.

Variable	Value
<i>prefix x.xx.xx</i>	Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default nickname allocation range is A.00.00-A.0F.FF.

*Display Dynamic Nickname Assignment***About This Task**

Use this procedure to display the current status and values for Dynamic Nickname Assignment.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display Dynamic Nickname Assignment configuration values:

```
show spbm
```

Example

```
Switch:1>show spbm
                spbm : enable
                ethertype : 0x8100
                nick-name server : disable
                nick-name allocation : static
                nick-name server range : A.00.00-A.0F.FF
```

Enable MSTP-Fabric Connect Multi Homing**Note**

This procedure does not apply to VSP 8600 Series or XA1400 Series.

Before You Begin

You must configure a nickname for the specific SPBM instance on which you enable MSTP-Fabric Connect Multi Homing.

About This Task

Perform this procedure to enable MSTP-Fabric Connect Multi Homing for a specific SPBM instance.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Enable MSTP-Fabric Connect Multi Homing on a specified SPBM instance:

```
spbm <1-100> stp-multi-homing enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 stp-multi-homing enable
```

Variable definitions

The following table defines parameters for the **spbm** command.

Variable	Value
<i><1-100></i>	Specifies the IS-IS SPBM instance ID to create an SPBM instance.
<i>stp-multi-homing enable</i>	Enables MSTP-Fabric Connect Multi Homing on the specific SPBM instance. The default is disabled.

Determine the Root Bridge in an MSTP-Fabric Connect Multi Homing Configuration

Identify the root bridge by determining where the Common and Internal Spanning Tree (CIST) regional root MAC address is learned for the STP-reserved I-SID. Check which MAC address has the same first five octets as the CIST regional root MAC address.

About This Task

When you enable MSTP-Fabric Connect Multi Homing, you can use the following two commands to determine which BEB is the root bridge:

- **show spanning-tree mstp status**
- **show i-sid mac-address-entry 16777003**

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Determine the CIST regional root:

```
show spanning-tree mstp status
```
3. Determine which MAC address has the same first five octets as seen in the CIST regional root MAC address:

```
show i-sid mac-address-entry 16777003
```

Example

In the following example, bold text identifies the relevant information in the command output. In the output of the second command, the DEST-MAC shows 10:cd:ae:6e:d8:84, which is the system ID of the CIST regional root BEB, and the system name is BEB-1000.

```
Switch:1>show spanning-tree mstp status
```

```

```

Fabric Extend configuration using the CLI

The following sections provide procedural information you can use to configure Fabric Extend (FE) using the Command Line Interface (CLI).

Configure Fabric Extend

Use the following procedure to configure Fabric Extend (FE) between a Main office to a Branch office, which is a typical deployment. However, if your deployment creates tunnels between two switches that support Fabric Extend natively, then repeat those steps and ignore the steps for switches that require an ONA.

Before You Begin

The tunnel source IP address can be a brouter port IP, a CLIP IP, or a VLAN IP.

Note

Product Notice: Except VSP 8600 Series, all product series support a VLAN IP as the Fabric Extend tunnel source IP address.

For information about product support, see [Fabric Extend Considerations](#) on page 960.

If using the tunnel originating address on the GRT, Fabric Extend has the following requirements:

- The tunnel source IP address must be on the GRT, not on a VRF.

Note

A best practice is to use separate IP addresses for the SPBM IP Shortcuts **ip-source-address** command and the Fabric Extend **ip-tunnel-source-address** command. However, if you want these IP addresses to be the same, you **MUST** exclude the **ip-source-address** address with an IS-IS accept policy. You cannot use the redistribute command with a route map exclusion.

Specify a CLIP interface to use as the source address for SPBM IP shortcuts.

- If IP Shortcuts is enabled, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.

If you are using the tunnel originating address on a VRF, Fabric Extend has the following requirements:

- Configure a CLIP and tunnel source IP address on the VRF.
- Remote management of the VSP 4450 Series is only possible after establishing IP Shortcut over IS-IS. (Alternatively, you can enable GRT-VRF redistribution locally.)

About This Task

Configuring Fabric Extend consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

The VSP 4450 Series source address command is different from other platforms. Also note that the logical interface commands are different between Layer 2 and Layer 3 networks.

Note

VRF is an optional parameter. If a VRF is not configured, then FE uses the GRT.

Procedure

The following steps are for platforms that support FE natively:

1. Enter IS-IS Router Configuration mode:

```
enable  
  
configure terminal  
  
router isis
```
2. Configure the IP tunnel source address:

```
ip-tunnel-source-address <A.B.C.D> [vrf WORD<1-16>] [overlay]
```
3. Enter Global Configuration mode:

```
exit
```
4. Use one of the following commands to create a logical IS-IS interface:
 - In a network with a Layer 3 Core, enter `logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>] [mtu <750-9000>]`
 - In a network with a Layer 2 Core, enter `logical-intf isis <1-255> vid <list of vids> primary-vid <2-4059> port <slot/port> mlt <mltId> [name WORD<1-64>] [mtu <750-9000>]`

Note

The primary VLAN ID (**primary-vid** must be one of the VLANs in the **vid <list of vids>**.

The following steps are for platforms that require an ONA to support FE:

Note

The interface VLAN connecting to the ONA network port is always in the GRT and the member port that the VLAN is part of is always an access port.

5. Enter IS-IS Router Configuration mode:

```
enable  
  
configure terminal  
  
router isis
```
6. Configure the IP tunnel source address on the port that connects to the Device side of the ONA:

```
ip-tunnel-source-address <A.B.C.D> port <slot/port> [mtu <mtu_value>]  
[vrf WORD<1-16>]
```
7. Exit back into Global Configuration mode:

```
exit
```

8. Use one of the following commands to create a logical IS-IS interface:

- In a network with a Layer 3 Core, enter:

```
logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>]
```

- In a network with a Layer 2 Core, enter:

```
logical-intf isis <1-255> vid <list of vids> primary-vid <2-4059>  
port <slot/port> mlt <mltId> [name WORD<1-64>]
```

Note

The primary VLAN ID (**primary-vid**) must be one of the VLANs in the **vid <list of vids>**.

Variable Definitions

The following table defines parameters for the **ip-tunnel-source-address** command.

Variable	Value
<A.B.C.D>	Specifies the IS-IS IPv4 tunnel source address, which can be a brouter interface IP, a CLIP IP, or a VLAN IP.
<i>overlay</i>	Permits the configuration of the tunnel source address even though it belongs to a VRF with an attached I-SID.
port <slot/port> Note: Exception: only supported on VSP 4450 Series.	Specifies the port that is connected to the ONA device port.
vrf WORD<1-16>	Specifies the VRF name associated with the IP tunnel.
mtu <mtu_value> Note: Exception: only supported on VSP 4450 Series.	Specifies the Maximum Transmission Unit (MTU) size for each packet. Different hardware platforms support different MTU ranges. Use the CLI Help to see the available range for the switch. This parameter only applies to an ONA configuration.

The following tables define parameters for the **logical-intf isis** command, depending on whether you have a Layer 2 or Layer 3 core.

Table 103: Layer 2 core

Variable	Value
<1-255>	Specifies the index number that uniquely identifies this logical interface.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies the physical port that the logical interface is connected to in a Layer 2 network.

Table 103: Layer 2 core (continued)

Variable	Value
<i>vid</i> <list of vids>	Specifies the list of VLANs that are associated with this logical interface.
<i>primary-vid</i> <2-4059>	Specifies the primary tunnel VLAN ID associated with this Layer 2 IS-IS logical interface.
<i>mlt</i> <mltId>	Specifies the MLT ID that the logical interface is connected to in a Layer 2 network.
<i>name</i> WORD<1-64>	Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters.
<i>mtu</i> <750-9000> Note: Exception: only supported on XA1400 Series.	Specifies the Maximum Transmission Unit (MTU) size of each packet. The default MTU value is 1950.

Table 104: Layer 3 core

Variable	Value
<1-255>	Specifies the index number that uniquely identifies this logical interface.
<i>dest-ip</i> <A.B.C.D>	Specifies the tunnel destination IP address of the remote BEB.
<i>name</i> WORD<1-64>	Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters.
<i>mtu</i> <750-9000> Note: Exception: only supported on XA1400 Series.	Specifies the Maximum Transmission Unit (MTU) size of each packet. The default MTU value is 1950.

Configure Fabric Extend Over IPsec**Note**

This procedure only applies to XA1400 Series.

Use the following procedure to configure Fabric Extend (FE) over IPsec.

Before You Begin

The tunnel source IP address can be a brouter port IP, a CLIP IP, or a VLAN IP.

About This Task

Configuring Fabric Extend over IPsec consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

For information about how to configure an IPsec NAT-T Responder, see [IPsec configuration using CLI](#) on page 1779.

Procedure

Switch A Steps

1. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```
2. Configure the IP tunnel source address:

```
ip-tunnel-source-address <A.B.C.D> [vrf WORD<1-16>]
```
3. Enter Global Configuration mode:

```
exit
```
4. Use one of the following commands to create a logical IS-IS interface:
 - In a network with a Layer 3 Core, enter `logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>] [mtu <750-9000>]`
5. Configure an IS-IS interface on the selected ports or MLTs:
 - a. Create an IS-IS circuit and interface on the selected ports or MLTs:

```
isis
```
 - b. Enable the SPBM instance on the IS-IS interfaces:

```
isis spbm <1-100>
```
 - c. Enable the IS-IS circuit/interface on the selected ports or MLTs:

```
isis enable
```
6. Configure the IPsec authentication method:

```
ipsec auth-method <pre-share |rsa-sig>
```
7. Create the authentication key, if using a pre-shared key:

```
auth-key WORD<1-32>
```
8. Configure IPsec encryption key length for FE tunnel.

```
ipsec encryption-key-length <128 | 256>
```

Note

- You cannot change the encryption key length when IPsec is enabled on the FE tunnel.

9. (Optional) Enable IPsec compression on the logical interface:

```
ipsec compression
```

By default, IPsec compression is disabled. If you enable it, you must enable it on both ends of the adjacency.

10. Enable IPsec on the logical interface:

```
ipsec
```

11. Exit interface configuration mode:

```
exit
```

Switch B Steps

12. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

13. Configure the IP tunnel source address:

```
ip-tunnel-source-address <A.B.C.D> [vrf WORD<1-16>]
```

14. Enter Global Configuration mode:

```
exit
```

15. Use one of the following commands to create a logical IS-IS interface:

- In a network with a Layer 3 Core, enter `logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>] [mtu <750-9000>]`

16. Configure an IS-IS interface on the selected ports or MLTs:

- a. Create an IS-IS circuit and interface on the selected ports or MLTs:

```
isis
```

- b. Enable the SPBM instance on the IS-IS interfaces:

```
isis spbm <1-100>
```

- c. Enable the IS-IS circuit/interface on the selected ports or MLTs:

```
isis enable
```

17. Configure the IPsec authentication method:

```
ipsec auth-method <pre-share |rsa-sig>
```

18. Create the authentication key, if using a pre-shared key:

```
auth-key WORD<1-32>
```

19. Configure IPsec encryption key length for FE tunnel.

```
ipsec encryption-key-length <128 | 256>
```

Note

- You cannot change the encryption key length when IPsec is enabled on the FE tunnel.

20. (Optional) Enable IPsec compression on the logical interface:

```
ipsec compression
```

By default, IPsec compression is disabled. If you enable it, you must enable it on both ends of the adjacency.

21. Enable IPsec on the logical interface:

```
ipsec
```

22. Exit interface configuration mode:

```
exit
```

Variable Definitions

The following table defines parameters to configure Fabric Extend (FE) over IPsec on a device.

The following table defines parameters for the **ip-tunnel-source-address** command.

Variable	Value
<A.B.C.D>	Specifies the IS-IS IPv4 tunnel source address, which can be a brouter IP, a CLIP IP, or a VLAN IP.
vrf WORD<1-16>	Specifies the VRF name associated with the IP tunnel.

Table 105: Layer 3 core

Variable	Value
<1-255>	Specifies the index number that uniquely identifies this logical interface.
<A.B.C.D>	Specifies the IS-IS IPv4 tunnel source address, which can be either a brouter interface IP or a CLIP IP.
name WORD<1-64>	Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters.
mtu <750-9000>	Specifies the Maximum Transmission Unit (MTU) size of each packet. The default MTU value is 1950.

The following table defines parameters for the **isis** command.

Variable	Value
enable	Enables or disables the IS-IS circuit/interface on the specified port or MLT. The default is disabled. Use the no option to disable IS-IS on the specified interface.
spbm <1-100>	Enable the SPBM instance on the IS-IS interfaces.

The following table defines parameters for the **auth-key** command.

Variable	Value
<code>WORD<1-32></code>	Specifies the authentication key on the assigned logical interface if using a pre-shared key. Use the <code>no</code> option to disable the authentication key on the specified interface.

The following table defines parameters for the **ipsec** command.

Variable	Value
<code>auth-method <pre-share rsa-sig></code>	Configures the authentication method for IPsec. The default is a pre-shared key. Use <code>rsa-sig</code> to use an installed digital certificate instead.
<code>encryption-key-length <128 256></code>	Specifies the IPsec encryption key length for FE tunnel, which is 128 bit or 256 bit. The default IPsec encryption key length value is 128 bit.

Configure Static Source IP Address for IPsec Tunnel

Note

This procedure only applies to XA1400 Series.

Perform this procedure to configure a specific source IP address for the IPsec tunnel when you deploy the XA1400 Series in an environment that requires more than one provider connection with IPsec.

Before You Begin

- Configure a VLAN, brouter, or CLIP IP address for the IPsec tunnel to use; this address must be in the same VRF as the tunnel.
- Disable IPsec on the logical interface.

About This Task

The static source IP address for the IPsec tunnel cannot be the same as the global or dynamically configured source IP address.

Procedure

1. Enter Logical IS-IS Interface Configuration mode:

```
enable
configure terminal
logical-intf isis <1-255>
```
2. Configure the IP address to use as the source IP address for IPsec tunnel:

```
ipsec tunnel-source-address type static {A.B.C.D}
```
3. Enable IPsec on the logical interface:

```
ipsec
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#logical-intf isis 3
Switch:1(config-isis-3-198.51.100.1)#ipsec tunnel-source-address type static 20.20.20.20
Switch:1(config-isis-3-198.51.100.1)#ipsec
```

Variable Definitions

The following table defines parameters for the **ipsec tunnel-source-address type static** command.

