For more information, see [Configuring directed broadcast](#) on page 3015.

*ARP Request Threshold*

The Address Resolution Protocol (ARP) request threshold defines the maximum number of outstanding unresolved ARP requests. The default value for this function is 500 ARP requests. To avoid excessive amounts of subnet scanning that a virus can cause, as a best practice, change the ARP request threshold to a value between 100 and 50. This configuration protects the CPU from causing excessive ARP requests, protects the network, and lessens the spread of the virus to other PCs. The following list provides further ARP threshold values:

- Default: 500
- Severe conditions: 50
- Continuous scanning conditions: 100
- Moderate: 200
- Relaxed: 500

For more information about how to configure the ARP threshold, see [Address Resolution Protocol](#) on page 297.

*Multicast Learning Limitation*

The Multicast Learning Limitation feature protects the CPU from multicast data packet bursts generated by malicious applications. If more than a certain number of multicast streams enter the CPU through a port during a sampling interval, the port is shut down until the user or administrator takes the appropriate action.

For more information, see [IP Multicast](#) on page 1456.

## Authentication for Privileged EXEC Command Mode

**Table 222: Authentication for Privileged EXEC Mode product support**

| Feature                                             | Product         | Release introduced |
|-----------------------------------------------------|-----------------|--------------------|
| Authentication for Privileged EXEC CLI Command Mode | VSP 4450 Series | VOSS 8.2           |
|                                                     | VSP 4900 Series | VOSS 8.2           |
|                                                     | VSP 7200 Series | VOSS 8.2           |
|                                                     | VSP 7400 Series | VOSS 8.2           |
|                                                     | VSP 8200 Series | VOSS 8.2           |
|                                                     | VSP 8400 Series | VOSS 8.2           |
|                                                     | VSP 8600 Series | VSP 8600 8.0       |
|                                                     | XA1400 Series   | VOSS 8.2           |

For enhanced security, you can enable user authentication to enter Privileged EXEC command mode. Use the **sys priv-exec-password** command to enable password authentication.

After you enable password authentication for Privileged EXEC command mode, the system prompts you to enter a password to access Privileged EXEC command mode from User EXEC command mode. You must enter the same password that you used to log on to the switch.

### *Considerations*

- The same username and password used to Telnet or SSH to the switch is used to access Privileged EXEC command mode when authentication is enabled.
- RADIUS and TACACS+ protocols are supported. If RADIUS and TACACS+ servers are not reachable, access to Privileged EXEC command mode is denied. You must open a new session and type the same username and password used to Telnet or SSH to the switch.
- No timeout exists for the password used to log on to the Privileged EXEC command mode.
- No limit to the number of retries if you enter an incorrect password.
- VSP 8600 Series authentication for Privileged EXEC command mode only allows HA support in hot-standby mode.

## Configuration Considerations

Use the information in this section to understand the limitations of some security functions, such as BSAC RADIUS servers and Layer 2 protocols before you attempt to configure security.

### *Attribute Format for a Third-party RADIUS Server*

If you use a third-party RADIUS server and need to modify the dictionary files, you must add a vendor-specific attribute (attribute #26) and use 1584 as vendor code for all the devices and then send back access-priority vendor-assigned attribute number 192 with a decimal value of 1 to 6, depending upon whether you want read only to read-write-all.

### *Authentication for Privileged EXEC Command Mode*

Authentication for Privileged EXEC command mode supports RADIUS and TACACS+ protocols. If RADIUS and TACACS+ servers are not reachable, access to Privileged EXEC command mode is denied. You must open a new session and type the same username and password used to Telnet or SSH to the switch

### *RADIUS on Management Ports*

The management port supports the RADIUS protocol. When RADIUS packets are sent out of the management port, the SRC-IP address is properly entered in the RADIUS header.

For more information about the supported RADIUS servers, see the documentation of the RADIUS server.

### *RADIUS Server SNMP Accounting*

An SNMP query sent by an unreachable RADIUS server configured as used-by snmp and with accounting enabled, can cause a timeout. A timeout can occur if the device that receives the SNMP query attempts to send accounting packets to the unreachable server. You can mitigate the timeout issue by configuring lower retry and timeout values on the RADIUS server. Alternatively, you can configure a higher timeout value for SNMP.

### *Single Profile Enhancement for BSAC RADIUS Servers*

Before enabling Remote Access Dial-In User Services (RADIUS) accounting on the device, you must configure at least one RADIUS server.

The switch software supports Microsoft Radius Servers (NPS Windows 2008, Windows 2003 IAS Server), BaySecure Access Control (BSAC), Merit Network servers and Linux based servers. To use these servers, you must first obtain the software for the server. You must also make changes to one or more configuration files for these servers.

Single Profile is a feature that is specific to BSAC RADIUS servers. In a BSAC RADIUS server, when you create a client profile, you can specify all the returnable attributes. When you use the same profile for different products, you specify all the returnable attributes in the single profile.

#### *SNMP Cloned User Considerations*

If the user from which you are cloning has authentication, you can choose for the new user to either have the same authentication protocol as the user from which it was cloned, or no authentication. If you choose authentication for the new user, you must provide a password for that user. If you want a new user to have authentication, you must indicate that at the time you create the new user. You can assign a privacy protocol only to a user that has authentication.

If the user from which you are cloning has no authentication, then the new user has no authentication.

#### *Source IP Configuration*

#### **Note**

The following Source IP configuration considerations are only applicable on hardware platforms running VOSS Release 8.2 and later.

The Source IP is the Internet Protocol address of the device sending the IP data packet. For devices running VOSS Release 8.2 and later, the system limits the Source IP to a maximum of three interfaces; the management Out-of-Band (OOB) management interface, the VLAN management interface, or the Circuitless IP (CLIP) management interface. The system uses separate routing tables for each Segmented Management Instance interface, plus a default main table. Since multiple routing tables are in use, each management interface can have overlapping or identical static routes without interfering with each other. The main table has a super-set of all routes where the weight of the static route can tie-break routes to the same destination going through different segmented management interfaces. By default, the following weights are used and the default route priority is management CLIP, then management VLAN, then management OOB:

- mgmt CLIP - 100
- mgmt VLAN - 200
- mgmt OOB - 300

You can route packets through a different management interface than the default configuration, but you must add a specific static route or change the default weight of the management interface.

For example, if the default route uses mgmt CLIP and you want to use the mgmt OOB interface as the source IP to reach a RADIUS server, you must perform one of the following options:

- Configure a specific source IP static route for the mgmt OOB interface:

```
mgmt oob
ip route 192.0.2.0/24 next-hop 198.51.100.1
```

OR

- Configure the default mgmt OOB route weight lower than the default mgmt CLIP route weight:

```
mgmt oob
no ip route 0.0.0.0/24 next-hop 198.51.100.1
ip route 0.0.0.0/24 next-hop 198.51.100.1 weight 50
```

#### Note

If you change the default route weight, the management interface with the lowest weight value becomes the default route for all segmented management interface traffic.

For VOSS Release 8.1.5 and earlier, there was a potential for thousands of different Source IP management interfaces for applications initiating an outbound connection without a Source IP specified. To avoid Source IP fluctuations for many management interfaces with frequent route updates, you could specify the Source IP for applications where the source IP identifies the client. Configuring a Source IP for specific management applications is deprecated in VOSS Release 8.2 and later.

#### Note

This applies only to client mgmt applications initiating an outgoing connection, where the source IP address is not specified. If an application is running in server mode, the source IP address of the reply packet is configured to the destination IP address of the original request for TCP connections.

## Interoperability configuration

The switch is compatible with RADIUS servers.

## Unicast Reverse Path Forwarding (uRPF)

**Table 223: Unicast Reverse Path Forwarding product support**

| Feature                                                | Product         | Release introduced |
|--------------------------------------------------------|-----------------|--------------------|
| Unicast Reverse Path Forwarding (URPF) checking (IPv4) | VSP 4450 Series | VOSS 5.0           |
|                                                        | VSP 4900 Series | VOSS 8.1           |
|                                                        | VSP 7200 Series | VOSS 5.0           |
|                                                        | VSP 7400 Series | VOSS 8.0           |
|                                                        | VSP 8200 Series | VOSS 5.0           |
|                                                        | VSP 8400 Series | VOSS 5.0           |
|                                                        | VSP 8600 Series | VSP 8600 4.5       |
|                                                        | XA1400 Series   | Not Supported      |

**Table 223: Unicast Reverse Path Forwarding product support (continued)**

| Feature                                                | Product         | Release introduced |
|--------------------------------------------------------|-----------------|--------------------|
| Unicast Reverse Path Forwarding (URPF) checking (IPv6) | VSP 4450 Series | VOSS 5.0           |
|                                                        | VSP 4900 Series | VOSS 8.1           |
|                                                        | VSP 7200 Series | VOSS 5.0           |
|                                                        | VSP 7400 Series | VOSS 8.0           |
|                                                        | VSP 8200 Series | VOSS 5.0           |
|                                                        | VSP 8400 Series | VOSS 5.0           |
|                                                        | VSP 8600 Series | VSP 8600 4.5       |
|                                                        | XA1400 Series   | Not Supported      |

The Unicast Reverse Path Forwarding (uRPF) feature prevents packet forwarding for incoming unicast IP packets that have incorrect or forged (spoofed) IP addresses. The uRPF feature checks that the traffic received on an interface comes from a valid IP address, thereby preventing address spoofing. On a reverse path check, if the source IP address of the received packet at the interface is not reachable using the FIB, the system drops the packet as the packet may have originated from a misconfigured or a malicious source.

You can configure uRPF for each IP interface or VLAN. When uRPF is enabled on an interface, the switch checks all routing packets that come through that interface. It ensures that the system displays the source address and source interface in the routing table, and that it matches the interface, on which the packet was received.

You can use one of two modes for uRPF:

- **Strict mode:** In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet. If the routing engine finds the source IP entry, uRPF further checks if the source IP interface matches the incoming interface of the packet. If they match, the system forwards the packet as usual, otherwise, the system discards the packet.

#### Note

The number of packets dropped due to uRPF check on the ingress interface gets incremented along with other general dropped statistics under the `IN-DISCARD` column in the output of the command `show interfaces gigabitEthernet error <collision|verbose> {slot/port[-slot/port] [, ...]}`.

- **Loose mode:** In loose mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router.

uRPF can be enabled independently for IPv4 and IPv6. However, on a given interface, if uRPF is enabled for both IPv4 and IPv6, the urpf-mode can be either strict-mode or loose-mode for both IPv4 and IPv6. That means we cannot have IPv4 urpf-mode configured differently than that of IPv6.

#### Note

When you enable uRPF mode the MTU values for both IPv4 and IPv6 packets on the same VLAN are matched. Different Layer 3 MTU sizes on the same VLAN are not allowed in uRPF mode.

#### Note

uRPF check cannot detect spoofed source IP address if the source IP address belongs to a known subnet.

## Digital Certificate/PKI

**Table 224: Digital Certificate/PKI product support**

| Feature                                                                                                 | Product         | Release introduced |
|---------------------------------------------------------------------------------------------------------|-----------------|--------------------|
| Digital Certificate/PKI<br><br><b>Note:</b><br>VOSS Releases 6.0 and 6.0.1 do not support this feature. | VSP 4450 Series | VOSS 5.1.2         |
|                                                                                                         | VSP 4900 Series | VOSS 8.1           |

|                                                             | VSP 7200 Series | VOSS 8.5           |
|                                                             | VSP 7400 Series | VOSS 8.5           |
|                                                             | VSP 8200 Series | VOSS 8.5           |
|                                                             | VSP 8400 Series | VOSS 8.5           |
|                                                             | VSP 8600 Series | Not Supported      |
|                                                             | XA1400 Series   | VOSS 8.5           |

This section provides information on the digital certificate framework and offline certificate management.

A digital certificate is an electronic document that identifies the subject, proves the ownership of a public key, and is digitally signed by a certificate authority (CA) that certifies the validity of the information in the certificate. A digital certificate is valid for a specific time period.

The switch uses Public Key Infrastructure (PKI) support to obtain and use digital certificates for secure communication in the network.

To be certified, a switch performs the following tasks:

- Generate a certificate signing request.
- Verify that a present certificate has not been revoked.
- Validate the certificate.
- Renew the certificate before it expires.
- Remove the certificate, if required.

#### *Subject*

An administrator configures the subject parameters, such as common name, organization name, organization unit, locality, state, country, and subject name for requesting the identity certificate.

### *Subject Name*

You can configure up to 10 distinguished subject names.

### *Subject Alternative Name*

A subject alternative name associates host name values, such as an e-mail address, an IP address, or a Fully qualified domain name (FQDN) with a security certificate. You can protect these additional host names with a single certificate.

### *Challenge Password*

A password is required for Simple Certificate Enrollment Protocol (SCEP) operations, such as the enrollment and renewal of identity certificates. This password is given offline by the CA during end entity registration. The administrator provides this password during enroll and renew operations.

### *UsePost*

There are different types of CAs such as EJBCA, Win2012, and others. The *usePost* parameter enables you to choose the style of HTTP request. The value for the *usePost* parameter can be **True** or **False**.

For example, if Win2012 SCEP does not support the POST mode of HTTP request, configure the *usePost* as False for Win2012 and configure *usePost* as True for EJBCA.

### *Root CA Certificate*

The Root CA certificate obtained offline from a CA must be installed for SCEP operations. This Root CA certificate is transferred to the device during the certificate installation. SCEP operations cannot be performed if the offline Root CA certificate is not installed and if error messages are logged.

### *Key Generation*

The supported key type is RSA with RSA key of size 2048. There can be only one active key-pair associated with the trustpoint CA and digital certificate. A new key-pair cannot be generated if there is a key-pair already associated with the active digital certificate. The system logs the error message if such new key generation is attempted. In such a case, the certificate must be revoked before a new key-pair is generated.

### *Trustpoint CA*

Use trustpoints to manage and track CAs and certificates. A trustpoint is a representation of a CA or of an identity pair. A trustpoint contains the identity of the CA, CA-specific configuration parameters, and an association with one generated key. The switch can enroll with a trustpoint to obtain an identity certificate. Trustpoint is configured after the RSA key pair is generated and the CA identity and other configuration parameters are available. You can configure up to eight CA trustpoints by providing the CA name.

#### **Note**

For VSP 8600 Series, you can configure only a single CA trustpoint.

You can configure a SHA-256 fingerprint to authenticate a received CA certificate that matches the configured common name. The switch first checks for an installed, offline root certificate and validates against it. If no root certificate is present, the switch checks the SHA-256 fingerprint in the received CA certificate. The SHA-256 fingerprint does not authenticate the root certificate.

### *Certificate Enrollment*

Certificate enrollment involves generating a certificate signing request (CSR). Before certificate enrollment, the trustpoint CA must be configured and the user configuration parameters should be available. The key usage extension parameter is required as an input; it indicates the purpose of the key contained in the certificate, that the key can be used for encipherment, digital signature, certificate signing and so on.

The certificate enrollment is not allowed if there is an active certificate already available. If new certificate enrollment is required, the existing active certificate must be revoked first. The system logs the enrollment success or failure responses.

### *Certificate Renewal*

The administrator must renew the certificate before it expires. A trap is configured for a pre-defined period before the expiry date of the certificate, and the system logs the certificate renewal due warning message. A certificate renewal request is not performed if an active certificate is not available. The system replaces the existing certificate with the newly obtained certificate on successful renewal. The system logs the renewal success or failure responses.

### *Certificate Revocation or Removal*

The certificate can be revoked or withdrawn from the specific device for a specific reason at any time. A certificate revocation request is not performed if an active certificate is not available. The system releases the existing certificate on successful revocation. The system logs the revocation success or failure responses.

During boot up, the system checks whether an active installed certificate is available. If a valid certificate is not available, the system logs the warning message.

### *Offline Certificate Management*

Offline certificate management supports switches that cannot communicate with the Certificate Authority to obtain the identity certificate or certificates online by certificate enrollment operation.

The certificate signing request (CSR) is used to obtain the offline identity certificate. Configure the subject and RSA key-pair to obtain the offline identity certificate. You can generate and store up to 10 RSA keys identified by the key name label. To obtain multiple offline certificates, you must specify a distinguished subject-name and key-name.

You must install the Root CA certificate and all the intermediate CA certificates of the certificate chain in the device before installing the offline identity or device certificate. All the intermediate and Root CA certificates are stored in the certificate store and are used for CA certificate chain validation. The CA certificate chain validation is performed starting from the issuing CA certificate to the Root CA certificate during the installation of offline identity certificate. The offline identity certificate is installed only if the CA certificate chain validation, subject, and key match.

### *Storage*

No digital certificate configuration is visible if you use the **show running-config** command. Instead, use the commands appropriate for displaying digital certificate information. For more information, see [View the Certificate Details](#) on page 3039.

## Certificate Order Priority

**Table 225: Certificate order priority product support**

| Feature                                                                  | Product         | Release introduced |
|--------------------------------------------------------------------------|-----------------|--------------------|
| <b>Note:</b><br>VOSS Releases 6.0 and 6.0.1 do not support this feature. | VSP 4450 Series | VOSS 5.1.2         |
|                                                                          | VSP 4900 Series | VOSS 8.1           |
|                                                                          | VSP 7200 Series | VOSS 5.1.2         |
|                                                                          | VSP 7400 Series | VOSS 8.0           |
|                                                                          | VSP 8200 Series | VOSS 5.1.2         |
|                                                                          | VSP 8400 Series | VOSS 5.1.2         |
|                                                                          | VSP 8600 Series | Not Supported      |
|                                                                          | XA1400 Series   | VOSS 8.0.50        |

Use the following information to understand the certificate order priority when the Transport Layer Security (TLS) server and switch connect.

**Note**

For certain switches in enhanced secure mode, all sensitive files are protected. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 3322.

The TLS server selects a certificate authority (CA)-signed certificate if the certificate is already installed in the Digital Certificate module.

If the server certificates are not available, the TLS server generates a new self-signed certificate at startup and uses that by default. You can choose to use an online or an offline CA-signed certificate, which takes precedence over the self-signed certificate.

**SSL-Based Self-Signed Certificate**

Some early releases use the default certificate available in the `/infFlash/.ssh` folder, which is the open SSL-based self-signed certificate that is named `host.cert`.

To use the Mocana stack-based self-signed certificate, delete the open SSL self-signed certificate prior to upgrading your software release. The Mocana certificate offers better and stronger encryption than open SSL-based certificates.

If you do not delete the `host.cert` file in the `/infFlash/.ssh` folder used in earlier releases, you must generate a self-signed certificate automatically during upgrade or post upgrade using the command **`config ssl certificate`**.

If you have a subscribed CA-signed certificate renamed as `host.cert` in folder `/infFlash/.ssh` in a previous release, it cannot be reused.

To use your subscribed CA-signed certificate, upgrade with the Mocana-based self-signed certificate, and then use the digital certificates feature to install a CA-signed certificate through the online or offline method.

You cannot obtain a CA-signed certificate and rename the certificate as host.cert. You must use the online or offline method to obtain a certificate.

### SAN Entries in Default TLS Certificates

The default TLS certificates add hostname.domainname and management IP address as subject alternative name (SAN) entries:

- If you configure both hostname and domain-name, the self-signed certificate uses `hostname.domain-name` for both common name (CN) and SAN DNS.
- If you configure domain-name but not hostname, the self-signed certificate uses `*.domain-name` for both CN and SAN DNS.
- If you configure hostname but not domain-name, the self-signed certificate uses `hostname.extremenetworks.com` for both CN and SAN DNS.
- If you do not configure either hostname or domain-name, the self-signed certificate uses `*.extremenetworks.com` for both CN and SAN DNS.
- All management IP addresses are added as SAN IP entries.

If you use default self-signed certificates generated in a release that did not include SAN entries in the certificate, generate the certificate again to avoid certificate errors in Web browsers that require these entries.

#### Note

As a best practice, use custom Public Key Infrastructure (PKI) certificates rather than the default self-signed certificates.

### Two-Factor Authentication for SSH

**Table 226: Two-Factor Authentication for SSH product support**

| Feature                           | Product         | Release introduced        |
|-----------------------------------|-----------------|---------------------------|
| Two-Factor Authentication for SSH | VSP 4450 Series | VOSS 8.0                  |
|                                   | VSP 4900 Series | VOSS 8.1                  |
|                                   | VSP 7200 Series | VOSS 8.0                  |
|                                   | VSP 7400 Series | VOSS 8.0                  |
|                                   | VSP 8200 Series | VOSS 8.0                  |
|                                   | VSP 8400 Series | VOSS 8.0                  |
|                                   | VSP 8600 Series | VSP 8600 8.0 demo feature |
|                                   | XA1400 Series   | VOSS 8.0.50               |

#### Note

DEMO FEATURE - Two-Factor Authentication-X.509v3 Certificates for SSH is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Use the following information to understand the Two-Factor Authentication feature.

Two-Factor Authentication uses smart card technology for remote device management. Two-Factor Authentication requires enhanced secure mode with Secure Shell (SSH) and X.509 V3 authorization enabled on the switch. You must provide the digital certificates to enable the identity management for the SSH client and SSH server. Two-Factor Authentication requires the following items:

- a VSP Operating System Software (VOSS) switch
- a switch
- a computer with Secure CRT 8.3.2 or 8.3.3 as the SSH client
- a smart card reader
- a Common Access Card (CAC) or Personal Identity Verification (PIV) card for each configured user

You can also use a Windows Server 2008, or newer, configured with a Remote Access Dial-In User Services (RADIUS) server and Active Directory.

Digital certificates in the X.509 V3 format provide identity management. A chain of signatures by a trusted certificate authority (CA) and its intermediate certificate CAs binds a given public signing key to a given digital identity. For user authentication, the SSH client sends the user certificate stored on the CAC or PIV card to the SSH server for verification. The SSH server validates the incoming user certificate using Public Key Infrastructure (PKI) trust-store.

After the switch validates the SSH certificate, the system parses for a username to forward to the RADIUS server for authorization. The switch prompts you to enter a password for the username. If the RADIUS server is unreachable or not configured, the authorization occurs locally on the switch for the username and password.

Two-Factor Authentication on the switch uses SSH and the X.509 V3 certificates stored on the smart card. X.509 V3 digital certificates are documented in RFC5280.

### **Smart Card Authentication Process**

The process for PIV or CAC card authentication is as follows:

1. The PIV Authentication or the Card Authentication certificate is read from the PIV Card Application.
2. The relying system validates the PIV Authentication certificate from the PIV Card Application using standards-compliant PKI path validation to ensure that the certificate is valid and from a trusted source.
3. The cardholder is prompted to submit a PIN to activate the card.
4. The relying system issues a challenge string to the card and requests an asymmetric operation in response.
5. The card responds to the previously issued challenge by signing using the PIV Authentication private key.
6. The relying system verifies that the response from the card is expected for the issued challenge.
7. A unique identifier from the PIV Authentication certificate is extracted and passed as input to the access control decision.

## **Security Configuration using CLI**

---

Configure security information used on the control and data paths to protect the network from uncontrolled access to network resources.

For more information about how to configure passwords and access policies, see [System access configuration using CLI](#) on page 3324.

## Enable hsecure

The hsecure flag is disabled by default. When you enable it, the software enforces the 10 character rule for all passwords.

### About This Task

When you upgrade from a previous release, if the password does not have at least 10 characters, you receive a prompt to change your password to the mandatory 10-character length.

If you enable hsecure for the first time and the password file does not exist, then the device creates a normal default username (rwa) and password (rwa). In this case, the password does not meet the minimum requirements for hsecure and as a result the system prompts you to change the password.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable or disable hsecure mode:  
`boot config flags hsecure`

The system displays the following warning messages:

```
Warning: For security purposes, all unsecure services - TFTP, FTP, Rlogin, Telnet,
SNMP are disabled. Individually enable the required services.
Warning: Please save boot configuration and reboot the switch for this to take effect.
```

#### Note

Warning message text can vary across hardware models.

3. Save the configuration and restart the device for the change to take effect.

### Example

Enable hsecure mode. Save the configuration. Restart the switch.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags hsecure
Warning: For security purposes, all unsecure services - TFTP, FTP, Rlogin, Telnet, SNMP
are disabled. Individually enable the required services. Warning: Please save boot
configuration and reboot the switch for this to take effect.
Switch:1(config)#save config
Switch:1(config)#reset
Are you sure you want to reset the switch (y/n)?y
```

## Change an Invalid-Length Password

### Before You Begin

#### Important

When you enable hsecure, passwords must contain a minimum of 10 characters or numbers. The password must contain a minimum of: two uppercase characters, two lowercase characters, two numbers, and two special characters.

### About This Task

After you enable hsecure mode and restart the system, change your password if you have an invalid-length password.

### Procedure

1. At the CLI prompt, log on to the system.
2. Enter the password.

If you have an invalid-length password, the system displays the following message:

```
Your password is valid but less than mandatory 10 characters.
Please change the password to continue.
```

3. When prompted, enter the new password.
4. When prompted, re-enter the new password.

### Example

Log on to the switch:

```
Login: rwa
```

Enter the password:

```
Password: ***
Your password is valid but less than mandatory 10 characters. Please change the password
to continue.
```

Enter the new password:

```
Enter the new password: *****
```

Re-enter the new password:

```
Re-enter the new password: *****
Password successfully changed.
```

## Configure New Passwords

Configure new passwords for each access level, or change the logon or password for the different access levels of the switch. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change encrypted passwords.

### Before You Begin

- You must use an account with read-write-all privileges to change passwords. For security, the switch saves passwords to a hidden file.

### About This Task

If you enable the hsecure flag, after the aging time expires, the system prompts you to change your password. If you do not configure the aging time, the default is 90 days.

### Procedure

- Enter Global Configuration mode:  
enable  
  
configure terminal
- Change a password:  
cli password WORD<1-20> {layer1|layer2|layer3|read-only|read-write|read-write-all}
- Enter the old password.
- Enter the new password.
- Enter the new password a second time.
- Configure password options:  
password access-level WORD<2-8>  
  
password aging-time day <1-365>  
  
password default-lockout-retries <1-255>  
  
password default-lockout-time <60-65000>  
  
password lockout WORD<0-46> [time <60-65000>]  
  
password min-passwd-len <10-20>  
  
password password-history <3-32>

### Example

```
Switch:1>enable
Switch:1#configure terminal
```

Change a password:

```
Switch:1(config)# password smith read-write-all
```

Enter the old password:

```
Switch:1(config)#*****
```

Enter the new password:

```
Switch:1(config)#*****
```

Enter the new password a second time:

```
Switch:1(config)#*****
```

Set password to an access level of read-write-all and the expiration period for the password to 60 days:

```
Switch:1(config)#access-level rwa aging-time 60
```

### Variable Definitions

The following table defines parameters for the **cli password** command.

| Variable                                                        | Value                                               |
|-----------------------------------------------------------------|-----------------------------------------------------|
| <i>layer1 layer2 layer3 read-only read-write read-write-all</i> | Changes the password for the specific access level. |
| <i>WORD&lt;1-20&gt;</i>                                         | Specifies the user logon name.                      |

The following table defines parameters for the **password** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>access level WORD&lt;2-8&gt;</i>                   | Permits or blocks this access level. The available access level values are as follows: <ul style="list-style-type: none"> <li>• l1</li> <li>• l2</li> <li>• l3</li> <li>• ro</li> <li>• rw</li> <li>• rwa</li> </ul>                                                                  |
| <i>aging-time day &lt;1-365&gt;</i>                   | Configures the expiration period for passwords in days, from 1-365. The default is 90 days.                                                                                                                                                                                           |
| <i>default-lockout-retries &lt;1-255&gt;</i>          | Configures the default number of login attempts. The default is 3.                                                                                                                                                                                                                    |
| <i>default-lockout-time &lt;60-65000&gt;</i>          | Changes the default lockout time after three invalid attempts. Configures the lockout time, in seconds, and is in the 60-65000 range. The default is 60 seconds.<br>To configure this option to the default value, use the <b>default</b> operator with the command.                  |
| <i>lockout WORD&lt;0-46&gt; time &lt;60-65000&gt;</i> | Configures the host lockout time. <ul style="list-style-type: none"> <li>• <i>WORD&lt;0-46&gt;</i> is the host IP address in the format a.b.c.d.</li> <li>• <i>&lt;60-65000&gt;</i> is the lockout-out time, in seconds, in the 60-65000 range. The default is 60 seconds.</li> </ul> |

| Variable                                   | Value                                                                                                                                                                                                                                                |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>min-passwd-len &lt;10-20&gt;</code>  | Configures the minimum length for passwords in high-secure mode. The default is 10 characters. To configure this option to the default value, use the <b>default</b> operator with the command.                                                      |
| <code>password-history &lt;3-32&gt;</code> | Specifies the number of previous passwords the switch stores. You cannot reuse a password that is stored in the password history. The default is 3. To configure this option to the default value, use the <b>default</b> operator with the command. |

## Configure Password Hash

### Note

This procedure only applies to the VSP 8600 Series.

You can configure the Secure Hash Algorithm (SHA) level for password hash security. After a password hash level change, all custom users and passwords are deleted, and on first login each default user must change their default password.

### Before You Begin

- You must use an account with read-write-all privileges to change password hash.

### About This Task

Configure the password hash level as SHA1 or SHA2.

### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Change the password hash level:
 

```
password hash sha1|sha2
```
- Read the warning prompt, then confirm the password hash change:
 

```
y
```

### Example

```
Switch:1>enable

Switch:1#configure terminal

Change password hash to SHA2 512-bit hash value:

Switch:1(config)# password hash sha2
```

Warning: Changing the password hash will reset all existing passwords and users to Factory defaults. All custom Users will be deleted. Are you sure you want to proceed (y/n) ? y

### Variable Definitions

The following table defines parameters for the **password hash** command.

| Variable                  | Value                                                                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>sha1</i>   <i>sha2</i> | Specifies the password hash SHA value: <ul style="list-style-type: none"> <li>• SHA1 - 160-bit password hash</li> <li>• SHA2 - 512-bit password hash</li> </ul> |

## Configuring directed broadcast

A directed broadcast is a frame sent to the subnet broadcast address on a remote IP subnet. When you disable (or suppress) directed broadcasts on an interface, all frames sent to the subnet broadcast address for a local router interface are dropped. Disabling directed broadcasts protects hosts from possible denial-of-service (DOS) attacks. By default, this feature is enabled on the device.

### Procedure

1. Enter VLAN Interface Configuration mode:
 

```
enable

configure terminal

interface vlan <1-4059>
```
2. Configure the switch to forward directed broadcasts for a VLAN:
 

```
ip directed-broadcast enable
```

### Example

Enable directed broadcast on a VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 2
Switch:1(config-if)#ip directed-broadcast enable
```

Display VLAN IDs with directed broadcast enabled:

```
Switch:1>show ip directed-broadcast vlan

 Vlan Directed-Broadcast

VLAN ID DIRECTED-BROADCAST

 2 true
```

### Variable Definitions

The following table defines parameters for the **ip directed-broadcast** command.

| Variable      | Value                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i> | Enables the device to forward directed broadcast frames to the specified VLAN. The default setting for this feature is enabled. |

## Preventing certain types of DOS attacks

Protect the switch against IP packets with illegal IP addresses such as loopback addresses or a source IP address of ones, or Class D or Class E addresses from being routed. The switch supports high-secure configurable flag.