Variable	Value
{A.B.C.D}	Specifies the manually configured source IP address for the IPsec tunnel. The source IP address must be on the same VRF as the source IP address for the IP tunnel.

Configure DHCP Source IP Address for IPsec Tunnel**Note**

This procedure only applies to XA1400 Series.

Perform this procedure to dynamically obtain the source IP address for the IPsec tunnel from DHCP when you deploy the XA1400 Series in an environment that requires more than one provider connection with IPsec.

Before You Begin

- Disable IPsec on the logical interface.
- Ensure that the DHCP client is enabled for the Management Instance VLAN interface.
- Ensure that there is coexistence between the VOSS routing stack and the Management Instance VLAN interface. Use the **propagate-to-routing** command from the mgmt VLAN level to move to the coexistence mode automatically. For more information, see [VLAN](#) on page 76.

About This Task

The static source IP address for the IPsec tunnel cannot be the same as the global or dynamically configured source IP address.

Procedure

1. Enter Logical IS-IS Interface Configuration mode:

```
enable

configure terminal

logical-intf isis <1-255>
```
2. Import the source IP address from DHCP:

```
ipsec tunnel-source-address type dhcp
```
3. Enable IPsec on the logical interface:

```
ipsec
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#logical-intf isis 3
Switch:1(config-isis-3-198.51.100.1)#ipsec tunnel-source-address type dhcp
Switch:1(config-isis-3-198.51.100.1)#ipsec
```

Configure ESP Cipher Suite for IPsec**Note**

This procedure only applies to XA1400 Series.

Before You Begin**About This Task**

Configure the Encapsulating Security Payload (ESP) cipher suite for IPsec.

Procedure

1. Enter Logical IS-IS Interface Configuration mode:

```
enable

configure terminal

logical-intf isis <1-255>
```
2. Configure the ESP cipher suite for IPsec:

```
ipsec esp [<aes128gcm16-sha256 | aes256-sha256 | aes256gcm16-sha256 >]
```

Variable Definitions

The following table defines parameters for the **ipsec esp** command.

Variable	Value
<aes128gcm16-sha256>	Specifies the AES cipher with a 128-bit encryption key and GCM block mode.
<aes256-sha256>	Specifies the AES cipher with a 256-bit encryption key and CBC block mode (for QAT performance mode).
<aes256gcm16-sha256>	Specifies the AES cipher with a 256-bit encryption key and GCM block mode.

Disable IPsec Compression**Note**

If you downgrade to an earlier release that does not support this feature, you must disable the feature and save the configuration. Downgrading to an earlier release will require a compatible configuration file.

Procedure

1. Enter Logical IS-IS Interface Configuration mode:

```
enable

configure terminal

logical-intf isis <1-255>
```
2. Disable IPsec:

```
no ipsec
```
3. Disable IPsec compression:

```
no ipsec compression
```
4. Enable IPsec:

```
ipsec
```
5. Save the configuration.
6. Verify the configuration:

```
show isis logical-interface ipsec
```

Example

```
Switch:1(config-isis-2-192.0.2.10)# no ipsec
Switch:1(config-isis-2-192.0.2.10)# no ipsec compression
Switch:1(config-isis-2-192.0.2.10)# ipsec
Switch:1(config-isis-2-192.0.2.10)#show isis logical-interface ipsec
=====
                        ISIS Logical Interface IPSec
=====
ID   Authentication-Key  Responder-Only  Remote NAT  IP Compression
-----
2    *****            False           -           False
-----

=====
```

Configure IS-IS Hello Padding**Note**

This procedure does not apply to VSP 8600 Series.

Perform this procedure to dynamically configure IS-IS hello padding on all IS-IS NNI links. IS-IS hello padding is enabled by default.

About This Task

Disable hello padding if the WAN-line MTU is less than 1596 bytes and fragmentation and reassembly functionality is enabled.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Perform one of the following actions:
 - Disable hello padding: `no hello-padding`
 - Enable hello padding, if previously disabled: `hello-padding`
3. Verify the configuration:

```
show isis
```

Example

Verify IS-IS hello padding status:

```
Switch:1>show isis
=====
                        ISIS General Info
=====
                        AdminState : enabled
                        RouterType : Level 1
                        System ID  : 0014.c7e1.33df

```

Enable IPsec Fragmentation Before Encryption**Note**

This procedure only applies to XA1400 Series.

Configure IPsec fragmentation before encryption to avoid possible throughput penalty for sending fragmented packets over the Internet.

Before You Begin

- Configure the IPsec tunnel source address globally.
- Disable IPsec on the logical interface.
- IPsec over Fabric Extend must be in IPsec decoupled mode. For more information, see [Fabric IPsec Gateway Fundamentals](#) on page 852.
- Configure one of the following:
 - the IPsec tunnel destination IP
 - IPsec NAT-T responder only mode
 - IPsec responder remote NAT IP address

Procedure

1. Enter Logical IS-IS Interface Configuration mode:

```
enable

configure terminal

logical-intf isis <1-255>
```
2. Enable IPsec fragmentation before encryption on the logical interface:

```
ipsec fragment-before-encrypt
```
3. Enable IPsec on the logical interface:

```
ipsec
```
4. Verify the configuration:

```
show isis logical-interface ipsec
```

Example

Enable IPsec fragment before encryption and verify the configuration:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#logical-intf isis 2
Switch:1(config-isis-2-192.0.2.24)#ipsec fragment-before-encrypt
Switch:1(config-isis-2-192.0.2.24)#ipsec

Switch:1>show isis logical-interface ipsec

```

Disable IPsec Fragmentation Before Encryption**Note**

This procedure only applies to XA1400 Series.

If you downgrade to an earlier release that does not support this feature, you must disable the feature and save the configuration. You must have a compatible configuration file if you downgrade to an earlier release.

Before You Begin**Procedure**

1. Enter Logical IS-IS Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
logical-intf isis <1-255>
```
2. Disable IPsec on the logical interface:

```
no ipsec
```
3. Disable IPsec fragmentation before encryption on the logical interface:

```
no ipsec fragment-before-encrypt
```
4. Enable IPsec on the logical interface:

```
ipsec
```
5. Verify the configuration:

```
show isis logical-interface ipsec
```

Example

Disable IPsec and IPsec fragmentation before encryption and verify the configuration:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#logical-intf isis 2
Switch:1(config-isis-2-192.168.20.1)#no ipsec

Adjust the TCP Maximum Segment Size

Note

This procedure only applies to VSP 4900 Series, VSP 7400 Series, and XA1400 Series.

Adjust the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency.

About This Task

Note

If you downgrade to an earlier release that does not support this feature, you must disable the feature and save the configuration. Downgrading to an earlier release requires a compatible configuration file.

The default varies depending on hardware platform:

- For XA1400 Series, this functionality is enabled when at least one Fabric Extend (FE) tunnel with a MTU less than or equal to 1500 is configured, and the value is auto-derived.
- For VSP 4900 Series and VSP 7400 Series, this functionality is disabled. The default value, when enabled, is 1300.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Use one of the following commands to configure the MSS adjustment functionality as required:

- a. Configure an explicit MSS adjust value:

```
ip tcp adjust-mss <max-segment-size> [enable]
```

- b. Disable MSS adjustment explicitly:

```
no ip tcp adjust-mss enable
```

- c. Disable a configured MSS adjustment value and return to the auto-derived value:

Note

auto-derived value is only supported on XA1400 Series.

```
no ip tcp adjust-mss enable
```

3. Verify the configuration:

```
show ip tcp adjust-mss
```

Examples

Configure an MSS value of 1100 and verify the configuration.

```
Switch:1>enable  
Switch:1#configure terminal
```

```

Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip tcp adjust-mss 1200
Switch:1>show ip tcp adjust-mss
=====
                        IP TCP Adjust MSS
=====
ENABLE          STATUS          TCP MSS          TCP MSS
                  TYPE          VALUE
-----
TRUE            ACTIVE          MANUAL-CONFIG    1200

```

Disable the configured MSS adjustment value on XA1400 Series and verify the configuration:

```

Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no ip tcp adjust-mss enable
Switch:1(config)#show ip tcp adjust-mss
=====
                        IP TCP Adjust MSS
=====
ENABLE          STATUS          TCP MSS          TCP MSS
                  TYPE          VALUE
-----
TRUE            ACTIVE          AUTO-DERIVED     1300

```

Displaying Fabric Extend over IPsec tunnel status

Use the following procedure to display the Fabric Extend over IPsec tunnel status on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Fabric Extend over IPsec tunnel status:

```
show io logical-intf-ipsec
```

Example of a Fabric Extend over IPsec tunnel status.

```

Switch:1> show io logical-intf-ipsec
bash-4.3# ipsec status | grep ESTABLISHED
ipsec1-192.0.2.192[12]: ESTABLISHED 13 hours ago,
192.0.2.193[192.0.2.193]...192.0.2.192[192.0.2.192]
ipsec0-192.0.2.182[11]: ESTABLISHED 13 hours ago,
192.0.2.193[192.0.2.193]...192.0.2.182[192.0.2.182]

```

Configure BFD on a Fabric Extend Tunnel

About This Task

Use the following procedure to configure BFD on a Fabric Extend Tunnel.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable BFD:

```
router bfd enable
```

3. In the VLAN Interface Configuration mode, you can enable BFD:

```
ip bfd enable
```

4. In the Loopback Interface Configuration mode, you can enable BFD:

```
ip bfd enable
```

5. Enable BFD on an IS-IS Logical Interface:

```
logical-intf isis <1-255> bfd enable
```

Example

Enable BFD on a Fabric Extend tunnel:

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bfd enable
Switch:1(config)#interface loopback 1
Switch:1(config-if)#ip bfd enable
Switch:1(config-if)#logical-intf isis 1
Switch:1(config-isis-1-1.2.3.5)#bfd enable
```

Display IS-IS Logical Interfaces

Use the following procedure to display the Intermediate-System-to-Intermediate-System (IS-IS) logical interfaces configured on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS logical interfaces:

```
show isis logical-interface [name | ipsec | shaper | mtu]
```

Examples

Example of a Layer 2 Core

```
Switch:1> show isis logical-interface

Variable Definitions

The following table defines parameters for the **show isis logical-interface** command.

Variable	Value
name	Displays the full name of the IS-IS logical interface (up to a maximum of 64 characters).
ipsec	Displays the IS-IS logical interface ID and IPsec authentication key.
shaper	Displays the IS-IS logical interface egress shaping rate values. Only interfaces that have egress shaping rates configured display.

Display BFD Fabric Extend Neighbor Information

About This Task

Use this procedure to display BFD Fabric Extend neighbors.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the BFD configurations:

```
show ip bfd neighbors vrf WORD<1-16>
```

Example

```
Switch:1>show ip bfd neighbors vrf vrf30
```

```

*Configure Global Source IP Address for IPsec Tunnel***About This Task**

Perform this procedure to configure the global source IP address for IPsec tunnel on the switch.

**Note**

Product Notice: This procedure only applies to XA1400 Series switches.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable
configure terminal
router isis
```
2. Configure the source IP address for IPsec tunnel:

```
ipsec tunnel-source-address {A.B.C.D}
```

**Note**

You must configure the source IP address for IPsec tunnel on the same VRF as the source address for IP tunnel.

Example

Configuring source IP address for IPsec tunnel.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#ipsec tunnel-source-address 192.0.2.10
```

Variable Definitions

The following table defines the variable for **ipsec tunnel-source-address** command.

Variable	Value
{A.B.C.D}	Specifies the global IP address for IPsec tunnel, which is configured on the same VRF as the source address for IP tunnel.

Configure Destination IP Address for IPsec Tunnel

About This Task

Perform this procedure to configure the destination IP address for the IPsec tunnel on a specific IS-IS logical interface on the switch.

Note

Product Notice: This procedure only applies to XA1400 Series switches.

Procedure

1. Enter Logical IS-IS Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
logical-intf isis <1-255>
```

2. Configure destination IP address for IPsec tunnel:

```
ipsec tunnel-dest-ip {A.B.C.D}
```

Example

Configuring destination IP address for IPsec tunnel.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#logical-intf isis 1
Switch:1(config-isis-1-192.0.2.25)ipsec tunnel-dest-ip 192.0.2.30
```

Variable Definitions

The following table defines the variable for **ipsec tunnel-dest-ip** command.

Variable	Value
{A.B.C.D}	Specifies destination IP address for the IPsec tunnel on a specific IS-IS logical interface. Note: When you configure the destination IP address for the IPsec tunnel, IKE protocol uses UDP port 500. However, if IPsec NAT-T is detected, IKE protocol uses UDP port 4500 instead.

Fabric Attach Configuration using the CLI

The following sections provide procedural information you can use to configure Fabric Attach (FA) and Logical Link Discovery Protocol (LLDP) using the Command Line Interface (CLI). For information about LLDP related to FA, see [Link Layer Discovery Protocol configuration using CLI](#) on page 2201.

Configure Fabric Attach Globally

For proper operation, FA must be enabled at both the global level and at the interface level on the FA Server. By default, FA is globally enabled. However, FA is disabled by default at the interface level and must be explicitly enabled on each interface.

Use this procedure to enable Fabric Attach globally on a switch.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable FA:

```
fa enable
```

3. (Optional) Disable FA:

```
no fa enable
```

Caution

Disabling FA flushes all FA element discovery and mappings.

4. View the FA configuration status. Use one of the following commands:

- `show fa`
- `show fa agent`

Example

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#fa enable

Switch:1>show fa

=====
Fabric Attach Configuration
=====
          FA Service : enabled
          FA Element Type : server
    FA Assignment Timeout : 240
    FA Discovery Timeout : 240
          FA Provision Mode : spbm

Switch:1>show fa agent

=====
Fabric Attach Configuration
=====
          FA Service : enabled
          FA Element Type : server
```

```

FA Assignment Timeout : 240
FA Discovery Timeout   : 240
FA Provision Mode     : spbm

```

Configuring Fabric Attach discovery timeout

Use this procedure to configure the Fabric Attach discovery time-out.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the FA discovery time-out in seconds:

```
fa discovery-timeout <45-480>
```

Note

The discovery time-out must be greater than or equal to the assignment time-out.