### About This Task

#### Important

After you enable this flag, the desired behavior (not routing source packets with an IP address of 255.255.255.255) applies to all ports that belong to the same port.

#### Important

The setting to enable hsecure only takes effect for packets going to the CP; not to datapath traffic.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable high-secure mode:

```
high-secure [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] enable
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface GigabitEthernet 1/16
Switch:1(config-if)# high-secure enable
```

### Variable Definitions

The following table defines parameters for the **high-secure** command.

| Variable                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Specifies the port on which you want to enable high-secure mode. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>enable</code>                                                     | Enables the high-secure feature that blocks packets with illegal IP addresses. This flag is disabled by default. Use the <b>no</b> operator to remove this configuration. To configure this option to the default value, use the <b>default</b> operator with the command.                                                                                                                                                     |

## Configuring port lock

Configure port lock to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify a locked port until you unlock the port.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable port lock globally:

```
portlock enable
```

3. Enter GigabitEthernet Interface Configuration mode:

```
interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

4. Lock a port:

```
lock [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]]
enable
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
```

Log on to GigabitEthernet Interface Configuration mode:

```
Switch:1(config)# interface GigabitEthernet 1/1
```

Lock port 1/1:

```
Switch:1(config-if)# lock port 1/1 enable
```

Unlock port 1/1:

```
Switch:1(config-if)# no lock port 1/1 enable
```

*Variable Definitions*

The following table defines parameters for the **interface gigabitethernet** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

The following table defines parameters for the **lock port** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Specifies the port you want to lock. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. The default is disabled. |

## Unicast Reverse Path Forwarding configuration using CLI

This section provides CLI procedures for Unicast Reverse Path Forwarding configuration.

### *Enable urpf-mode Boot Flag*

To configure Unicast Reverse Path Forwarding on a port or VLAN, you are required to enable the urpf-mode boot flag. If you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.

#### **About This Task**

Use the following procedure to enable the urpf-mode boot flag. By default, urpf-mode is disabled.

#### **Procedure**

1. Enter Global Configuration mode:
 

```
enable
configure terminal
```
2. Enable the urpf-mode boot flag:
 

```
boot config flags urpf-mode
```

- When you get the following prompt to reboot the switch, enter `y` to reboot.  
The new setting requires a reboot to take effect!  
  
The configuration will be saved and rebooted.  
  
Are you sure you want to re-boot the switch (y/n)?

**Note**

If you enter `n`, the following message is displayed: Warning: Please save the configuration and reboot the switch for this configuration to take effect.

- Check the status of the urpf-mode boot flag:  
`show boot config flags`

**Example**

Enable the urpf-mode boot flag:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# boot config flags urpf-mode
The new setting requires a reboot to take effect!
The configuration will be saved and rebooted.
Are you sure you want to re-boot the switch (y/n)? y
```

View the status of the urpf-boot flag:

**Note**

Flag support can vary across hardware models.

```
Switch:1#show boot config flags

```

### Configuring unicast reverse path forwarding on a port

#### About This Task

You can use the Unicast Reverse Path Forwarding (uRPF) feature to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. When you enable uRPF, the switch performs a check to determine if the source IP address of the packet is verifiable. If the address is not verifiable, the system drops the packet.

uRPF runs in two modes:

- strict mode
- loose mode (exist-only mode)

#### Before You Begin

- You must enable the urpf-mode boot flag. See [Enable urpf-mode Boot Flag](#) on page 3018.

#### Note

When you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: `Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.`

- You must log on to the GigabitEthernet Interface Configuration mode in CLI.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

2. Set or change the urpf operating mode on a port:

For IPv4, enter: `ip rvs-path-chk mode {strict|exist-only}`

For IPv6, enter: `ipv6 rvs-path-chk mode {strict|exist-only}`

3. Verify the configuration on the port:

For IPv4, enter: `show ip interface gigabitethernet`

For IPv6, enter: `show ipv6 interface gigabitethernet`

**Example**

Example for IPv4:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface GigabitEthernet 1/10
```

Check whether the source IP address of the incoming packet exists in the FIB table:

```
Switch:1(config-if)# ip rvs-path-chk mode strict
```

Verify the configuration on the port:

```
Switch:1(config-if)# show ip interface gigabitethernet
```

```

## Variable Definitions

The following table defines parameters for the **ip rvs-path-chk mode** and **ipv6 rvs-path-chk mode** commands.

| Variable                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mode{strict exist-only} | Specifies the mode for Unicast Reverse Path Forwarding (uRPF). In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet. In exist-only mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router. |

### Configuring unicast reverse path forwarding on a VLAN

#### About This Task

Use the Unicast Reverse Path Forwarding (uRPF) feature to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. When you enable uRPF, the switch performs a check to determine if the source IP address of the packet is verifiable. If the address is not verifiable, the system drops the packet.

uRPF runs in two modes:

- strict mode
- loose mode (exist-only mode)

#### Before You Begin

- You must enable the urpf-mode boot flag.

#### Note

When you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.

- You must log on to the VLAN Interface Configuration mode in CLI.

#### Important

You must assign a valid IP address to the selected port.

#### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

- Set or change the urpf operating mode on a VLAN:

For IPv4, enter: `ip rvs-path-chk mode {strict|exist-only}`

For IPv6, enter: `ipv6 rvs-path-chk mode {strict|exist-only}`

- Verify the configuration on the VLAN:

For IPv4, enter: `show interfaces vlan ip`

For IPv6, enter: `show ipv6 interface vlan`

### Example

Example for IPv4:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface vlan 2
```

Check whether the source IP address of the incoming packet exists in the FIB table:

```
Switch:1(config-if)# ip rvs-path-chk mode exist-only
```

Verify the configuration on the VLAN:

```
Switch:1(config-if)# show interfaces vlan ip
```

```

**Variable Definitions**

The following table defines parameters for the **ip rvs-path-chk mode** and **ipv6 rvs-path-chk mode** commands.

| Variable                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mode{strict exist-only} | Specifies the mode for Unicast Reverse Path Forwarding (uRPF). In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet. In exist-only mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router. |

*Viewing unicast reverse path forwarding configuration on a port*

**About This Task**

Use the following procedure to view the status of the uRPF configuration on a port.

**Before You Begin**

- You must enable the urpf-mode boot flag.

**Note**

When you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.

- You must log on to the GigabitEthernet Interface Configuration mode in CLI.
- You must configure unicast reverse path forwarding on a port.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Verify the configuration on the port:

For IPv4, enter: `show ip interface gigabitethernet`

For IPv6, enter: `show ipv6 interface gigabitethernet`

### Example

Example for IPv4:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface GigabitEthernet 1/10
```

Verify the configuration on the port:

```
Switch:1(config-if)# show ip interface gigabitethernet

### Viewing unicast reverse path forwarding configuration on a VLAN

#### About This Task

Use the following procedure to view the status of the uRPF configuration on a VLAN.

#### Before You Begin

- You must enable the urpf-mode boot flag.

#### Note

When you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.

- You must log on to the VLAN Interface Configuration mode in CLI.

#### Important

You must assign a valid IP address to the selected port.

- You must configure unicast reverse path forwarding on a VLAN.

#### Procedure

- Enter VLAN Interface Configuration mode:
 

```
enable
configure terminal
interface vlan <1-4059>
```
- Verify the configuration on the VLAN:
 

For IPv4, enter: `show interfaces vlan ip`

For IPv6, enter: `show ipv6 interface vlan`

**Example**

Example for IPv4:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface vlan 2
```

Verify the configuration on the VLAN:

```
Switch:1(config-if)# show interfaces vlan ip

## Configuring Digital Certificates using CLI

The following section provides procedures to configure digital certificates using CLI.

### Configure Device Subject Parameters

#### About This Task

Use this procedure to configure the device subject parameters to identify the device, such as the name, Email ID, company, department, location, and subject name.

#### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Configure the subject parameters of the device:
 

```
certificate subject {[common-name WORD<0-64>] [country WORD<2-2>] [e-mail WORD<0-254>] [locality WORD<0-128>] [organization WORD<0-64>] [province WORD<0-128>] [subject-name WORD<1-45>] [unit WORD<0-64>]}
```
- Verify the subject names configured on the switch:
 

```
show certificate subject
```

#### Example

Configuring subject parameters:

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# certificate subject common-name 822-pki e-mail
client1@extemenetworks.com unit Engineering
organization ExtremeNetworks locality Salem province Massachusetts country US subject-
name 822

```

View the configuration.

```

Switch:1>show certificate subject
Subject Name : 822
Common Name : 822-pki
Email Address : client1@extemenetworks.com
Organizational Unit : Engineering
Organization : ExtremeNetworks
Locality : Salem

```

```

Province : Massachusetts
Country : US

Subject Name : 823
Common Name : 823-pki
Email Address : client1@extemenetworks.com
Organizational Unit : Engineering
Organization : ExtremeNetworks
Locality : Salem
Province : Massachusetts
Country : US

Subject Name : Global
Common Name : 821
Email Address : client1@extemenetworks.com
Organizational Unit : Engineering
Organization : ExtremeNetworks
Locality : Salem
Province : Massachusetts
Country : US

```

### Variable Definitions

The following table defines parameters for the **certificate subject** command.

| Variable                                                     | Value                                                                                                                                                                                                              |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>common-name</i><br><i>WORD&lt;0-64&gt;</i>                | Specifies the name of the subject sending the Certificate Signing Request to the Certificate Authority.                                                                                                            |
| <i>country</i> <i>WORD&lt;2-2&gt;</i>                        | Specifies the country of the subject sending the Certificate Signing Request to the Certificate Authority.                                                                                                         |
| <i>e-mail</i> <i>WORD&lt;0-254&gt;</i>                       | Specifies the Email address of the subject sending the Certificate Signing Request to the Certificate Authority.                                                                                                   |
| <i>locality</i><br><i>WORD&lt;0-128&gt;</i>                  | Specifies the locality of the subject sending the Certificate Signing Request to the Certificate Authority.                                                                                                        |
| <i>organization</i><br><i>WORD&lt;0-64&gt;</i>               | Specifies the organization of the subject sending the Certificate Signing Request to the Certificate Authority.                                                                                                    |
| <i>province</i><br><i>WORD&lt;0-128&gt;</i>                  | Specifies the state or province of the subject sending the Certificate Signing Request to the Certificate Authority.                                                                                               |
| <i>subject-name</i><br><i>WORD&lt;1-45&gt;</i>               | Specifies the Subject Identity Label to be used in local digital certificate request.<br>You can configure up to 10 subject DN identities. If a subject name is not specified, the default subject name is Global. |
| <b>Note:</b><br>Exception: Not supported on VSP 8600 Series. |                                                                                                                                                                                                                    |
| <i>unit</i> <i>WORD&lt;0-64&gt;</i>                          | Specifies the organizational unit of the subject sending the Certificate Signing Request to the Certificate Authority.                                                                                             |

*Configure Subject Alternative Names***About This Task**

Use this procedure to protect additional host names with a single certificate.

**Note**

The switch supports 100 subject alternative names.

**Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a subject alternative name for the entity:

```
certificate subject-alternative-name {[dns WORD<1-255>] [e-mail
WORD<1-255>] [ip> WORD<1-255>] [subject-name WORD<1-45>]}
```

**Note****Note**

You can configure up to 10 distinct subject names. The default subject name is Global.

3. View the subject alternative names configured on the switch:

```
show certificate subject-alternative-name
```

**Examples**

Configure a subject alternative name subject name 822:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#certificate subject-alternative-name subject-name 822 dns
822.extremenetworks.com
Switch:1(config)#certificate subject-alternative-name subject-name 822 e-mail
name@company.com
Switch:1(config)#certificate subject-alternative-name subject-name 822 ip 192.0.2.22
```

View the configuration:

```
Switch:1>show certificate subject-alternative-name
```

```
=====

### Variable Definitions

The following table defines parameters for the **certificate subject-alternative-name** command.

| Variable                                                     | Value                                                                                                                                                                                                             |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dns</i> WORD<1-255>                                       | Specifies the DNS subject alternative name.                                                                                                                                                                       |
| <i>e-mail</i> WORD<1-255>                                    | Specifies the e-mail subject alternative name.                                                                                                                                                                    |
| <i>ip</i> WORD<1-255>                                        | Specifies the IP subject alternative name.                                                                                                                                                                        |
| <i>subject-name</i> WORD<1-45>                               | Specifies the Subject Identity Label to be used in local digital certificate request. You can configure up to 10 subject DN identities. If the subject-name is not specified, the default subject name is Global. |
| <b>Note:</b><br>Exception: Not supported on VSP 8600 Series. |                                                                                                                                                                                                                   |

### Generate the Key Pair

#### About This Task

Use the following procedure to generate the private and public key pair for the specific cryptography type. By default, the switch generates a 2,048 RSA key when the system starts. You can use this procedure to generate a new RSA key or to generate multiple RSA keys identified by a key-name. You can generate up to 10 RSA keys.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```

2. Generate the key pair:

```
certificate generate-keypair {[type rsa size 2048] | [key-name
WORD<1-45>]}
```

### Example

Generating the key pair identified by a key-name:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#certificate generate-keypair key-name pki_key
Switch:1(config)#1 2021-06-22T11:33:53.036Z VSP-4900-24XE CP1 - 0x003a864c - 00000000
GlobalRouter DIGITALCERT INFO Digicert Key-pair generation is in progress
Switch:1(config):#1 2021-06-22T11:33:53.052Z VSP-4900-24XE CP1 - 0x003a8604 - 00000000
GlobalRouter
DIGITALCERT INFO Generation of RSA key-pair for digital certificate is successful
1 2021-06-22T11:33:58.711Z Switch CP1 - 0x003a864d - 00000000 GlobalRouter DIGITALCERT
INFO Digicert Key-pair generation completed successfully for key-name: pki_key
```

Display the configured key pairs:

```
Switch:1>show certificate key-name
Key Name: pki_key
Public Key Value:
0000000000000010000000000301000100000100bdb1cf8382d66a2d2d0d24b4477908641c16423c

### Variable Definition

The following table defines parameters for the **generate-keypair** command.

| Variable                                                                                                                   | Value                                                                                                                                                                                 |
|----------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>type rsa</code>                                                                                                      | Specifies type of cryptography algorithm used to generate the key-pair. The switch uses only <code>rsa</code> as the cryptography algorithm type.                                     |
| <code>size 2048</code>                                                                                                     | Specifies the size or modulus of key-pair to be generated. The switch only supports 2048.                                                                                             |
| <code>key-name</code><br><code>WORD&lt;1-45&gt;</code><br><br><b>Note:</b><br>Exception: Not supported on VSP 8600 Series. | Specifies the key label for RSA 2048 key to be generated. You can configure up to 10 RSA keys by specifying the key-name label. The default key-name label is <code>rsa_2048</code> . |

### Configure a Trustpoint CA

#### About This Task

Use this procedure to configure the certificate authority and perform related actions. You can configure up to eight CA trustpoints.

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the trustpoint and associate it with the generated key pair:

```
certificate ca WORD<1-45> {[subject-name WORD<1-45>] [common-name WORD<0-64>] [key-name WORD<0-45>] [ca-url WORD<0-1000>] [use-post <true|false>]}
```

3. Configure an SHA-256 fingerprint to authenticate the received CA certificate:

```
certificate ca WORD<1-45> sha256-fingerprint WORD<64-64>
```

4. Configure the appropriate action:

- Configure trustpoint, authenticate the trustpoint CA by getting the certificate of the CA, and store the CA certificate locally:

```
certificate ca WORD<1-45> action caauth
```

- Generate certificate signing request to obtain identity certificate from configured trustpoint CA, get the digital certificate, and store it locally, associating with the trustpoint CA:

```
certificate ca WORD<1-45> action enroll [validity-days <7-1185>]
```

- Get the Certificate Revocation List from the CDP and store into a file:

```
certificate ca WORD<1-45> action get-crl
```

- Install the subject certificate obtained from the given trustpoint CA:

```
certificate ca WORD<1-45> action install
```

- Configure trustpoint and perform no other operation:

```
certificate ca WORD<1-45> action noop
```

- Release the locally stored certificate associated with the trustpoint CA post revocation:

```
certificate ca WORD<1-45> action remove
```

- Generate certificate renew request for given trustpoint CA, get the new digital certificate, and store it locally by replacing the old certificate with the new one:

```
certificate ca WORD<1-45> action renew [validity-days <7-1185>]
```

5. Install the Root Certificate Authority certificate obtained offline:

```
certificate ca WORD<1-45> install-file {root-ca-filename WORD<1-80>}
```

6. Set the HTTP request type to support the type of CA:

```
certificate ca WORD<1-45> use-post <false | true>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#certificate ca ej common-name CaA2 key-name pki_key subject-name 822
Switch:1(config)#certificate ca ej action enroll
Switch:1(config)#CP1 [07/21/16 12:22:11.992:CEST] 0x003a8604 00000000 GlobalRouter

### Variable Definitions

The following table defines parameters for the **certificate ca** command.

| Variable                                                                       | Value                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>action caauth</i>                                                           | Authenticates the trustpoint CA by getting the certificate of the CA and stores the CA certificate locally.                                                                                                                                                                                                                |
| <i>action enroll</i><br><i>[validity-days &lt;7-1185&gt;]</i>                  | Generates certificate signing request to obtain identity certificate from configured trustpoint CA, gets the digital certificate, and stores it locally, associating with the trustpoint CA.<br>The validity-days specifies the number of days for which the certificate will remain valid. The default value is 365 days. |
| <i>action get-crl</i>                                                          | Gets the Certificate Revocation List from the CDP and stores into a file.                                                                                                                                                                                                                                                  |
| <i>action install</i>                                                          | Installs the subject certificate obtained from the given trustpoint CA.                                                                                                                                                                                                                                                    |
| <i>action noop</i>                                                             | Specifies that no operation should be performed after configuring trustpoint.                                                                                                                                                                                                                                              |
| <i>action remove</i>                                                           | Releases the locally stored certificate associated with the trustpoint CA post revocation.                                                                                                                                                                                                                                 |
| <i>action renew</i><br><i>[challenge-password</i><br><i>WORD&lt;0-128&gt;]</i> | Specifies the password. This password is provided offline by the CA during the end entity registration.                                                                                                                                                                                                                    |
| <i>action renew</i><br><i>[validity-days &lt;7-1185&gt;]</i>                   | Generates certificate renewal request for given trustpoint CA, gets the digital certificate, and stores it locally by replacing the old certificate with the new one.<br>The validity-days specifies the number of days for which the certificate will remain valid. The default value is 365 days.                        |
| <i>ca WORD&lt;1-45&gt;</i>                                                     | Specifies the name of the CA. You can configure up to 8 CA trustpoints by specifying the CA name. It should be alphanumeric and case-sensitive. The maximum length should be 45 characters.                                                                                                                                |
| <i>ca-url WORD&lt;0-1000&gt;</i>                                               | Specifies the trusted CA url.                                                                                                                                                                                                                                                                                              |
| <i>common-name</i><br><i>WORD&lt;0-64&gt;</i>                                  | Specifies the name of the owner of the device or user.                                                                                                                                                                                                                                                                     |
| <i>key-name WORD&lt;0-45&gt;</i>                                               | Specifies the key pair generated by the command that was first associated with the CA trustpoint.                                                                                                                                                                                                                          |
| <i>install-file root-ca-filename</i><br><i>WORD&lt;1-80&gt;</i>                | Installs the Root CA file obtained offline from the CA.                                                                                                                                                                                                                                                                    |

| Variable                                                                                                                       | Value                                                                                                            |
|--------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>sha256-fingerprint</code><br><code>WORD&lt;64-64&gt;</code>                                                              | Specifies an encrypted fingerprint of the expected certificate to match.                                         |
| <code>subject-name</code><br><code>WORD&lt;1-45&gt;</code><br><br><b>Note:</b><br>Exception: Not supported on VSP 8600 Series. | Specifies the configured Subject Identity label. The default is Global.                                          |
| <code>use-post</code> <code>&lt;false   true&gt;</code>                                                                        | Specify the HTTP request style. The default value is True. For example, True for EJBCA and False for Win2012 CA. |

### Install the Certificate

#### About This Task

Use this procedure to install the following:

- certificate authority (CA) certificate
- root CA certificates
- subject certificates
- Certificate Revocation List (CRL) file obtained offline from the CA

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Install the offline CA certificate:

```
certificate install-file offline-ca-filename WORD<1-80>
```

3. Install the CRL offline file:

```
certificate install-file offline-crl-filename WORD<1-80>
```

4. Install the root CA offline certificate:

```
certificate install-file offline-root-ca-filename WORD<1-80>
```

5. Install the subject offline certificate:

```
certificate install-file offline-subject-filename WORD<1-80> [relaxed]
[key-name WORD<1-45>] [subject-name WORD<1-45>]
```

#### Note

To obtain the offline subject certificate, you must first generate a certificate signing request (CSR).

6. (Optional) Install the subject offline certificate with PKCS12-format:

```
certificate install-file offline-subject-filename WORD<1-80> relaxed
pkcs12-password WORD<1-128>
```

## Example

View the installed offline subject certificate:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1#certificate install-file offline-subject-filename 823pki.crt subject-name 823 key-

## Variable Definitions

The following table defines parameters for the **certificate install-file** command.

| Variable                                   | Definition                                                               |
|--------------------------------------------|--------------------------------------------------------------------------|
| <i>offline-ca-filename</i> WORD<1-80>      | Specifies the certificate authority (CA) file name obtained from the CA. |
| <i>offline-crl-filename</i> WORD<1-80>     | Specifies the CRL file obtained from the CA.                             |
| <i>offline-root-ca-filename</i> WORD<1-80> | Specifies the root CA file name obtained from the CA.                    |
| <i>offline-subject-filename</i> WORD<1-80> | Specifies the subject certificate file name obtained from the CA.        |

| Variable                                                                                                                                     | Definition                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><i>relaxed</i> [<i>pkcs12-password</i> <i>WORD&lt;1-128&gt;</i>]</p> <p><b>Note:</b><br/>Exception: not supported on VSP 8600 Series.</p> | <p>Uses the relaxed mode for offline subject certificate installation for less restrictive consistency checks. You can also install a PKCS12 format certificate and secret key in relaxed mode. <i>WORD&lt;1-128&gt;</i> is the password to extract the PKCS12 container. If you do not include this parameter, the supported format is Distinguished Encoding Rules (DER).</p> |

| <p><i>subject-name</i> <i>WORD&lt;1-45&gt;</i></p> <p><b>Note:</b><br/>Exception: Not supported on VSP 8600 Series.</p>                      | <p>Refers to the subject identity name.</p>                                                                                                                                                                                                                                                                                                                                     |

### Generate the Certificate Signing Request

#### About This Task

Use this procedure to generate a certificate signing request (CSR) and store it into a file. This CSR is required to obtain the offline subject certificate. The generated file is located in the `/intflash/shared/certs` folder.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Generate certificate signing request:
 

```
certificate generate-csr [relaxed]
```
3. (Optional) Configure the subject-name and the key name:
 

```
certificate generate-csr subject-name WORD<1-45> key-name WORD<1-45>
```

#### Example

Display the generated CSR.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#certificate generate-crs subject-name 823 key-name pki
Switch:1(config)#1 2021-02-02T13:57:39.716z Switch CP1 - 0x003a8635 - 0000000
GlobalRouter DIGITALCERTIFICATE INFO Generate CSR for Digital Certificate successful!
```

*Display Configured Key Pairs***About This Task****Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Display the names and public keys of all the key-pairs:  

```
show certificate key-name [WORD<1-64>]
```

**Example**

The following output example displays the names and public keys of all the key-pairs.

```
Switch:1(config)#show certificate key-name

Key Name: pki_key
Public Key Value:
000000000000000100000000003010001000001009a8d66a1efaeac7bd2a4918ffdda59d8bebfd682

*View the Certificate Details***About This Task**

Use this procedure for the following tasks:

- Displaying the digital certificate for given certificate type or list all the certificate details from the local store for given certificate type.
- Displaying the CA details for a given trustpoint CA name or listing all the CA details from the local store if the CA name is not specified.
- Displaying the configured key details for given key name.
- Displaying the configured subject details.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the digital certificate for given certificate type:
 

```
show certificate cert-type [default-tls-certificate] | [intermediate-ca-cert WORD<1-80>] | [offline-ca-cert] | [offline-subject-cert] | [online-ca-cert] | [online-subject-cert] | [root-ca-cert WORD<1-80>]
```
3. Display the certificate authority details:
 

```
show certificate ca WORD<1-45>
```
4. Display the name and public key of all the key-pairs:
 

```
show certificate key-name
```
5. Display the details of the configured subject:
 

```
show certificate subject
```

## Example

Display the Root CA certificate:

```

### Variable Definitions

The following table defines parameters for the **show certificate** command.

| Variable                                    | Value                                                                                                                                   |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| cert-type default-tls-certificate           | Displays the default TLS certificate (self-signed).                                                                                     |
| cert-type online-ca-cert                    | Specifies Certificate Authority's Certificate obtained online from Certificate Authority.                                               |
| cert-type online-subject-cert               | Specifies subject certificate obtained online from Certificate Authority.                                                               |
| cert-type offline-ca-cert                   | Specifies Certificate Authority's certificate obtained offline from Certificate Authority.                                              |
| cert-type offline-subject-cert              | Specifies subject certificate obtained offline from Certificate Authority.                                                              |
| cert-type intermediate-ca-cert [WORD<1-80>] | Specifies the intermediate certificate obtained offline from Certificate Authority.                                                     |
| cert-type root-ca-cert [WORD<1-80>]         | Specifies root certificate obtained offline from Root Certificate Authority.                                                            |
| ca [WORD<1-45>]                             | Specifies name of the Certificate Authority.<br>If the name is not specified, the command displays the CA details of all configured CA. |

### Configure a Web Server Certificate

#### Note

This procedure does not apply to VSP 8600 Series.

### About This Task

Use this task to configure a web server certificate.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Configure the Certificate Authority for the installed digital certificate:
 

```
web-server certificate ca-name <1-45>
```
3. Configure the subject identity label to be used
 

```
web-server certificate cert-subject-name <1-45>
```

### Example

Display the web server certificate information:

```
Switch:1(config)#web-server certificate cert-subject-name 823
Switch:1(config)#1 2021--2--2T14:35:38.865z Switch CP1 - 0x003z8604 - 0000000
```

```
GlobalRouter DIGITALCERT INFO Digital Certificate Module: Configuration Saved
1 2021--2--2T14:35:38.865z Switch CP1 Switch CP1 - 0x00040601 - 0000000 Global Router
WEB INFO HTTPS: Using the CA Signed Server Cert
```

### Variable Definitions

Use the data in the following table to use the **web-server certificate** command

| Variable                                       | Value                                             |
|------------------------------------------------|---------------------------------------------------|
| <code>ca-name WORD&lt;1-45&gt;</code>          | Specifies the name of the Certificate Authority.  |
| <code>ca-subject-label WORD&lt;1-45&gt;</code> | Specifies the name of the local certificate used. |

### Configure Certificate Authority Trustpoint for Syslog

#### Note

This procedure does not apply to VSP 8600 Series.

### Before You Begin

Configure and install the digital certificate.

### About This Task

Use this procedure to configure the certificate authority for the syslog.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the Certificate Authority trustpoint:
 

```
syslog certificate ca-common-name WORD<1-45>
```

### Variable Definitions

The following table defines parameters for the **syslog certificate** command.

| Variable                                     | Value                                            |
|----------------------------------------------|--------------------------------------------------|
| <code>ca-common-name WORD&lt;1-45&gt;</code> | Specifies the Certificate Authority common name. |

### Digital certificate configuration examples

This section shows how to obtain an online CA signed certificate, remove the expired certificate, renew the certificate, and install an offline subject certificate.

#### Obtain an Online CA-signed Subject Certificate

Use the following procedure as an example to obtain an online CA signed subject certificate that the application can use.

## About This Task

In the following commands, the variable `WORD<1-45>` refers to the name of the certificate authority and the variable `WORD<1-80>` refers to the certificate filename.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the subject:

```
certificate subject common-name 822-pki
certificate subject e-mail 822@extremenetworks.com
certificate subject unit Engineering
certificate subject organization ExtremeNetworks
certificate subject locality Salem
certificate subject country US
certificate subject province Massachusetts
certificate subject subject-name 822

certificate subject common-name 823-pki
certificate subject e-mail 823@extremenetworks.com
certificate subject unit Engineering
certificate subject organization ExtremeNetworks
certificate subject locality Salem
certificate subject country US
certificate subject province Massachusetts
certificate subject subject-name 823
```

### Note

The values mentioned are for example only.

3. Generate the key pair:

```
certificate generate-keypair {[type rsa size 2048] | [key-name WORD<1-45>]}
```

4. Configure the certificate authority (CA):

```
certificate ca ej common-name subca5
certificate ca ej key-name rsa_2048
certificate ca ej ca-url http://192.51.100.9:8080/ejbca/publicweb/apply/scep/test/
pkiclient.exe
certificate ca ej use-post true
```

### Note

The values mentioned are for example.

5. Use SCP to upload the Root CA certificate to: `/intflash/shared/certs`.

6. Install the Root CA certificate:

```
certificate ca WORD<1-45> install-file root-ca-filename WORD<1-80>
```

7. Authenticate the CA:

```
certificate ca WORD<1-45> action caauth
```

8. Enroll the subject certificate by the CA:

```
certificate ca WORD<1-45> action enroll
```

- Install the certificate:

```
certificate ca WORD<1-45> action install
```

- (Optional) If the certificate expires, remove the enrolled subject certificate:

```
certificate ca WORD<1-45> action remove
```

- (Optional) To obtain the new certificate before the old certificate expires, enter the following command to renew the certificate:

```
certificate ca WORD<1-45> action renew
```

The Certificate Authority generates a new certificate for the subject.

### Install an Offline CA Certificate

Use the following procedure as an example to install an offline CA certificate.

#### About This Task

In the following commands, the variable *WORD<1-80>* refers to the certificate filename.

#### Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure the subject:

```
certificate subject common-name 822-pki
certificate subject e-mail client1@extemenetworks.com
certificate subject unit Engineering
certificate subject organization ExtremeNetworks
certificate subject locality Salem
certificate subject province Massachusetts
certificate subject country US
certificate subject subject-name 822
```

#### Note

The values mentioned are for example only.

- Generate the certificate signing request to support multiple subject identities on the switch:

```
certificate generate-csr subject-name WORD< 1-45> key-name WORD<1-64>
```

```
#certificate generate-csr subject-name 823 key-name mimi
Switch:1(config)#1 2021-02-02T13:57:39.716Z VSP-8284XSQ CP1 - 0x003a8635 - 00000000
GlobalRouter DIGITALCERT
INFO Generate CSR For Digital Certificate successful!
```

- Use the generated CSR file to enroll the certificate on the server.
- Use SCP to upload the enrolled certificate along with Root certificate and all intermediary certificates to:

```
/intflash/shared/certs/
```

6. Install the Root CA certificate:

```
certificate install-file offline-root-ca-filename WORD<1-80>
```

#### Note

If the subject certificate issuer is directly the Root, then Step 7 and 8 are optional. If the subject is issued by Intermediate CA, then Step 7 and 8 are mandatory, also in the certificate chain between Root and Subject, all the Intermediates must be installed using these steps.

7. Copy and paste the Intermediate CA certificate to:

```
/intflash/shared/certs/
```

8. Install the intermediate CA:

```
certificate install-file offline-ca-filename WORD<1-80>
```

9. Install the offline subject filename:

```
certificate install-file offline-subject-filename WORD<1-80>
```

```
#certificate install-file offline-subject-filename sd
```

```
Error: File Name Not Found in /intflash/shared/certs/ or /intflash/.cert/.offlineCert/
#certificate install-file offline-subject-filename 823mimi.crt subject-name 823 key-
name mimi
```

```
1 2021-02-02T14:19:01.587Z VSP-8284XSQ CP1 - 0x003a864f - 00000000 GlobalRouter

## Configuring X.509 V3 certificates for SSH Two Factor Authentication

#### Note

DEMO FEATURE - Two-Factor Authentication-X.509v3 Certificates for SSH is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Use the following procedure as an example to configure the SSH server on the VOSS switch, and the SSH client Secure CRT for two factor authentication using X.509 V3 certificates.

### Before You Begin

The following certificates must be loaded on the SSH server and SSH client:

- For the Secure CRT (SSH client):
  - subject certificate from the PIV card.

- For the VOSS switch (SSH server):
  - `CAC-server.pem` - the subject certificate
  - `ca.cert.pem` - the root CA certificate
  - `Self-signedTrustAnchorCertificate.cer` - the root CA certificate that signed the intermediate certificate
  - `RSA2048IssuingCACertificate.cer` - the intermediate certificate signed by the previous root CA that signed the subject certificate.

### About This Task

Use the following steps as an example to configure the SSH server on the VOSS switch, the RADIUS Windows server, and the SSH client Secure CRT.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Ensure the switch is running in Enhanced Secure Mode:

```
Switch:1(config)#show boot config flags
flags enhancedsecure-mode true
```

#### Note

This shows a partial output of only the relevant entry.

3. Ensure the switch clock is synchronized:

```
Switch:1#show clock
System Clock time : Fri Oct 12 19:36:36 2018 UTC
```

4. Provision PKI with certificates.

For information about provisioning PKI with certificates, see the following sections:

- [Obtain an Online CA-signed Subject Certificate](#) on page 3048
- [Install an Offline CA Certificate](#) on page 3050

### X.509 Authentication Username Option Example

Use the following procedure as an example to configure username authentication options using X.509 V3 certificates.

### Procedure

1. Enable X.509 V3 authentication username override:

```
Switch:1(config)# ssh x509v3-auth username overwrite
```

The switch disregards the username sent by the SSH client and uses the principal name from the client's certificate for authentication. If RADIUS authentication is configured, the username is sent after you type the RADIUS password. For example, if you configure the SSH client with the

username "John" and enable x509v3-auth username overwrite on the device, the switch sends the principal name 1403824387@mil to the RADIUS server for authorization.

```
Test CAC John Smith
Issuer: CN=DOD JITC ID CA-49, OU=PKI, OU=DoD, O=U.S. Government, C=US

Government, C=US
Serial: 019ab3
SubjectAltName: Other Name:Principal Name=1403824387@mil, Other
Name:2.16.840.1.101.3.6.6=04 19 d4 f8 10 da 08 26 6c 10 e7 22 e5 83 68 5a 04 0e 44 82
64 5c 85 78 10 93 ee
Cert: 8066aec3484d3740d7d99ec2f5ed1983365bb1
```

2. Enable X.509 V3 authentication username strip:

```
Switch:1(config)#ssh x509v3-auth username strip-domain
```

If x509v3-auth username strip-domain is configured, the switch sends the principal name without the domain to the RADIUS for authorization. The username is sent after you type the RADIUS password. For example: If you select principal name 1403824387@mil, the switch sends the principal name 1403824387 without the domain to the RADIUS server for authorization.

```
Test CAC John Smith
Issuer: CN=DOD JITC ID CA-49, OU=PKI, OU=DoD, O=U.S. Government, C=US

Serial: 019ab3
SubjectAltName: Other Name:Principal Name=1403824387@mil, Other
Name:2.16.840.1.101.3.6.6=04 19 d4 f8 10 da 08 26 6c 10 e7 22 e5 83 68 5a 04 0e 44 82
64 5c 85 78 10 93 ee
Cert: 8066aec3484d3740d7d99ec2f5ed1983365bb129
```

3. Enable X.509 V3 authentication username use-domain:

```
Switch:1(config)ssh x509v3-auth username use-domain extreme.com
```

If you select the username as the principal name, the switch sends the principal name from the certificate with the domain configured on the switch to the RADIUS for authorization. The username is sent after typing the RADIUS password. For example: If you configure use-domain "extreme.com" on the switch and you configure the username to be the principal name 1403824387@mil, the switch sends the username 1403824387@extreme.com to the RADIUS server for authorization.

```
Test CAC John Smith
Issuer: CN=DOD JITC ID CA-49, OU=PKI, OU=DoD, O=U.S. Government, C=US
NotBefore: 12/19/2017 7:00 PM
NotAfter: 12/19/2020 6:59 PM

Government, C=US
Serial: 019ab3
SubjectAltName: Other Name:Principal Name=1403824387@mil, Other
Name:2.16.840.1.101.3.6.6=04 19 d4 f8 10 da 08 26 6c 10 e7 22 e5 83 68 5a 04 0e 44 82
64 5c 85 78 10 93 ee
Cert: 8066aec3484d3740d7d99ec2f5ed1983365bb129
```

4. RADIUS server is not configured:

If the Radius server is not configured, the authorization fallbacks locally on the switch, for the username. You must configure the usernames on the switch. You are prompted for the password. For example: If you select the principal name 1403824387@mil, the switch authorizes locally the

username as 1403824387@mil or 1403824387 if strip domain is enabled. You are prompted for the password.

### Install Online Certificates for Fabric Extend with IPsec

Use the following procedure as an example to install subject certificates for switches that use Fabric Extend with IPsec. After you complete the certificate configuration, you must configure the IPsec authentication method for the Fabric Extend tunnel. For more information about IPsec configuration, see [IPsec configuration using CLI](#) on page 1779. For more information about Fabric Extend, see [Fabric Extend configuration using the CLI](#) on page 1042.

#### Note

The values mentioned are for example only.

### Before You Begin

Configure the Fabric Extend tunnels between the branch and hub switches.

### Procedure

1. Configure the CA instance:

```
Switch:1(config)#certificate ca aaa common-name CaAaa
Switch:1(config)#certificate ca aaa key-name rsa_2048
Switch:1(config)#certificate ca aaa ca-url http://192.0.2.9:8080/ejbca/publicweb/apply/
scep/test/pkiclient.exe
Switch:1(config)#certificate ca aaa use-post true
Switch:1(config)#certificate ca aaa sha256-fingerprint
EEA68F35CC6195CBB038073F520AA385A5A78F42
```

2. Authenticate the CA TrustPoint:

```
Switch:1(config)# certificate ca aaa action caauth
1 2020-06-10T15:07:16.814Z XA1440 CP1 - 0x003a863d - 00000000 GlobalRouter DIGITALCERT

### 4. Configure the IPsec authentication-method:

```
Switch:1(config-isis-1-192.0.2.74)#ipsec auth-method rsa-sig
```

## Configure TCP Keepalive and TCP Timestamp

### About This Task

TCP Keepalive configures the system TCP keepalive interval, probes, and time.

TCP Timestamp option (RFC 1323) allows TCP to determine the order in which the packets are sent. The TCP Timestamp provides protection against Wrapped Sequence numbers. However, it is possible to calculate the system uptime when the Timestamp option is enabled. The analysis of timestamp behaviour can provide information on the system identity, which poses security threats and can cause a potential attack.

The TCP Timestamp option is enabled by default. You can disable the timestamp to avoid any security risks.

#### Note

The configuration will be applied only to the new TCP connections and the existing connections are not affected. You must perform a **config save** and **reboot** to apply the new configuration to all TCP connections.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure the TCP keepalive interval:  
`sys control tcp-keepalive-interval <1-3600>`
3. Configure the TCP keepalive probes:  
`sys control tcp-keepalive-probes <1-50>`
4. Configure the TCP keepalive time:  
`sys control tcp-keepalive-time <5-65535>`
5. Enable the TCP Timestamp:  
`sys control tcp-timestamp`
6. Disable the TCP Timestamp:  
`no sys control tcp-timestamp`
7. View the status of TCP Timestamp:  
`show sys control`

### Examples

Configure the TCP keepalive to interval 60 seconds, with 15 probes, and 120 seconds time:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys control tcp-keepalive-interval 60
Switch:1(config)#sys control tcp-keepalive-probes 15
Switch:1(config)#sys control tcp-keepalive-time 120
```

Disable TCP Timestamp:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#no sys control tcp-timestamp
```

Warning: Existing TCP connections won't be affected.  
A config save and reboot is required to apply this configuration for all TCP connections

Display the status of the TCP Timestamp:

```
Switch:1>show sys control
=====
 System Control Settings
=====
 tcp-timestamp : disable
 tcp-keepalive-time : 120
 tcp-keepalive-interval : 60
 tcp-keepalive-probes : 15
 mac-move-protection : on
```

### Variable Definitions

The following table defines parameters for the **sys control** command.

| Variable                                                                                                                | Value                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><i>tcp-keepalive-interval</i> &lt;1-3600&gt;</p> <p><b>Note:</b><br/>Exception: Not supported on VSP 8600 Series</p> | Configure the TCP keepalive interval in seconds. The default is 10.                                                                                                                                                                                                                                                                            |
| <p><i>tcp-keepalive-probes</i> &lt;1-50&gt;</p> <p><b>Note:</b><br/>Exception: Not supported on VSP 8600 Series</p>     | Configure the TCP keepalive probes. The default is 5.                                                                                                                                                                                                                                                                                          |
| <p><i>tcp-keepalive-time</i> &lt;5-65535&gt;</p> <p><b>Note:</b><br/>Exception: Not supported on VSP 8600 Series</p>    | Configure the TCP keepalive time in seconds. The default is 60.                                                                                                                                                                                                                                                                                |
| <p><i>tcp-timestamp</i></p>                                                                                             | <p>Enable or disable tcp-timestamp.</p> <p><b>Note:</b><br/>The timestamp is enabled by default. The system displays the following warning message when a new configuration is applied:<br/>Warning: Existing TCP connections won't be affected. A config save and reboot is required to apply this configuration for all TCP connections.</p> |

## Enable Authentication for Privileged EXEC Command Mode using CLI

With authentication enabled, you must enter a username and password to access Privileged EXEC command mode from User-EXEC command mode. The username and password is the same username and password you used to Telnet or SSH to the switch.

### Note

When you enable authentication for the Privileged EXEC CLI command mode, the changes do not affect any existing CLI sessions. For the changes to take effect, you must first log out from your current CLI session and log back in on a new session.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable authentication for Privileged EXEC CLI command mode:  
`sys priv-exec-password`
3. Verify the configuration:  
`show sys priv-exec-password`

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#sys priv-exec-password
```

## Enable MAC Move Protection on vIST

### About This Task

Perform this procedure to enable MAC move protection on virtual interswitch trunk (vIST).

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable MAC move protection:  
`sys control virtual-ist mac-move-protection`
3. Confirm the configuration:  
`show sys control`

### Examples

Enable MAC move protection on vIST:

```
Switch:1>enable
```

```

Switch:1#configure terminal
Switch:1(config)#sys control virtual-ist mac-move-protection
Switch:1>show sys control
=====
 System Control Settings
=====
 tcp-timestamp : disable
 tcp-keepalive-time : 120
 tcp-keepalive-interval : 60
 tcp-keepalive-probes : 15
 mac-move-protection : on

```

### Variable Definitions

The following table defines parameters for the **sys control virtual-ist** command.

| Variable                   | Value                                                              |
|----------------------------|--------------------------------------------------------------------|
| <i>mac-move-protection</i> | Enable MAC move protection on vIST. The default value is disabled. |

## Security Configuration using EDM

Configure security information used on the control and data paths to protect the network from uncontrolled access to network resources.

For more information about how to configure passwords and access policies, see [System access configuration using EDM](#) on page 3349.

### Enable Port Lock

#### About This Task

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

#### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Port Lock** tab.
4. To enable port lock, select the **Enable** check box.
5. Click **Apply**.

**Port Lock** field descriptions

Use the data in the following table to use the **Port Lock** tab.

| Name               | Description                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Enable</b>      | Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.         |
| <b>LockedPorts</b> | Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock. |

## Lock a Port

**Before You Begin**

- You must enable port lock before you lock or unlock a port.

**About This Task**

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

**Procedure**

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **General**.
- Click the **Port Lock** tab.
- In the **LockedPorts** box, click the ellipsis (...) button.
- Click the desired port or ports.
- Click **Ok**.
- In the **Port Lock** tab, click **Apply**.

**Port Lock** field descriptions

Use the data in the following table to use the **Port Lock** tab.

| Name               | Description                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Enable</b>      | Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.         |
| <b>LockedPorts</b> | Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock. |

## Change Passwords

**About This Task**

Configure new passwords for each access level, or change the logon or password for the different access levels of the system to prevent unauthorized access. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change passwords in encrypted format.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **CLI** tab.
4. Specify the username and password for the appropriate access level.
5. Click **Apply**.

### *CLI Field Descriptions*

The following table defines parameters for the **CLI** tab.

| Name                     | Description                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------|
| <b>RWAUserName</b>       | Specifies the user name for the read-write-all CLI account.                                       |
| <b>RWAPassword</b>       | Specifies the password for the read-write-all CLI account.                                        |
| <b>RWEnable</b>          | Activates the read-write access. The default is enabled.                                          |
| <b>RWUserName</b>        | Specifies the user name for the read-write CLI account.                                           |
| <b>RWPassword</b>        | Specifies the password for the read-write CLI account.                                            |
| <b>RWL3Enable</b>        | Activates the read-write Layer 3 access. The default is enabled.                                  |
| <b>RWL3UserName</b>      | Specifies the user name for the Layer 3 read-write CLI account.                                   |
| <b>RWL3Password</b>      | Specifies the password for the Layer 3 read-write CLI account.                                    |
| <b>RWL2Enable</b>        | Activates the read-write Layer 2 access. The default is enabled.                                  |
| <b>RWL2UserName</b>      | Specifies the user name for the Layer 2 read-write CLI account.                                   |
| <b>RWL2Password</b>      | Specifies the password for the Layer 2 read-write CLI account.                                    |
| <b>RWL1Enable</b>        | Activates the read-write Layer 1 access. The default is enabled.                                  |
| <b>RWL1UserName</b>      | Specifies the user name for the Layer 1 read-write CLI account.                                   |
| <b>RWL1Password</b>      | Specifies the password for the Layer 1 read-write CLI account.                                    |
| <b>ROEnable</b>          | Activates the read-only CLI account. The default is enabled.                                      |
| <b>ROUserName</b>        | Specifies the user name for the read-only CLI account.                                            |
| <b>ROPassword</b>        | Specifies the password for the read-only CLI account.                                             |
| <b>MaxTelnetSessions</b> | Specifies the maximum number of concurrent Telnet sessions in a range from 0–8. The default is 8. |

| Name                                                                                      | Description                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MaxRloginSessions</b><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series. | Specifies the maximum number of concurrent rlogin sessions in a range from 0–8. The default is 8.                                                                                                                                                                                                 |
| <b>Timeout</b>                                                                            | Specifies the number of seconds of inactivity for a Telnet or Rlogin session before the system initiates automatic timeout and disconnect, expressed in a range from 30–65535. The default is 900 seconds.<br><br><b>Note:</b><br>rlogin is supported only on the VSP 8600 Series.                |
| <b>NumAccessViolations</b>                                                                | Indicates the number of CLI access violations detected by the system. This variable is a read-only field.                                                                                                                                                                                         |
| <b>CustomBannerText</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series.   | Specifies the text message that is displayed to users on the CLI before authentication. The message can be company information, such as company name and contact, or a warning message for the users of CLI. With character limitation from 1-1800, the text box displays 79 characters per line. |
| <b>CustomBannerEnable</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series. | Specifies whether custom logon banner is enabled or disabled. The default is enabled.                                                                                                                                                                                                             |

## Configure Directed Broadcast on a VLAN

Configure directed broadcast on a VLAN to enable or disable directed broadcast traffic forwarding for an IP interface.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **Direct Broadcast** tab.
7. Select **DirectBroadcastEnable**.

#### Important

Configure multiple VLANs or IPs in the same subnet but in different systems simultaneously.

8. Click **Apply**.

**Direct Broadcast** field descriptions

Use the data in the following table to use the **Direct Broadcast** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DirectBroadcastEnable</b> | Specifies that an Isolated Routing Port (IRP) can forward directed broadcast traffic. A directed broadcast is a frame sent to the subnet broadcast address on a remote IP subnet. By disabling or suppressing directed broadcast on an interface, all frames sent to the subnet broadcast address for a local router interface are dropped. Disabling this function protects a host from possible denial of service (DoS) attacks.<br>With the feature enabled, the Control Processor (CP) does not receive a copy of the directed broadcast. As a result, the system does not respond to a subnet broadcast ping sent from a remote subnet.<br>The default is disabled. |

## Unicast Reverse Path Forwarding configuration using EDM

This section provides EDM procedures for Unicast Reverse Path Forwarding configuration.

*Configure Reverse Path Checking on a Port***Before You Begin**

- The system supports reverse path checking only on ports that have a valid IP address.

**About This Task**

Configure reverse path checking on a port to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

**Procedure**

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **Reverse Path Checking** tab.
5. Select the **Enable** check box to enable reverse path checking.
6. Select **exist-only** or **strict**.
7. Click **Apply**.

**Reverse Path Checking field descriptions**

Use the data in the following table to use the **Reverse Path Checking** tab.

| Name          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b> | Enables reverse path checking on the selected port. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Mode</b>   | Specifies the mode for reverse path checking. The modes are <ul style="list-style-type: none"> <li>• exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise the packet is discarded.</li> <li>• strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, the packet is dropped; otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, the packet is forwarded; otherwise the packet is discarded.</li> </ul> The default is exist-only. |

*Configure Reverse Path Checking on an IPv6 Port***Before You Begin**

- The system supports reverse path checking only on ports that have a valid IP address.

**About This Task**

Configure reverse path checking on a port to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

**Procedure**

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IPv6**.
4. Click the **Reverse Path Checking** tab.
5. Select the **ReversePathCheckEnable** check box to enable reverse path checking.
6. Select **exist-only** or **strict**.
7. Click **Apply**.

**Reverse Path Checking field descriptions**

Use the data in the following table to use the **Reverse Path Checking** tab.

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

*Configure Reverse Path Checking on an IPv6 VLAN***Before You Begin**

- Before you can configure reverse path checking on a VLAN, you must assign a valid IP address to the selected VLAN.

**About This Task**

Configure reverse path checking on a VLAN to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

**Procedure**

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Click the VLAN on which you want to configure reverse path checking.
5. Click **IPv6**.
6. Click the **Reverse Path Checking** tab.
7. Select the **ReversePathCheckEnable** box to enable reverse path checking.
8. Select **exist-only** or **strict**.

- Click **Apply**.

### Reverse Path Checking field descriptions

Use the data in the following table to use the **Reverse Path Checking** tab.

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ReversePathCheckEnable</b> | Enables reverse path checking on the selected VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ReversePathCheckMode</b>   | <p>Specifies the mode for reverse path checking. The modes are</p> <ul style="list-style-type: none"> <li>• exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise, the packet is discarded.</li> <li>• strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, then the packet is dropped. Otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, then the packet is forwarded. Otherwise, the packet is discarded.</li> </ul> <p>The default is exist-only.</p> |

## Digital certificate configuration using EDM

The following section provides procedures to configure digital certificates using EDM.

### *Configure Device Subject Parameters*

Use this procedure to configure the device subject parameters to identify the device. The parameters include name, Email ID, company, department, and location of the subject.

#### **Procedure**

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Select **Certificate**.
- Select the **Subject** or **Global Subject** tab.
- In the **CommonName** field, type the name of the subject.
- Complete the remaining optional configuration to customize the policy.
- Select **Apply**.

## Subject field descriptions

Use the data in the following table to use the **Subject** tab.

| Name                      | Description                                                                                                            |
|---------------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>CommonName</b>         | Specifies the name of the subject sending the Certificate Signing Request to the Certificate Authority.                |
| <b>EmailAddress</b>       | Specifies the Email address of the subject sending the Certificate Signing Request to the Certificate Authority.       |
| <b>OrganizationalUnit</b> | Specifies the organizational unit of the subject sending the Certificate Signing Request to the Certificate Authority. |
| <b>Organization</b>       | Specifies the organization of the subject sending the Certificate Signing Request to the Certificate Authority.        |
| <b>Locality</b>           | Specifies the locality of the subject sending the Certificate Signing Request to the Certificate Authority.            |
| <b>Province</b>           | Specifies the province of the subject sending the Certificate Signing Request to the Certificate Authority.            |
| <b>Country</b>            | Specifies the country of the subject sending the Certificate Signing Request to the Certificate Authority.             |
| <b>InstallFile</b>        | Installs the specific certificate file type obtained offline from the Certificate Authority.                           |
| <b>InstallFileName</b>    | Specifies the certificate file name to install.                                                                        |
| <b>UninstallFile</b>      | Uninstalls the specific certificate file type obtained offline from the Certificate Authority.                         |
| <b>UninstallFileName</b>  | Specifies the certificate file name to uninstall.                                                                      |
| <b>GenerateCsr</b>        | Generates the certificate signing request to obtain the offline subject certificate.                                   |

### Configure Device Subject Entries Parameters

Use this procedure to configure the device subject parameters to identify the device. The parameters include name, Email ID, company, department, and location of the subject.

#### Note

This procedure does not apply to VSP 8600 Series.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **Subject Entries** tab.
4. Select **Insert**.

5. In the **Name** field, type the name of the subject.
6. Complete the remaining optional configuration to customize the policy.
7. Select **Insert**.

### Subject Entries Field Descriptions

Use the data in the following table to use the **Subject Entries** tab.

| Name                                                                            | Description                                                                                                            |
|---------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>                                                                     | Specifies the user defined name referring to the subject.                                                              |
| <b>CommonName</b>                                                               | Specifies the name of the subject sending the Certificate Signing Request to the Certificate Authority.                |
| <b>EmailAddress</b>                                                             | Specifies the Email address of the subject sending the Certificate Signing Request to the Certificate Authority.       |
| <b>OrganizationalUnit</b>                                                       | Specifies the organizational unit of the subject sending the Certificate Signing Request to the Certificate Authority. |
| <b>Organization</b>                                                             | Specifies the organization of the subject sending the Certificate Signing Request to the Certificate Authority.        |
| <b>Locality</b>                                                                 | Specifies the locality of the subject sending the Certificate Signing Request to the Certificate Authority.            |
| <b>Province</b>                                                                 | Specifies the province of the subject sending the Certificate Signing Request to the Certificate Authority.            |
| <b>Country</b>                                                                  | Specifies the country of the subject sending the Certificate Signing Request to the Certificate Authority.             |
| <b>InstallFile</b>                                                              | Installs the specific certificate file type obtained offline from the Certificate Authority.                           |
| <b>InstallFileName</b>                                                          | Specifies the certificate file name to install.                                                                        |
| <b>UninstallFile</b>                                                            | Uninstalls the specific certificate file type obtained offline from the Certificate Authority.                         |
| <b>UninstallFileName</b>                                                        | Specifies the certificate file name to uninstall.                                                                      |
| <b>GenerateCsr</b>                                                              | Generates the certificate signing request to obtain the offline subject certificate.                                   |
| <b>RelaxedMode</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series. | Specifies relaxed mode for offline subject certificate installation for less restrictive consistency checks.           |

| Name                                                                              | Description                                                                  |
|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| <b>Pkcs1Password</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series. | Specifies the password to extract the PKCS12 container when in relaxed mode. |
| <b>KeyName</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series.       | Specifies the key name of the generated key-pair.                            |

### *Generate the Key Pair*

Use the following procedure to generate the private and public key pair for the specific cryptography type.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **Key-Pair** tab.
4. Select **Insert**.
5. In the **Type** field, select the cryptography type.
6. In the **Size** field, type the size of the key.
7. Select **Insert**.

#### **Certificate key-pair field description**

Use the data in the following table to use the **Certificate > Key-Pair** tab.

| Name        | Description                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Type</b> | Specifies the cryptography algorithm used to generate the key-pair.<br>Only RSA is supported.                                             |
| <b>Size</b> | Specifies the size of the key-pair to be generated.<br>Only 2048 is supported.                                                            |
| <b>Name</b> | Specifies the name of the key-pair generated for the subject.<br>This name is auto-generated as the combination of key-type and key-size. |

### *Configure the Certificate Authority*

Use this procedure to configure the certificate authority (CA) and perform related actions. You can configure only one CA in a device at a time.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **CA** tab.

4. Select **Insert**.
5. In the **Name** field, type a user-defined name of the CA.
6. In the **CommonName** field, type the common name of the CA.
7. In the **KeyName** field, type the name of the associated key pair.
8. Complete the remaining optional configuration to customize the policy.
9. Select **Insert**.
10. (Optional) Select **Retry Action** if the trustpoint CA certificate authentication fails or takes time for authentication. This can be done only when the selected Action is **caauth**.

### CA field descriptions

Use the data in the following table to use the **CA** tab.

| Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>                    | Specifies the user-defined name referring to the Certificate Authority issuing the Digital Certificate.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>CommonName</b>              | Specifies the Common Name of the Certificate Authority issuing the Digital Certificate.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>KeyName</b>                 | Specifies the name of the associated key pair.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>CaUrl</b>                   | Specifies the URL of the Certificate Authority issuing the Digital Certificate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Action</b>                  | Specifies the action the Certificate Authority can take: <ul style="list-style-type: none"> <li>• noop — no operation</li> <li>• caauth — CA authentication</li> <li>• enroll — certificate enrolment request</li> <li>• renew — certificate renew request</li> <li>• remove — remove the subject certificate obtained online from the CA</li> <li>• install — install the subject certificate obtained online from the CA</li> <li>• getCrl — retrieve the Certificate Revocation List (CRL) from the CRL Distribution Point (CDP).</li> </ul> |
| <b>ActionChallengePassword</b> | Specifies the challenge password required to perform the SCEP operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>LastActionStatus</b>        | Specifies the status of the last action: <ul style="list-style-type: none"> <li>• none - No action is performed yet</li> <li>• success - Execution of the action triggered is completed successfully</li> <li>• failed - Execution of the action triggered has failed</li> <li>• inProgress - Execution of the action triggered is in progress</li> </ul>                                                                                                                                                                                       |
| <b>LastActionFailureReason</b> | Specifies the reason of failure for the last action performed by the Certificate Authority.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Name                                                                                     | Description                                                                                                                        |
|------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>InstallRootCaFileName</b>                                                             | Specifies the certificate file obtained offline from the Root Certificate Authority.                                               |
| <b>SubjectCertificateValidityDays</b>                                                    | Specifies the number of days for which subject certificate will remain valid.<br>The default value is 365 days.                    |
| <b>UsePost</b>                                                                           | Specifies the HTTP request type: URL or POST.<br>TRUE for EJBCA and FALSE for Win2012 CA                                           |
| <b>Sha256Fingerprint</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series. | Specifies an encrypted fingerprint of the expected certificate to match.                                                           |
| <b>SubjectName</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series.       | Specifies the Subject Name of the subject sending the Certificate Signing Request to the Certificate Authority.                    |
| <b>UsedFor</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series.           | Specifies the name of the application the certificate uses.<br>The default is enabled if there is only 1 CA trustpoint configured. |

### *View the Certificate Details*

Use this procedure to:

- display the configured key details for given key name.
- display the digital certificate for the given certificate index or list all the certificate details from the local store if the certificate index is not specified.
- display the CA details for given trustpoint CA name or list all the CA details from the local store if the CA name is not specified.