3. (Optional) Configure the default FA discovery time-out:

```
default fa discovery-timeout
```

Example

Configure the FA discovery time-out.

```

Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#fa discovery-timeout 50

```

Verify the configuration.

```

Switch:1(config)#show fa

=====
                          Fabric Attach Configuration
=====

                          FA Service : enabled
                          FA Element Type : server
                          FA Assignment Timeout : 45
                          FA Discovery Timeout : 50
                          FA Provision Mode : spbm

```

Variable definitions

The following table defines parameters for the **fa discovery-timeout** command.

Variable	Value
<45-480>	Specifies the Fabric Attach discovery time-out in seconds. The default value is 240 seconds.

Configuring Fabric Attach assignment timeout

Use this procedure to configure the Fabric Attach assignment time-out.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the FA assignment time-out in seconds:

```
fa assignment-timeout <45-480>
```

**Note**

The assignment time-out must be less than or equal to the discovery time-out.

3. (Optional) Configure the default FA assignment time-out value:

```
default fa assignment-timeout
```

Example

Configure the FA assignment time-out:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#fa assignment-timeout 50
```

Verify the configuration:

```
Switch:1(config)#show fa

=====
                          Fabric Attach Configuration
=====

          FA Service : enabled
          FA Element Type : server
          FA Assignment Timeout : 50
          FA Discovery Timeout : 240
          FA Provision Mode : spbm
```

Variable definitions

The following table defines parameters for the **fa assignment-timeout** command.

Variable	Value
<45-480>	Specifies the Fabric Attach assignment time-out in seconds. The default value is 240 seconds.

Enabling Fabric Attach on an interface

Use this procedure to enable Fabric Attach on an interface (port, static MLT or LACP MLT). Enabling FA on an MLT enables FA on all ports of the MLT. If your platform supports channelization, FA can also be enabled on channelized ports.

Before You Begin

Verify that FA is enabled globally on the switch.

About This Task

Enabling FA on a port or MLT is necessary for element discovery.

On the FA Server, FA is enabled globally by default. However, you must explicitly enable FA on the desired port or MLT interface. FA is successfully enabled on an MLT only if all ports of the MLT have FA successfully enabled. Enabling FA automatically configures LLDP on all ports. Tagging is configured and spanning tree is disabled.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable FA on the interface:

```
fa enable
```

3. (Optional) Disable FA on the interface:

```
no fa enable
```

Caution

Disabling FA flushes all FA element discovery and I-SID-to-VLAN mappings associated with the interface.

4. View the FA configuration status:

```
show fa interface [disabled-auth] [enabled-auth] [mlt <1-512>] [port
<{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}>]
```

Example

Enable FA on a port:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#fa enable
Switch:1(config-if)#exit
Switch:1(config)#
```

Enable FA on an MLT:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#fa enable
```

```
Switch:1(config-mlt)#exit
Switch:1(config)#
```

Verify that FA is enabled on the interfaces.

Note

When FA is enabled, message authentication is enabled by default. The authentication key is set to the default value and displays encrypted on the output.

```
Switch:1>show fa interface
```

```
=====
                        Fabric Attach Interfaces
=====

```

Variable definitions

The following table defines parameters for the **show fa interface** command.

Variable	Value
disabled-auth	Displays the FA interfaces (port or MLT) that have authentication disabled.
enabled-auth	Displays the FA interfaces (port or MLT) that have authentication enabled.
<1-512>	The valid range for MLT ID. Displays FA configuration on the specified MLT interface.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. Displays FA configuration on the specified port.

Configuring FA message authentication on an interface

Use this procedure to configure FA message authentication on an interface (port or MLT).

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure FA message authentication on a port or MLT:

```
[default] [no] fa message-authentication
```

Note

When FA is enabled, message authentication is enabled by default. The authentication key is set to the default value and displays encrypted on the output.

Example

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#
```

Enable message authentication on a port.

```
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#fa message-authentication
Switch:1(config-if)#show fa interface port 1/2
```

```

-----
```

Configuring the FA authentication key on an interface

On the FA Server, you can configure an authentication key on an interface (port, static MLT or LACP MLT), to authenticate a client or proxy device on that interface. The authentication key is stored in encrypted form when you save configuration on the FA Server.

Before You Begin

Ensure that:

- On the FA Server, FA is enabled globally and also on the interface.
- FA message authentication is enabled on the interface.

Note

By default, enabling FA enables message authentication. The authentication key is set to the default value and the system displays the encrypted authentication key on the output.

About This Task

Use this procedure to configure an FA authentication key on a specified port or on all ports of an MLT, on the switch. If you do not configure an authentication key, the default value is used. If you specify a key, the default value is overridden and is stored in encrypted format in a separate file other than the configuration file, when you execute the `save config` command.

Caution

For an FA Client or an FA Proxy device to successfully authenticate and attach to the FA Server, the authentication key must match on both the client and the server. If the authentication key is changed on the FA Server switch, it must correspondingly be changed on the FA Client or Proxy attached to it, for FA to operate properly.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface mlt <1-512>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the FA authentication key:

```
fa authentication-key WORD<0-32>
```

3. (Optional) Configure the default FA authentication key:

```
default fa authentication-key
```

Example

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
```

Enable FA and message authentication on a port. Configure the authentication key `phone-network` on the port.

```
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#fa enable
Switch:1(config-if)#fa message-authentication
Switch:1(config-mlt)#fa authentication-key phone-network
Switch:1(config-if)#exit
Switch:1(config)#
```

Enable FA and message authentication on an MLT. Configure the authentication key `client-network` on the MLT.

```
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#fa enable
Switch:1(config-mlt)#fa message-authentication
Switch:1(config-mlt)#fa authentication-key client-network
```

Verify configuration of the FA authentication key. The system displays the encrypted authentication key on the output.

```
Switch:1(config-if)#show fa interface

```

Variable Definitions

The following table defines parameters for the **fa authentication-key** command.

Variable	Value
WORD<0-32>	Specifies the authentication key on the port or MLT.

Configure FA Management on a Port or MLT

Use this procedure to configure a management I-SID on a Fabric Attach (FA)-enabled port or MLT.

To configure an FA management I-SID for Auto-sense-enabled ports, see [Configure a Management I-SID for Auto-sense Fabric Attach Proxy Switches](#) on page 36.

Before You Begin

Ensure that the port or MLT is enabled for FA.

About This Task

This command applies to all traffic sent or received on a port or MLT, carrying the VLAN ID specified using the `c-vid` parameter. This parameter is optional.

Depending on whether the `c-vid` parameter is specified or not, the behavior is as follows:

- If you specify the `c-vid` parameter, the FA Server transmits this VLAN ID as the management VLAN in the FA Element TLV. A client or proxy receiving this TLV uses this VLAN-ID for management traffic on the FA Server uplink.
- If you do not specify the `c-vid` parameter, the FA Server transmits a management VLAN with a VLAN ID value of 4095 in the FA Element TLV. A client or proxy receiving this TLV uses untagged traffic for network management on the FA Server uplink.

An FA management I-SID can have a platform VLAN associated with it. For Layer 3 support on the management I-SID, you must create a platform VLAN by port and associate the platform VLAN with the management I-SID. The C-VID can be of the same value or of a different value than that of the platform VLAN.

If the management I-SID matches one of the FA Switched UNI (ELAN) I-SIDs (as displayed by the command `show i-sid elan`), then the platform VLAN is automatically associated with the FA-enabled interface (port or MLT).

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface mlt <1-512>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

2. Configure the FA management I-SID:

```
fa management i-sid <i-sid><c-vid>
```

Important

If you do not specify a C-VID value, the port or MLT is untagged.

3. Verify configuration of FA management on the port or MLT, using the following commands:

- `show i-sid <i-sid>`
- `show interfaces gigabitEthernet i-sid [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show mlt i-sid [<1-512>]`

Examples

Configure FA management on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#fa management i-sid 101 c-vid 101
Switch:1(config-if)#show i-sid 101

Variable Definitions

The following table defines parameters for the **fa management** command.

Variable	Value
<code>i-sid <i-sid></code>	Specifies the management I-SID. Different hardware platforms support different customer I-SID ranges. To see the available range for the switch, use the CLI Help.
<code><c-vid></code>	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch. Important: If you do not specify a C-VID value, the port or MLT is untagged .

View Fabric Attach Global Configuration Status

Use this procedure to display the Fabric Attach global configuration status on a switch.

Procedure

- To enter User EXEC mode, log on to the switch.
- Display the FA configuration status using one of the following commands:
 - `show fa`
 - `show fa agent`

Example

Sample output for the **show fa** command:

```
Switch:1>show fa

=====
                Fabric Attach Configuration
=====
                FA Service : enabled
                FA Element Type : server
                FA Assignment Timeout : 240
                FA Discovery Timeout : 240
                FA Provision Mode : spbm
```

Sample output for the **show fa agent** command:

```
Switch:1>show fa agent

=====
                Fabric Attach Configuration
=====
                FA Service : enabled
                FA Element Type : server
                FA Assignment Timeout : 240
                FA Discovery Timeout : 240
                FA Provision Mode : spbm
```

Viewing Fabric Attach interface configuration

Use this procedure to view FA interface configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. View all FA interfaces (ports and MLTs):

```
show fa interface
```

3. To view FA interface configuration on ports, use one of the following commands:

- View FA configuration on all ports:

```
show fa interface port
```

- View FA configuration on a specific port, enter:

```
show fa interface port [{slot/port[/sub-port] [-slot/port[/sub-  
port]] [,...]]
```

4. To view FA interface configuration on MLTs, use one of the following commands:

- View FA configuration on all MLTs:

```
show fa interface mlt
```

- View FA configuration on a specific MLT:

```
show fa interface mlt [<1-512>]
```

Example

The following example displays sample outputs for the **show fa interface** command.

```
Switch:1>show fa interface

Variable definitions

The following table defines parameters for the `show fa interface port` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

The following table defines parameters for the `show fa interface mlt` command.

Variable	Value
<code><1-512></code>	The valid range for MLT ID.

Viewing Fabric Attach Discovered Elements

Use this procedure to view Fabric Attach discovered elements.

About This Task

When FA is enabled on an FA Server switch, LLDP PDUs are exchanged between the FA Server and FA Clients or FA Proxies. Standard LLDPs allow neighbors to be learned. With the help of organizational-specific element discovery TLVs, the client or proxy recognizes that it has attached to the FA Server. Only after the discovery handshake is complete, an FA Client or FA Proxy can transmit I-SID-to-VLAN assignments to join the SPB Fabric network through the FA Server.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display FA discovered elements:

```
show fa elements
```

3. Display FA discovered elements on a specific port:

```
show fa elements [{slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]]
```

Example

The following example displays the sample output for the `show fa elements` command.

```
Switch:1#show fa elements

-----

2 out of 2 Total Num of fabric attach discovery elements displayed
```

Variable definitions

The following table defines parameters for the `show fa elements` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing Fabric Attach I-SID-to-VLAN Assignments

Use this procedure to display the I-SID-to-VLAN assignments advertised by an FA Client or an FA Proxy, to be supported on the FA Server. These assignments can be accepted or rejected by the FA Server. An

assignment that is successfully accepted by the FA Server results in the creation of a Switched UNI I-SID on the interface.

Before You Begin

Verify that IS-IS and SPBM are properly configured on the FA Server switch.

- Verify SPBM configuration using the command **show running-config module spbm**.
- Verify IS-IS configuration using one of the following commands:
 - **show isis**
 - **show isis interface**
 - **show isis adjacency**
 - **show isis lsdb**

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display FA I-SID-to-VLAN assignments:

```
show fa assignment
```

3. Display FA I-SID-to-VLAN assignments on specific ports:

```
show fa assignment [{slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]]
```

Example

The following example displays a sample output for the `show fa assignment` command.

Note

The state of I-SID-to-VLAN assignments on a client or proxy device is pending until it is changed by the FA Server to `active` or `reject`.

```
Switch:>en
Switch:1#show fa assignment
=====
                          Fabric Attach Assignment Map
=====
Interface  I-SID      Vlan      State      Origin
-----
1/1        2          2         active     proxy
1/2        3          3         active     proxy
1/2        4          4         active     proxy
1/3        5          5         reject     proxy
-----
4 out of 4 Total Num of fabric attach assignment mappings displayed
-----
```

Variable definitions

The following table defines parameters for the **show fa assignment** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing Fabric Attach Statistics

If FA discovery fails, use this procedure to display FA statistics to determine if FA discovery TLVs were processed. You can also view the FA assignment statistics to determine the number of FA assignments that were accepted or rejected by the FA Server.

You can view the statistics at either the global level or at the port (interface) level.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View global level FA statistics:
show fa statistics [summary]
3. View FA statistics at the slot/port level:
show fa statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]

Note

If a slot is removed from the switch chassis, the FA statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

4. (Optional) Clear FA statistics:
clear fa statistics [summary] [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]

Examples

Viewing FA discovery and assignment statistics:

```
Switch:1>en
Switch:1#show fa statistics
```

```

1/2      0         0         0         0         0         0
-----

```

Variable Definitions

The following table defines parameters for the **show fa statistics** command.

Variable	Value
summary	Displays a summary of Fabric Attach element discovery and assignment statistics at the global level.
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Display Learned LLDP Neighbors

Use this procedure to verify details of the LLDP neighbors learned.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Verify details of LLDP neighbors learned:
show lldp neighbor
3. Verify details of LLDP neighbors learned on a specific port:
show lldp neighbor port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*

Example

The following example shows how two switches—an FA Server and an FA Proxy discover each other as LLDP neighbors.

Switch A, which is the FA Server is a VSP 7200 Series switch (model 7254XSQ) and switch B which is the proxy device is an ERS 4826GTS switch.

The following examples show neighbor discovery on non-channelized ports.

On the non-channelized port 1/1 on the FA Server, verify neighbor discovery of the proxy switch.

```

Switch:1>enable
Switch:1#show lldp neighbor

```

```

Total neighbors: 1

```

Variable Definitions

The following table defines parameters for the **show lldp neighbor** command.