### **Procedure**

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **Certificate** tab.

### **Certificate Field Descriptions**

Use the data in the following table to use the **Certificate** tab.

| Name                 | Description                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------|
| <b>Type</b>          | Specifies the certificate type.                                                                         |
| <b>VersionNumber</b> | Specifies the version number of the certificate for the subject as issued by the Certificate Authority. |
| <b>SerialNumber</b>  | Specifies the serial number of the certificate for the subject as issued by the Certificate Authority.  |

| Name                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IssuerName</b>                    | Specifies the name of the issuer of the certificate for the subject as issued by the Certificate Authority.                                                                                                                                                                                                                                                                                                                                                        |
| <b>ValidStartPeriod</b>              | Specifies the start date of the validation period of the certificate for the subject as issued by the Certificate Authority.                                                                                                                                                                                                                                                                                                                                       |
| <b>ValidEndPeriod</b>                | Specifies the last date of the validation period of the certificate for the subject as issued by the Certificate Authority.                                                                                                                                                                                                                                                                                                                                        |
| <b>CertificateSignatureAlgorithm</b> | Specifies the algorithm used for the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.                                                                                                                                                                                                                                                                                                                            |
| <b>CertificateSignature</b>          | Specifies the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.                                                                                                                                                                                                                                                                                                                                                   |
| <b>Subject</b>                       | Specifies the details of the subject on its certificate as issued by Certificate Authority.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SubjectPublicKeyAlgorithm</b>     | Specifies the algorithm used to generate the public key of the subject for the certificate issued by the Certificate Authority.                                                                                                                                                                                                                                                                                                                                    |
| <b>SubjectPublicKey</b>              | Specifies the public key of the subject used for the Certificate Signing Request.                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>HasBasicConstraint</b>            | Specifies whether the certificate contains any basic certificate constraint or not.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>HasKeyUsage</b>                   | Specifies whether the certificate contains basic key usage constraint or not.                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>IsCa</b>                          | Specifies whether the certificate is a ca certificate or not.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>KeyUsage</b>                      | <p>Specifies the purpose of the key used in the certificate. It is represented in the form of bits as follows:</p> <ul style="list-style-type: none"> <li>• bit 0 - digitalSignature</li> <li>• bit 1 - nonRepudiation</li> <li>• bit 2 - keyEncipherment</li> <li>• bit 3 - dataEncipherment</li> <li>• bit 4 - keyAgreement</li> <li>• bit 5 - keyCertSign</li> <li>• bit 6 - cRLSign</li> <li>• bit 7 - encipherOnly</li> <li>• bit 8 - decipherOnly</li> </ul> |
| <b>Status</b>                        | Specifies the status of the certificate.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Installed</b>                     | Specifies whether the certificate is installed or not.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>CdpUrl</b>                        | Specifies the CDP URL present in the Digital Certificate Extensions field.                                                                                                                                                                                                                                                                                                                                                                                         |

| Name                                                                                     | Description                                                                                                                                           |
|------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OcspUrl</b>                                                                           | Specifies the OCSP URL present in the Digital Certificate AIA field.                                                                                  |
| <b>ExtendedKeyUsage</b>                                                                  | Indicates the purpose for which the key is used in addition to or in place of the basic purposes indicated in the key-usage field of the certificate. |
| <b>RevocationStatus</b><br><br><b>Note:</b> Exception: not supported on VSP 8600 Series. | Specifies the revocation status of the certificate.                                                                                                   |

### Install the Root CA Certificate

Use the following procedure to install the Root CA certificate obtained offline.

#### Note

This procedure applies to VSP 8600 Series only.

#### Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **System Log**.
3. Select **Root Certificate Table** tab.
4. Select **Insert**.
5. In the **Filename** field, enter the filename obtained offline from the CA.
6. In the **Action** field, select the action.
7. Select **Insert**.

#### Root Certificate Table field description

Use the data in the following table to use the **System Log > Root Certificate Table** tab.

| Name            | Description                                                                                                                                                                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Filename</b> | Specifies the certificate filename obtained offline from the Root Certificate Authority.                                                                                                                                                                                                                                                              |
| <b>Action</b>   | Specifies the action to be performed on Root CA. <ul style="list-style-type: none"> <li>• noaction: No action is performed.</li> <li>• install: Installs the Root CA certificate obtained offline.</li> <li>• uninstall: Uninstalls the Root CA certificate.</li> </ul> The system displays the Conversion Fail if the execution of the action fails. |

### View the Certificate Store

Use the following procedure to view the online, offline and root certificates in the local store.

## Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **Certificate**.
3. Click the **Certificate Store** tab.

## Certificate Store field descriptions

Use the data in the following table to use the **Certificate Store** tab.

| Name                                 | Description                                                                                                                             |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>CommonName</b>                    | Specifies the Common Name of the Certificate Authority issuing the Digital Certificate.                                                 |
| <b>Type</b>                          | Specifies the certificate type.                                                                                                         |
| <b>VersionNumber</b>                 | Specifies the version number of the certificate for the subject as issued by the Certificate Authority.                                 |
| <b>SerialNumber</b>                  | Specifies the serial number of the certificate for the subject as issued by the Certificate Authority.                                  |
| <b>IssuerName</b>                    | Specifies the name of the issuer of the certificate for the subject as issued by the Certificate Authority.                             |
| <b>ValidStartPeriod</b>              | Specifies the start date of the validation period of the certificate for the subject as issued by the Certificate Authority.            |
| <b>ValidEndPeriod</b>                | Specifies the last date of the validation period of the certificate for the subject as issued by the Certificate Authority.             |
| <b>CertificateSignatureAlgorithm</b> | Specifies the algorithm used for the signature of the issuer on the certificate for the subject as issued by the Certificate Authority. |
| <b>CertificateSignature</b>          | Specifies the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.                        |
| <b>Subject</b>                       | Specifies the details of the subject on its certificate as issued by Certificate Authority.                                             |
| <b>SubjectPublicKeyAlgorithm</b>     | Specifies the algorithm used to generate the subject's public key for the certificate issued by the Certificate Authority.              |
| <b>SubjectPublicKey</b>              | Specifies the public key of the subject used for Certificate Signing Request.                                                           |
| <b>HasBasicConstraint</b>            | Specifies whether certificate contains basic certificate constraint.                                                                    |
| <b>HasKeyUsage</b>                   | Specifies whether certificate contains basic key usage constraint.                                                                      |
| <b>IsCa</b>                          | Specifies if the certificate is a CA certificate or not.                                                                                |

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>KeyUsage</b>         | Specifies the purpose of the key used in the certificate. It is represented in the form of bits as follows: <ul style="list-style-type: none"> <li>• bit 0 - digitalSignature</li> <li>• bit 1 - nonRepudiation</li> <li>• bit 2 - keyEncipherment</li> <li>• bit 3 - dataEncipherment</li> <li>• bit 4 - keyAgreement</li> <li>• bit 5 - keyCertSign</li> <li>• bit 6 - cRLSign</li> <li>• bit 7 - encipherOnly</li> <li>• bit 8 - decipherOnly</li> </ul> |
| <b>Status</b>           | Specifies the status of the certificate.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Installed</b>        | Specifies whether the certificate is installed or not.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>CdpUrl</b>           | Specifies the CDP URL present in the Digital Certificate Extensions field.                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>OscpUrl</b>          | Specifies the OCSP URL present in the Digital Certificate AIA field.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>ExtendedKeyUsage</b> | Indicates the purpose for which the key is used in addition to or in place of the basic purposes indicated in the key-usage field of the certificate.                                                                                                                                                                                                                                                                                                       |
| <b>CaFileName</b>       | Specifies the certificate file obtained offline from the Root Certificate Authority.                                                                                                                                                                                                                                                                                                                                                                        |

## Configure TCP Keepalive and TCP Timestamp

### About This Task

TCP Keepalive configures the system TCP keepalive interval, probes, and time.

TCP Timestamp option (RFC 1323) allows TCP to determine the order in which the packets are sent. The TCP Timestamp provides protection against Wrapped Sequence numbers. However, it is possible to calculate the system uptime when the Timestamp option is enabled. The analysis of timestamp behaviour can provide information on the system identity, which poses security threats and can cause a potential attack.

The TCP Timestamp option is enabled by default. You can disable the timestamp to avoid any security risks.

#### Note

The configuration will be applied only to the new TCP connections and the existing connections are not affected. You must save the configuration and reboot the switch to apply the new configuration to all TCP connections.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.

2. Select **Chassis**.
3. Select the **System Control** tab.
4. Configure the TCP timestamp by performing one of the following actions:
  - a. Select **TcpTimestamp** to enable the TCP timestamp.
  - b. Clear **TcpTimestamp** to disable the TCP timestamp.
5. In **KeepaliveTime**, enter a number in seconds.
6. In **KeepaliveInterval**, enter a number in seconds.
7. In **KeepaliveProbes**, enter a number of probes.
8. Select **Apply**.

### **System Control** Field Descriptions

Use the data in the following table to use the **System Control** tab.

| Name                                                                                  | Description                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TcpTimestampEnable</b>                                                             | Enables or disables the TCP timestamp. The timestamp is enabled by default. The system displays the following warning message after you apply a new configuration:<br><b>Warning: Existing TCP connections won't be affected. A config save and reboot is required to apply this configuration for all TCP connections.</b> |
| <b>KeepaliveTime</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series.     | Specify the TCP keepalive time in seconds. The default is 60.                                                                                                                                                                                                                                                               |
| <b>KeepaliveInterval</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series. | Specify the TCP keepalive interval in seconds. The default is 10.                                                                                                                                                                                                                                                           |
| <b>KeepaliveProbes</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series.   | Specify the TCP keepalive probes. The default is 5.                                                                                                                                                                                                                                                                         |
| <b>PrivExecPasswordEnable</b>                                                         | Enables authentication to access Privileged EXEC CLI command mode. Authentication is disabled by default.                                                                                                                                                                                                                   |

## Enable Authentication for Privileged EXEC Command Mode

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **System Control** tab.

4. Select **PrivExecPasswordEnable**.

**Table 227: SLA Mon product support**

| Feature | Product         | Release introduced |
|---------|-----------------|--------------------|
| SLA Mon | VSP 4450 Series | VOSS 4.1           |
|         | VSP 4900 Series | VOSS 8.1           |
|         | VSP 7200 Series | VOSS 6.0           |
|         | VSP 7400 Series | VOSS 8.0           |
|         | VSP 8200 Series | VOSS 4.1           |
|         | VSP 8400 Series | VOSS 4.2           |
|         | VSP 8600 Series | VSP 8600 4.5       |
|         | XA1400 Series   | Not Supported      |

The switch supports the Service Level Agreement Monitor (SLA Mon) agent as part of the SLA Mon solution.

SLA Mon uses a server and agent relationship to perform end-to-end network Quality of Service (QoS) validation and to distribute monitoring devices. You can use the test results to target under-performing areas of the network for deeper analysis.

## SLA Mon Server and Agent

---

The switch supports the SLA Mon agent. You must have an Avaya Diagnostic Server with SLA Mon technology in your network to use the SLA Mon feature. Most of the SLA Mon configuration occurs on the server; configuration on the SLA Mon agent is minimal.

The SLA Mon server initiates the SLA Mon functions on one or more agents, and the agents run specific QoS tests at the request of the server. Agents can exchange packets between one another to conduct the QoS tests.

SLA Mon can monitor a number of key items, including the following:

- network paths
- Differentiated Services Code Point (DSCP) markings
- loss
- jitter
- delay

The following figure shows an SLA Mon implementation.

**Figure 237: SLA Monitor network**

An SLA Mon agent remains dormant until it receives a User Datagram Protocol (UDP) discovery packet from a server. The agent accepts the discovery packet to register with an SLA Mon server. If the registration process fails, the agent remains dormant until it receives another discovery packet.

An agent can attempt to register with an SLA Mon server once every 60 seconds. After a successful registration, the agent reregisters with the server every 6 hours to exchange a new encryption key.

An agent only accepts commands from the SLA Mon server to which it is registered. An agent can use alternate SLA Mon servers to provide backup for time-out and communication issues with the primary SLA Mon server.

**Note**

If you configure the SLA Mon agent address under an IP address for a VLAN or router, you must remove the SLA Mon address before you can remove the IP address for the VLAN or router.

## HA Support

SLA Monitor agent provides partial HA support. In HA mode, the agent startup and initialization occurs only on the master CP module. When reset occurs, the standby CP takes over the operations. Based on

the SLAMon agent operation-mode, the agent on the standby CP restarts the initialization and registration and gets registered only when the server sends a discovery. The user configuration updates on the Master CP is saved on the Standby CP and used when the reset occurs.

## QoS tests

---

SLA Mon uses two types of tests to determine QoS benchmarks:

- Real Time Protocol (RTP)

This test measures network performance — for example, jitter, delay, and loss — by injecting a short stream of UDP packets from source to destination (an SLA Mon agent).

- New Trace Route (NTR)

This test is similar to traceroute but also includes DSCP values at each hop in the path from the source to the destination. The destination does not need to be an SLA Mon agent.

## Limitations

---

SLA Mon agent communications are IPv4-based. Agent communications do not currently support IPv6.

## SLA Mon configuration using CLI

---

### Configure the SLA Mon Agent

Configure the SLA Mon agent to communicate with an SLA Mon with SLA Mon technology to perform Quality of Service (QoS) tests of the network.

#### Before You Begin

- To use the SLA Mon agent, you must have an Avaya Diagnostic Server with SLA Mon technology in your network.

#### About This Task

To configure the SLA Mon agent, you must assign an IP address and enable it. Remaining agent parameters are optional and you can operate the agent using the default values.

#### Note

- If you want to change SLA Mon parameters, you must first disable SLA Mon.

If you are configuring SLA Mon at the switch side for the first time, make sure you configure the SLA Mon agent address under an IP address for a VLAN or brouter, and you must remove the SLA Mon address before you can remove the IP address for the VLAN or brouter. To remove the SLA Mon address, first use the command **no slamon oper-mode enable**, followed by **slamon agent ip address 0.0.0.0**.

## Procedure

1. Enter Application Configuration mode:  

```
enable
```

```
configure terminal
```

```
application
```
2. Configure the SLA Mon agent IP address:

### Note

The SLA Mon Agent uses its own reserved Host IP address, reachable via the Switch VLAN IP interface of the same IP subnet.

- ```
slamon agent ip address {A.B.C.D} [vrf WORD<1-16>]
```
3. (Optional) Configure the UDP port for agent-server communication:

```
slamon agent port <0-65535>
```
 4. (Optional) Restrict which servers an agent can use:

```
slamon server ip address {A.B.C.D} [{A.B.C.D}]
```

```
slamon server port <0-65535>
```
 5. (Optional) Control the port used for Real Time Protocol (RTP) and New Trace Route (NTR) testing:

```
slamon agent-comm-port <0-65535>
```
 6. (Optional) Install a Secure Socket Layer (SSL) certificate for the agent:

```
slamon install-cert-file WORD<0-128>
```
 7. Enable the agent:

```
slamon oper-mode enable
```
 8. Verify the agent configuration:

```
show application slamon agent
```

Example

Configure the SLA Mon agent IP address. Configure the agent so that it only accepts registration packets from a specific server communicating on a specific port. Finally, enable the SLA Mon agent, and then verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#application
Switch:1(config-app)#slamon agent ip address 192.0.2.1
Switch:1(config-app)#slamon server ip address 192.0.2.24
Switch:1(config-app)#slamon server port 50011
Switch:1(config-app)#slamon oper-mode enable
Switch:1(config-app)#show application slamon agent

```

What to Do Next

If you have configured SLA Mon, but the agent does not function as expected, use the **show khi performance pthread** `[{slot[-slot]}[,...]]` command to verify that the slamon task is running.

If the SLA Mon agent is not running, use the commands **no slamon oper-mode enable** and **slamon oper-mode enable** to start the agent.

If the agent task is running, perform typical troubleshooting steps to verify agent accessibility:

- Verify IP address assignment and port use.
- Ping the server IP address.
- Verify the server configuration.
- Use the **trace level 192 <0-4>** command to observe the status of the SLA Mon software module.

Variable definitions

Use the data in the following table to use the **slamon** command.

Variable	Value
<i>agent-comm-port</i> <0-65535>	Configures the port used for RTP and NTR testing in agent-to-agent communication. The default port is 50012. If you configure this value to zero (0), the default port is used.
<i>agent ip address</i> {A.B.C.D}	Configures the SLA Mon agent IP address. You must configure the IP address before the agent can process received discovery packets from the server. The agent ip address is a mandatory parameter. The default value is 0.0.0.0.
<i>agent port</i> <0-65535>	Configures the UDP port for agent-server communication. The SLA Mon agent receives discovery packets on this port. The default is port 50011. The server must use the same port.
<i>install-cert-file</i>	Installs an SSL certificate. <i>WORD</i> <0-128> specifies the file name and path of the certificate to install. If you install a certificate on the SLA Mon agent, you must ensure a matching configuration on the server.
<i>oper-mode enable</i>	Enables the SLA Mon agent. The default is disabled. If you disable the agent, it does not respond to discovery packets from a server. If you disable the agent because of resource concerns, consider changing the server configuration instead, to alter the test frequency or duration, or the number of targets.
<i>server ip address</i> {A.B.C.D} [{A.B.C.D}]	Restricts the SLA Mon agent to use the server at this IP address only. The default is 0.0.0.0, which means the agent can register with any server. You can specify a secondary server as well.
<i>server port</i> <0-65535>	Restricts the SLA Mon agent to use this registration port only. The default is 0, which means the agent disregards the source port information in server traffic. The server must use the same port.
<i>vrf</i> <i>WORD</i> <1-16>	Specifies the name of a VRF.

SLA Mon Configuration using EDM

Configure the SLA Mon Agent

Configure the SLA Mon agent to communicate with an Avaya Diagnostic Server with SLA Mon technology to perform Quality of Service (QoS) tests of the network.

Before You Begin

- To use the SLA Mon agent, you must have an Avaya Diagnostic Server with SLA Mon technology in your network.

About This Task

To configure the SLA Mon agent, you must assign an IP address and enable it. Remaining agent parameters are optional and you can operate the agent using the default values.

Note

If you want to change SLA Mon parameters, you must first disable SLA Mon.

If you configure the SLA Mon agent address under an IP address for a VLAN or router, you must remove the SLA Mon address, before you can remove the IP address for the VLAN or router. To remove the SLA Mon address, first select disabled from the **Status** field, then configure the IP address in the **ConfiguredAgentAddr** field to 0.0.0.0.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Select **SLA Monitor**.
3. Select the **SLA Monitor** tab.
4. For the status, select **enabled**.
5. In the **ConfiguredAgentAddr** field, enter the SLA Mon agent IP address
6. Configure optional parameters as required.
7. Select **Apply**.

SLA Monitor field descriptions

Use the data in the following table to use the **SLA Monitor** tab.

Name	Description
Status	Enables or disables the SLA Mon agent. The default is disabled. If you disable the agent, it does not respond to discovery packets from a server. If you disable the agent because of resource concerns, consider changing the server configuration instead, to alter the test frequency or duration, or the number of targets.
CertFileInstallAction	Installs or uninstalls a Secure Sockets Layer (SSL) certificate file. The default is noAction.
CertFile	Specifies the file name and path of the SSL certificate. If you install a certificate on the SLA Mon agent, you must ensure a matching configuration on the server.
ConfiguredAgentAddrType	Specifies the address type of the agent: IPv4.
ConfiguredAgentAddr	Configures the agent IP address. You must configure the IP address before the agent can process received discovery packets from the server. The agent IP address is a mandatory parameter. The default value is 0.0.0.0.
ConfiguredAgentPort	Configures the UDP port for agent-server communication. The SLA Mon agent receives discovery packets on this port. The default is port 50011. The server must use the same port.
ConfiguredAgentVrfName	Specifies the name of a VRF.
ConfiguredServerAddrType	Specifies the address type of the server: IPv4.

Name	Description
ConfiguredServerAddr	Restricts the SLA Mon agent to use the server at this IP address only. If the default of 0.0.0.0 is used, then the SLA Mon agent can register with any server.
ConfiguredServerPort	Restricts the SLA Mon agent to use this registration port only. The default is 0, which means the agent disregards the source port information in server traffic. The server must use the same port.
ConfiguredAltServerAddrType	Specifies the address type of the secondary server: IPv4.
ConfiguredAltServerAddr	Configures a secondary server in the event that the primary server is unreachable.
ConfiguredAltServerPort	Restricts the SLA Mon agent to use this registration port on the secondary server only. The default is 0, which means the agent disregards the source port information in server traffic. The server must use the same port.
SupportedApps	Shows the type of testing supported: Real Time Protocol (RTP) and New Trace Route (NTR).
AgentAddressType	Shows the SLA Mon agent address type.
AgentAddress	Shows the configured SLA Mon agent IP address.
AgentPort	Shows the configured SLA Mon agent port.
RegisteredWithServer	Indicates if the SLA Mon agent has registered with a server.
RegisteredServerAddrType	Shows the address type for the registered server.
RegisteredServerAddr	Shows the IP address for the registered server.
RegisteredServerPort	Shows the port number for the registered server.
RegistrationTime	Shows the amount of time, in seconds, since the SLA Mon agent registered with the server.
AgentToAgentPort	Shows the port for SLA Mon agent-to-agent communication.
ConfiguredAgentToAgentPort	Configures the port used for RTP and NTR testing in SLA Mon agent-to-agent communication. The default port is 50012. If you configure this value as zero (0), the default port is used.

sFlow Fundamentals

sFlow monitors traffic in a data network. Use sFlow to monitor routers and switches in the network, and capture traffic statistics about those devices. sFlow uses sampling to provide scalability for network-

wide monitoring, and therefore applies to high speed networks. The switch sends the sampled data as a User Datagram Protocol (UDP) packet to the specified host and port.

**Note**

sFlow and Application Telemetry send mirrored packets from a common source to a common destination. sFlow sends samples directly to the destination, while Application Telemetry sends mirrored packets through a GRE tunnel, to the same destination. For more information, see [Common Elements Between sFlow and Application Telemetry](#) on page 333.

sFlow consists of the following:

- sFlow agent—Performs two types of sampling:
 - Flow samples: Flow sampling randomly samples an average of 1 out of n packets for each operation.
 - Counter samples: Counter sampling periodically polls and exports counters for a configured interface. This type of sampling uses a counter to determine if the packet is sampled. Each packet that an interface receives, and that a filter does not drop, reduces the counter by one. After the counter reaches zero, the sFlow agent takes a sample.

**Note**

Only generic interface counters and Ethernet interface counters are supported.

- sFlow datagrams—Supports both flow samples and counter samples. Datagrams can be sent from the front panel port or an out-of-band (OOB) port. Each datagram provides information about the sFlow version, the originating IP address of the device, a sequence number, the number of samples it contains, and one or more flow and/or counter samples.
- sFlow collector—Located on a central server and runs software that analyzes and reports on network traffic. Two sFlow collectors can be configured to be reachable over a management network or Shortest Path Bridging (SPB). The preferred network is SPB.

Limitations

- Application-specific integrated circuit (ASIC) or Software Development Kit (SDK) limitation—To avoid wobbling, the counter interval for sFlow is 20 seconds. Minor wobbling can still occur even after configuring the counter interval due to the interaction between the sFlow agent counter export schedule and the frequency with which the switch ASIC SDK copies and caches counters from the ASIC.
- sFlow supports a maximum of two collectors.
- UDP datagram size and the collector buffer are restricted to 1400 bytes. sFlow sends datagrams to the collector when the buffer reaches the 1400-byte capacity or after a timeout of one second is triggered. The collector buffer size cannot be modified.
- The switch supports IPv4 collector IP addresses.
- VLAN counters/statistics are not supported.
- sFlow can be enabled only on the front panel ports.
- You cannot configure the sampling limit. The sampling limit applies system-wide rather than on a per port basis. Sampling rates differ depending on the hardware platform so any sampled packets beyond the limit are dropped. For more information about feature support, see [VOSS Release Notes](#).
- The switch supports only ingress sampling. The switch does not support egress sampling.

- The switch does not support enabling sFlow on a link aggregation group (LAG) interface. However, you can enable sFlow on the member interfaces of a LAG.
- The sFlow collector can be reachable through the Management VRF, the Global Routing Table (GRT) or if your switch supports doing so, through a user created VRF (virtual routing and forwarding). If the sFlow collector is hosted in either the GRT or a user created VRF, SPB reachability only supports using Layer 2 VSN or IP shortcuts to access the collector. Layer 3 VSNs are not supported in accessing the collector when it is hosted in the GRT or a User created VRF.
-  **Note**
This restriction applies to the VSP 8600 Series only. Other platforms mirror copies to both destinations.

A packet can have only one mirror destination so you cannot configure sFlow and Port Mirroring on the same port.

- For Segmented Management Instance interfaces, sFlow is only supported on Segmented Management Instance OOB and on circuitless IP (CLIP) in GRT.

Configuration considerations

- If the sFlow collector has two network interface controller (NIC) cards, to avoid dropped sFlow datagrams that are a result of reverse path checks, you can add a route to the agent-ip address for the NIC card on which the sFlow datagrams are received.
- First preference is always given to either the GRT or management VRF to where the sFlow agent IP address is configured. For example, if you configure the sFlow agent IP address as part of GRT, the GRT route to the collector is given preference over the management VRF. If the management network hosts a collector with a collector IP address that is reachable over SPB as a result of redistributing direct routes on a peer Backbone Edge Bridge (BEB) or in situations where the GRT has a default route (0.0.0.0) and the collector route is in the local management VRF, first preference is given to the VRF where you have configured the sFlow agent IP address.
- For Segmented Management Instance interfaces, preference for sFlow collector reachability checks is determined by agent-ip configuration. If you configure the sFlow agent IP address to Segmented Management Instance OOB, preference for route lookup is given to the management VRF. If no route is found, lookup occurs in GRT.

If you do not configure the agent-ip address to Segmented Management Instance OOB, preference for route lookup is given to GRT. If no route is found, lookup occurs in the management VRF.

After you configure the sFlow agent on the network device that you want to monitor, the system collects flow samples or counter samples, and exports these traffic statistics as sFlow datagrams to the sFlow collector on a server or appliance.

For example, after the buffers reach capacity or a timeout is triggered, an sFlow datagram, which is a UDP packet, sends the measurement information to the sFlow collector buffers. The UDP payload contains the sFlow datagram.

The following figure shows the sFlow agent on various routers and switches with sFlow datagrams being sent to the sFlow collector.

Table 229: sFlow legend

Number	Description
1	sFlow collector
2	sFlow datagrams
3	sFlow agents

As a general rule, drop action occurs after sampling completes. However, in situations related to Layer 1 errors such as, MTU exceeded packets, the drop action occurs before sampling begins. For errors such as, frame too long, packets are dropped due to the size of the frame being greater than the interface MTU. In this situation, the packets are dropped before sampling begins so only counter polling occurs. To enable trace, use **line-card 1 trace level 232 <0-4>**.

Important

The defined sampling rate, an average of 1 out of n packets/operations does not provide a 100% accurate result, but it does provide a result with quantifiable accuracy.

sFlow Configuration Using CLI

Use sFlow to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure sFlow using CLI.

Configuring the agent-ip and Enabling sFlow Globally

Configure the sFlow agent IPv4 address, and then enable sFlow before the system can monitor and capture traffic statistics to send to an sFlow collector. By default, sFlow is globally disabled.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable the agent IPv4 address:
`sflow agent-ip {A.B.C.D}`
3. Enable sFlow:
`sflow enable`
4. Verify the global configuration:
`show sflow`

Example

Globally enable sFlow, and then verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow agent-ip 192.0.2.27
INFO: Please be aware that sFlow agent IP address is only supported in MGMT or GRT VRF.
Switch:1(config)#sflow enable
Switch:1(config)#show sflow
=====
                        sFlow Global Configuration
=====
Global State           : Enabled
Agent IP               : 192.0.2.27
```

What to Do Next

After you configure the agent-ip and globally enable sFlow, proceed to configuring the sFlow collector.

Variable Definitions

Use the data in the following table to use the **sflow agent-ip** command.

Variable	Definition
{A.B.C.D. }	Specifies the agent-ip address (IPv4). Note: For Segmented Management Instance interfaces, you must configure the agent-ip address to the IP address of the Segmented Management Instance interface on which datagrams egress.

Configuring an sFlow Collector

Configure an sFlow collector to determine the device to which the sFlow agent sends sFlow datagrams. You can configure up to two collectors for each interface slot in the chassis.

Before You Begin

- You must globally enable sFlow.

About This Task

The sFlow datagrams that the agent sends to the collector are not encrypted. Use a VLAN to create a secure measurement network to route sFlow datagrams.

To further protect the sFlow collector, configure it to accept only sFlow datagrams, or to check sequence numbers and verify source addresses.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Configure the collector information:

```
sflow collector <1-2> address {A.B.C.D} [Owner WORD <1-20>] [port <1-65535>] [timeout <1-65535>]
```
- Verify the collector configuration:

```
show sflow collector <1-2>
```

Example

Configure collector ID, and then verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow collector 1 address 192.0.2.26 owner sflow1 port 6343 timeout 497
Switch:1(config)#sflow collector 2 address 192.0.2.27 owner sflow2 port 6343 timeout 531
Switch:1(config)#show sflow collector
```

sFlow Collector Configuration Info					
Id	Owner	Collector-IP	Port	Timeout (secs)	Reachable via
1	sflow1	192.0.2.26	6343	497	192.0.2.15
2	sflow2	192.0.2.27	6343	531	192.0.2.16

All 2 out of 2 Total Num of sflow collector entries displayed

What to Do Next

After you configure the sFlow collector, configure the packet sampling rate to enable sFlow on a port or ports.

Variable Definitions

Use the data in the following table to use the **sflow collector** command.

Variable	Value
<code>collector <1-2></code>	Specifies the id to export sFlow datagrams to the collector id. Use the no operator to remove an sflow collector id and a collector name. no <code>sflow collector <1-2> owner WORD<1-20></code> To configure the default value, enter <code>default sflow collector <1-2></code>
<code>address {A.B.C.D. }</code>	Specifies the collector IP address. Use the no operator to remove an sflow collector address. no <code>sflow collector <1-2> address {A.B.C.D}</code>
<code>owner WORD<1-20></code>	Specifies the sFlow collector name.
<code>port <1-65535></code>	Specifies the destination UDP port. The default port is 6343. To configure the default value, enter <code>default sflow collector <1-2> port</code>
<code>timeout <1-65535></code>	Specifies the time remaining (in seconds) before the collector is released. The default timeout is 0, which means the timeout is not used and the collector sends data forever. To configure the default value, enter <code>default sflow collector <1-2> timeout</code>
<code>vrf WORD<1-16></code>	Specifies the name of the VRF used to reach the collector. Note: This parameter is not supported on all hardware platforms.

Configuring the Packet Sampling Rate

Configure the packet sampling rate at port level to determine how many packets the system counts before it takes a sample. Configuring the sampling rate enables sFlow on the port.

Before You Begin

- You must globally enable sFlow.

About This Task

If you configure a conservative sampling rate to prevent overloading the sFlow agent, the result will reflect high values that do not reflect typical traffic levels.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the collector id:

```
sflow collector <1-2>
```

3. Configure the sampling rate:

```
sflow sampling-rate <1024-1000000>
```

4. Verify the configuration:

```
show sflow interface {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Example

Configure sampling rates for ports 2/1, 2/2, 2/3, and 2/4.

```
Switch:1(config-if)#interface gigabitethernet 2/1,2/2
Switch:1(config-if)#sflow collector 1
Switch:1(config-if)#sflow sampling-rate 10000
Switch:1(config-if)#interface gigabitethernet 2/3
Switch:1(config-if)#sflow collector 2
Switch:1(config-if)#sflow sampling-rate 8192
Switch:1(config-if)#interface gigabitethernet 2/4
Switch:1(config-if)#sflow collector 2
Switch:1(config-if)#sflow sampling-rate 12001
Switch:1(config-if)#show sflow interface enabled
```

sFlow Port Configuration Info

Port	Packet-Sample-Rate	Max-Header-Size	Counter-interval (in secs)	Collector-list
2/1	10000	128	0	1
2/2	10000	128	0	1
2/3	8192	128	0	2
2/4	12001	128	0	2

All 4 out of 4 Total Num of sflow port entries displayed

Variable Definitions

Use the data in the following table to use the **sflow sampling-rate** and **show sflow interface** commands.

Variable	Value
<1024-1000000>	Configures the packet sampling rate on a port. The default value is 0 (disabled). To configure the default value, enter <code>default sflow sampling-rate</code> .
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring sFlow Maximum Header Size

Configure the maximum header size on a single port or multiple ports.

Before You Begin

- You must globally enable sFlow.

Procedure

- Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure the maximum-header size:

```
sflow max-header-size <64-256>
```

- Verify the configuration:

```
show sflow interface {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Example

For ports 1/1 to 1/10, configure the maximum header size, and then verify the configuration.

```
Switch:1(config-if)#interface gigabitethernet 1/1-1/10
Switch:1(config-if)#sflow max-header-size 255
Switch:1(config-if)#show sflow interface 1/1-1/10
```

```
=====
sFlow Port Configuration Info
```

Port	Packet-Sample-Rate	Max-Header-Size	Counter-interval (in secs)	Collector-list
1/1	0	255	525	1,2
1/2	0	255	525	1,2
1/3	0	255	525	1,2
1/4	0	255	525	1,2
1/5	0	255	525	1,2
1/6	0	255	525	1,2
1/7	0	255	525	1,2
1/8	0	255	525	1,2
1/9	0	255	525	1,2
1/10	0	255	525	1,2

Variable Definitions

Use the data in the following table to use the **max-header-size** command.

Variable	Value
<64-256>	Identifies the maximum number of bytes to be copied from the sampled packet. Default 128 bytes.

Configuring the Counter Sampling Interval

Configure the counter sampling interval values at port level to determine how often the sFlow agent polls and exports counters for a configured interface.

Before You Begin

- You must globally enable sFlow.

Procedure

- Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure the counter sampling interval:

```
sflow counter-interval <1-3600>
```

- Verify the configuration:

```
show sflow interface {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Example

Verify all slots use the default polling-interval configuration.

```
Switch:1(config-if)#sflow counter-interval 525
Switch:1(config-if)#show sflow interface 1/1-1/10
```

```

Variable Definitions

Use the data in the following table to use the **sflow counter-interval** and **show sflow interface** commands.

Variable	Value
<1-3600>	Specifies the polling interval for a slot. Default value is 0 (disabled).
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing sFlow Statistics

Display statistics for sFlow datagrams.

Before You Begin

- You must globally enable sFlow.

Procedure

- To enter User EXEC mode, log on to the switch.
- View sFlow statistics:

```
show sflow statistics [collector <1-2>]
```

Example

```
Switch:1>show sflow statistics

=====
sFlow Statistics Info
=====
Collector-id          sFlow-Datagrams
-----
1                    1001
2                    0
-----

sFlow Configuration Using EDM

Use sFlow to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure sFlow using EDM.

Enabling sFlow and Configuring the Agent IP Address

Use this procedure to enable sFlow and configure the sFlow agent IP address so the system can send packets to an sFlow collector.

About This Task

Application Telemetry and sFlow both use the **sFlow Globals** tab.

Before You Begin

You must enable sFlow before you enable Application Telemetry.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Sflow**.
3. Click the **Globals** tab.
4. Check **AdminEnable** to enable sFlow.
5. In the **AgentAddress** field, enter the agent IPv4 address.
6. Click **Apply**.

What to Do Next

After you configure the agent IP address and globally enable sFlow, proceed to configuring the sFlow collector.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AdminEnable	Shows whether sFlow is enabled. By default, the check box is not enabled.
AgentAddressType	Specifies the collector IP address type. Only IPv4 collector addresses are supported.
AgentAddress	Specifies the agent IP address of an interface that exists in the local management VRF or GRT. Note: For Segmented Management Instance interfaces, you must configure AgentAddress to the IP address of the Segmented Management Instance interface on which datagrams egress.

Configuring an sFlow Collector

Use this procedure to configure the device used as either an sFlow Collector or an Application Telemetry Analytics Engine. This device is where the agent sends sFlow datagrams and Application Telemetry packets for analysis.

sFlow supports up to two collectors for each interface slot in the chassis. However, Application Telemetry supports Collector 1 only.

Note

- You can configure two Collectors, but Application Telemetry uses Collector 1 only. You must configure Collector 1 before you enable Application Telemetry.
- Before you change or remove Collector 1, you must disable Application Telemetry.
- By default, Application Telemetry is globally disabled.

About This Task

Tip

You can configure the **Collector** tab to select only the columns you are interested in seeing. By default, the system does not display **AddressType** option. To make the **AddressType** column visible, click the down arrow on one of the menu headings, navigate to **Columns**, and select the **AddressType** check box.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Sflow**.
3. Click the **Collector** tab.
4. Configure the fields for Collector 1.
5. Click **Apply**.

What to Do Next

After you configure the sFlow collector, configure the packet sampling rate to enable sFlow on a port or ports.

Collector Field Descriptions

Use the data in the following table to use the **Collector** tab.

Name	Description
Index	Shows collector 1 and collector 2. The switch exports sFlow and Application Telemetry traffic to the collector.
Owner	Specifies the sFlow collector name. The string length is 1 to 20 characters.
Timeout	Specifies the time remaining (in seconds) before the collector is released and stops sampling. The default timeout is 0, which means the timeout is not used and the switch sends data forever.
Address	Specifies the collector IP address. If the default address is set to 0.0.0.0, no traffic is sent.
Port	Specifies the destination port. The default port is 6343.

Name	Description
IsReachable	Shows whether the sFlow collector is reachable.
NextHop	If the collector is reachable, shows the name or address of the next hop through which the collector is reachable.

Configure the Packet Samples and Counter Samples

Configure the packet sampling rate to determine how many packets the system counts before it takes a sample and configure the counter sampling interval to determine how often the sFlow agent polls and exports counters for a configured interface. You can also configure the maximum header size on a single port or multiple ports.

Configuring the sampling rate enables sFlow on the port.

Before You Begin

- You must globally enable sFlow.

About This Task

Tip

You can configure the **Interfaces** tab to select only the columns you are interested in seeing. By default, the system does not display **Instances** option. To make the **Instances** column visible, click the down arrow on one of the menu headings, navigate to **Columns**, and select the **Instances** check box.

Procedure

- In the navigation pane, expand **Configuration > Serviceability**.
- Select **Sflow**.
- Select the **Interfaces** tab.
- In the **DataSource** column, navigate to the slot and port where you want to configure sFlow, and configure the following:
 - PacketSamplingRate—Double-click the field, and enter a sampling rate value.
 - MaximumHeaderSize—Double-click the field, and enter a maximum header size value.
 - Interval—Double-click the field, and enter the counter sampling interval value in seconds.
- Select **Apply**.

Interfaces Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
DataSource	Shows the slot and port for which traffic statistics are collected. The field name is different on different hardware platforms.
Instance	Shows the number of sFlow samplers associated with a specific datasource. Note: You must select this field for it to display on the Interfaces tab.
Collectors	Shows the collectors that have been configured for the sFlow agent to send sFlow datagrams. Two collectors are supported. The field name is different on different hardware platforms.
PacketSamplingRate	Specifies the packet sampling rate to determine how many packets the system counts before it take a sample. The default is 0.
MaximumHeaderSize	Specifies the maximum header size on a single port or multiple ports. The default is 128 bytes.
Interval	Specifies the counter sampling interval to determine how often the sFlow agent polls and exports counters for a configured interface. The default is 0.

Displaying sFlow Statistics

Use the following procedure to display (true) sFlow statistics. Statistics for sFlow are cleared (false), by default.

About This Task

Tip

You can configure the **Stats** tab to select only the columns you are interested in seeing. The system displays all the options, by default. To hide a column, click the down arrow on one of the menu headings, navigate to **Columns**, and select the check box for the column you want to hide.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **sFlow**.
3. Click the **Stats** tab.
4. In the **ClearStats** column, double-click the field, and select true or false from the list.
5. Click **Apply**.

Stats Field Descriptions

Use the data in the following table to use the **Statistics** tab.

Name	Description
Index	Shows sFlow collector ID 1 and 2
DatagramCount	Shows the number of datagrams that have been sent to the collector.
ClearStats	Shows whether the sFlow statistics are displayed (true) or cleared (false). The default is false.

Configuring counter polling

About This Task

Use this procedure to configure counter polling using the EDM.

This tab is not supported on all hardware platforms.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **sFlow**.
3. Click the **Counter Polling** tab.
4. In the **Index** column, navigate to the slot and port where you want to configure sFlow.
5. Double-click the **Interval** field and enter a value in seconds.
6. Click **Apply**.

Counter Polling Field Descriptions

Use the data in the following table to use the **Counter Polling** tab.

Name	Description
Index	Identifies the source of the data for counter polling.
Receiver	The sFlow receiver associated with the counter polling.
Interval	The maximum number of seconds between successive samples of the counters associated with this data source. A sampling interval of 0 disables counter sampling.

	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 6.2
	XA1400 Series	Not Supported

You can use the Simple Network Management Protocol (SNMP) to remotely collect management data and configure devices.

An SNMP agent is a software process that monitors the UDP port 161 for SNMP messages. Each SNMP message sent to the agent contains a list of management objects to retrieve or modify.

SNMPv3

The SNMP version 3 (v3) is the third version of the Internet Standard Management Framework and is derived from and builds upon both the original Internet Standard Management Framework SNMP version 1 (v1) and the second Internet Standard Management Framework SNMP version 2 (v2).

The SNMPv3 is not a stand-alone replacement for SNMPv1 or SNMPv2. The SNMPv3 defines security capabilities you must use in conjunction with SNMPv2 (preferred) or SNMPv1. The following figure shows how SNMPv3 specifies a user-based security model (USM) that uses a payload of either an SNMPv1 or an SNMPv2 Protocol Data Unit (PDU).

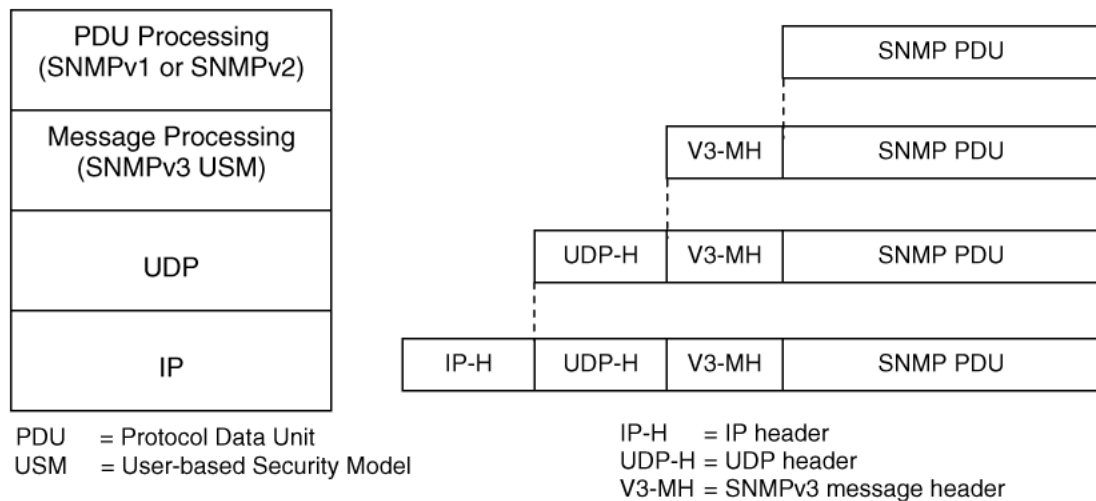

Figure 238: SNMPv3 USM

SNMPv3 is an SNMP framework that supplements SNMPv2 by supporting the following:

- New SNMP message formats
- Security for messages
- Access control
- Remote configuration of SNMP parameters

The recipient of a message can use authentication within the USM to verify the message sender and to detect if the message is altered. According to RFC2574, if you use authentication, the USM checks the entire message for integrity.

An SNMP entity is an implementation of this architecture. Each SNMP entity consists of an SNMP engine and one or more associated applications.

SNMP Engine

An SNMP engine provides services for sending and receiving messages, authenticating and encrypting messages, and controlling access to managed objects. A one-to-one association exists between an SNMP engine and the SNMP entity, which contains the SNMP engine.

EngineID

Within an administrative domain, an EngineID is the unique identifier of an SNMP engine. Because there is a one-to-one association between SNMP engines and SNMP entities, the ID also uniquely and unambiguously identifies the SNMP entity within that administrative domain. The system generates an EngineID during the startup process. The SNMP engine contains a:

- [Dispatcher](#) on page 3106.
- [Message Processing Subsystem](#) on page 3106.
- [Security Subsystem](#) on page 3106.
- [Access Control Subsystem](#) on page 3107.

Automatic discovery of a Remote EngineID is performed so that Inform messages are populated properly and not rejected by the SNMP Manager. This automatic discovery is performed by the switch using a request to the Manager for a response that contains the EngineID. The switch then uses this Remote EngineID value to populate all subsequent Inform messages.

Dispatcher

The dispatcher is part of an SNMP engine. You can use the dispatcher for concurrent support of multiple versions of SNMP messages in the SNMP engine through the following ways:

- To send and receive SNMP messages to and from the network.
- To determine the SNMP message version and interact with the corresponding message processing model.
- To provide an abstract interface to SNMP applications for delivery of a PDU to an application.
- To provide an abstract interface for SNMP applications to send a PDU to a remote SNMP entity.

Message Processing Subsystem

The message processing subsystem prepares messages for sending and extracts data from received messages. The subsystem can contain multiple message processing models.

Security Subsystem

The security subsystem provides the following features:

- Authentication
- Privacy
- Security

Authentication

You can use authentication within the SNMPv3 to verify the message sender and whether the message is altered. If you use authentication, the integrity of the message is verified. The supported SNMPv3 authentication protocols are HMAC-MD5 and HMAC-SHA-96. By default, the switch uses HMAC-SHA1-96 with 160-bit key length.

Privacy

SNMPv3 is an encryption protocol for privacy. Only the data portion of a message is encrypted; the header and the security parameters are not. The privacy protocol that SNMPv3 supports is CBC-DES Symmetric Encryption Protocol and Advanced Encryption Standard (AES).

Security

The SNMPv3 security protects against:

- Modification of information—protects against altering information in transit.
- Masquerade—protects against an unauthorized entity assuming the identity of an authorized entity.
- Message stream modification—protects against delaying or replaying messages.
- Disclosure—protects against eavesdropping.

The SNMPv3 security also offers:

- Discovery procedure—finds the EngineID of an SNMP entity for a given transport address or transport endpoint address.
- Time synchronization procedure—facilitates authenticated communication between entities

The SNMPv3 does not protect against the following:

- Denial-of-service—prevention of exchanges between manager and agent.
- Traffic analysis—general pattern of traffic between managers and agents.

Access Control Subsystem

SNMPv3 provides a group option for access policies.

The access policy feature in the switch determines the access level for the users connecting to the device with different services like File Transfer Protocol (FTP), Trivial FTP (TFTP), Telnet, and rlogin. The system access policy feature is based on the user access levels and network address. This feature covers services, such as TFTP, HTTP, SSH, rlogin, and SNMP. However, with the SNMPv3 engine, the community names do not map to an access level. The View-based Access Control Model (VACM) determines the access privileges.

Note

Rlogin is only supported on VSP 8600 Series.

Use the configuration feature to specify groups for the SNMP access policy. You can use the access policy services to cover SNMP. Because the access restriction is based on groups defined through the VACM, the synchronization is made using the SNMPv3 VACM configuration. The administrator uses this feature to create SNMP users (USM community) and associate them to groups. You can configure the access policy for each group and network.

The following are feature specifications for the group options:

- After you enable SNMP service, this policy covers all users associated with the groups configured under the access policy. The access privileges are based on access allow or deny. If you select allow, the VACM configuration determines the management information base (MIB)-views for access.

- The SNMP service is disabled by default for all access policies.
- The access level configured under **access-policy policy <id>** does not affect SNMP service. The VACM configuration determines the SNMP access rights.

User-Based Security Model

In a USM system, the security model uses a defined set of user identities for any authorized user on a particular SNMP engine. A user with authority on one SNMP engine must also have authorization on all SNMP engines with which the original SNMP engine communicates.

The USM provides the following levels of communication:

- NoAuthNoPriv—communication without authentication and privacy.
- AuthNoPriv—communication with authentication and without privacy.
- AuthPriv—communication with authentication and privacy.

The following figure shows the relationship between USM and VACM.

Figure 239: USM association with VACM

View-Based Access Control

View-based Access Control Model (VACM) provides group access, group security levels, and context based on a predefined subset of MIB objects. These MIB objects define a set of managed objects and instances.

VACM is the standard access control mechanism for SNMPv3, and it provides:

- Authorization service to control access to MIB objects at the PDU level.

- Alternative access control subsystems.

The access is based on principal, security level, MIB context, object instance, and type of access requested (read or write). You can use the VACM MIB to define the policy and control remote management.

SNMPv3 Encryption

A user-based security port for SNMPv3 is defined as a security subsystem within an SNMP engine. The switch USM uses HMAC-MD5-96 and HMAC-SHA-96 as the authentication protocols, and CBC-DES as the privacy protocol. Use USM to use other protocols instead of, or concurrently with, these protocols. CFB128-AES-128, an AES-based Symmetric Encryption Protocol, is an alternative privacy protocol for the USM.

The AES standard is the current encryption standard, Federal Information Processing Standard 140-2 (FIPS 140-2), intended to be used by the U.S. Government organizations to protect sensitive information. The AES standard is also becoming a global standard for commercial software and hardware that uses encryption or other security features.

The AES-Based Symmetric Encryption Protocol

This symmetric encryption protocol provides support for data confidentiality. The system encrypts the designated portion of the SNMP message and includes it as part of the transmitted message.

The USM specifies that the scoped PDU is the portion of the message that requires encryption. An SNMP engine that can legitimately originate messages on behalf of the appropriate user shares a secret value, in combination with a timeliness value and a 64-bit integer, used to create the (localized) encryption/decryption key and the initialization vector.

The AES Encryption Key and Initialization Vector

The AES encryption key uses the first 128 bits of the localized key. The 128-bit Initialization Vector (IV) is the combination of the authoritative SNMP engine 32-bit `snmpEngineBoot`, the SNMP engine 32-bit `snmpEngineTime`, and a local 64-bit integer. The system initializes the 64-bit integer to a pseudo-random value at startup time.

Data Encryption

The switch handles data encryption in the following manner:

1. The system treats data as a sequence of octets.
2. The system divides the plaintext into 128-bit blocks.

The first input block is the IV, and the forward cipher operation is applied to the IV to produce the first output block.

3. The system produces the first cipher text block by executing an exclusive-OR function on the first plaintext block with the first output block.
4. The system uses the cipher text block as the input block for the subsequent forward cipher operation.

5. The system repeats the forward cipher operation with the successive input blocks until it produces a cipher text segment from every plaintext segment.
6. The system produces the last cipher text block by executing an exclusive-OR function on the last plaintext segment of r bits (r is less than or equal to 128) with the segment of the r most significant bits of the last output block.

Data Decryption

The switch handles data decryption in the following manner:

1. In CFB decryption, the IV is the first input block, the system uses the first cipher text for the second input block, the second cipher text for the third input block, and this continues until the system runs out of blocks to decrypt.
2. The system applies the forward cipher function to each input block to produce the output blocks.
3. The system passes the output blocks through an exclusive-OR function with the corresponding cipher text blocks to recover the plaintext blocks.
4. The system sends the last cipher text block (whose size r is less than or equal to 128) through an exclusive-OR function with the segment of the r most significant bits of the last output block to recover the last plaintext block of r bits.

Trap Notifications

You configure traps by creating SNMP trap notifications, creating a target address to which you want to send the notifications, and specifying target parameters. For more information about how to configure trap notifications, see [Logs and Traps](#) on page 2260.

SNMP Community Strings

For security reasons for SNMPv1 and SNMPv2, the SNMP agent validates each request from an SNMP manager before responding to the request by verifying that the manager belongs to a valid SNMP community. An SNMP community is a logical relationship between an SNMP agent and one or more SNMP managers (the manager software implements the protocols used to exchange data with SNMP agents). You define communities locally at the agent level.

The agent establishes one community for each combination of authentication and access control characteristics that you choose. You assign each community a unique name (community string), and all members of a community have the same access privileges, either read-only or read-write:

- Read-only: members can view configuration and performance information.
- Read-write: members can view configuration and performance information, and change the configuration.

By defining a community, an agent limits access to its MIB to a selected set of management stations. By using more than one community, the agent can provide different levels of MIB access to different management stations.

SNMP community strings are used when a user logs on to the device over SNMP, for example, using an SNMP-based management software. You set the SNMP community strings using CLI . If you have read/write/all access authority, you can modify the SNMP community strings for access to the device through Enterprise Device Manager (EDM).

You are provided with community strings for SNMPv1 and SNMPv2. If you want to use SNMPv3 only, you must disable SNMPv1 and SNMPv2 access by deleting the default community string entries and create the SNMPv3 user and group.[SNMPv3](#).

Note

If you enable enhanced secure mode, the switch does not support the default SNMPv1 and default SNMPv2 community strings, and default SNMPv3 user name. The individual in the administrator access level role can configure a non-default value for the community strings, and the switch can continue to support SNMPv1 and SNMPv2. The individual in the administrator access level role can also configure a non-default value for the SNMPv3 user name and the switch can continue to support SNMPv3.

If you disable enhanced secure mode, the SNMPv1 and SNMPv2 support for community strings remains the same, and the default SNMPv3 user name remains the same. Enhanced secure mode is disabled by default.

For more information on enhanced secure mode, see [Enhanced Secure Mode](#) on page 3317.

The following table lists the default community strings for SNMPv1 and SNMPv2.

VRF	Default community string	Access
GlobalRouter VRF	public	Read access
	private	Write access
ManagementRouter VRF	public:512	Read access
	private:512	Write access

Community strings are encrypted using the AES encryption algorithm. The system does not display community strings on the device and are not stored in the configuration file.

Caution Security risk

For security reasons, as a best practice, set the community strings to values other than the factory defaults.

The switch handles community string encryption in the following manner:

- When the device starts up, community strings are restored from the hidden file.
- When the SNMP community strings are modified, the modifications are updated to the hidden file.
- Stale snmp-server community entries for different VRFs that the system displays it after reboot with no VRFs . On an node with any valid config file saved with more than the default vrf0 , snmp_community entries for that VRF are created and maintained in a separate txt file, snmp_comm.txt, on every boot. The node reads this file and updates the snmp communities available on the node. As a result for a boot with config having no VRFs, you may still see snmp_community entries for VRFs other than the globalRouter vrf0.

Hsecure with SNMP

If you enable hsecure, the system disables SNMPv1, SNMPv2 and SNMPv3. If you want to use SNMP, you must use the command **no boot config flag block-snmp** to re-enable SNMP.

SNMPv3 support for VRF

Use Virtual Router Forwarding (VRF) to offer networking capabilities and traffic isolation to customers that operate over the same node (switch). Each virtual router emulates the behavior of a dedicated hardware router and is treated by the network as a separate physical router. You can use VRF Lite to perform the functions of many routers using a single router running VRF Lite. This substantially reduces the cost associated with providing routing and traffic isolation for multiple clients.

SNMPv3 Remote Engine ID Discovery

The following sections contain information about SNMPv3 remote engine ID discovery.

Traps and Informs

SNMPv3 supports two types of notifications, traps and informs.

Traps are unacknowledged notifications sent by agents to managers. Traps are generated by the agent, and the authoritative SNMP engine for a trap packet is the sending SNMP agent. Because the generator of the message and the authoritative engine are the same, there is no need for the SNMPv3 discovery process.

Informs are acknowledged notifications. An agent sends an inform notification and waits for acknowledgement. If the agent does not receive the acknowledgement within the configured timeout period, it resends the inform notification. The agent continues to resend the inform notification until a reply is received or until the maximum retry value is reached. For information about configuring an inform timeout period or configuring a maximum retry value, see [Configure SNMP settings](#) on page 3114.

Remote Engine ID Discovery

Inform packets must contain the management (remote) SNMP engine ID. The agent generates informs, but the authoritative SNMP engine is the manager. To generate valid inform packets and avoid manual configuration of the manager SNMP engine ID, the agent must discover the SNMP engine ID of the manager.

The agent discovers the management SNMP Engine ID by sending a probe message to the manager. The manager response to the probe message is a report message that contains the SNMP engine ID of the authoritative SNMP engine. The agent stores the SNMP engine ID received from the manager in the engine table, and sends inform packets using the manager SNMP engine ID. If the manager SNMP engine ID changes, the discovery process updates the manager SNMP engine ID value in the engine table.

Note

Remote engine ID discovery cannot use SNMP config files created in releases prior to VOSS 8.1. Config files must be saved in Release VOSS 8.1 or higher in order to be compatible with remote engine ID discovery.

SNMP configuration using CLI

Configure the SNMP engine to provide services to send and receive messages, authenticate and encrypt messages, and control access to managed objects. A one-to-one association exists between an SNMP engine and the SNMP entity.

- To perform the procedures in this section, you must log on to the Global Configuration mode in CLI. For more information about how to use CLI, see [CLI Procedures](#) on page 251.

This task flow shows you the sequence of procedures you perform to configure basic elements of SNMP when using CLI.