Variable	Value
port {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. Displays LLDP neighbor information on the specified port.

Display Switched UNI (ELAN) I-SID Information

Use this procedure to display information on FA-created Switched UNI (ELAN) I-SIDs.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Display all Switched UNI (ELAN) I-SIDs:

```
show i-sid elan
```

3. Display ELAN I-SID information on an MLT:

```
show mlt i-sid [<1-512>]
```

Note

Viewing ELAN I-SID information on an MLT is useful to understand the origin of the I-SID when multiple client or proxy devices connecting to the FA Server using SMLT MLT advertise the same I-SID-to-VLAN mappings. In the event of a link failure on an MLT, the origin of the I-SID helps determine on which MLT, and thereby from which proxy or client device, the mappings were successfully learnt.

4. Display ELAN I-SID information on ports:

```
show interfaces gigabitEthernet i-sid [{slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]]
```

Examples

Display information on all Switched UNI (ELAN) I-SIDs.

The following sample output displays, for example, the I-SID information on one of the peer switches of the FA Server, in a dual-homed SMLT configuration.

```
Switch:1>enable
Switch:1#show i-sid elan

Variable Definitions

The following table defines parameters for the **show i-sid** command.

Variable	Value
elan	Displays all ELAN I-SIDs.

The following table defines parameters for the **show mlt i-sid** command.

Variable	Value
<1-512>	The valid range for MLT ID.

The following table defines parameters for the **show interfaces gigabitEthernet i-sid** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Enabling or disabling FA Zero Touch Client Attachment

Use this procedure to enable or disable the global FA Zero Touch Client Attachment feature on an FA Proxy or Server. By default, FA Zero Touch Client Attachment support is enabled.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable an FA Zero Touch client:

```
fa zero-touch-client standard <camera|ona-sdn|ona-spb-over-ip|phone|  
router|security-device|srvr-endpt|switch|video|virtual-switch|wap-  
type1|wap-type2> i-sid <1-15999999>
```

3. Disable an FA Zero Touch client:

```
no fa zero-touch-client standard <camera|ona-sdn|ona-spb-over-ip|  
phone|router|security-device|srvr-endpt|switch|video|virtual-switch|  
wap-type1|wap-type2>
```

Example

```
Switch:1(config)# fa zero-touch-client standard camera i-sid 1003  
Switch:1(config)# no fa zero-touch-client standard camera
```

Variable definitions

The following table defines parameters for the **fa zero-touch-client standard** command.

Variable	Value
<i>camera</i>	Specify element type to match camera.
<i>ona-sdn</i>	Specify element type to match ona-sdn.
<i>ona-spb-over-ip</i>	Specify element type to match ona-spb-over-ip.
<i>phone</i>	Specify element type to match phone.
<i>router</i>	Specify element type to match router.
<i>security-device</i>	Specify element type to match security-device.
<i>svr-endpt</i>	Specify element type to match svr-endpt.
<i>switch</i>	Specify element type to match switch.
<i>video</i>	Specify element type to match video.
<i>virtual-switch</i>	Specify element type to match virtual-switch.
<i>wap-type1</i>	Specify element type to match wap-type1.
<i>wap-type2</i>	Specify element type to match wap-type2.

Displaying FA Zero Touch Client Attachment

Use this procedure to display the Zero Touch Client Attachment data you have configured on an FA Server.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display Zero Touch Client Attachment data:
show fa zero-touch-client

Example

The following example displays sample output for the **show fa zero-touch-client** command.

```
Switch:1#show fa zero-touch-client

=====
                        Fabric Attach Zero Touch Client
=====
Type      Description      I-SID      VLAN

Configure Endpoint Tracking Using CLI

The following sections provide procedural information to configure Endpoint Tracking using CLI.

Configure Endpoint Tracking Interfaces

Create and enable Endpoint Tracking on ports and MLT/SMLT interfaces. Creating, deleting, enabling, and disabling Endpoint Tracking on interfaces can be accomplished as separate steps using this procedure.

Before You Begin

- In Extreme Management Center or ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center or ExtremeCloud IQ - Site Engine.

About This Task

Configure ports and MLT/SMLT interfaces to function as Switched UNI interfaces, and then create and enable Endpoint Tracking on those interfaces.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface mlt <1-512>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Flex UNI on the interface:

```
flex-uni enable
```

3. Create and enable Endpoint Tracking:

- Create Endpoint Tracking on the interface:

```
endpoint-tracking
```

- Create and enable Endpoint Tracking on the interface:

```
endpoint-tracking enable
```

What to Do Next

Configure Endpoint Tracking globally on the switch.

Configure Endpoint Tracking Globally

Configure Endpoint Tracking globally on the switch.

Before You Begin

- In Extreme Management Center or ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center or ExtremeCloud IQ - Site Engine.
- Create and enable Endpoint Tracking on interfaces.

About This Task

Optionally, if the RADIUS outbound attributes do not include an I-SID value, configure an I-SID offset value, and globally enable I-SID offset for Endpoint Tracking. The I-SID offset value is used to calculate an I-SID value for a switched UNI if no I-SID value is provided by the RADIUS server. In that case, the I-SID value is calculated as follows: I-SID = VLAN ID + configured I-SID offset value.

After optionally configuring an I-SID offset value, enable Endpoint Tracking globally on the switch.

Note

If you have previously enabled Endpoint Tracking globally and want to change the currently configured I-SID offset value, you must disable Endpoint Tracking globally, change the I-SID value, and then re-enable Endpoint Tracking globally.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. (Optional) Configure an I-SID offset value, and enable I-SID offset globally on the switch:

```
endpoint-tracking auto-isid-offset <0-15995903>
endpoint-tracking auto-isid-offset enable
```
3. Enable Endpoint Tracking globally on the switch:

```
endpoint-tracking enable
```

Variable Definitions

The following table defines parameters for the **endpoint-tracking auto-isid-offset** command.

Variable	Value
<code><0-15995903></code>	The I-SID offset value. The default is 15990000.
<code>enable</code>	Enables or disables I-SID offset value globally on the switch. The default is disabled.

Configure Endpoint Tracking Visibility Mode

Configure Endpoint Tracking visibility mode on the switch.

Before You Begin

- In Extreme Management Center or ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center or ExtremeCloud IQ - Site Engine.
- Create and enable Endpoint Tracking on interfaces.
- Enable Endpoint Tracking globally on the switch.

About This Task

Enable visibility mode to allow MAC learning on static S-UNIs for Endpoint Tracking.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable Endpoint Tracking visibility mode on the switch:
`endpoint-tracking visibility-mode`

Display Endpoint Tracking Configuration Information

Perform this procedure to display configuration information for Endpoint Tracking.

About This Task

Perform this procedure to display global, interface and binding information for Endpoint Tracking.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the global status of Endpoint Tracking on the switch, and the configured I-SID offset value, if applicable:
`show endpoint-tracking`
3. Display the status of all interfaces that have Endpoint Tracking created:
`show endpoint-tracking interfaces [gigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] | [mlt <1-512>]`
4. Display a summary of the VLAN:ISID binding information for all ports, or MLT/SMLT interfaces:
`show endpoint-tracking bindings summary`
5. Display the VLAN:ISID binding information for the switch, for ports, or for MLT/SMLT interfaces:
`show endpoint-tracking bindings [gigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] | [mlt <1-512>]`

Example

The following example displays all of the Endpoint Tracking configuration information for a switch.

```
Switch:1>show endpoint-tracking
=====
Endpoint Tracking Configuration
=====

endpoint tracking status : ENABLED
auto-isid-offset value : 15990000
auto-isid-offset enabled : ENABLED
visibility-mode status : ENABLED

Switch:1>show endpoint-tracking interfaces

1/10      201    00:00:00:00:1b:05  accept  27       15990027 autoconfig  0 day(s), 00:01:40  0 day(s), 00:00:00

5 out of 5 Total Num of Endpoint Tracking bindings displayed.
```

Variable Definitions

The following table defines parameters for the **show endpoint-tracking bindings** command.

Variable	Value
gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
MLT <1-512>	Specifies the MLT ID.
summary	Provides a summary of the total number and status of bindings for all interfaces.

IS-IS external metric configuration using the CLI

This section provides procedures for IS-IS external metric configuration.

Matching metric type for IS-IS routes

About This Task

Use this procedure to match the external metric-type by using a route-map for any of the following cases:

- accepting a remote IS-IS route with the help of IS-IS accept policies.
- redistributing IS-IS routes into other protocols.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must log on to the route-map configuration mode in the CLI.

Procedure

1. Enter Route-Map Configuration mode:

```
enable

configure terminal

route-map WORD<1-64> <1-65535>
```
2. Match IS-IS metric type:

```
match metric-type-isis {any|internal|external}
```
3. Permit the route policy action:

```
permit
```
4. Enable the route policy

```
enable
```

Example

Match metric type for IS-IS routes:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
```

Match metric type for IS-IS routes in accept policies:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# accept route-map rol
Switch:1(config-isis)# exit
Switch:1(config)# isis apply accept
```

Match metric type to redistribute IS-IS routes into some other protocol (OSPF,RIP,BGP)

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router bgp
Switch:1(router-bgp)# redistribute isis route-map rol
Switch:1(router-bgp)# exit
Switch:1(config)# ip bgp apply redistribute
```

Variable definitions

The following table defines parameters for the **match metric-type-isis** command.

Variable	Value
metric-type-isis {any internal external}	Specifies the IS-IS metric type. <ul style="list-style-type: none"> • internal – permits or denies routes that are internal to the IS-IS domain. • external – permits or denies routes that originate from an external routing protocol domain. • any – permits or denies both internal routes as well as external routes.

Setting metric type for IS-IS routes

About This Task

Use this procedure to set the IS-IS external metric-type by using a route-map for any of the following cases:

- accepting a remote IS-IS route with the help of IS-IS accept policies.
- redistributing routes from other protocols into IS-IS.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must log on to the route-map configuration mode in the CLI.

Procedure

1. Enter Route-Map Configuration mode:
enable

configure terminal

route-map *WORD*<1-64> <1-65535>
2. Set IS-IS metric type:
set metric-type-isis {any|internal|external}
3. Permit the route policy action:
permit
4. Enable the route policy
enable

Example

Set metric type for IS-IS routes:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# set metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
```

Set metric type for IS-IS routes in accept policies:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# set metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# accept route-map rol
Switch:1(config-isis)# exit
Switch:1(config)# isis apply accept
```

Set metric type to redistribute routes from other protocols into IS-IS:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# redistribute bgp route-map rol
Switch:1(config-isis)# exit
Switch:1(config)# isis apply redistribute
```

Variable definitions

The following table defines parameters for the **set metric-type-isis** command.

Variable	Value
metric-type-isis {any internal external}	Specifies the IS-IS metric type. <ul style="list-style-type: none"> • internal – permits or denies routes that are internal to the IS-IS domain. • external – permits or denies routes that originate from an external routing protocol domain. • any – permits or denies both internal routes as well as external routes.

Setting metric type for IS-IS routes using global redistribute command

About This Task

Use this procedure to set the IS-IS external metric-type using the global redistribute command for the following cases redistributing routes from other protocols into IS-IS.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must log on to the IS-IS router configuration mode in the CLI.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Set IS-IS metric type using global redistribute command:

```
redistribute direct metric-type {internal|external}
```
3. Enable the route policy

```
redistribute direct enable
```

Example

Set metric type for IS-IS routes using global redistribute command:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# router isis
Switch:1(config-isis)# redistribute direct metric-type internal
Switch:1(config-isis)# redistribute direct enable
```

Variable definitions

The following table defines parameters for the **redistribute direct metric-type** command.

Variable	Value
metric-type {internal external}	Specifies the IS-IS metric type. <ul style="list-style-type: none"> • internal – permits or denies routes that are internal to the IS-IS domain. • external – permits or denies routes that originate from an external routing protocol domain.

Multi-area SPB Configuration using CLI

Perform the procedures in this section to configure Multi-area SPB parameters like virtual node, router remote Intermediate-System-to-Intermediate-System (IS-IS), layer 2 unicast and multicast redistribution, and IPv4 and IPv6 route redistribution on the switch using the Command Line Interface (CLI).

Multi-area SPB Configuration Flow

Note

This procedure only applies to the VSP 7400 Series.

Perform the following procedures in sequence to configure the Multi-area SPB feature on the switch.

Procedure

1. [Configure Remote IS-IS Multi-area SPB Nickname for an SPBM Instance](#) on page 1099.
2. [Display the Remote IS-IS SPBM Nickname Configuration](#) on page 1126.
3. [Configure Remote IS-IS Manual Area](#) on page 1100.
4. [Configure Remote IS-IS System ID](#) on page 1101.
5. [Configure an IS-IS Area Name](#) on page 1101.
6. [Display IS-IS Remote Area Configuration](#) on page 1126.
7. [Display IS-IS Area Configuration](#) on page 1127.
8. [Configure IS-IS Multi-area SPB Virtual Node](#) on page 1102.
9. [Display IS-IS Area Virtual Node Configuration](#) on page 1127.
10. [Configure Remote IS-IS Hello Authentication on a Port](#) on page 1104.
11. [Configure Remote IS-IS Layer 1 Designated Router Priority on a Port](#) on page 1105.
12. [Configure Remote IS-IS Hello Interval on a Port](#) on page 1106.
13. [Configure Remote IS-IS Hello Multiplier on a Port](#) on page 1107.
14. [Configure Remote IS-IS SPBM Parameters on a Port](#) on page 1108.
15. [Enable Remote IS-IS on a Port](#) on page 1109.
16. [Enable Remote IS-IS Router Configuration Globally](#) on page 1110.
17. [Display IS-IS Remote Area Configuration](#) on page 1126.
18. [Configure Multi-area SPB Layer 2 I-SID List](#) on page 1111.
19. [Display IS-IS Multi-area SPB Layer 2 I-SID List Information](#) on page 1128.
20. [Configure Multi-area SPB Layer 2 I-SID Redistribution](#) on page 1111.
21. [Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution](#) on page 1113.
22. [Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution](#) on page 1114.

23. [Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution on a VRF Instance](#) on page 1116.
24. [Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution on a VRF Instance](#) on page 1117.
25. [Configure Multi-area SPB DvR Backbone Redistribution](#) on page 1119.
26. [Display IS-IS Multi-area SPB DvR Configuration](#) on page 1131.
27. [Configure Multi-area SPB Layer 2 Multicast Snooping Redistribution](#) on page 1120.
28. [Configure Multi-area SPB IPv4 Routed Multicast Redistribution](#) on page 1122.
29. [Configure IS-IS Multi-area SPB IPv4 Routed Multicast Redistribution on a VRF Instance](#) on page 1123.

Configure Remote IS-IS Multi-area SPB Nickname for an SPBM Instance

Note

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure remote IS-IS Multi-area SPB nickname for a specific SPBM instance on the switch.

Procedure

1. Enter IS-IS Router Remote Configuration mode:

```
enable  
  
configure terminal  
  
router isis remote
```
2. Configure IS-IS Multi-area SPB nickname:

```
spbm <1-100> nick-name <x.xx.xx>
```

Example

Configuring remote IS-IS Multi-area SPB nickname for SPBM instance:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#router isis remote  
Switch:1(config-remote)spbm 4 nick-name 1.11.16
```

What to Do Next

To verify the configuration, see [Display the Remote IS-IS SPBM Nickname Configuration](#) on page 1126.

Variable Definitions

The following table defines parameters for the **spbm** command.

Variable	Value
<1-100>	Specifies the SPBM instance on the remote IS-IS interface.
<i>nick-name</i> <x.xx.xx>	Specifies a nickname for the remote IS-IS SPBM Multi-area SPB instance. The value is 2.5 bytes in the format <x.xx.xx>.

Configure Remote IS-IS Manual Area

Note

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure the remote Intermediate System-to-Intermediate System (IS-IS) manual area.

Procedure

1. Enter IS-IS Router Remote Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis remote
```

2. Configure the manual-area:

```
manual-area xx.xxxx.xxxx...xxxx
```

Example

Configuring remote IS-IS manual area:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote
Switch:1(config-isis-remote)manual-area c1.1000.000.00
```

What to Do Next

To verify the configuration, see [Display IS-IS Remote Area Configuration](#) on page 1126 and [Display IS-IS Area Configuration](#) on page 1127.

Variable Definitions

The following table defines parameters for the **manual-area** command.

Variable	Value
<xx.xxxx.xxxx...xxx x>	Specifies the remote IS-IS manual-area in the range of 1 to 13 bytes.

Configure Remote IS-IS System ID**Note**

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure the remote Intermediate System-to-Intermediate System (IS-IS) system ID on the switch.

Procedure

1. Enter IS-IS Router Remote Configuration mode:

```
enable

configure terminal

router isis remote
```
2. Configure the remote IS-IS system ID:

```
system-id xxxx.xxxx.xxxx
```

Example

Configuring the remote IS-IS system ID:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote
Switch:1(config-isis-remote)#system-id 0017.c6ed.44df
```

What to Do Next

To verify the configuration, see [Display IS-IS Remote Area Configuration](#) on page 1126 and [Display IS-IS Area Configuration](#) on page 1127.

Variable Definitions

The following table defines parameters for the **system-id** command.

Variable	Value
xxxx.xxxx.xxxx	Specifies the remote IS-IS system ID for the switch.

Configure an IS-IS Area Name**Note**

This procedure only applies to the VSP 7400 Series.

Before You Begin

- You must disable IS-IS or remote IS-IS.

About This Task

Perform this procedure to configure the area name for home and remote areas.

Procedure

1. Enter either IS-IS Router Configuration or IS-IS Router Remote Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis OR router isis remote
```

2. Configure the area name:

```
area-name WORD<0-255>
```

3. Enable IS-IS or remote IS-IS:

```
router isis enable OR router isis remote enable
```

Example

Configure the home and remote area names:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router isis
Switch:1(config-isis)#area-name 30
Switch:1(config)#router isis remote
Switch:1(config-isis-remote)# area-name 50
```

Variable Definitions

The following table defines parameters for the **area-name** command.

Variable	Value
<i>WORD</i> <0-255>	Specifies the area name. The default value is area-manual-area, where manual-area represents the IS-IS or remote IS-IS manual-area value that you configure.

Configure IS-IS Multi-area SPB Virtual Node

Note

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure the IS-IS Multi-area SPB virtual node parameters like nick-name, system ID, and system name in the home or remote area.

Procedure

1. Enter either IS-IS Router Configuration or IS-IS Router Remote Configuration mode:

```
enable

configure terminal

router isis Or router isis remote
```

2. Configure the nick-name for the IS-IS Multi-area SPB virtual node:

```
area-vnode nick-name <x.xx.xx>
```

3. Configure the system name for the IS-IS Multi-area SPB virtual node:

```
area-vnode sys-name WORD<0-255>
```

4. Configure the system ID for the IS-IS Multi-area SPB virtual node:

```
area-vnode system-id xxxx.xxxx.xxxx
```

Example

Configuring the IS-IS Multi-area SPB virtual node in the home area:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#area-vnode nick-name 0.82.40
Switch:1(config-isis)#area-vnode sys-name SwitchC
Switch:1(config-isis)#area-vnode system-id 1222.3300.0000
```

Configuring the IS-IS Multi-area SPB virtual node in the remote area:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote
Switch:1(config-isis)#area-vnode nick-name 0.82.60
Switch:1(config-isis)#area-vnode sys-name SwitchA
Switch:1(config-isis)#area-vnode system-id 1222.3311.2222
```

What to Do Next

To verify the configuration, see [Display IS-IS Area Virtual Node Configuration](#) on page 1127.

Variable Definitions

The following table defines parameters for the **area-vnode** command.

Variable	Value
<i>nick-name</i> x.xx.xx	Specifies a nickname for the IS-IS SPBM Multi-area SPB instance. The value is 2.5 bytes in the format x.xx.xx.
<i>sys-name</i> WORD<0-255>	Specifies the name of the system.
<i>system-id</i> xxxx.xxxx.xxxx	Specifies the IS-IS Multi-area SPB virtual node system ID.

Configure Remote IS-IS Hello Authentication on a Port

**Note**

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure authentication type used for remote Intermediate-System-to-Intermediate-System (IS-IS) hello packets on the interface. The type can be one of the following: none, simple, hmac-md5, or hmac-sha-256.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the hello authentication type:

```
isis remote hello-auth type {none | simple | hmac-md5 | hmac-sha-256}  
[key WORD<1-16>] [key-id <1-255>]
```

Example

Configuring the simple authentication type for remote IS-IS hello packets on port 1/2:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface gigabitEthernet 1/2  
Switch:1(config-if)#isis remote hello-auth type simple key Test key-id 125
```

Variable Definitions

The following table defines parameters for the **isis remote hello-auth** command.

Variable	Value
<code>key WORD<1-16></code>	Specifies the authentication key (password) that the receiving router uses to verify the packet.
<code>key-id <1-255></code>	Specifies the optional key ID.
<code>type {none simple hmac-md5 hmac-sha-256}</code>	<p>Specifies the authentication type used for remote IS-IS hello packets on the interface. The type can be one of the following:</p> <ul style="list-style-type: none"> Simple - Simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet. You can also specify a key value. hmac-md5 - MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. You can also specify a key value and key-id. hmac-sha-256 - With SHA-256 authentication, the switch adds an HMAC-SHA256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet. You can also specify a key value and key-id. <p>The default type is none.</p>

Configure Remote IS-IS Layer 1 Designated Router Priority on a Port

Note

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure the Level 1 remote Intermediate-System-to-Intermediate-System (IS-IS) designated router priority to the specified value.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Level 1 remote IS-IS designated router priority:

```
isis remote ll-dr-priority <0-127>
```

Example

Configuring the remote IS-IS designated router priority for port 1/4:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#isis remote l1-dr-priority 1
```

Variable Definitions

The following table defines parameters for the **isis remote l1-dr-priority** command.

Variable	Value
<0-127>	Specifies the level 1 remote Intermediate-System-to-Intermediate-System (IS-IS) designated router priority value. The default value is 64.

Configure Remote IS-IS Hello Interval on a Port

Note

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure the remote hello interval to change how often hello packets are sent out from an interface level.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the remote hello interval:

```
isis remote l1-hello-interval <1-600>
```

Example

Configuring the remote hello interval on port 1/3:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/3
Switch:1(config-if)#isis remote l1-hello-interval 1
```

Variable Definitions

The following table defines parameters for the **isis remote l1-hello-interval** command.

Variable	Value
<1-600>	Configures the Level 1 remote hello interval. The default value is 9 seconds.

Configure Remote IS-IS Hello Multiplier on a Port

Note

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure the remote hello multiplier to specify how many hellos the switch must miss before it considers the adjacency with a neighboring switch down.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the level 1 hello multiplier:

```
isis remote l1-hello-multiplier <1-600>
```

Example

Configuring the remote hello multiplier on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#isis remote l1-hello-multiplier 1
```

Variable Definitions

The following table defines parameters for the **isis remote l1-hello-multiplier** command.

Variable	Value
<1-600>	Configures the Level 1 hello multiplier. The default value is 3 seconds.

Configure Remote IS-IS SPBM Parameters on a Port**Note**

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure the remote Intermediate-System-to-Intermediate-System (IS-IS) Shortest Path Bridging MAC (SPBM) parameters on a specific port.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the remote IS-IS SPBM interface type:

```
isis remote spbm <1-100> interface-type {broadcast | pt-pt}
```

3. Configure the cost of the remote SPBM instance:

```
isis remote spbm <1-100> ll-metric <1-16777215>
```

Example

Configuring the remote IS-IS SPBM interface type and layer 1 metric on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#isis remote spbm 2 interface-type broadcast
Switch:1(config-if)#isis remote spbm 2 ll-metric 2
```

Variable Definitions

The following table defines parameters for the **isis remote spbm** command.

Variable	Value
<1-100>	Specifies the SPBM instance.
<i>interface-type</i> { <i>broadcast</i> <i>pt-pt</i> }	Specifies the IS-IS SPBM interface type as broadcast or point-to-point (pt-pt).
<i>ll-metric</i> <1-16777215>	Specifies the SPBM instance layer 1 metric on the IS-IS interface located on a specific port.

Enable Remote IS-IS on a Port

Note

This procedure only applies to the VSP 7400 Series.

Before You Begin

- Configure manual-area in both home and remote area.
- Configure the Shortest Path Bridging MAC (SPBM) instance and backbone VLANs (B-VLAN) manually.
- Configure the nickname in both home and remote area manually.
- Disable Auto-sense on the port.
- Make sure that the physical node nickname, virtual node nickname and system ID are different.

About This Task

Perform this procedure to enable remote Intermediate-System-to-Intermediate-System (IS-IS) interface on the selected port(s).

Note

When the switch receives a Fabric Connect TLV through LLDP on a port that has remote IS-IS enabled on it, the port transitions to the Auto-sense NNI pending state. For more information, see [Auto-sense Port States](#) on page 17.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable remote IS-IS interface:

```
isis remote enable
```

Example

Enabling remote IS-IS interface on port 1/2:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface gigabitEthernet 1/2  
Switch:1(config-if)isis remote enable
```

Variable Definitions

The following table defines parameters for the **isis remote** command.

Variable	Value
<i>enable</i>	Enables a remote IS-IS interface on the selected ports.

Enable Remote IS-IS Router Configuration Globally

Note

This procedure only applies to the VSP 7400 Series.

Before You Begin

- Configure manual-area in both home and remote area.
- Configure the Shortest Path Bridging MAC (SPBM) instance and backbone VLANs (B-VLAN) manually.
- Configure the nickname in both home and remote area manually.

About This Task

Perform this procedure to enable remote IS-IS router configuration on the switch, globally.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable IS-IS router remote configuration:

```
router isis remote [enable]
```

Example

Enabling IS-IS router remote configuration globally:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote enable
```

What to Do Next

To verify the configuration, see [Display IS-IS Remote Area Configuration](#) on page 1126.

Variable Definitions

The following table defines parameters for the **router isis remote** command.

Variable	Value
<i>enable</i>	Enables router IS-IS remote configuration globally on the switch.

Configure Multi-area SPB Layer 2 I-SID List**Note**

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure the Multi-area SPB layer 2 I-SID list.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Configure the Multi-area SPB layer 2 I-SID list:

```
multi-area 12 isid-list WORD<1-32> WORD<1-1024>
```

Example

Configuring the Multi-area SPB layer 2 I-SID list that includes specific I-SID values:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area 12 isid-list testlist 1,3,5,100-200
```

What to Do Next

To verify the configuration, see [Display IS-IS Multi-area SPB Layer 2 I-SID List Information](#) on page 1128.

Variable Definitions

The following table defines parameters for the **multi-area 12 isid-list** command.

Variable	Value
<i>WORD<1-32></i>	Specifies the name of the I-SID list.
<i>WORD<1-1024></i>	Specifies the list of I-SID values.

Configure Multi-area SPB Layer 2 I-SID Redistribution**Note**

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure Multi-area SPB layer 2 I-SID redistribution.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Configure the Multi-area SPB layer2 I-SID redistribution:

```
multi-area l2 redistribute i-sid {deny-all | permit-all} [except-isid-
list WORD<1-32>]
```
3. Verify the Multi-area SPB layer2 I-SID redistribution configuration:

```
show isis multi-area l2 redistribute i-sid
```
4. Apply the layer 2 I-SID redistribution:

```
isis multi-area l2 apply redistribute i-sid
```

Example

Configuring Multi-area SPB layer 2 I-SID redistribution and exclude the I-SID values specified in the I-SID list:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area l2 redistribute i-sid permit-all except-isid-list
testlist
Switch:1(config-isis)#show isis multi-area l2 redistribute i-sid
=====
MULTI AREA L2 ISID REDIST POLICY
=====
Permit          Except List Name
-----
permit-all     testlist
-----
Switch:1(config-isis)#isis multi-area l2 apply redistribute i-sid
```

Variable Definitions

The following table defines parameters for the **multi-area l2 redistribute i-sid** command.