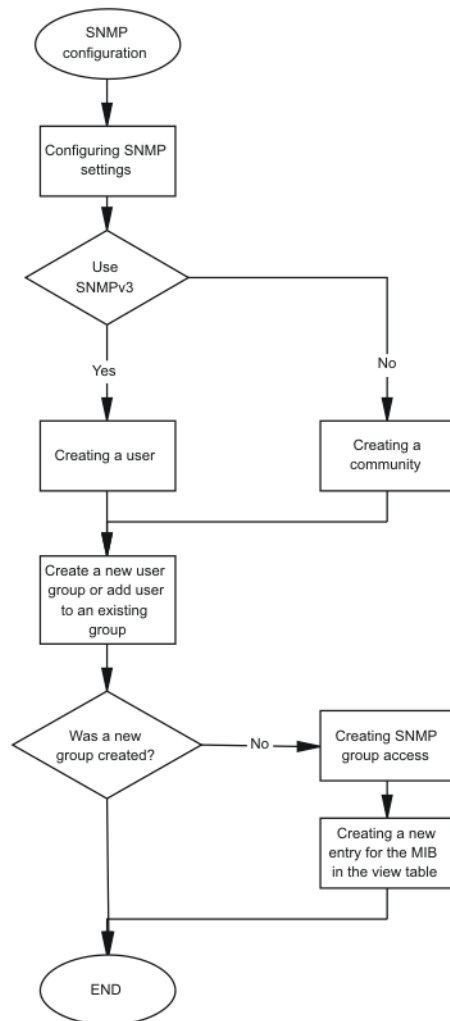

Figure 240: SNMP configuration procedures

Configure SNMP settings

Configure Simple Network Management Protocol (SNMP) to define or modify the SNMP settings, and specify the security level for SNMP communications.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable the generation of authentication traps:

```
snmp-server authentication-trap enable
```

3. Configure the contact information for the system:

```
snmp-server contact WORD<0-255>
```

4. Configure the SNMP and IP sender flag to the same value:

Note

This step only applies to VSP 8600 Series.

```
snmp-server force-iphdr-sender enable
```

5. Send the configured source address (sender IP) as the sender network in the notification message:

Note

This step only applies to VSP 8600 Series.

```
snmp-server force-trap-sender enable
```

6. Create an SNMPv1 server host:

```
snmp-server host WORD<1-256> [port <1-65535>] v1 WORD<1-32> [filter WORD<1-32>]
```

7. Create an SNMPv2 server host:

```
snmp-server host WORD<1-256> [port <1-65535>] v2c WORD<1-32> [inform] [timeout <1-2147483647>] [retries <0-255>] [mms <0-2147483647>]] [filter WORD<1-32>]
```

8. Create an SNMPv3 server host:

```
snmp-server host WORD<1-256> [port <1-65535>] v3 {noAuthNoPriv|authNoPriv|authPriv WORD<1-32> [inform] [timeout <1-2147483647>] [retries <0-255>]] [filter WORD<1-32>]
```

9. Configure the system location:

```
snmp-server location WORD<0-255>
```

10. Enable login-success traps:

```
snmp-server login-success-trap enable
```

11. Configure the system name:

```
snmp-server name WORD<0-255>
```

12. Create a new entry in the notify filter table:

```
snmp-server notify-filter WORD<1-32> WORD<1-32>
```

13. Configure the SNMP trap receiver and source IP addresses:

Note

This step only applies to VSP 8600 Series.

```
snmp-server sender-ip {A.B.C.D} {A.B.C.D}
```

Example

Enable the generation of SNMP traps. Configure the contact information for the system. Configure hosts to receive SNMP notifications:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server authentication-trap enable
Switch:1(config)#snmp-server contact xxxx@company.com
Switch:1(config)#snmp-server host 192.0.2.16 port 1 v1 SNMPv1 filter SNMPfilterv1
```

Configure the SNMP and IP sender flag to the same value.

Note

Exception: configuring the SNMP and IP sender flag to the same value only applies to VSP 8600 Series.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server force-iphdr-sender enable
```

Variable Definitions

The following table defines parameters for the `snmp-server` command.

Variable	Value
<code>authentication-trap {enable}</code>	Enables generation of SNMP server authentication traps.
<code>contact WORD<0-255></code>	Changes the sysContact information for the switch. WORD<0-255> is an ASCII string from 0-255 characters (for example, a phone extension or email address).

Variable	Value
<pre>host WORD<1-256> [port <1-65535>] {v1 WORD<1-32> v2c WORD<1-32> [inform] [timeout <1-2147483647>] [retries <0-255>][mms <0-2147483647>]} v3 {noAuthPriv authNoPriv authPriv} WORD<1-32> [inform [timeout <1-2147483647>][retries <0-255>]]} [filter WORD<1-32>]</pre>	<p>Configures hosts to receive SNMP notifications.</p> <ul style="list-style-type: none"> <i>host</i> WORD<1-256> specifies the IPv4 or IPv6 host address <i>port</i> <1-65535> specifies the port number <i>v1</i> WORD<1-32> specifies the SNMPv1 security name <i>v2c</i> WORD<1-32> specifies the SNMPv2 security name <i>inform</i> specifies the notify type <i>timeout</i> <1-2147483647> specifies the timeout value <i>retries</i> <0-255> specifies the number of retries <i>mms</i> <1-2147483647> specifies the maximum message size <i>v3</i> specifies SNMPv3 <i>noAuthPriv</i> <i>authNoPriv</i> <i>authPriv</i> specifies the security level <i>WORD</i><1-32> specifies the user name <i>filter</i> specifies a filter profile name
<pre>location WORD<0-255></pre>	<p>Configures the sysLocation information for the system. <WORD 0-255> is an ASCII string from 0-255 characters.</p>
<pre>login-success-trap {enable}</pre>	<p>Enables generation of SNMP server login-success traps.</p>
<pre>name WORD<0-255></pre>	<p>Configures the sysName information for the system. <WORD 0-255> is an ASCII string from 0-255 characters.</p>
<pre>notify-filter WORD<1-32> WORD<1-32></pre>	<p>Creates a new entry in the notify filter table. The first WORD<1-32> specifies the filter profile name, and the second WORD<1-32> specifies the subtree object identifier (OID).</p>
<pre>sender-ip {A.B.C.D} {A.B.C.D}</pre> <p>Note: Exception: only supported on VSP 8600 Series.</p>	<p>The first {A.B.C.D} configures the SNMP trap receiver and source IP addresses. Specify the IP address of the destination SNMP server that receives the SNMP trap notification in the first IP address.</p> <p>The second {A.B.C.D} specifies the source IP address of the SNMP trap notification packet that is transmitted in the second IP address. If you set this to 0.0.0.0, the system uses the IP address of the local interface that is closest (from an IP routing table perspective) to the destination SNMP server.</p>

Creating a user

Create a new user in the USM table to authorize a user on a particular SNMP engine.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a user on a remote system:

```
snmp-server user engine-id WORD<16-97> WORD<1-32> {md5 | sha } [aes |
des ]
```

3. Enter and confirm your password.

4. Create a user on the local system:

```
snmp-server user WORD<1-32> [notify-view WORD<0-32>] [read-view
WORD<0-32>] [write-view WORD<0-32>] {md5 | sha} [aes | des ]
```

5. Enter and confirm your password.

6. Add the user to a group:

```
snmp-server user WORD<1-32> group WORD<1-32> {md5 | sha} [aes | des ]
```

7. Enter and confirm your password.

8. Verify the configuration:

```
show snmp-server user
```

Example

Create a user named test1 on a remote system with MD5:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server user engine-id 0x80:00:08:E0:03:10:CD:AE:6B:D0:00 test1 md5
aes
Enter the authentication protocol password : *****
Re-enter the authentication protocol password : *****
Enter the privacy protocol password : *****
Re-enter the privacy protocol password : *****

WARNING: For best security practices avoid the use
of repeated patterns in passwords.

Switch:1(config)#show snmp-server user
*****
Engine ID = 0x80:00:08:E0:03:10:CD:AE:6B:D0:00

-----
```

Variable Definitions

The following table defines parameters for the `snmp-server user` command.

Variable	Value
<code>{aes des}</code>	Specifies a privacy protocol. If no value is entered, no authentication capability exists. The choices are aes or des. Important: You must set authentication before you can set the privacy option.
<code>engine-id WORD<16-97></code>	Assigns an SNMPv3 engine ID. Use the no operator to remove this configuration.
<code>group WORD<1-32></code>	Specifies the group access name.
<code>{md5 sha}</code>	Specifies an authentication protocol. If no value is entered, no authentication capability exists. The protocol choices are: MD5 and SHA.
<code>notify-view WORD<0-32></code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>read-view WORD<0-32></code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>write-view WORD<0-32></code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>user WORD<1-32></code>	Creates the new entry with this security name. The name is used as an index to the table. The range is 1-32 characters. Use the no operator to remove this configuration.

Creating a new user group

Create a new user group to logically group users who require the same level of access. Create new access for a group in the View-based Access Control Model (VACM) table to provide access to managed objects.

Note

There are several default groups (public and private) created that you can use. To see the list of default groups and their associated security names (secnames), enter **show snmp-server group**. If you use one of these groups, there is no need to create a new group.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a new user group:

```
snmp-server group WORD <1-32> WORD<1-32> {auth-no-priv|auth-priv|no-
auth-no-priv} [notify-view WORD<1-32>] [read-view WORD<1-32>] [write-
view WORD<1-32>]
```

Example

This example uses the following variable names:

- The new group name is *lan6grp*.
- The context of the group is *"*, which represents the Global Router (VRF 0).
- The security level is *no-auth-no-priv*.
- The access view name is *v1v2only* for all three views: **notify-view**, **read-view**, and **write-view**.

```
Switch:1>enable
Switch:1#configure terminal
```

Create a new user group:

```
Switch:1(config)#snmp-server group lan6grp "" no-auth-no-priv notify-view v1v2only read-
view v1v2only write-view v1v2only
```

Variable Definitions

The following table defines parameters for the `snmp-server group` command.

Variable	Value
<i>auth-no-priv</i>	Assigns the minimum level of security required to gain the access rights allowed by this conceptual row. If the <i>auth-no-priv</i> parameter is included, it creates one entry for SNMPv3 access.
<i>auth-priv</i>	Assigns the minimum level of security required to gain the access rights allowed by this conceptual row. If the <i>auth-priv</i> parameter is included, it creates one entry for SNMPv3 access.
<i>group WORD<1-32> WORD<1-32></i>	The first <i>WORD<1-32></i> specifies the group name for data access. The range is 1-32 characters. Use the no operator to remove this configuration. The second <i>WORD<1-32></i> specifies the context name. The range is 1-32 characters. If you use a particular group name value but with different context names, you create multiple entries for different contexts for the same group. You can omit the context name and use the default. If the context name value ends in the wildcard character (*), the resulting entries match a context name that begins with that context. For example, a context name value of <i>foo*</i> matches contexts starting with <i>foo</i> , such as <i>foo6</i> and <i>foofofum</i> . Use the no operator to remove this configuration.
<i>no-auth-no-priv</i>	Assigns the minimum level of security required to gain the access rights allowed by this conceptual row. If the <i>no-auth-no-priv</i> parameter is included, it creates 3 entries, one for SNMPv1 access, one for SNMPv2c access, and one for SNMPv3 access.
<i>notify-view WORD<1-32></i>	Specifies the view name in the range of 0-32 characters.

Variable	Value
<code>read-view WORD<1-32></code>	Specifies the view name in the range of 0-32 characters.
<code>write-view WORD<1-32></code>	Specifies the view name in the range of 0-32 characters.

Creating a new entry for the MIB in the view table

Create a new entry in the MIB view table. The default Layer 2 MIB view cannot modify SNMP settings. However, a new MIB view created with Layer 2 permission can modify SNMP settings.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Create a new entry:

```
snmp-server view WORD<1-32> WORD<1-32>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Create MIB views:

```
Switch:1(config)#snmp-server view 2 1.3.8.7.1.4
```

Variable Definitions

The following table defines parameters for the `snmp-server view` command.

Variable	Value
The first <code>WORD<1-32></code>	Specifies the prefix that defines the set of MIB objects accessible by this SNMP entity. The range is 1-32 characters.
The second <code>WORD<1-32></code>	Specifies a new entry with this group name. The range is 1-32 characters.

Creating a community

Create a community to use in forming a relationship between an SNMP agent and one or more SNMP managers. You require SNMP community strings to access the system using an SNMP-based management software.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```

2. Create a community:

```
snmp-server community WORD<1-32> [group WORD<1-32>] [index WORD<1-32>]
[secname WORD<1-32>]
```

**Important**

- The **group** parameter is only required if you created a new user group using the procedure in [Creating a new user group](#). If you use any of the default groups, the **secname** automatically links the community to its associated group so there is no need specify the group in this command.
- If you do create a new group, use the **snmp-server community** command to create an SNMP community with a new security name and link it to the new group you created. There is no separate command to create a security name (secname). You use the **snmp-server community** command. The security name is the key to link the community name to a group.
- You cannot use the @ character or the string :: when you create community strings.

Example

In the following example, the community name is *anewcommunity*, the index is *third*, and the secname is *readview*. There is no group specified because this is a default public/read only group.

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#snmp-server community anewcommunity index third secname
readview
```

Variable Definitions

The following table defines parameters for the `snmp-server community` command.

Variable	Value
<i>community</i> <i>WORD<1-32></i>	Specifies a community string. The range is 1-32 characters.
<i>group</i> <i>WORD<1-32></i>	Specifies the group name. The range is 1-32 characters.
<i>index</i> <i>WORD<1-32></i>	Specifies the unique index value of a row in this table. The range is 1-32 characters.
<i>secname</i> <i>WORD<1-32></i>	Maps the community string to the security name in the VACM Group Member Table. The range is 1-32 characters.

Add a User to a Group

Add a user to a group to logically group users who require the same level of access.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Create a new user group:
snmp-server user *WORD<1-32>* group *WORD<1-32>* {md5 | sha} [aes | des]
3. Enter and confirm your password.
4. Verify the configuration:
show snmp-server group

Example

Add a user to a group to logically group users who require the same level of access:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server user test4 group grouptest4 md5 aes
Enter the authentication protocol password : *****
Re-enter the authentication protocol password : *****
Enter the privacy protocol password : *****
Re-enter the privacy protocol password : *****

WARNING: For best security practices avoid the use
of repeated patterns in passwords.

Switch:1(config)#show snmp-server group
*****

Variable Definitions

The following table defines parameters for the `snmp-server user` command.

Variable	Value
<code>{aes des}</code>	Specifies a privacy protocol. If no value is entered, no authentication capability exists. The choices are aes or des. Important: You must set authentication before you can set the privacy option.
<code>engine-id WORD<16-97></code>	Assigns an SNMPv3 engine ID. Use the no operator to remove this configuration.
<code>group WORD<1-32></code>	Specifies the group access name.
<code>{md5 sha}</code>	Specifies an authentication protocol. If no value is entered, no authentication capability exists. The protocol choices are: MD5 and SHA.
<code>notify-view WORD<0-32></code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>read-view WORD<0-32></code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>write-view WORD<0-32></code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>user WORD<1-32></code>	Creates the new entry with this security name. The name is used as an index to the table. The range is 1-32 characters. Use the no operator to remove this configuration.

Blocking SNMP

Disable SNMP by using the SNMP block flag. By default, SNMP access is enabled.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Disable SNMP:

```
boot config flags block-snmp
```

Example

```
Switch:1>enable

Switch:1#configure terminal

Disable SNMP:

Switch:1(config)#boot config flags block-snmp
```

Variable Definitions

The following table defines parameters for the `boot config flags` command.

Variable	Value
<code>block-snmp</code>	Configures the block SNMP flag as active. Use the no operator to remove this configuration. The default is off. To set this option to the default value, use the default operator with the command.

View SNMP System Information

View SNMP system information to view trap and authentication profiles.

For a comprehensive set of SNMP-related `show` commands, see [VOSS CLI Commands Reference](#).

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View SNMP system information:

```
show snmp-server
```

Example

```
Switch:1>show snmp-server

      trap-sender :
force-trap-sender : FALSE
force-iphdr-sender : FALSE
      contact: none
      location : none
      name : Switch:1
```

```
AuthenticationTrap : false
LoginSuccessTrap  : false
```

**Note**

The *trap-sender*, *force-trap-sender*, and *force-iphdr-sender* only applies to VSP 8600 Series.

SNMP configuration using Enterprise Device Manager

Configure SNMP to provide services to send and receive messages, authenticate and encrypt messages, and control access to managed objects with Enterprise Device Manager (EDM).

The following task flow shows you the sequence of procedures you perform to configure basic elements of SNMP using EDM.

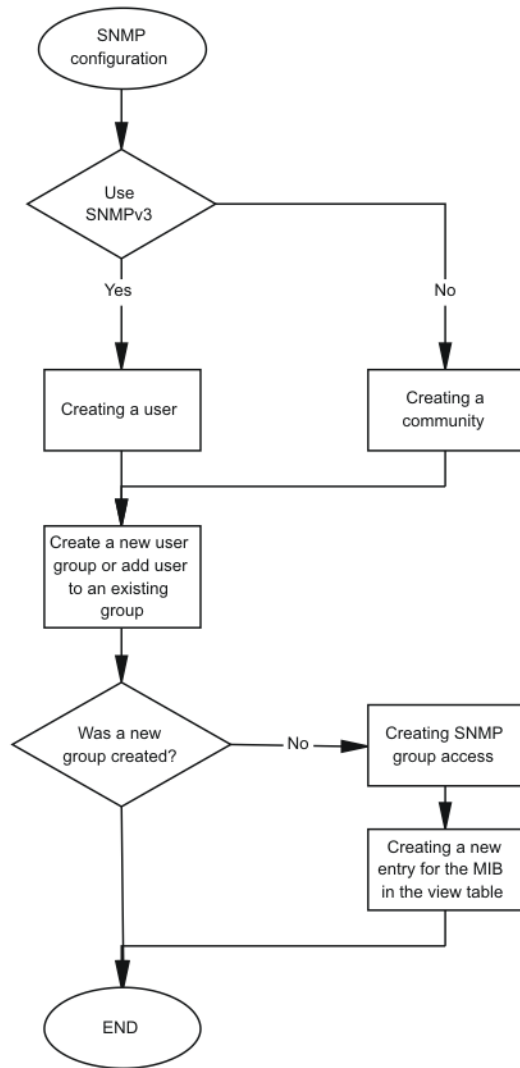

Figure 241: SNMP configuration using Enterprise Device Manager procedures

Create a User

About This Task

Create a new user in the USM table to authorize a user on a particular SNMP engine.

Note

In EDM, to create new SNMPv3 users you must use the **CloneFromUser** option. However, you cannot clone the default user, named initial. As a result, you must first use CLI to configure at least one user, and then you can use EDM to create subsequent users with the **CloneFromUser** option.

Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **USM Table**.
3. Click **Insert**.
4. In the **EngineID** box, use the default Engine ID provided or type an administratively-unique identifier to an SNMP engine.
5. In the **User Name** box, type a name.
6. From the **CloneFromUser** list, select a security name from which the new entry copies authentication data and private data, if required.
7. From the **Auth Protocol** list, select an authentication protocol.
8. In the **Cloned User's Auth Password** box, type the authentication password of the cloned user.
9. In the **New User's Auth Password** box, type an authentication password for the new user.
10. From the **Priv Protocol** list, select a privacy protocol.
11. In the **Cloned User's Priv Password** box, type the privacy password of the cloned user.
12. In the **New User's Priv Password** box, type a privacy password for the new user.
13. Click **Insert**.

Caution Security risk

To ensure security, change the GroupAccess table default view after you set up a new user in the USM table. This prevents unauthorized people from accessing the system using the default user logon. Also, change the Community table defaults, because the community name is used as a community string in SNMPv1/v2 PDU.

USM Table field descriptions

Use the data in the following table to use the **USM Table** tab and the **Insert USM Table** dialog box. The system displays some fields only on the Insert USM Table dialog box.

Name	Description
EngineID	Specifies an administratively-unique identifier to an SNMP engine.
UserName	Creates the new entry with this security name. The name is used as an index to the table. The range is 1-32 characters.
SecurityName	Identifies the name on whose behalf SNMP messages are generated.
Clone From User	Specifies the security name from which the new entry must copy privacy and authentication parameters. The range is 1-32 characters. The system displays this option only in the Insert USM Table dialog box.
Auth Protocol (Optional)	Assigns an authentication protocol (or no authentication) from a list. If you select an authentication protocol, you must enter an old AuthPass and a new AuthPass.
Cloned User's Auth Password	Specifies the current authentication password of the cloned user. The system displays this option only in the Insert USM Table dialog box.
New User's Auth Password	Specifies the authentication password of the new user. The system displays this option only in the Insert USM Table dialog box.

Name	Description
Priv Protocol (Optional)	Assigns a privacy protocol (or no privacy) from a list. If you select a privacy protocol, you must enter an old PrivPass and a new PrivPass.
Cloned User's Priv Password	Specifies the current privacy password of the cloned user. The system displays this option only in the Insert USM Table dialog box.
New User's Priv Password	Specifies the privacy password of the new user. The system displays this option only in the Insert USM Table dialog box.

Create a New Group Membership

About This Task

Create a new group membership to logically group users who require the same level of access.

Note

There are several default groups (public and private) created that you can use. To see the list of default groups and their associated security names (secnames), enter **show snmp-server group**. If you use one of these groups, there is no need to create a new group.

Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. Click the **Group Membership** tab.
4. Click **Insert**.
5. From the **SecurityModel** options, select a security model.
6. In the **SecurityName** box, type a security name.
7. In the **GroupName** box, type a group name.
8. Click **Insert**.

Group Membership field descriptions

Use the data in the following table to use the **Group Membership** tab.

Name	Description
SecurityModel	Specifies the security model to use with this group membership.
SecurityName	Specifies the security name assigned to this entry in the View-based Access Control Model (VACM) table. The range is 1-32 characters.
GroupName	Specifies the name assigned to this group in the VACM table. The range is 1-32 characters.

Create Access for a Group

About This Task

Create access for a group in the View-based Access Control Model (VACM) table to provide access to managed objects.

Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. Click the **Group Access Right** tab.
4. Click **Insert**.
5. In the **GroupName** box, type a VACM group name.
6. In the **ContextPrefix** box, select a VRF instance. This is an optional step.
7. From the **SecurityModel** options, select a model.
8. From the **SecurityLevel** options, select a security level.
9. In the **ContextMatch** option, select a value to match the context name. This value is **exact** by default.
10. (Optional) In the **ReadViewName** box, type the name of the MIB view that forms the basis of authorization when reading objects. This is an optional step.
11. (Optional) In the **WriteViewName** box, type the name of the MIB view that forms the basis of authorization when writing objects. This is an optional step.
12. (Optional) In the **NotifyViewName** box, type MIB view that forms the basis of authorization for notifications. This is an optional step.
13. Click **Insert**.

Group Access Right field descriptions

Use the data in the following table to use the **Group Access Right** tab.

Name	Description
GroupName	Specifies the name of the new group in the VACM table. The range is 1–32 characters.
ContextPrefix	Specifies if the contextName must match the value of the instance of this object exactly or partially. The range is an SnmpAdminString, 1–32 characters.
SecurityModel	Specifies the authentication checking to communicate to the switch. The security models are: <ul style="list-style-type: none"> • SNMPv1 • SNMPv2 • USM
SecurityLevel	Specifies the minimum level of security required to gain the access rights allowed. The security levels are: <ul style="list-style-type: none"> • noAuthNoPriv • authNoPriv • authpriv

Name	Description
ContextMatch	Specifies if the prefix and the context name must match. If the value is exact, all rows where the contextName exactly matches vacmAccessContextPrefix are selected. If you do not select exact, all rows where the contextName with starting octets that exactly match vacmAccessContextPrefix are selected.
ReadViewName	Identifies the MIB view of the SNMP context to which this conceptual row authorizes read access. The default is the empty string.
WriteViewName	Identifies the MIB view of the SNMP context to which this conceptual row authorizes write access. The default is the empty string.
NotifyViewName	Identifies the MIB view of the SNMP context to which this conceptual row authorizes access for notifications. The default is the empty string.

Create Access Policies for SNMP Groups

About This Task

Create an access policy to determine the access level for the users who connect to the switch with different services like File Transfer Protocol (FTP), Trivial FTP (TFTP), Telnet, and rlogin.

Note

Rlogin is only supported on VSP 8600 Series.

You only need to create access policies for SNMP groups if you have the access policy feature enabled.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Access Policies**.
3. Select the **Access Policies-SNMP Groups** tab.
4. Select **Insert**.
5. Enter an **ID**.
6. In the **Name** box, type a name.
7. From the **Model** options, select a security model.
8. Select **Insert**.

Access Policies – SNMP Groups field descriptions

The following table defines parameters for the **Access Policies-SNMP Groups** tab.

Name	Description
Id	Specifies the ID of the group policy.
Name	Specifies the name assigned to the group policy. The range is 1–32 characters.
Model	Specifies the security model {SNMPv1 SNMPv2c USM}.

Assign MIB View Access for an Object

About This Task

Create a new entry in the MIB View table.

You cannot modify SNMP settings with the default Layer 2 MIB view. However, you can modify SNMP settings with a new MIB view created with Layer 2 permissions.

Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. In the **VACM Table** tab, click the **MIB View** tab.
4. Click **Insert**.
5. In the **ViewName** box, type a view name.
6. In the **Subtree** box, type a subtree.
7. In the **Mask** box, type a mask.
8. From the **Type** options, select whether access to the MIB object is granted.
9. Click **Insert**.

MIB View field descriptions

Use the data in the following table to use the **MIB View** tab.

Name	Description
ViewName	Creates a new entry with this group name. The range is 1-32 characters.
Subtree	Specifies a valid object identifier that defines the set of MIB objects accessible by this SNMP entity, for example, 1.3.6.1.1.5.
Mask (optional)	Specifies a bit mask with vacmViewTreeFamilySubtree to determine whether an OID falls under a view subtree.
Type	Determines whether access to a MIB object is granted (included) or denied (excluded). The default is included.

Create a Community

About This Task

Create a community to use in forming a relationship between an SNMP agent and one or more SNMP managers. You require SNMP community strings for access to the switch using an SNMP-based management software.

Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **Community Table**.
3. Click **Insert**.
4. In the **Index** box, type an index.

5. In the **Name** box, type a name that is a community string.
6. In the **SecurityName** box, type a security name.
7. In the **ContextName** box, type the context name.
8. Click **Insert**.

Community Table field descriptions

Use the data in the following table to use the **Community Table** tab.

Name	Description
Index	Specifies the unique index value of a row in this table. The range is 1-32 characters.
Name	Specifies the community string for which a row in this table represents a configuration.
SecurityName	Specifies the security name in the VACM group member table to which the community string is mapped. The range is 1-32 characters.
ContextEngineID	Indicates the location of the context in which management information is accessed when using the community string specified in Name .
ContextName	Specifies the context in which management information is accessed when you use the specified community string.

View All Contexts for an SNMP Entity

About This Task

View contexts to see the contents of the context table in the View-based Access Control Model (VACM). This table provides information to SNMP command generator applications so that they can properly configure the VACM access table to control access to all contexts at the SNMP entity.

Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. In the **VACM Table** tab, click the **Contexts** tab.

Contexts field descriptions

Use the data in the following table to use the **Contexts** tab.

Variable	Value
ContextName	Shows the name identifying a particular context at a particular SNMP entity. The empty contextName (zero length) represents the default context.

Showing SNMP Statistics

About This Task

Display SNMP statistics to monitor the number of specific error messages, such as the number of messages that were delivered to SNMP but were not allowed.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Control Path** folders.
2. Click **General**.
3. Click the **SNMP** tab.

SNMP Field Descriptions

Use the data in the following table to display SNMP statistics.

Name	Description
OutTooBig	Shows the number of SNMP PDUs that the SNMP protocol entity generated and for which the value of the error-status field is tooBig.
OutNoSuchNames	Shows the number of SNMP PDUs that the SNMP protocol entity generated and for which the value of the error-status is noSuchName.
OutBadValues	Shows the number of SNMP PDUs that SNMP protocol entity generated and for which the value of the error-status field is badValue.
OutGenErrors	Shows the number of SNMP PDUs that the SNMP protocol entity generated and for which the value of the error-status field is genErr.
InBadVersions	Shows the number of SNMP messages that were delivered to the SNMP protocol entity and were for an unsupported SNMP version.
InBadCommunityNames	Shows the number of SNMP messages delivered to the SNMP protocol entity that used an SNMP community name not known to the entity.
InBadCommunityUsers	Shows the number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation not allowed by the SNMP community named in the message.
InASNParseErrs	Shows the number of ASN.1 or BER errors encountered by the SNMP protocol entity when decoding received SNMP messages.
InTooBig	Shows the number of SNMP PDUs that were delivered to the SNMP protocol entity and for which the value of the error-status field is tooBig.
InNoSuchNames	Shows the number of SNMP PDUs that were delivered to the SNMP protocol entity and for which the value of the error-status field is noSuchName.
InBadValues	Shows the number of SNMP PDUs that were delivered to the SNMP protocol entity and for which the value of the error-status field is badValue.

Name	Description
InReadOnlys	Shows the number of valid SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is "read-only". It is a protocol error to generate an SNMP PDU that contains the value "read-only" in the error-status field; this object is provided as a means of detecting incorrect implementations of the SNMP.
InGenErrors	Shows the number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is "genErr."

Spanning Tree Configuration

[Spanning Tree Fundamentals](#) on page 3135

[Spanning Tree Configuration Using CLI](#) on page 3142

[Spanning Tree Configuration Using EDM](#) on page 3163

Spanning Tree Fundamentals

Table 231: Spanning Tree Protocol product support

Feature	Product	Release introduced
Spanning Tree Protocol (STP): <ul style="list-style-type: none">• Multiple STP (MSTP)• Rapid STP (RSTP)	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1

	XA1400 Series	VOSS 8.0.50

The switch supports Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP).

Spanning Tree

Spanning Tree protocols detect and eliminate logical loops in a bridged or switched network. If multiple paths exist, the spanning Tree algorithm configures the network so that a bridge or device uses the root bridge path based on hop counts. Although link speed is taken into account, the path is based on the root bridge rather than on an optimized path. If that path fails, the protocol automatically reconfigures the network and makes another path active, thereby sustaining network operations. The switch

supports RSTP and MSTP but can downgrade a port automatically if it receives an STP Bridge Protocol Data Unit (BPDU) from a switch that runs STP.

**Note**

Spanning Tree is disabled on all Switched UNI (S-UNI) ports. The ports will move into forwarding state as soon as the physical port or VLACP or LACP comes up on the port. If the platform VLAN is associated to the S-UNI Service Instance Identifier (I-SID), then the S-UNI ports added to the platform VLAN will become the member of MSTP instances associated with the platform VLAN. To enable SLPP on the S-UNI ports, the platform VLAN must be associated with the S-UNI I-SID.

Spanning Tree Groups

Spanning Tree Groups (STGs) represent logical topologies. A topology is created based on bridge configuration values such as root bridge priority. In the case of multiple STGs, you can map a VLAN to the most appropriate logical topology in the physical network.

The switch supports Spanning Tree modes RSTP and MSTP. The default Spanning Tree mode is MSTP. The default STG is 0. In RSTP mode, all VLANs run in the default STG. In MSTP mode, you can create additional STGs by using the VLAN create command. The switch supports up to 64 STGs.

Although STP and MSTP are variations of the same Spanning Tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the Spanning Tree groups running on a chassis configured with STP. MSTP Spanning Tree groups are not the same as STP Spanning Tree groups. Using a switch in MSTP mode with a chassis in STP mode can create a loop in the network.

The root bridge for Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP) is determined by comparing attributes of each bridge in the network.

The protocol considers bridge priority first. If more than one bridge has the same priority, then the protocol must consider the bridge ID. The bridge with the lowest ID becomes the root bridge. For MSTP, this bridge is called the Common and Internal Spanning Tree (CIST) Root because it is the root of the entire physical network.

In MSTP mode, you can create additional Spanning Tree instances, by using the VLAN command. These instances, known as Multiple Spanning Tree Instances (MSTIs), can assign different priorities to switches. The MSTIs have different link costs or port priorities and as a result create separate logical topologies.

MSTP also allows the creation of MSTP regions. A region is a collection of switches sharing the same view of physical and logical topologies. For switches to belong to the same region, the following attributes must match:

- MSTP configuration ID selector
- MSTP configuration name
- MSTP configuration revision number
- VLAN instance mapping

Links connecting sections are called boundary ports. In a region, the boundary switch that contains the boundary port providing the shortest external path cost to the CIST Root is the CIST Regional Root.

STGs and VLANs

When you map VLANs to STGs, be aware that all links on the bridge belong to all STGs. Because each Spanning Tree group can differ in its decision to make a link forwarding or blocking, you must ensure that the ports you add to a VLAN are in the expected state.

Untagged ports can only belong to one VLAN and therefore can only belong to one STG. Tagged ports can belong to multiple VLANs and therefore to multiple STGs.

BPDUs handling on S-UNI port/MLT

The switch handles Bridge Protocol Data Units (BPDUs) according to whether or not you configure a platform VLAN.

- When you configure a platform VLAN:
 - BPDUs are forwarded to the CPU by default.
 - For both the ingress and egress ports, BPDUs are not flooded in the S-UNI I-SID associated with the platform VLAN.

Note

If the platform VLAN is configured for the S-UNI port, you cannot enable BPDU forwarding.

- When you DO NOT configure a platform VLAN:
 - BPDUs received on untagged-traffic ports are dropped by default.
 - To flood BPDUs in its I-SID, enable BPDU forwarding under S-UNI I-SID using the command **untagged-traffic port <port no> bpdu enable**.

BPDUs Guard

Table 232: Bridge Protocol Data Unit (BPDU) Guard product support

Feature	Product	Release introduced
Bridge Protocol Data Unit (BPDU) Guard	VSP 4450 Series	VOSS 6.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 6.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.0
	VSP 8400 Series	VOSS 6.0
	VSP 8600 Series	VSP 8600 6.2
	XA1400 Series	Not Supported

The switch supports Bridge Protocol Data Unit (BPDU) Guard for STGs, RSTP, and MSTP.

Overview

Spanning Tree eliminates loops in a network. A bridge that participates in spanning tree uses BPDUs to exchange information with other bridges. The bridges select a single bridge as the root bridge based on the BPDU information exchange. The bridge with the lowest priority becomes the root bridge. If all bridges share the same priority, the bridge with the lowest bridge ID becomes the root bridge. This process is the root selection process.

After you add a new bridge to the network, or remove an existing bridge, the bridges repeat the root selection process, and then select a new root bridge.

To ensure the correct operation of Spanning Tree in the network, BPDU Guard protects the stability of the Root Bridge by dropping stray, unexpected, or unwanted BPDU packets entering a port, and immediately shutting down those ports for a specified time period. BPDU Guard is normally enabled on access ports connecting to end user devices such as servers that are not expected to operate Spanning Tree.

Use BPDU Guard to achieve the following results:

- Block the root selection process after an edge device, such as a laptop that uses Linux with STP enabled, is added to the network. Blocking the root selection process prevents unknown devices from influencing the spanning tree topology.
- Block BPDU flooding of the switch from an unknown device.

Operation

You can enable or disable BPDU Guard on an individual port basis, regardless of the spanning tree state. Each port uses a timer to determine port-state recovery.

After you enable BPDU Guard on a port and the port receives a BPDU, the following actions occur:

1. The guard disables the port.
2. The switch generates an SNMP trap and alarm, and the following log message:

```
BPDU Guard - Port <slot/port> is being shutdown by BPDU Guard, timeout <time_seconds>
```

3. The port timer begins.
4. The port remains in the disabled state until the timer expires.

If you disable BPDU Guard before the timer expires, the timer stops and the port remains in the disabled state. You must manually enable the port.

BPDU Guard is enabled at the interface level. You can configure the BPDU Guard timer for each port, for 10 to 65535 seconds. If you set the port timer to zero, it will not expire.

Rapid Spanning Tree Protocol and Multiple Spanning Tree Protocol

The Rapid Spanning Tree Protocol (RSTP or IEEE 802.1w) reduces the recovery time after a network breakdown. It also maintains backward compatibility with IEEE 802.1d (the spanning tree implementation prior to RSTP). In certain configurations, the recovery time of RSTP can be reduced to less than 1 second. RSTP also reduces the amount of flooding in the network by enhancing the way Topology Change Notification (TCN) packets are generated.

With Multiple Spanning Tree Protocol (MSTP or IEEE 802.1s), you can configure multiple instances or Spanning Tree groups on the same device. Each instance or Spanning Tree group can include one or more VLANs.

By using RSTP and MSTP, the switch achieves the following:

- reduces convergence time after a topology change (from 30 seconds to less than 1 or 2 seconds)
- eliminates unnecessary flushing of the MAC database and the flooding of traffic to the network
- creates backward compatibility with classic 802.1d switches
- creates support for 64 instances of spanning tree in MSTP mode

The following sections relate to RSTP and MSTP:

- [RSTP interoperability with STP](#) on page 3139
- [Differences in port roles for STP and RSTP](#) on page 3139
- [Port roles: root forwarding role](#) on page 3140
- [Port roles: designated forwarding role](#) on page 3140
- [Port roles: alternate blocking role](#) on page 3140
- [Edge port](#) on page 3141
- [Path cost values](#) on page 3141
- [RSTP negotiation process](#) on page 3141

RSTP interoperability with STP

RSTP provides a parameter called ForceVersion to provide backward compatibility with standard STP. A user can configure a port in either STP-compatible mode or RSTP mode:

- An STP-compatible port transmits and receives only STP Bridge Protocol Data Units (BPDUs). An RSTP BPDU that the port receives in this mode is discarded.
- An RSTP-compatible port transmits and receives only RSTP BPDUs. If an RSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to RSTP mode. This process is called Port Protocol Migration.

Note

You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.

Before implement MSTP or RSTP you must be aware of the following:

- The default mode is MSTP. A special boot configuration flag identifies the mode.
- You can lose your configuration if you change the spanning tree mode from MSTP to RSTP and the configuration file contains VLANs configured with MSTI greater than 0. RSTP only supports VLANs configured with the default instance 0.
- For best interoperability results, contact your vendor representative.

Differences in port roles for STP and RSTP

RSTP is an enhanced version of STP. These two protocols have almost the same parameters.

The following table lists the differences in port roles for STP and RSTP. STP supports two port roles, while RSTP supports four port roles.

Table 233: Differences in port roles for STP and RSTP

Port Role	STP	RSTP	Description
Root	Yes	Yes	This port receives a better BPDU than its own and has the best path to reach the Root. The root port is in Forwarding state. The root port and designated ports can be in the Discarding state before they go to root forwarding.
Designated	Yes	Yes	This port has the best BPDU on the segment. The designated port is in the Forwarding state.
Alternate	No	Yes	This port receives a better BPDU than its own BPDU, and a root port exists within the same device. The alternate port is in the Discarding state.
Backup	No	Yes	This port receives a better BPDU than its own BPDU, and this BPDU is from another port within the same device. The backup port is in the Discarding state.

Port roles: root forwarding role

MSTP and RSTP root forwarding roles are as follows:

- The port that receives the best path BPDU on a device is the root port, and is referred to as a Root Forwarding (RF) port. This is the port that is the closest to the root bridge in terms of path cost.
- The spanning tree algorithm elects a single root bridge in a bridged network. With MSTP, a root bridge is selected for the Common and Internal Spanning Tree (CIST). A root bridge is selected for the region, and a root bridge is selected for each spanning tree instance.
- The root bridge is the only bridge in a network that does not have root ports; all ports on a root bridge are Designated Forwarding (DF).
- Only one path towards a root bridge can exist on a given segment; otherwise, loops can occur.

Port roles: designated forwarding role

MSTP and RSTP designated forwarding roles are as follows:

- All bridges connected on a segment monitor the BPDUs of all other bridges. The bridge that sends the best BPDU is the root bridge for the segment.
- The corresponding port on the bridge is referred to as a Designated Forwarding Port.

Port roles: alternate blocking role

MSTP and RSTP alternate blocking roles are as follows:

- A blocked port is defined as not being the designated or root port. An alternate port provides an alternate path to the root and can replace the root port if it fails.

- An alternate blocked port is a port that is blocked because it received better path cost BPDUs from another bridge.

Port roles: backup blocking role

MSTP and RSTP backup blocking roles are as follows:

- A backup port receives the more useful BPDUs from the bridge on which the port exists.

Edge port

RSTP uses a parameter called the edge port. After a port connects to a nonswitch device, such as a PC or a workstation, it must be configured as an edge port. An active edge port enters the forwarding state without delay. An edge port becomes a nonedge port if it receives a BPDU.

Path cost values

RSTP and MSTP path cost values support a wide range of link speeds. The following table lists the path cost values.

Table 234: Path cost values

Link speed	Value
Less than or equal to 100 Kbps	200 000 000
1 Mbps	20 000 000
10 Mbps	2 000 000
100 Mbps	200 000
1 Gbps	20 000
10 Gbps	2000
100 Gbps	200
1 Tbps	20
10 Tbps	2

RSTP negotiation process

The following section describes the negotiation process between switches that takes place before PCs can exchange data (see the following figure).

Figure 242: RSTP negotiation process

After turning on, all ports assume the role of designated ports. All ports are in the discarding state except edge ports. Edge ports go directly into the forwarding state without delay.

Unit A port 1 and Unit B port 1 exchange BPDUs. Unit A knows that it is the root and that Unit A port 1 is the designated port. Unit B learns that Unit A has higher priority. Unit B port 1 becomes the root port. Both Unit A port 1 and Unit B port 1 are still in the discarding state.

Unit A starts the negotiation process by sending a BPDU with the proposal bit set.

Unit B receives the proposal BPDU and configures its nonedge ports to discarding state. This operation occurs during the synchronization process.

Unit B sends a BPDU to Unit A with the agreement bit set.

Unit A configures port 1 to the forwarding state, and Unit B configures port 1 to the forwarding state. PC 1 and PC 2 can now communicate. The negotiation process now moves on to Unit B port 3 and its partner port. PC 3 cannot exchange data with either PC 1 or PC 2 until the negotiation process between Unit B and Unit C finishes.

The RSTP convergence time depends on how quickly the switches can exchange BPDUs during the negotiation process, and on the number of switches in the network.

Spanning Tree Configuration Using CLI

Important

The switch supports up to 64 STGs on a device, however, SPBM uses STG 63 and MSTI 62 for internal use. STG 63 or MSTI 62 cannot be used by other VLANs or MSTIs.

Configuring Spanning Tree

Configure the STP mode to configure the spanning tree mode on the device.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the STP mode:

```
boot config flags spanning-tree-mode {rstp|mstp}
```

Example

Configure the STP mode:

```
Switch:1(config)#boot config flags spanning-tree-mode mstp
```

```
Warning: Please save the configuration and reboot the switch
```

```
for this to take effect.
```

```
Warning: Please carefully save your configuration files before
```

```
starting configuring the switch in RSTP or MSTP mode.
```

Variable Definitions

Use the data in the following table to use the **boot config flags spanning-tree-mode** command.

Variable	Value
<i>rstp mstp</i>	Specifies the Spanning Tree modes: Rapid Spanning Tree Protocol (RSTP) or Multiple Spanning Tree Protocol (MSTP).

Configure BPDU Guard

Configure BPDU Guard to block the root selection process or to prevent BPDU flooding from unknown devices.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
```

```
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable BPDU Guard for the port:

```
spanning-tree bpduguard enable
```
3. (Optional) Configure the timer for port-state recovery:

```
spanning-tree bpduguard timeout <0, 10-65535>
```
4. (Optional) Enable BPDU Guard on an additional port or group of ports:

```
spanning-tree bpduguard port {slot/port[/sub-port] [-slot/port[/subport]] [, ...]} enable
```
5. (Optional) Configure the timer for port-state recovery for an additional port or group of ports:

```
spanning-tree bpduguard port {slot/port[/sub-port] [-slot/port[/subport]] [, ...]} timeout <0-65535>
```
6. Verify the configuration:

```
show spanning-tree bpduguard [GigabitEthernet {slot/port[/sub-port] [-slot/port[/subport]] [, ...]}] [{slot/port[/sub-port] [-slot/port[/subport]] [, ...]}]
```

Example

Enable BPDU Guard on port 1/8, and specify a timer value of 200 seconds. Verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/8
Switch:1(config-if)#spanning-tree bpduguard enable
Switch:1(config-if)#spanning-tree bpduguard timeout 200
Switch:1(config-if)#show spanning-tree bpduguard 1/8
```

```
=====
                                Bpdu Guard
=====
```

Port	PORT	PORT	TIMER	BPDU	BPDU	
NUM	MLTID	ADMIN_STATE	TIMEOUT	COUNT	ADMIN_STATE	ORIGIN
1/8	Up	Up	200	0	Enabled	CONFIG

Variable Definitions

Use the data in the following table to use the **spanning-tree bpduguard** commands.

Variable	Value
<i>enable</i>	Enables BPDU Guard on the port. The default is disabled.
<i>port {slot/port[/sub-port] [-slot/port[/subport]] [, ...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>timeout <0, 10-65535></i>	Specifies the value to use for port-state recovery. After a BPDU guard disables a port, the port remains in the disabled state until this timer expires. You can configure a value from 10 to 65535. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.

Use the data in the following table to use the **show spanning-tree bpduguard** command.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring Rapid Spanning Tree Protocol

Configure Rapid Spanning Tree Protocol (RSTP) to reduce the recovery time after a network breakdown.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure RSTP:

```
spanning-tree rstp [forward-time <400-3000>] [group-stp enable]
[hello-time <100-1000>] [max-age <600-4000>] [pathcost-type <bits16|
bits32>] [priority <0-61440>] [tx-holdcount <1-10>] [version <rstp|
stp-compatible>]
```

Example

Configure RSTP:

```
Switch:1(config)# spanning-tree rstp forward-time 1000 hello-time 200 max-age 4000
pathcost-type bits16 priority 4096 tx-holdcount 10 version rstp group-stp enable
```

Variable Definitions

Use the data in the following table to use the **spanning-tree rstp** command.

Variable	Value
<i>forward-time <400-3000></i>	Configures the RSTP forward delay for the bridge in hundredths of a second.
<i>group-stp enable</i>	Enables or disables RSTP for a specific STG. Enter the no form of the command to disable RSTP for the STG (no spanning-tree rstp group-stp enable).
<i>hello-time <100-1000></i>	Assigns the RSTP hello time delay for the bridge in hundredths of a second.
<i>max-age <600-4000></i>	Assigns the RSTP maximum age time for the bridge in hundredths of a second.
<i>pathcost-type {bits16 bits32}</i>	Assigns the RSTP default pathcost version. The default is 32 bits.

Variable	Value
<code>priority <0-61440></code>	Assigns the RSTP bridge priority.
<code>tx-holdcount <1-10></code>	Assigns the RSTP transmit hold count from 1 to 10. The default value is 6.
<code>version {rstp/stp-compatible}</code>	Sets the version to RSTP or STP compatible.

Configuring Rapid Spanning Tree Protocol for a port

Configure RSTP to reduce the recovery time after a network breakdown.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure RSTP:

```
spanning-tree rstp cost <1-200000000> edge-port <false|true> p2p
<auto|force-false|force-true> priority <0-240> protocol-migration
<false|true> stp enable
```

Example

Configure RSTP:

```
Switch:1(config-if)# spanning-tree rstp cost 100 edge-port true p2p auto
priority 32 protocol-migration true stp enable
```

Variable Definitions

Use the data in the following table to use the **spanning-tree rstp** command.

Variable	Value
<code>cost <1-200000000></code>	Specifies the contribution of this port to the path cost.
<code>edge-port <false true></code>	Configures the edge-port value for the port. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.

Variable	Value
<code>p2p <auto force-false force-true></code>	Specifies the point-to-point status of the LAN segment attached to this port. A value of <code>force-true</code> indicates that this port is treated as if it connects to a point-to-point link. A value of <code>force-false</code> indicates that this port is treated as having a shared media connection. A value of <code>auto</code> indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means.
<code>priority <0-240></code>	Assigns the RSTP bridge priority in a range of 0-240. The value has to increment in steps of 16.
<code>protocol-migration <false true></code>	If you chose <code>true</code> , the option initiates protocol migration for a port. If you chose <code>false</code> , the option terminates protocol migration for a port. An RSTP-compatible port transmits and receives only RSTP BPDUs. If an RSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to RSTP mode. This process is called Port Protocol Migration.
<code>stp enable</code>	Configures STP for the port.

Configuring the Rapid Spanning Tree Protocol version

Perform this procedure to specify the RSTP mode.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure Rapid Spanning Tree Protocol version:

```
spanning-tree rstp version {rstp|stp-compatible}
```

Example

Configure Rapid Spanning Tree Protocol version:

```
Switch:1(config)# spanning-tree rstp version rstp
```

Variable Definitions

Use the data in the following table to use the **spanning-tree rstp version** command.

Variable	Value
<code>rstp version {rstp stp-compatible}</code>	Sets the version to RSTP or to STP compatible. The default is RSTP.

Viewing the global RSTP configuration information

View the global RSTP configuration information to display the Rapid Spanning Tree Protocol (RSTP) configuration details.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View global RSTP configuration information:

```
show spanning-tree rstp config
```

Example

View global RSTP configuration information:

```
Switch:1>show spanning-tree rstp config
```

```

Variable Definitions

Use the data in the following table to use optional parameters with the **show spanning-tree rstp port config** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing the RSTP Status for a Port

View the RSTP status for a port to display the RSTP-related status information for a selected port.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the RSTP status for a port:

```
show spanning-tree rstp port status {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

Note

If your platform supports channelization for 40 Gbps ports and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Example

View the RSTP status for a port:

```
Switch:1>show spanning-tree rstp port status 1/2
```

```
=====
                        RSTP Port Status
                        (Port Priority Vector)
=====
Port Number              : 1/2
Port Designated Root     : 80:00:00:24:7f:9f:60:00
Port Designated Cost     : 0
Port Designated Bridge   : 80:00:00:24:7f:9f:60:00
Port Designated Port     : 80:c1
```

Variable Definitions

Use the data in the following table to use optional parameters with the **show spanning-tree rstp port status** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing RSTP information for a selected port

View the RSTP information for a selected port to display the RSTP-related configuration information for the selected port.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. View the RSTP information for a selected port:

```
show spanning-tree rstp port statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

Example

View the RSTP information for a selected port:

```
Switch:1# show spanning-tree rstp port statistics 1/4
```

```

=====
                        RSTP Port Statistics
=====
Port Number                : 1/4
Number of Fwd Transitions  : 0
Rx RST BPDUs Count        : 0
Rx Config BPDU Count      : 0
Rx TCN BPDU Count         : 0
Tx RST BPDUs Count        : 9
Tx Config BPDU Count      : 0
Tx TCN BPDU Count         : 0
Invalid RST BPDUs Rx Count : 0
Invalid Config BPDU Rx Count : 0
Invalid TCN BPDU Rx Count  : 0
Protocol Migration Count   : 0
=====

```

Variable definitions

Use the data in the following table to use optional parameters with the `show spanning-tree rstp port statistics` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing the RSTP role

View the RSTP role to display the RSTP information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the RSTP role:

```
show spanning-tree rstp port role [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

Example

View the RSTP role:

```
Switch:1> show spanning-tree rstp port role 1/3
```

```

=====
                        RSTP Port Roles and States
=====
Port-Index  Port-Role  Port-State  PortSTPStatus  PortOperStatus
-----
1/3         Designated  Forwarding  Enabled        Enabled

```

Variable definitions

Use the data in the following table to use optional parameters with the `show spanning-tree rstp port role` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing spanning tree configuration

Perform this procedure to view configuration and status information for spanning tree in your network.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View spanning tree configuration information:

```
show spanning-tree config
```
3. View spanning tree status information:

```
show spanning-tree status
```

Example

View spanning tree configuration information:

```
Switch:1> show spanning-tree config
```

```

=====
                        Spanning Tree Config
=====

```

STG ID	DESIGNATED ROOT	ROOT COST	ROOT PORT	MAX AGE	HELLO TIME	HOLD TIME	FORWARD DELAY
0	80:00:00:24:7f:a1:70:00	0	cpp	20	0	1	15
1	80:00:00:24:7f:a1:70:00	0	cpp	20	0	1	15

Total number of Spanning Tree IDs : 2

Configuring Multiple Spanning Tree Protocol

Use the following procedure to configure the Multiple Spanning Tree Protocol.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure MSTP:

```
spanning-tree mstp
```

Example

Configure Multiple Spanning Tree Protocol to configure the MSTP configuration version.

```
Switch:1(config)# spanning-tree mstp forward-time 500 max-age 3000 max-hop 200 pathcost-type bits32 priority 8192 tx-holdcount 10 version mstp
```

Variable Definitions

Use the data in the following table to use the **spanning-tree mstp** command.

Variable	Value
<i>forward-time</i> <400-3000>	Configures the MSTP forward delay for the bridge from 400 to 3000 hundredths of a second.
<i>max-age</i> <600-4000>	Assigns the MSTP maximum age time for the bridge from 600 to 4000 one hundredths of a second.
<i>max-hop</i> <100-4000>	Assigns the MSTP bridge maximum hop count. The range is 100 to 4000 one hundredths of a second. The original MIB erroneously designated the value in hundredths of a second, when it should have been in hops. The replacement MIB kept the range at 100-4000 to remain backwards compatible. To convert this value to hops, divide by 100 so 100-4000 equals 1-40 hops.
<i>msti</i> <1-63> <i>priority</i> <0-65535>	Assigns the MSTP MSTI instance parameter.
<i>pathcost-type</i> { <i>bits16</i> <i>bits32</i> }	Assigns the MSTP default pathcost type to either 16 bits or 32 bits. The default is 32 bits.
<i>priority</i> <0-61440>	Assigns the MSTP bridge priority in a range of 0 to 61440 in steps of 4096.
<i>region</i> [<i>config-id-sel</i> <0-255>] [<i>region-name</i> <WORD 1-32>] [<i>region-version</i> <0-65535>]	Assigns the MSTP region commands: <ul style="list-style-type: none"> • <i>config-id-sel</i>—Assigns the MSTP region configuration ID number. The range is 0 to 255. • <i>region-name</i>—Assigns the MSTP region name. The character string can be a range of 1 to 32 characters • <i>region-version</i>—Assigns the MSTP region version. The range is 0 to 65535.

Variable	Value
<code>tx-holdcount <1-10></code>	Assigns the MSTP transmit hold count. The range is 1 to 10. The default value is 3.
<code>version {mstp rstp stp-compatible}</code>	Assigns the bridge version. Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with another chassis in STP mode can create a loop in the network. You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.

Configuring MSTP MSTI options

Use the following procedure to configure MSTP multiple spanning tree instance (MSTI) options.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure MSTP MSTI:

```
spanning-tree mstp msti <1-63> priority <0-65535>
```

Example

Configure MSTP MSTI:

```
Switch:1(config)# spanning-tree mstp msti 62 priority 4096
```

Variable Definitions

Use the data in the following table to use the **spanning-tree mstp msti <1-63> priority <0-65535>** command.

Variable	Value
<1-63>	Specifies the instance ID.
<0-65535>	Specifies the priority value. Enter values in increments of 4096: <ul style="list-style-type: none"> • 4096 • 8192 • 12288 • 16384 • 20480 • 24576 • 28672 • 32768 • 36864 • 40960 • 45056 • 49152 • 53248 • 57344 • 61440

Configuring Ethernet MSTP

Configure Ethernet MSTP on a port to enable this feature.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...]
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Ethernet MSTP:

```
spanning-tree mstp [cost <1-200000000>] [edge-port <false|true>]
[force-port-state enable] [hello-time <100-1000>] [msti <1-63>] [p2p
{auto|force-false|force-true}] [port {slot/port[/sub-port]}] [priority
<0-240>] [protocol-migration <false|true>]
```

Example

Configure Ethernet MSTP:

```
Switch:1(config)# spanning-tree mstp cost 1 edge-port true force-port-
state enable hello-time 100 p2p auto priority 2 protocol-migration true
```

Variable Definitions

Use the data in the following table to use the **spanning-tree mstp** command.

Variable	Value
<i>cost</i> <1-200000000>	Configures the path cost for a port. Valid values are 1 to 200000000
<i>edge-port</i> <false true>	Enables or disables the port as an edge port.
<i>force-port-state enable</i>	Enables STP.
<i>hello-time</i> <100-1000>	Configures the hello-time for a port.
<i>msti</i> <1-63>	Configures the port MSTP MSTI.
<i>p2p</i> {auto force-false force-true}	Enables or disables point-to-point for a port.
{slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>priority</i> <0-240>	Configures priority for the port.
<i>protocol-migration</i> {false true}	If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port. An MSTP-compatible port transmits and receives only RSTP BPDUs. If an MSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to MSTP mode. This process is called Port Protocol Migration. You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.

Configuring Ethernet MSTP MSTI

Use the following procedure to configure the Ethernet MSTP MSTI parameters on a port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Ethernet MSTP MSTI:

```
spanning-tree mstp msti <1-63> [cost <1-200000000>] [force-port-state
enable] [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
[priority <0-240>]
```

Example

Configure Ethernet MSTP MSTI:

```
Switch(config-if)# spanning-tree mstp msti 62 priority 32
```

Variable Definitions

Use the data in the following table to use the **spanning-tree mstp msti <1-63>** command.

Variable	Value
<1-63>	Specifies the instance ID.
<i>cost <1-200000000></i>	Configures the path cost for the port
<i>force-port-state enable</i>	Enables MSTI learning for the port.
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>priority <0-240></i>	Configures the priority for the port. Enter the priority value (0-240) as increments of 16.

Viewing MSTP configurations

View the MSTP configurations to display the MSTP-related bridge-level VLAN and region information.

Procedure

1. To enter User EXEC mode, log on to the switch.

- View the MSTP configurations:

```
show spanning-tree mstp config
```

Example

View the MSTP configurations:

```
Switch:1> show spanning-tree mstp config
```

```
=====
                        MSTP Configurations

Configuring tc-receive-alarm-threshold

About This Task

You can establish a threshold rate for receiving TC/TCN packets by configuring values for count and interval. If the threshold rate is exceeded, you receive a warning message. Use the following procedure to configure values for **tc-receive-alarm-threshold count** and **tc-receive-alarm-threshold interval**.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure a value for count:

```
spanning-tree tc-receive-alarm-threshold count <1-1000>
```
3. Configure a value for interval:

```
spanning-tree tc-receive-alarm-threshold interval <1-15>
```

Example

Configure count and interval values:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spanning-tree tc-receive-alarm-threshold count 3
Switch:1(config)#spanning-tree tc-receive-alarm-threshold interval 2
```

Display the alarm threshold configuration:

```
Switch:1#show spanning-tree tc-receive-alarm-threshold
```

```
=====
                        Spanning Tree TC/TCN Rx Alarm Threshold Configuration
=====
Interval           : 2 minutes
Count              : 3
=====
```

Variable definitions

Use the data in the following table to use the **tc-receive-alarm-threshold** command.

Variable	Value
count <1-1000>	Specifies the number of packets used to establish the threshold rate. The default is 2.
interval <1-15>	Specifies the time interval (in minutes) used to establish the threshold rate. The default is 1.