Variable	Value
<i>deny-all</i>	Denies the Multi-area SPB IPv6 unicast redistribution configuration for the specified I-SID list name.
<i>except-isid-list</i> <i>WORD<1-32></i>	Specifies the name of the I-SID list.
<i>permit-all</i>	Permits the Multi-area SPB IPv6 unicast redistribution configuration for the specified I-SID list name.

Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution**Note**

This procedure only applies to the VSP 7400 Series.

Before You Begin

Configure IP Shortcuts on the boundary nodes.

About This Task

Perform this procedure to configure Multi-area SPB IPv4 unicast redistribution on the switch.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```

2. Create the Multi-area SPB IPv4 unicast redistribution instance:

```
multi-area ip redistribute unicast [home-to-remote | remote-to-home]
```

**Note**

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
multi-area ip redistribute unicast [home-to-remote | remote-to-home]
route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv4 unicast redistribution instance:

```
multi-area ip redistribute unicast [home-to-remote | remote-to-home]
enable
```

5. Verify the Multi-area SPB IPv4 unicast redistribution configuration:

```
show isis multi-area ip redistribute unicast [home-to-remote | remote-
to-home]
```

6. Apply the Multi-area SPB IPv4 unicast redistribution:

```
isis multi-area ip apply redistribute unicast [home-to-remote |
remote-to-home]
```

Example

Configuring Multi-area SPB IPv4 unicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area ip redistribute unicast home-to-remote
Switch:1(config-isis)#multi-area ip redistribute unicast home-to-remote route-map test
Switch:1(config-isis)#multi-area ip redistribute unicast home-to-remote enable
```

```

Switch:1(config-isis)#show isis multi-area ip redistribute home-to-remote
=====
                ISIS Multiarea Redistribute List for ip unicast - GlobalRouter
=====
DIRECTION          ENABLE      RPOLICY
-----
home-to-remote     TRUE       test
-----
Switch:1(config-isis)#isis multi-area ip apply redistribute unicast home-to-remote

```

Variable Definitions

The following table defines parameters for the **multi-area ip redistribute unicast** and the **isis multi-area ip apply redistribute unicast** commands.

Variable	Value
<i>enable</i>	Enables Multi-area SPB IPv4 unicast redistribution.
<i>home-to-remote</i>	Specifies the IPv4 unicast redistribution configuration for home to remote direction.
<i>remote-to-home</i>	Specifies the IPv4 unicast redistribution configuration for remote to home direction.
<i>route-map</i> <i>WORD<1-64></i>	Specifies the name of the route policy.
<i>vrf WORD<1-16></i>	Specifies the unicast redistribution configuration for specific VRF instance.

Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution

Note

This procedure only applies to the VSP 7400 Series.

Before You Begin

Configure IP Shortcuts on the boundary nodes.

About This Task

Perform this procedure to configure Multi-area SPB IPv6 unicast redistribution on the switch.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

2. Create the Multi-area SPB IPv6 unicast redistribution:

```
multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home]
```

Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home]
route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv6 unicast redistribution instance:

```
multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home]
enable
```

5. Verify the Multi-area SPB IPv6 unicast redistribution configuration:

```
show isis multi-area ipv6 redistribute unicast [home-to-remote |
remote-to-home]
```

6. Apply the Multi-area SPB IPv6 unicast redistribution:

```
isis multi-area ipv6 apply redistribute unicast [home-to-remote |
remote-to-home]
```

Example

Configuring Multi-area SPB IPv6 unicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area ipv6 redistribute unicast home-to-remote
Switch:1(config-isis)#multi-area ipv6 redistribute unicast home-to-remote route-map test
Switch:1(config-isis)#multi-area ipv6 redistribute unicast home-to-remote enable
Switch:1(config-isis)#show isis multi-area ipv6 redistribute home-to-remote
=====
                ISIS Multiarea Redistribute List for ipv6 unicast - GlobalRouter
=====
DIRECTION          ENABLE          RPOLICY
-----
home-to-remote     TRUE           test
-----
Switch:1(config-isis)#isis multi-area ipv6 apply redistribute unicast home-to-remote
```

Variable Definitions

The following table defines parameters for the **multi-area ipv6 redistribute unicast** and the **isis multi-area ipv6 apply redistribute unicast** commands.

Variable	Value
<i>enable</i>	Enables Multi-area SPB IPv6 unicast redistribution on the switch.
<i>home-to-remote</i>	Specifies the IPv6 unicast redistribution configuration for home to remote direction.

Variable	Value
<code>remote-to-home</code>	Specifies the IPv6 unicast redistribution configuration for remote to home direction.
<code>route-map WORD<1-64></code>	Specifies the name of the route policy.
<code>vrf WORD<1-16></code>	Specifies the IPv6 unicast redistribution configuration for a specific VRF instance.

Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution on a VRF Instance

Note

This procedure only applies to the VSP 7400 Series.

Before You Begin

Configure IP Shortcuts and layer 3 VSN on the Virtual Router Forwarding (VRF) instance.

About This Task

Perform this procedure to configure IS-IS Multi-area SPB IPv4 unicast redistribution on a specific VRF instance on the switch.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Create the IS-IS Multi-area SPB IPv4 unicast redistribution instance on the VRF:

```
isis multi-area ip redistribute unicast [home-to-remote | remote-to-home]
```

Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
isis multi-area ip redistribute unicast [home-to-remote | remote-to-home] route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv4 unicast redistribution instance on the VRF:

```
isis multi-area ip redistribute unicast [home-to-remote | remote-to-home] enable
```

5. Verify the Multi-area SPB IPv4 unicast redistribution configuration on the VRF:

```
show isis multi-area ip redistribute unicast [home-to-remote | remote-to-home] vrf WORD<1-16>
```

6. Exit to Global Configuration mode:

```
exit
```

7. Apply the Multi-area SPB IPv4 unicast redistribution on the VRF:

```
isis multi-area ip apply redistribute unicast [home-to-remote |
[remote-to-home] vrf WORD<1-16>
```

Example

Configuring IS-IS Multi-area SPB IPv4 unicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf VRF1
Switch:1(router-vrf)#isis multi-area ip redistribute unicast home-to-remote
Switch:1(router-vrf)#isis multi-area ip redistribute unicast home-to-remote route-map test
Switch:1(router-vrf)#isis multi-area ip redistribute unicast home-to-remote enable
Switch:1(router-vrf)#show isis multi-area ip redistribute unicast home-to-remote vrf VRF1
=====
                ISIS Multiarea Redistribute List for ip unicast - VRF VRF1
=====
DIRECTION          ENABLE          RPOLICY
-----
home-to-remote     TRUE           test
-----
Switch:1(router-vrf)#exit
Switch:1(config)#isis multi-area ip apply redistribute unicast home-to-remote vrf VRF1
```

Variable Definitions

The following table defines parameters for the **isis multi-area ip redistribute unicast** and the **isis multi-area ip apply redistribute unicast** commands.

Variable	Value
<i>enable</i>	Enables IPv4 unicast redistribution on the VRF instance.
<i>home-to-remote</i>	Specifies the IPv4 unicast redistribution configuration for home to remote direction.
<i>remote-to-home</i>	Specifies the IPv4 unicast redistribution configuration for remote to home direction.
<i>route-map</i> <i>WORD<1-64></i>	Specifies the name of the route policy.
<i>vrf WORD<1-16></i>	Specifies the IPv4 unicast redistribution configuration for specific VRF instance.

Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution on a VRF Instance

Note

This procedure only applies to the VSP 7400 Series.

Before You Begin

Configure IP Shortcuts and layer 3 VSN on the Virtual Router Forwarding (VRF) instance.

About This Task

Perform this procedure to configure IS-IS Multi-area SPB IPv6 unicast redistribution on a specific Virtual Router Forwarding (VRF) instance on the switch.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Create the IS-IS Multi-area SPB IPv6 unicast redistribution instance on the VRF:

```
isis multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home]
```

Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
isis multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home] route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv6 unicast redistribution instance on the VRF:

```
isis multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home] enable
```

5. Verify the Multi-area SPB IPv6 unicast redistribution configuration on the VRF:

```
show isis multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home] vrf WORD<1-16>
```

6. Exit to Global Configuration mode:

```
exit
```

7. Apply the Multi-area SPB IPv6 unicast redistribution on the VRF:

```
isis multi-area ipv6 apply redistribute unicast [home-to-remote | remote-to-home] vrf WORD<1-16>
```

Example

Configuring IS-IS Multi-area SPB IPv6 unicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf VRF1
Switch:1(router-vrf)#isis multi-area ipv6 redistribute unicast home-to-remote
Switch:1(router-vrf)#isis multi-area ipv6 redistribute unicast home-to-remote route-map test
Switch:1(router-vrf)#isis multi-area ipv6 redistribute unicast home-to-remote enable
Switch:1(router-vrf)#show isis multi-area ipv6 redistribute unicast home-to-remote vrf VRF1
=====
```

```

=====
ISIS Multiarea Redistribute List for ipv6 unicast - VRF VRF1
=====
DIRECTION          ENABLE      RPOLICY
-----
home-to-remote     TRUE       test
-----
Switch:1(router-vrf)#exit
Switch:1(config)#isis multi-area ipv6 apply redistribute unicast home-to-remote vrf VRF1

```

Variable Definitions

The following table defines parameters for the **isis multi-area ipv6 redistribute unicast** and the **isis multi-area ipv6 apply redistribute unicast** commands.

Variable	Value
<i>enable</i>	Enables IPv6 unicast redistribution on the VRF instance.
<i>home-to-remote</i>	Specifies the IPv6 unicast redistribution configuration for home to remote direction.
<i>remote-to-home</i>	Specifies the IPv6 unicast redistribution configuration for remote to home direction.
<i>route-map</i> <i>WORD<1-64></i>	Specifies the name of the route policy.
<i>vrf WORD<1-16></i>	Specifies the IPv6 unicast redistribution configuration for a specific VRF instance.

Configure Multi-area SPB DvR Backbone Redistribution

Note

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure Multi-area SPB Distributed Virtual Routing (DvR) backbone redistribution on the switch.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable
configure terminal
router isis
```
2. Configure IS-IS Multi-area SPB DvR backbone redistribution:

```
multi-area dvr redistribute backbone
```

Example

Configuring Multi-area SPB DvR backbone redistribution:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#router isis
Switch:1(config-isis)multi-area dvr redistribute backbone
```

What to Do Next

To verify the configuration, see [Display IS-IS Multi-area SPB DvR Configuration](#) on page 1131.

Configure Multi-area SPB Layer 2 Multicast Snooping Redistribution

Note

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure Multi-area SPB layer 2 multicast snooping redistribution for specific I-SID values or a specific I-SID list.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Create the Multi-area SPB layer 2 snooping multicast redistribution for a specific I-SID or I-SID list:

```
multi-area l2 redistribute snoop-multicast {home-to-remote | remote-to-home} {i-sid <1-16777215> | isid-list WORD<1-32>}
```
3. (Optional) Configure a route policy to govern the redistribution:

```
multi-area l2 redistribute snoop-multicast {home-to-remote | remote-to-home} {i-sid <1-16777215> | isid-list WORD<1-32>} route-map WORD<1-64>
```
4. Enable the Multi-area SPB layer 2 snooping multicast redistribution instance:

```
multi-area l2 redistribute snoop-multicast {home-to-remote | remote-to-home} {i-sid <1-16777215> | isid-list WORD<1-32>} enable
```
5. Verify the Multi-area SPB layer 2 snooping multicast redistribution configuration:

```
show isis multi-area l2 redistribute snoop-multicast
```
6. Apply the Multi-area SPB layer 2 snooping multicast redistribution:

```
isis multi-area l2 apply redistribute snoop-multicast [home-to-remote | remote-to-home]
```

Example

Configuring Multi-area SPB layer 2 home to remote multicast snooping redistribution:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
```

Configuring Multi-area SPB layer 2 home to remote multicast snooping redistribution for I-SID 1100:

```
Switch:1(config-isis)#multi-area 12 redistribute snoop-multicast home-to-remote i-sid 1100
Switch:1(config-isis)#multi-area 12 redistribute snoop-multicast home-to-remote i-sid
1100
route-map test
Switch:1(config-isis)#multi-area 12 redistribute snoop-multicast home-to-remote i-sid
1100
enable
```

Configuring Multi-area SPB layer 2 home to remote multicast snooping redistribution for I-SID list List1:

```
Switch:1(config-isis)#multi-area 12 redistribute snoop-multicast home-to-remote isid-list
List1
Switch:1(config-isis)#multi-area 12 redistribute snoop-multicast home-to-remote isid-list
List1 route-map test
Switch:1(config-isis)#multi-area 12 redistribute snoop-multicast home-to-remote isid-list
List1 enable
```

Verifying the Multi-area SPB layer 2 home to remote multicast snooping redistribution configuration:

```
Switch:1(config-isis)#show isis multi-area 12 redistribute snoop-multicast
=====
MULTI-AREA L2 SNOOP MULTICAST REDISTRIBUTE BY ISID
=====

Applying the Multi-area SPB layer 2 home to remote multicast snooping redistribution:

```
Switch:1(config-isis)#isis multi-area 12 apply redistribute snoop-multicast home-to-remote
```

Variable Definitions

The following table defines parameters for the **multi-area 12 redistribute snoop-multicast** and the **isis multi-area 12 apply redistribute snoop-multicast** commands.

Variable	Value
<i>enable</i>	Enables Multi-area SPB layer 2 multicast snooping redistribution.
<i>i-sid</i> <1-16777215>	Specifies the I-SID value.
<i>isid-list</i> <i>WORD</i> <1-32>	Specifies the name of the I-SID list.
<i>home-to-remote</i>	Specifies the layer 2 multicast snooping redistribution configuration for home to remote direction.

Variable	Value
<code>remote-to-home</code>	Specifies the layer 2 multicast snooping redistribution configuration for remote to home direction.
<code>route-map</code> <code>WORD<1-64></code>	Specifies the name of the route policy.

Configure Multi-area SPB IPv4 Routed Multicast Redistribution

Note

This procedure only applies to the VSP 7400 Series.

Before You Begin

- Enable multicast on the boundary nodes.
- Configure Multiprotocol Label Switching Virtual Private Network (MVPN) on the boundary nodes, for layer 3 VSN.
- Configure the same policies as the boundary node on the peer boundary nodes.

About This Task

Perform this procedure to configure Multi-area SPB IPv4 routed multicast redistribution on the switch.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```

2. Create the Multi-area SPB IPv4 routed multicast redistribution instance:

```
multi-area ip redistribute routed-multicast [home-to-remote | remote-to-home]
```

Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
multi-area ip redistribute routed-multicast [home-to-remote | remote-to-home] route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv4 routed multicast redistribution instance:

```
multi-area ip redistribute routed-multicast [home-to-remote | remote-to-home] enable
```

5. Verify the Multi-area SPB IPv4 routed multicast redistribution configuration:

```
show isis multi-area ip redistribute routed-multicast [home-to-remote | remote-to-home]
```

6. Apply the Multi-area SPB IPv4 routed multicast redistribution:

```
isis multi-area ip apply redistribute routed-multicast [home-to-remote
| remote-to-home]
```

Example

Configuring Multi-area SPB IPv4 routed multicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area ip redistribute routed-multicast home-to-remote
Switch:1(config-isis)#multi-area ip redistribute routed-multicast home-to-remote route-
map test
Switch:1(config-isis)#multi-area ip redistribute routed-multicast home-to-remote enable
Switch:1(config-isis)#show isis multi-area ip redistribute routed-multicast home-to-remote
=====
      ISIS Multiarea Redistribute List for routed multicast - GlobalRouter
=====
DIRECTION          ENABLE          RPOLICY
-----
home-to-remote     TRUE           test
-----
Switch:1(config-isis)#isis multi-area ip apply redistribute routed-multicast home-to-
remote
```

Variable Definitions

The following table defines parameters for the **multi-area ip redistribute routed-multicast** and the **isis multi-area ip apply redistribute routed-multicast** command.

Variable	Value
<i>enable</i>	Enables Multi-area SPB IPv4 routed multicast redistribution.
<i>home-to-remote</i>	Specifies the IPv4 routed multicast redistribution configuration for home to remote direction.
<i>remote-to-home</i>	Specifies the IPv4 routed multicast redistribution configuration for remote to home direction.
<i>route-map</i> <i>WORD<1-64></i>	Specifies the name of the route policy.
<i>vrf WORD<1-16></i>	Specifies the multicast routing redistribution configuration for specific VRF instance.

Configure IS-IS Multi-area SPB IPv4 Routed Multicast Redistribution on a VRF Instance

Note

This procedure only applies to the VSP 7400 Series.

Before You Begin

- Enable multicast on the boundary nodes.
- Configure Multiprotocol Label Switching Virtual Private Network (MVPN) on the boundary nodes, for layer 3 VSN.

- Configure the same policies as the boundary node on the peer boundary nodes.

About This Task

Perform this procedure to configure IS-IS Multi-area SPB IPv4 routed multicast redistribution on a specific Virtual Router Forwarding (VRF) instance on the switch.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Create the IS-IS Multi-area SPB IPv4 routed multicast redistribution instance on the VRF:

```
isis multi-area ip redistribute routed-multicast [home-to-remote |
remote-to-home]
```

Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
isis multi-area ip redistribute routed-multicast [home-to-remote |
remote-to-home] route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv4 routed multicast redistribution instance on the VRF:

```
isis multi-area ip redistribute routed-multicast [home-to-remote |
remote-to-home] enable
```

5. Verify the Multi-area SPB IPv4 routed multicast redistribution configuration on the VRF:

```
show isis multi-area ip redistribute routed-multicast [home-to-remote
| remote-to-home] [vrf WORD<1-16> | vrfids WORD<0-512>]
```

6. Exit to Global Configuration mode:

```
exit
```

7. Apply the Multi-area SPB IPv4 routed multicast redistribution on the VRF:

```
isis multi-area ip apply redistribute routed-multicast [home-to-remote
| [remote-to-home] vrf WORD<1-16>
```

Example

Configuring IS-IS Multi-area SPB IPv4 routed multicast redistribution for home to remote direction on VRF VRF1:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf VRF1
Switch:1(router-vrf)#isis multi-area ip redistribute routed-multicast home-to-remote
Switch:1(router-vrf)#isis multi-area ip redistribute routed-multicast home-to-remote
route-map test
Switch:1(router-vrf)#isis multi-area ip redistribute routed-multicast home-to-remote
enable
```

```

Switch:1(router-vrf)#show isis multi-area ip redistribute routed-multicast home-to-remote
vrf VRF1
=====
                ISIS Multiarea Redistribute List for routed multicast - VRF VRF1
=====
DIRECTION          ENABLE          RPOLICY
-----
home-to-remote     TRUE           test
-----
Switch:1(router-vrf)#exit
Switch:1(config)#isis multi-area ip apply redistribute routed-multicast home-to-remote
vrf VRF1

```

Variable Definitions

The following table defines parameters for the **isis multi-area ip redistribute routed-multicast** and the **isis multi-area ip apply redistribute routed-multicast** commands.

Variable	Value
<i>enable</i>	Enables IPv4 routed multicast redistribution on the VRF instance.
<i>home-to-remote</i>	Specifies the IPv4 routed multicast redistribution configuration for home to remote direction.
<i>remote-to-home</i>	Specifies the IPv4 routed multicast redistribution configuration for remote to home direction.
<i>route-map</i> <i>WORD<1-64></i>	Specifies the name of the route policy.
<i>vrf</i> <i>WORD<1-16></i>	Specifies the multicast routing redistribution configuration for specific VRF instance.

Configure Multi-area Flags Functionality

Note

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to configure the Multi-area SPB node as a boundary node to forward traffic from the UNIs to the remote-area and from the remote-area to the UNIs without requiring an established adjacency in the home area.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Configure the multi-area flags functionality:

```
multi-area flags home-always-up
```

Multi-area SPB Verification using CLI

Perform the procedures in this section to verify the Multi-area SPB configuration on the switch using the Command Line Interface (CLI).

Display the Remote IS-IS SPBM Nickname Configuration

Note

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to display the remote Intermediate-System-to-Intermediate-System (IS-IS) Shortest Path Bridging MAC (SPBM) nickname configuration on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the remote IS-IS SPBM nickname configuration:

```
show isis spbm nick-name remote
```

Example

Displaying the remote IS-IS SPBM nickname configuration:

```
Switch:1>show isis spbm nick-name remote

```

Display IS-IS Multi-area SPB Layer 2 I-SID List Information

**Note**

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to display the IS-IS Multi-area SPB layer 2 I-SID list information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the I-SID list information on the switch:

```
show isis multi-area l2 isid-list WORD<1-32>
```

Example

Displaying the IS-IS Multi-area SPB layer 2 I-SID list information:

```
Switch:1>show isis multi-area l2 isid-list test
=====
MULTI AREA L2 ISID LIST
=====
List Name          I-SID / I-SID RANGE
-----
test               50510-50513

All 1 out of 1 Total Num of Isid Lists displayed
```

Display IS-IS Multi-area SPB I-SID Redistribution Configuration

**Note**

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to display the IS-IS Multi-area SPB layer 2 I-SID redistribution configuration on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS Multi-area SPB layer 2 I-SID redistribution configuration:

```
show isis multi-area l2 redistribute i-sid
```

Example

Displaying the IS-IS Multi-area SPB layer 2 I-SID redistribution configuration:

```
Switch:1>show isis multi-area l2 redistribute i-sid
=====
MULTI AREA L2 ISID REDIST POLICY
=====
Permit          Except List Name
-----
permit-all     TestList1
```

Display IS-IS Multi-area SPB IPv4 Redistribution Configuration**Note**

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to display the IS-IS Multi-area SPB IPv4 redistribution configuration for home to remote, remote to home, unicast, routed multicast, specific Virtual Router Forwarding (VRF) instance, and VRF IDs on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS Multi-area SPB IPv4 home to remote redistribution configuration:

```
show isis multi-area ip redistribute [home-to-remote [vrf WORD<1-16> | vrfids WORD<0-512>]]
```
3. Display the IS-IS Multi-area SPB IPv4 remote to home redistribution configuration:

```
show isis multi-area ip redistribute [remote-to-home [vrf WORD<1-16> | vrfids WORD<0-512>]]
```
4. Display the IS-IS Multi-area SPB IPv4 routed multicast redistribution configuration:

```
show isis multi-area ip redistribute routed-multicast [home-to-remote [vrf WORD<1-16> | vrfids WORD<0-512>] | remote-to-home [vrf WORD<1-16> | vrfids WORD<0-512>] | vrf WORD<1-16> | vrfids WORD<0-512>]]
```
5. Display the IS-IS Multi-area SPB IPv4 unicast redistribution configuration:

```
show isis multi-area ip redistribute unicast [home-to-remote [vrf WORD<1-16> | vrfids WORD<0-512>] | remote-to-home [vrf WORD<1-16> | vrfids WORD<0-512>] | vrf WORD<1-16> | vrfids WORD<0-512>]]
```
6. Display the IS-IS Multi-area SPB IPv4 redistribution configuration for VRF instance:

```
show isis multi-area ip redistribute vrf WORD<1-16>
```
7. Display the IS-IS Multi-area SPB IPv4 redistribution configuration for VRF ID:

```
show isis multi-area ip redistribute vrfids WORD<0-512>
```

Example

Displaying the IS-IS Multi-area SPB IPv4 unicast redistribution configuration on the switch:

```
Switch:1>show isis multi-area ip redistribute unicast
=====
                ISIS Multiarea Redistribute List for ip unicast - GlobalRouter
=====
DIRECTION                ENABLE      RPOLICY
-----
home-to-remote           TRUE
remote-to-home           TRUE
```

Display IS-IS Multi-area SPB IPv6 Redistribution Configuration

Note

This procedure only applies to the VSP 7400 Series.

About This Task

Perform this procedure to display the IS-IS Multi-area SPB IPv6 redistribution configuration for home to remote, remote to home, unicast, specific Virtual Router Forwarding (VRF) instance, and VRF IDs on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS Multi-area SPB IPv6 home to remote redistribution configuration:

```
show isis multi-area ipv6 redistribute [home-to-remote [vrf WORD<1-16>
| vrfids WORD<0-512>]]
```
3. Display the IS-IS Multi-area SPB IPv6 remote to home redistribution configuration:

```
show isis multi-area ipv6 redistribute [remote-to-home [vrf WORD<1-16>
| vrfids WORD<0-512>]]
```
4. Display the IS-IS Multi-area SPB IPv6 unicast redistribution configuration:

```
show isis multi-area ipv6 redistribute unicast [home-to-remote [vrf
WORD<1-16> | vrfids WORD<0-512>] | remote-to-home [vrf WORD<1-16> |
vrfids WORD<0-512>] | vrf WORD<1-16> | vrfids WORD<0-512>]]
```
5. Display the IS-IS Multi-area SPB IPv6 redistribution configuration for VRF instance:

```
show isis multi-area ipv6 redistribute [vrf WORD<1-16>]
```
6. Display the IS-IS Multi-area SPB IPv6 redistribution configuration for VRF ID:

```
show isis multi-area ipv6 redistribute [vrfids WORD<0-512>]
```

Example

Displaying the IS-IS Multi-area SPB IPv6 unicast redistribution configuration:

```
Switch:1>show isis multi-area ipv6 redistribute unicast
=====
                ISIS Multiarea Redistribute List for ipv6 unicast - GlobalRouter
=====
DIRECTION                ENABLE      RPOLICY
-----
```

SPBM and IS-IS infrastructure configuration using EDM

This section provides procedures to configure basic SPBM and IS-IS infrastructure using Enterprise Device Manager (EDM).

Important

The **EnableSpbmConfigMode** boot flag must be enabled (default) before you can configure SPBM or IS-IS. To verify the setting, navigate to **Configuration > Edit > Chassis** and click on the **Boot Config** tab.

Configure Required SPBM and IS-IS Parameters

About This Task

Use the following procedure to configure the minimum required SPBM and IS-IS parameters to enable SPBM to operate on the switch. SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

Procedure

1. Configure SBPM B-VLANs:

Note

Always configure two B-VLANs in the core to enable load distribution over both B-VLANs.

- a. In the navigation pane, expand **Configuration > VLAN**.
 - b. Select **VLANs**.
 - c. Select the **Basic** tab.
 - d. Select **Insert**.
 - e. In the **type** field, select **spb-bvlan**.
 - f. Select **Insert**.
2. Enable SPBM globally:
 - a. In the navigation pane, expand **Configuration > Fabric**.
 - b. Select **SPBM**.
 - c. Select the **Globals** tab.

- d. In the **GlobalEnable** field, select **enable** to enable SPBM globally.
 - e. Select **Apply**.
3. Create an SPBM instance:

**Note**

Only one SBPM instance is supported.

- a. In the navigation pane, expand **Configuration > Fabric**.
 - b. Select **SPBM**.
 - c. Select the **SPBM** tab.
 - d. Select **Insert** to create an SPBM instance.
 - e. In the **Id** field, specify the SPBM instance ID.
 - f. In the **NodeNickName** field, specify the node nickname (valid value is 2.5 bytes in the format <x.xx.xx>).
 - g. In the **Vlans** field, specify the IDs of the SPBM B-VLANs to add to the SPBM instance.
 - h. In the **PrimaryVlan** field, specify which of the SPBM B-VLANs specified in the previous step is the primary B-VLAN.
 - i. Select **Insert**.
4. Create a manual area:

**Note**

Only one manual area is supported.

- a. In the navigation pane, expand **Configuration > Fabric**.
 - b. Select **IS-IS**.
 - c. Select the **Manual Area** tab.
 - d. Select **Insert**.
 - e. Specify the Manual Area address (a valid value is 1-13 bytes in the format <xx.xxxx.xxxx...xxxx>).
 - f. Select **Insert**.
5. Update the default IS-IS system ID to a recognizable address:
- a. In the navigation pane, expand **Configuration > Fabric**.
 - b. Select **IS-IS**.
 - c. Select the **Globals** tab.
 - d. In the **SystemId** field, update the default B-MAC value to a recognizable address.

**Note**

Although it is not strictly required for SPBM operation, you must change the IS-IS system ID from the default B-MAC value to a recognizable address to easily identify a switch. This helps to recognize the source and destination addresses for troubleshooting purposes.

- e. In the **AdminState** field, select **on**.
- f. Select **Apply**.

6. Create an IS-IS circuit and enable SPBM on the circuit:
 - a. In the navigation pane, expand **Configuration > Fabric**.
 - b. Select **IS-IS**.
 - c. Select the **Interfaces** tab.
 - d. Select **Insert** to create an IS-IS circuit.
 - e. In the **IfIndex** field, specify the port or MLT on which to create the IS-IS circuit.
 - f. Select **Insert**.
 - g. Select the newly created IS-IS circuit entry, and select **SPBM**.
 - h. In the **Interfaces SPBM** tab, select **Insert**.
 - i. In the **State** field, select **enable**.
 - j. Select **Insert**. This enables the SPBM instance on the IS-IS circuit.
 - k. Navigate back to the **Interfaces** tab.
 - l. In the **AdminState** field for the IS-IS circuit entry, select **on** to enable the IS-IS circuit.
 - m. Select **Apply**.

SPBM Field Descriptions

Note

The following tables list the minimum required SPBM and IS-IS parameters to allow SPBM to operate on the switch. For more detailed information on all of the parameters see the procedures that follow. For more information on how to configure VLANs, see [VLAN Configuration using EDM](#) on page 3802.

Use the data in the following table to use the **VLANs Basic** tab.

Name	Description
Type	Specifies the type of VLAN: <ul style="list-style-type: none"> • byPort • byProtocolId • spbm-bvlan • private

Use the data in the following table to use the **SPBM Globals** tab.

Name	Description
GlobalEnable	Enables or disables SPBM globally. The default is disabled. To ensure proper cleanup of MAC tables after you disable SPBM, save the configuration, and then reboot the switch.
GlobalEtherType	Specifies the global ethertype value as 0x8100 or 0x88a8. The default value is 0x8100.

Name	Description
NicknameServerEnable Note: Exception: not supported on VSP 8600 Series or XA1400 Series.	Enables or disables the nickname server. The default is disabled.
NicknameDynamicAllocationStatus Note: Exception: not supported on VSP 8600 Series or XA1400 Series.	Displays the Dynamic Nickname Allocation service operational status.
NicknameServerPrefix Note: Exception: not supported on VSP 8600 Series or XA1400 Series.	Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default is A.00.00.

Use the data in the following table to use the **SPBM** tab.

Name	Description
Id	Specifies the SPBM instance ID. Only one SPBM instance is supported.
NodeNickName	Specifies a nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.
PrimaryVlan	Specifies the primary SPBM B-VLANs to add to the SPBM instance.
Vlans	Specifies the SPBM B-VLANs to add to the SPBM instance.
LsdbTrap	Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disable.
IpShortcut	Enables or disables SPBM IP shortcut state. The default is disable.
SmltSplitBEB	Specifies whether the switch is the primary or secondary vIST peer. The default is primary.
SmltVirtualBmac	Specifies a virtual MAC address that can be used by both peers.
SmltPeerSysId	Specifies the system ID of the SPBM SMLT for this SPBM instance.
Mcast	Specifies if IP multicast over SPBM is enabled. The default is disabled.
McastFwdCacheTimeout	Specifies the global forward cache timeout in seconds. The default is 210 seconds.

Name	Description
Ipv6Shortcut	Enables or disables SPBM IPv6 shortcut state. The default is disable.
McastSpbPimGwControllerEnable	Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default.
McastSpbPimGwGatewayEnable	Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default.
StpMultiHoming	Enables or disables MSTP-Fabric Connect Multi Homing. The default is disabled (false).
BVlanOrigin Note: Exception: not supported on XA1400 Series and VSP 8600 Series.	Shows how the B-VLAN was created. The values can be config for manual configuration using CLI or SNMP, or dynamic through Zero Touch Fabric Configuration and Auto-sense. The default is dynamic.

Use the data in the following table to use the **IS-IS Manual Area** tab.

Name	Description
AreaAddr	Specifies the IS-IS manual area. Valid value is 1-13 bytes in the format <xx.xxxx.xxxx...xxxx>. Only one manual area is supported. Use the same manual area across the entire SPBM cloud. For IS-IS to operate, you must configure at least one manual area.

Use the data in the following table to use the **IS-IS Globals** tab.

Name	Description
AdminState	Specifies the global status of IS-IS on the switch: on or off. The default is off.
SystemId	Specifies the IS-IS system ID for the switch. Valid value is a 6-byte value in the format <xxxx.xxxx.xxxx>. Important: After you have configured the SPBM nickname and enabled IS-IS, if you require a change of the system ID, you must also change the nickname. However, for naming convention purposes or configuration purposes, you may not want to change the nickname. To maintain the same nickname with a different system ID, see Job aid on page 1008.

Use the data in the following table to use the **IS-IS Interfaces** tab.

Name	Description
Index	The identifier of this circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value.
AdminState	Specifies the administrative state of the circuit: on or off.

Use the data in the following table to use the **IS-IS Interfaces SPBM** tab.

Name	Description
State	Specifies whether the SPBM interface is enabled or disabled.

Job aid

Important

After you have configured the SPBM nickname and enabled IS-IS. To maintain the same nickname with a different system ID, perform the following steps:

1. Disable IS-IS.
2. Change the system ID.
3. Change the nickname to a temporary one.
4. Enable IS-IS.
5. Wait up to 20 minutes for the LSPs with the original system ID to age out.

Note

To check the age out time, use the **show isis lsdb sysid <original-sys-id>** command on any of the other SPB nodes in the network. When there is no output from this command, proceed to the next step. The time left (in seconds) for the LSPs to age out is shown under the column **LIFETIME**.

6. Disable IS-IS.
7. Change the nickname to the original nickname.
8. Enable IS-IS.

Displaying SPBM and IS-IS summary information

Use the following procedure to view a summary of SPBM and IS-IS protocol information.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **IS-IS**.
3. Select the **Protocol Summary** tab.

Protocol Summary field descriptions

Use the data in the following table to use the **Protocol Summary** tab.

Name	Description
Globals ISIS	
AdminState	Indicates the global status of IS-IS on the switch.
SystemId	Indicates the IS-IS system ID for the switch. Valid value is a 6-byte value in the format <xxxx.xxxx.xxxx>
HostName	Indicates a name for the system. This may be used as the host name for dynamic host name exchange in accordance with RFC 2763. By default, the system name comes from the host name configured at the system level.
Globals SPBM	
GlobalEnable	Indicates whether SPBM is enabled or disabled at the global level.
NodeNickName	Indicates the nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.
PrimaryVlan	Indicates the primary VLAN ID for this SPBM instance.
SmltSplitBEB	Indicates whether the switch is the primary or secondary IST peer.
ISIS Interfaces	
Circuit Index	Displays the identifier of this IS-IS circuit, unique within the Intermediate System. This is for SNMP Indexing purposes only and need not have any relation to any protocol value.
IfIndex	Indicates the interface to which this circuit corresponds.
AdminState	Indicates the administrative state of the circuit: on or off.
OperState	Indicates the operational state of the circuit: up or down.
ISIS Adjacency View	
Circuit Index	Displays the identifier of this IS-IS circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value.
AdjIndex	Displays a unique value identifying the IS adjacency from all other such adjacencies on this circuit. This value is automatically assigned by the system when the adjacency is created
AdjIfIndex	Indicates the interface to which this circuit corresponds.
AdjState	Indicates the state of the adjacency: <ul style="list-style-type: none"> • down • initializing • up • failed

Name	Description
AdjNeighSysID	Indicates the system ID of the neighboring Intermediate System.
AdjHostName	Indicates the host name listed in the LSP, or the system name if the host name is not configured.

View the SPBM I-SID Information

Use the following procedure to display the SPBM Service Instance Identifier (I-SID) information. The SPBM B-MAC header includes an I-SID with a length of 24 bits. This I-SID can be used to identify and transmit any virtualized traffic in an encapsulated SPBM frame.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **I-SID** tab.

I-SID field descriptions

Use the data in the following table to use the **I-SID** tab.

Name	Description
SysId	Indicates the system identifier.
Vlan	Indicates the B-VLAN where this I-SID was configured or discovered.
Isid	Indicates the IS-IS SPBM I-SID identifier.
NickName	Indicates the nickname of the node where this I-SID was configured or discovered.
HostName	Indicates the host name listed in the LSP, or the system name if the host name is not configured.
Type	Indicates the SPBM I-SID type; either configured or discovered.

View Level 1 Area Information

Use the following procedure to display Level 1 area information. IS-IS provides support for hierarchical routing, which enables you to partition large routing domains into smaller areas. IS-IS uses a two-level hierarchy, dividing the domain into multiple Level 1 areas and one Level 2 area. The Level 2 area serves as backbone of the domain, connecting to all the Level 1 areas.

Important

The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **IS-IS**.

3. Select the **L1 Area** tab.

L1 Area field descriptions

Use the data in the following table to use the **L1 Area** tab.

Table 106:

Name	Description
AreaAddr	Specifies an area address reported in a Level 1 link-state packets (LSP) generated or received by this Intermediate System.

Configure SMLT Parameters for SPBM

Use the following procedure to configure the required Split MultiLink Trunking (SMLT) parameters to enable SPBM to interoperate with SMLT on the switch.

Note

- The assignment of primary and secondary roles to the vIST peers is automatic. The switch with the lower system ID (between the two vIST peers) is primary, and the switch with the higher system ID is secondary when default system-id values are being used.
- SMLT peer system ID is part of the required configuration. You must configure the SMLT peer system ID as the nodal MAC of the peer device. In the IS-IS network, the nodal MAC of devices should be eight apart from each other.
- When using the default hardware assigned system-id value, the SMLT Virtual BMAC is automatically derived by comparing the system-id values of the two vIST peers. A value of 0x01 plus the lower of the two system-id values is used as the SMLT Virtual BMAC.

When using a manually configured system-id value, the SMLT Virtual BMAC must also be manually configured.

- An I-SID must be assigned to every VLAN that is a member of an Layer 2 VSN. Also if an Layer 2 VSN is created on one vIST Peer, it must also be created on the other vIST peer.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **SPBM** tab.
4. Use the **SmltSplitBEB** field to see whether the switch is the primary or secondary vIST peer. This field cannot be modified.
5. Use the **SmltVirtualBmac** field to specify a virtual MAC address that can be used by both peers.
6. Use the **SmltPeerSysId** field to specify the vIST peer B-MAC address.
7. Select **Apply**.

Enable or Disable SPBM at the Global Level

Use the following procedure to enable or disable SPBM at the global level. SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet

topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **Globals** tab.
4. To enable or disable SPBM, select **enable** or **disable** in the **GlobalEnable** field.
5. To configure the global ethertype value, select the desired option in the **GlobalEtherType** field.
6. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
GlobalEnable	Enables or disables SPBM globally. The default is disabled. To ensure proper cleanup of MAC tables after you disable SPBM, save the configuration, and then reboot the switch.
GlobalEtherType	Specifies the global ethertype value as 0x8100 or 0x88a8. The default value is 0x8100.
NicknameServerEnable Note: Exception: not supported on VSP 8600 Series or XA1400 Series.	Enables or disables the nickname server. The default is disabled.
NicknameDynamicAllocationStatus Note: Exception: not supported on VSP 8600 Series or XA1400 Series.	Displays the Dynamic Nickname Allocation service operational status.
NicknameServerPrefix Note: Exception: not supported on VSP 8600 Series or XA1400 Series.	Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default is A.00.00.

Configuring SPBM parameters

Use the following procedure to configure SPBM global parameters. SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.

2. Select **SPBM**.
3. Select the **SPBM** tab.
4. To create an SPBM instance, click **Insert**.
5. Configure the SPBM parameters.
6. Select **Apply**.

SPBM Field Descriptions

Use the data in the following table to use the **SPBM** tab.

Name	Description
Id	Specifies the SPBM instance ID. Only one SPBM instance is supported.
NodeNickName	Specifies a nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.
PrimaryVlan	Specifies the primary SPBM B-VLANs to add to the SPBM instance.
Vlans	Specifies the SPBM B-VLANs to add to the SPBM instance.
LsdbTrap	Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disable.
IpShortcut	Enables or disables SPBM IP shortcut state. The default is disable.
SmltSplitBEB	Specifies whether the switch is the primary or secondary vIST peer. The default is primary.
SmltVirtualBmac	Specifies a virtual MAC address that can be used by both peers.
SmltPeerSysId	Specifies the system ID of the SPBM SMLT for this SPBM instance.
Mcast	Specifies if IP multicast over SPBM is enabled. The default is disabled.
McastFwdCacheTimeout	Specifies the global forward cache timeout in seconds. The default is 210 seconds.
Ipv6Shortcut	Enables or disables SPBM IPv6 shortcut state. The default is disable.
McastSpbPimGwControllerEnable	Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default.
McastSpbPimGwGatewayEnable	Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default.

Name	Description
StpMultiHoming	Enables or disables MSTP-Fabric Connect Multi Homing. The default is disabled (false).
BVlanOrigin Note: Exception: not supported on XA1400 Series and VSP 8600 Series.	Shows how the B-VLAN was created. The values can be config for manual configuration using CLI or SNMP, or dynamic through Zero Touch Fabric Configuration and Auto-sense. The default is dynamic.

Displaying SPBM nicknames

Use the following procedure to display SPBM nicknames.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **Nick Names** tab.

Nickname field descriptions

Use the data in the following table to use the **NickName** tab.

Name	Description
Level	Indicates the level at which the system displays this LSP.
ID	Indicates the 8 byte LSP ID, consisting of the SystemID, Circuit ID, and Fragment Number.
LifetimeRemain	Indicates the remaining lifetime in seconds for the LSP.
NickName	Indicates the nickname for the SPBM node.
HostName	Indicates the hostname listed in the LSP, or the system name if the host name is not configured.

Configure Interface SPBM Parameters

Use the following procedure to configure the SPBM interface parameters.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **Interfaces SPBM** tab.
4. Configure the SPBM interface parameters.
5. Select **Apply**.

Interfaces SPBM Field Descriptions

Use the data in the following table to use the **Interfaces SPBM** tab.

Name	Description
Index	Specifies an Index value for the SPBM interface.
SpbmId	Specifies the SPBM ID.
State	Specifies whether the SPBM interface is enabled or disabled.