Displaying the tc-receive-alarm-threshold configuration

About This Task

You can configure a threshold rate for receiving TC/TCN packets. If the threshold is exceeded, you receive a warning message. Use the following procedure to display the tc-receive-alarm-threshold configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the tc-receive-alarm-threshold configuration:

```
show spanning-tree tc-receive-alarm-threshold
```

Example

```
Switch:1(config)#show spanning-tree tc-receive-alarm-threshold
```

```
=====
                          Spanning Tree TC/TCN Rx Alarm Threshold Configuration
=====
Interval                   : 1 minutes
Count                      : 2
```

Spanning Tree Configuration Using EDM

This section describes how to create, manage, and monitor spanning tree groups (STG). It also describes how to configure the Rapid Spanning Tree Protocol (RSTP) and the Multiple Spanning Tree Protocol (MSTP) using Enterprise Device Manager (EDM).

Important

The switch supports up to 64 STGs in a device, however, SPBM uses STG 63 and MSTI 62 for internal use. STG 63 or MSTI 62 cannot be used by other VLANs or MSTIs.

Configuring the Spanning Tree mode

Configure the Spanning Tree mode to change the mode to MSTP or RSTP mode.

Important

After you change the mode, restart the system for the changes to take effect.

Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **Globals**.
3. Select the required spanning tree mode.
4. Click **Apply**.

The system notifies you that the setting takes effect after you save the configuration and restart the server.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
SpanningTreeAdminMode	Configures the spanning tree mode as either RSTP or MSTP. The default is MSTP.
SpanningTreeOperMode	Specifies the current mode of the spanning tree.

Restarting the switch

Restart the switch so that changes to the bootconfig parameters (or other parameters) take effect. For example, you must restart the device to enable a change to the Spanning Tree mode.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Edit**.
2. Click **Chassis**.
3. In the System tab, locate the **ActionGroup1** box.
4. Select **saveRuntimeConfig**.
5. Click **Apply**.
6. In the **ActionGroup4** box, select **softReset**.
7. Click **Apply**.

Configure BPDU Guard

Configure BPDU Guard to block the root selection process or to prevent BPDU flooding from unknown devices.

About This Task

To configure multiple ports simultaneously, select more than one port in the Device Physical View tab. The system displays **BPDU Guard** tab as a table-based tab.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **Interface** tab.

5. Select **BpduGuardAdminEnabled** to enable BPDU Guard for the port.
6. (Optional) Type a value in **BpduGuardTimeout** to configure the timer for port-state recovery
7. Click **Apply**.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
Index	Displays the index of the port, written in the slot/port[/sub-port] format.
Name	Configures the name of the port.
Descr	Displays the description of the port. A textual string containing information about the interface.
Type	Displays the type of connector plugged in the port.
Mtu	Displays the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.
PhysAddress	Displays the physical address of the port. The address of the interface at the protocol layer immediately `below' the network layer in the protocol stack. For interfaces which do not have such an address, for example, a serial line, this object should contain an octet string of zero length.
VendorDescr	Displays the vendor of the connector plugged in the port.
DisplayFormat	Identifies the slot and port numbers (slot/port). If the port is channelized, the format also includes the sub-port in the format slot/port/sub-port
AdminStatus	Configures the port as enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.
OperStatus	Displays the current status of the port. The status includes enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.
LicenseControlStatus	Shows the port license status.
Note: Exception: only supported on VSP 7200 Series.	
ShutdownReason	Indicates the reason for a port state change.
LastChange	Displays the timestamp of the last change.

Name	Description
LinkTrap	Enable or disable link trapping.
AutoNegotiate	Enables or disables Auto-Negotiation for this port. The default Auto-Negotiation behavior depends on the switch model and transceiver type.
AutoNegAd	Specifies the port speed and duplex abilities to advertise during link negotiation. Supported speeds and duplex modes vary, depending on your hardware. The abilities specified in this object are only used when auto-negotiation is enabled on the port. If all bits in this object are disabled, and auto-negotiation is enabled on the port, then the physical link process on the port will be disabled (if hardware supports this ability). Any change to this configuration restarts the auto-negotiation process, which has the same effect as physically unplugging and reattaching the cable attached to the port. If you select default , all capabilities supported by the hardware are advertised.
AdminDuplex	Configures the administrative duplex setting for the port.
OperDuplex	Indicates the operational duplex setting for the port.
AdminSpeed	Configures the administrative speed for the port. Important: If Auto-Negotiation is disabled and you change the administrative speed on a port that results in a configuration mismatch in speed between two ports, VSP 4450 Series and VSP 4900 Series switches can show an incorrect operational status of "up" for the mismatched ports.
OperSpeed	Indicates the operational speed for the port.
QoSLevel	Selects the Quality of Service (QoS) level for this port. The default is level1.
DiffServ	Enables the Differentiated Service feature for this port. The default is disabled.
Layer3Trust	Configures if the system should trust Layer 3 packets coming from access links or core links only. The default is core.
Layer2Override8021p	Specifies whether Layer 2 802.1p override is enabled (selected) or disabled (cleared) on the port. The default is disabled (clear).
Mltid	Shows the MLT ID associated with this port. The default is 0.
Locked	Shows if the port is locked. The default is unlocked.

Name	Description
UnknownMacDiscard	Discards packets that have an unknown source MAC address, and prevents other ports from sending packets with that same MAC address as the destination MAC address. The default is disabled.
DirectBroadcastEnable	Specifies if this interface forwards direct broadcast traffic.
OperRouting	Shows the routing status of the port.
HighSecureEnable	Enables or disables the high secure feature for this port.
RmonEnable	Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.
FlexUniEnable	Enables Flex UNI on the port. The default is disabled.
IngressRateLimit Note: Exception: not supported on VSP 4450 Series, VSP 7400 Series, or VSP 8600 Series.	Limits the traffic rate that the specific ingress port accepts.
IngressRatePeak	Configures the peak rate in Kbps. The default is 0.
IngressRateSvc	Configures the service rate in Kbps. The default is 0.
EgressRateLimitState	Enables or disables egress port-based shaping to bind the maximum rate at which traffic leaves the port. The default is disabled.
EgressRateLimit Note: Exception: not supported on VSP 7400 Series, VSP 8600 Series, or XA1400 Series.	Specifies the egress rate limit in Kbps. Different hardware platforms support different egress rate limits, depending on the port with the highest speed available on the platform. You cannot configure the egress shaper rate to exceed the port capability. If you configure this value to 0, shaping is disabled on the port.
TxFlowControl Note: Exception: not supported on VSP 8600 Series	Configures if the port sends pause frames. By default, an interface does not send pause frames. You must also enable the flow control feature globally before an interface can send pause frames.
TxFlowControlOperState	Shows the operational state of flow control.
BpduGuardTimerCount	Shows the time, starting at 0, since the port became disabled. When the BpduGuardTimerCount reaches the BpduGuardTimeout value, the port is enabled. Displays in 1/100 seconds.

Name	Description
BpduGuardTimeout	Specifies the value to use for port-state recovery. After a BPDU guard disables a port, the port remains in the disabled state until this timer expires. You can configure a value of 0 or to 65535. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.
BpduGuardAdminEnabled	Enables BPDU Guard on the port. The default is disabled.
ForwardErrorCorrection	Configures one of the following options for Forward Error Correction (FEC) on the port: <ul style="list-style-type: none"> • CL 91 • CL 108 • CL 74 • disable • auto The disable option disables this configuration on the port.
ForwardErrorCorrectionApplicability	Displays whether FEC is applicable on the interface.
OperAutoNegotiate	Shows the operational state of Auto-Negotiation.
OperForwardErrorCorrection	Shows the negotiated operational FEC clause. If the value is off, the port supports FEC and is up but not configured for FEC. If the value is notApplicable, the port does not support FEC. If the value is unknown, the port supports FEC but is down.
IsPortShared	Indicates whether the port is combo or not. <ul style="list-style-type: none"> • portShared—Combo port. • portNotShared—Not a combo port.
PortActiveComponent	Specifies whether the copper port is active or fabric port is active if port is a combo port. <ul style="list-style-type: none"> • fixed port—Copper port is active. • gbic port—Fabric port is active.
Action	Performs one of the following actions on the port <ul style="list-style-type: none"> • none - none of the following actions • flushMacFdb - flush the MAC forwarding table • flushArp - flush the ARP table • flushIp - flush the IP route table • flushAll - flush all tables • triggerRipUpdate — manually triggers a RIP update The default is none.
Result	Displays the result of the selected action. The default is none.

Name	Description
AutoSense Note: Exception: not supported on VSP 8600 Series and XA1400 Series.	Enables or disables Auto-sense on the specific port. The default value is disabled for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.
AutoSenseKeepAutoConfig Note: Exception: not supported on VSP 8600 Series and XA1400 Series.	Retains the Auto-sense configuration if you disable Auto-sense on the port. The dynamic configuration becomes a manual configuration and is visible in the show running-config output.
CustomAutoNegAdOrigin	Specifies the origin of Custom Auto Negotiation Advertisements (CANA) configuration on the port. The supported values are: <ul style="list-style-type: none"> • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.
BpduGuardOrigin	Specifies the origin of BPDU Guard configuration on the port. The supported values are: <ul style="list-style-type: none"> • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.
AutoSenseState Note: Exception: not supported on VSP 8600 Series and XA1400 Series.	Displays the Auto-sense port state.
LinkDebounce Note: Exception: not supported on VSP 8600 Series and XA1400 Series.	Specifies the extended debounce timer on the port. The range is 0 to 300000 milliseconds. The value 0 milliseconds disables debounce time. The default value is 1000.
AutoSenseDatalsid Note: Exception: not supported on VSP 8600 Series and XA1400 Series.	Specifies the Auto-sense data I-SID per port. The range is 0 to 16777215.

Configuring RSTP global parameters

Perform this procedure to configure the RSTP global parameters.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **RSTP**.

3. Configure the parameters as required.
4. Click **Apply**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
PathCostDefault	Specifies the version of the spanning tree default path costs that are used by this bridge. A value of 8021d1998 indicates the use of the 16-bit default path costs from IEEE Std. 802.1d-1998. A value of stp8021t2001 indicates the use of the 32-bit default path costs from IEEE Std. 802.1t.
TxHoldCount	Specifies the value used by the port transmit state machine to limit the maximum transmission rate. The default is 3.
Version	Specifies the version of STP that the bridge currently runs. The value stpCompatible indicates that the Spanning Tree Protocol as specified in IEEE 802.1d is in use; rstp indicates that the Rapid Spanning Tree Protocol as specified in IEEE 802.1w is in use.
EnableStp	Indicates whether the spanning tree protocol is active in this STG. The default is enabled.
Priority	Specifies the RSTP bridge priority.
BridgeMaxAge	Specifies the value that all bridges use for MaxAge while this bridge acts as the root.
BridgeHelloTime	The value that all bridges use for HelloTime while this bridge acts as the root.
BridgeForwardDelay	Specifies the value that all bridges use for forward delay while this bridge acts as the root.
DesignatedRoot	Specifies the unique bridge identifier of the bridge recorded as the root in the configuration BPDUs transmitted by the designated bridge for the segment to which the port is attached.
RootCost	Specifies the cost of the path to the root from this bridge.
RootPort	Specifies the port number of the port which offers the lowest cost path from this bridge to the root bridge.
MaxAge	Specifies the maximum age of Spanning Tree Protocol information in hundredths of a second learned from the network on any port before the port is discarded.

Name	Description
HelloTime	Specifies the amount of time in hundredths of a second between the transmission of configuration bridge PDUs by this node on any port while it is the root of the spanning tree (or trying to become the root).
ForwardDelay	Specifies a time value, measured in hundredths of a second, controls how fast a port changes its spanning state after moving towards the forwarding state. The value determines how long the port stays in each of the listening and learning states, which precede the forwarding state. This value is also used after a topology change is detected, and is underway, to age all dynamic entries in the forwarding database.
RstpUpCount	Specifies the number of times the RSTP module is enabled. A trap is generated on the occurrence of this event.
RstpDownCount	Specifies the number of times the RSTP module is disabled. A trap is generated on the occurrence of this event.
NewRootIdCount	Specifies the number of times this bridge detects a root identifier change. A trap is generated on the occurrence of this event.
TimeSinceTopology Change	Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for Common Spanning Tree.
TopChanges	Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for Common Spanning Tree.

Configuring RSTP ports

Configure RSTP to reduce the recovery time after a network breakdown.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **RSTP**.
3. Click the **RSTP Ports** tab.
4. Use the fields in the **RSTP Ports** tab to configure the RSTP ports.
5. Click **Apply**.

RSTP Ports field descriptions

Use the data in the following table to use the **RSTP Ports** tab.

Name	Description
Port	Specifies a unique value, greater than zero, indicating the port number.
Priority	Specifies the value of the priority field.
PathCost	Specifies the contribution of this port to the path cost of paths towards the root that includes this port.
ProtocolMigration	Specifies a port to transmit RSTP BPDUs if operating in RSTP mode. Any other operation on this object has no effect, and RSTP mode returns false if read.
AdminEdgePort	Specifies the administrative value of the Edge Port parameter. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.
OperEdgePort	Specifies the operational value of the Edge Port parameter. The object is initialized to the value of AdminEdgePort and is configured to false on reception of a BPDU.
AdminPointToPoint	Specifies the administrative point-to-point status of the LAN segment attached to this port. A value of forceTrue indicates that this port is treated as if it is connected to a point-to-point link. A value of forceFalse indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means.
OperPointToPoint	Specifies the operational point-to-point status of the LAN segment attached to this port. It indicates whether a port is considered to have a point-to-point connection or not. The value is determined by management or by autodetection as described in the AdminPointToPoint object.
OperVersion	Indicates if the port is in MSTP mode, RSTP mode or STP-compatible mode. MSTP mode transmits MST BDUs, RSTP mode transmits RST BPDUs and STP-compatible transmits Config/TCN BPDUs.

Viewing RSTP port status

View the RSTP port status to ensure proper functioning of RSTP.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **RSTP**.
3. In the RSTP tab, click the **RSTP Status** tab.

RSTP Status field descriptions

Use the data in the following table to use the **RSTP Status** tab.

Name	Description
Port	Specifies a unique value, greater than zero, indicating the port number.
State	Specifies the current state of the port as defined by application of the Spanning Tree Protocol. This state controls what action a port takes on reception of a frame.
Role	Indicates the current port role assumed by this port.
OperVersion	Indicates whether the port is operationally in the RSTP- or STP-compatible mode; that is, whether the port transmits RSTP BPDUs or Config/TCN BPDUs.
EffectivePortState	Specifies the effective operational state of the port. This object is configured to true if the port is operationally up in the Interface Manager, and if Force Port State for this port and the specified port state is enabled. Otherwise, this object is configured to false.

Viewing RSTP Status Statistics

About This Task

You can view status statistics for Rapid Spanning Tree Protocol (RSTP).

Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **RSTP**.
3. In the **RSTP Status** tab, select a port, and then click **Graph**.

RSTP Status Field Descriptions

The following table describes the **RSTP Status** fields.

Name	Description
RxRstBpduCount	Specifies the number of RSTP BPDUs this port received.
RxConfigBpduCount	Specifies the number of configuration BPDUs this port received.
RxTcnBpduCount	Specifies the number of TCN BPDUs this port received.

Name	Description
TxRstBpduCount	Specifies the number of RSTP BPDUs this port transmitted.
TxConfigBpduCount	Specifies the number of Config BPDUs this port transmitted.
TxTcnBpduCount	Specifies the number of TCN BPDUs this port transmitted.
InvalidRstBpduRxCount	Specifies the number of invalid RSTP BPDUs this port received. A trap is generated on the occurrence of this event.
InvalidConfigBpduRx Count	Specifies the number of invalid configuration BPDUs this port received. A trap is generated on the occurrence of this event.
InvalidTcnBpduRxCount	Specifies the number of invalid TCN BPDUs this port received. A trap is generated on the occurrence of this event.
ProtocolMigrationCount	Specifies the number of times this port migrated from one STP protocol version to another. The relevant protocols are STP-Compatible and RSTP. A trap is generated on the occurrence of this event.

Viewing Port Spanning Tree Statistics

View port spanning tree statistics to manage network performance.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **Spanning Tree** tab.

Spanning Tree Field Descriptions

The following table describes parameters on the **Spanning Tree** tab.

Name	Description
InConfigBpdus	The number of Config BPDUs received.
InTcnBpdus	The number of Topology Change Notifications BPDUs received.
InBadBpdus	The number of unknown or malformed BPDUs received.
OutConfigBpdus	The number of Config BPDUs transmitted.
OutTcnBpdus	The number of Topology Change Notifications BPDUs transmitted.

Configuring MSTP global parameters

Configure the global MSTP parameters to determine how MSTP operates for the system. Interface-level parameters override global settings.

Before You Begin

- The system must be in MSTP mode.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.
3. Click the **Globals** tab.
4. Configure MSTP as required.
5. Click **Apply**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
PathCostDefaultType	Specifies the version of the spanning tree default path costs to be used by this bridge. A value of 8021d1998 denotes the use of the 16-bit default path costs from IEEE 802.1d-1998. A value of stp8021t2001 denotes the use of the 32-bit default path costs from IEEE 802.1t.
TxHoldCount	Specifies the value used by the port transmit state to limit the maximum transmission rate. The default is 3.
MaxHopCount	Assigns the MSTP bridge maximum hop count. The range is 100 to 4000 one hundredths of a second. The original MIB erroneously designated the value in hundredths of a second, when it should have been in hops. The replacement MIB kept the range at 100-4000 to remain backwards compatible. To convert this value to hops, divide by 100 so 100-4000 equals 1-40 hops.
NoOfInstancesSupported	Indicates the maximum number of spanning tree instances supported.
MstpUpCount	The number of times the MSTP module is enabled. A trap is generated on the occurrence of this event.
MstpDownCount	The number of times the MSTP module is disabled. A trap is generated on the occurrence of this event.

Name	Description
ForceProtocolVersion	Specifies the version of Spanning Tree Protocol that the bridge currently runs. stpCompatible indicates that the Spanning Tree Protocol as specified in IEEE 802.1d is in use; rstp indicates that the Rapid Spanning Tree Protocol as specified in IEEE 802.1w is in use; and mstp indicates that the multiple spanning tree protocol as specified in IEEE 802.1s is in use. Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with a chassis in STP mode can create a loop in the network. The default is MSTP.
BrgAddress	Specifies the MAC address used by this bridge if it must be referred to in a unique fashion. This should be the numerically smallest MAC address of all ports that belong to this bridge. If concatenated with MstCistBridgePriority or MstBridgePriority, a unique bridge identifier is formed, which is used in the STP.
Root	Specifies the bridge identifier of the root of the common spanning tree as determined by the STP by this node. This value is used as the CIST root identifier parameter in all configuration bridge PDUs originated by this node.
RegionalRoot	Specifies the bridge identifier of the root of the multiple spanning tree region as determined by the STP as executed of this node. This value is used as the common and internal spanning tree (CIST) regional root identifier parameter in all configuration bridge PDUs originated by this node.
RootCost	Specifies the cost of the path to the CIST root from this bridge.
RegionalRootCost	Specifies the cost of the path to the CIST regional root from this bridge.
RootPort	Specifies the port number of the port which offers the lowest path cost from this bridge to the CIST root bridge.
BridgePriority	Specifies the value of the writable portion of the bridge identifier comprising the first two octets. The values you enter for bridge priority must be in steps of 4096. The default is 32768.

Name	Description
BridgeMaxAge	Specifies the value that all bridges use for MaxAge while this bridge acts as the root. The granularity of this timer is specified as 1 second. An agent can return a bad value error if you attempt to configure a value which is not a whole number of seconds. The default is 2000.
BridgeForwardDelay	Specifies the value that all bridges use for forward delay if this bridge acts as the root. Note that 802.1d specifies that the range for this parameter is related to the value of BridgeMaxAge. The granularity of this timer is specified as 1 second. An agent can return a bad value error if you attempt to configure a value which is not a whole number of seconds. The default is 1500.
HoldTime	Determines the interval length in hundredths of a second during which no more than two configuration bridge PDUs can be transmitted by this node.
MaxAge	Specifies the maximum age of Spanning Tree Protocol information learned from the network on any port before it is discarded. This is the value that this bridge currently uses.
ForwardDelay	Specifies the time value, measured in units of hundredths of a second, that controls how fast a port changes its spanning state after moving towards the forwarding state. This value determines how long the port stays in a particular state before moving to the next state.
TimeSinceTopology Change	Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for Common Spanning Tree.
TopChanges	Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for Common Spanning Tree.
NewRootBridgeCount	Specifies the number of times this bridge detects a root bridge change for Common Spanning Tree. A trap is generated on the occurrence of this event.
RegionName	Specifies the name for the region configuration. By default, the region name is equal to the bridge MAC Address.
RegionVersion	Specifies the version of the MST region.
ConfigIdSel	Specifies the configuration identifier format selector used by the bridge. This has a fixed value of 0 to indicate RegionName. RegionVersions are specified as in the standard.

Name	Description
ConfigDigest	Specifies the configured MD5 digest value for this region, which must be 16 octets long.
RegionConfigChange Count	Specifies the number of times a region configuration identifier change is detected. A trap is generated on the occurrence of this event.

Configuring CIST ports for MSTP

Configure Common and Internal Spanning Tree (CIST) ports to configure ports for MSTP.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.
3. Click the **CIST Port** tab.

Note

The MSTP, CIST Port tab contains information for each port that is common to all bridge and spanning tree instances.

4. Use the fields in the **CIST Port** box to configure the MSTP CIST port.
5. Click **Apply**.

CIST Port field descriptions

Use the data in the following table to use the **CIST Port** tab.

Name	Description
Port	Specifies the port number of the port for which this entry contains spanning tree information.
PathCost	Specifies the contribution of this port to the path cost of paths towards the CIST root that includes this port.
Priority	Specifies the four most significant bits of the port identifier of the spanning tree instance which are modified by setting the CistPortPriority value. The values that are configured for port priority must be in steps of 16. Although port priority values can range from 0 to 255, only the following values are used: 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, 240. The default is 128.
DesignatedRoot	Specifies the unique bridge identifier of the bridge recorded as the CIST root in the configuration BPDUs transmitted.
DesignatedCost	Specifies the path cost of the designated port of the segment that connects to this port.

Name	Description
DesignatedBridge	Specifies the unique bridge identifier of the bridge which that port considers to be the designated bridge for the ports segment.
DesignatedPort	Specifies the port identifier of the port on the designated bridge for this port segment.
RegionalRoot	Specifies the unique bridge identifier of the bridge recorded as the CIST regional root identifier in the configuration BPDUs transmitted.
RegionalPathCost	Specifies the contribution of this port to the path cost of paths towards the CIST regional root that include this port.
ProtocolMigration	Indicates the protocol migration state of this port. If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port. An MSTP-compatible port transmits and receives only RSTP BPDUs. If an MSTP port receives an STP BDU, it becomes an STP port. User intervention is required to change this port back to MSTP mode. This process is called Port Protocol Migration. You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.
AdminEdgeStatus	Specifies the administrative value of the Edge Port parameter. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.
OperEdgeStatus	Specifies the operational value of the Edge Port parameter. The object is initialized to the value of AdminEdgeStatus and is configured to false on reception of a BPDU.
AdminP2P	Specifies the administrative point-to-point status of the LAN segment attached to this port. A value of forceTrue indicates that this port is treated as if it connects to a point-to-point link. A value of forceFalse indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means.
OperP2P	Specifies the operational point-to-point status of the LAN segment attached to this port. It indicates whether a port is considered to have a point-to-point connection or not. The value is determined by management or by autodetection as described in the AdminP2P object.

Name	Description
HelloTime	Specifies the amount of time in hundredths of a second between the transmission of configuration bridge PDUs by this node on this port.
OperVersion	Indicates whether the port is operationally in the MSTP mode, the RSTP mode, or the STP-compatible mode; that is, whether the port transmits MST BPDUs, RST BPDUs, or Config/TCN BPDUs. Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with another chassis in STP mode can create a loop in the network.
EffectivePortState	Specifies the effective operational state of the port for CIST. This is true only if the port is operationally up at the interface and protocol levels for CIST. This is configured to false for all other conditions.
State	Specifies the current state of the port as defined by the common spanning tree protocol. It can be disabled, discarding, learning, or forwarding.
ForcePortState	Specifies the current state of the port. You can change the port to either Disabled or Enabled for the base spanning tree instance.
SelectedPortRole	Specifies the selected port role of the port for this spanning tree instance.
CurrentPortRole	Specifies the current port role of the port for this spanning tree instance.

Configuring MSTI bridges for MSTP

Perform this procedure to configure multiple spanning tree instance (MSTI) bridges for MSTP.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.
3. Click the **MSTI Bridges** tab.

Note

The systems generates MSTI bridge instances after you create a VLAN in MSTP mode.

4. Use the fields in the **MSTI Bridges** box to configure the MSTP bridge.
5. Click **Apply**.

MSTI Bridges field descriptions

Use the data in the following table to use the **MSTI Bridges** tab.

Name	Description
Instance	Specifies the spanning tree instance to which this information belongs.
RegionalRoot	Specifies the MSTI regional root identifier value for the instance. This value is used as the MSTI regional root identifier parameter in all configuration bridge PDUs originated by this node.
Priority	Specifies the writable portion of the MSTI bridge identifier comprising the first two octets. The values that are configured for bridge priority must be in steps of 4096. The default is 32768.
RootCost	Specifies the cost of the path to the MSTI regional root as seen by this bridge.
RootPort	Specifies the port number of the port that offers the lowest path cost from this bridge to the MSTI region root bridge.
TimeSinceTopologyChange	Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for this spanning tree instance.
TopChanges	Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for this spanning tree instance.
NewRootCount	Specifies the number of times this bridge detects a root bridge change for this spanning tree instance. A trap is generated on the occurrence of this event.
InstanceUpCount	Specifies the number of times a new spanning tree instance is created. A trap is generated on the occurrence of this event.
InstanceDownCount	Specifies the number of times a spanning tree instance is deleted. A trap is generated on the occurrence of this event.

Configuring MSTI ports for MSTP

Perform the following procedure to configure MSTI ports for MSTP.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.

- Click the **MSTI Port** tab.

**Note**

Port members you select on the VLAN, the system displays **Basic** tab in the **MSTI Port** tab.

- Use the fields in the **MSTI Port** box to configure the MSTP.
- Click **Apply**.

MSTI Port field descriptions

Use the data in the following procedure to use the **MSTI Port** tab.

Name	Description
Port	Specifies the port number of the port for which this entry contains spanning tree information.
Instance	Specifies the spanning tree instance to which the information belongs.
PathCost	Specifies the contribution of this port to the path cost of paths towards the MSTI root that includes this port.
Priority	Specifies the four most significant bits of the port identifier for a given spanning tree instance can be modified independently for each spanning tree instance supported by the bridge. The values configured for port priority must be in steps of 16. The default is 128.
DesignatedRoot	Specifies the unique bridge identifier of the bridge recorded as the MSTI regional root in the configuration BPDUs transmitted.
DesignatedBridge	Specifies the unique bridge identifier of the bridge that this port considers to be the designated bridge for the port segment.
DesignatedPort	Specifies the port identifier of the port on the designated bridge for this port segment.
State	Specifies the current state of the port, as defined by the MSTP. A port which is in forwarding state in one instance can be in discarding (blocking) state in another instance.
ForcePortState	Specifies the current state of the port, that is changed to either disabled or enabled for the specific spanning tree instance.
DesignatedCost	Specifies the path cost of the designated port of the segment connected to this port.

Name	Description
CurrentPortRole	Specifies the current port role of the port for this spanning tree instance.
EffectivePortState	Specifies the effective operational state of the port for a specific instance. This is configured to true if the port is operationally up at the interface and protocol levels for the specific instance. This is configured to false at all other times.

Viewing VLAN and Spanning Tree CIST Statistics

About This Task

View CIST port statistics to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **MSTP**.
3. Click the **CIST Port** tab.
4. Select a port, and then click **Graph**.

CIST Field Descriptions

The following table describes parameters on the **CIST** tab.

Name	Descriptions
ForwardTransitions	Specifies the number of times this port has transitioned to the forwarding state.
RxMstBpduCount	Specifies the number of MSTP BPDUs received on this port.
RxRstBpduCount	Specifies the number of RSTP BPDUs received on this port.
RxConfigBpduCount	Specifies the number of configuration BPDUs received on this port.
RxTcnBpduCount	Specifies the number of TCN BPDUs received on this port.
TxMstBpduCount	Specifies the number of MSTP BPDUs transmitted from this port.
TxRstBpduCount	Specifies the number of RSTP BPDUs transmitted from this port.
TxConfigBpduCount	Specifies the number of configuration BPDUs transmitted from this port.
TxTcnBpduCount	Specifies the number of TCN BPDUs transmitted from this port.
InvalidMstBpduRxCount	Specifies the number of Invalid MSTP BPDUs received on this port.
InvalidRstBpduRxCount	Specifies the number of Invalid RSTP BPDUs received on this port.
InvalidConfigBpduRxCount	Specifies the number of invalid configuration BPDUs received on this port.

Name	Descriptions
InvalidTcnBpduRxCount	Specifies the number of invalid TCN BPDUs received on this port. The number of times this port has migrated from one STP protocol version to another. The relevant protocols are STP-compatible and RSTP/MSTP. A trap is generated on the occurrence of this event.
ProtocolMigrationCount	Specifies the number of times this port has migrated from one STP protocol version to another. The relevant protocols are STP-compatible and RSTP. A trap is generated on the occurrence of this event.

Viewing VLAN and Spanning Tree MSTI Statistics

About This Task

View multiple spanning tree instance (MSTI) port statistics to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **MSTP**.
3. Click the **MSTI Port** tab.
4. Select a port, and then click **Graph**.

MSTI Field Descriptions

The following table describes parameters on the **MSTI** tab.

Name	Description
ForwardTransitions	Specifies the number of times this port has transitioned to the forwarding state for this specific instance.
ReceivedBPDUs	Specifies the number of BPDUs received by this port for this spanning tree instance.
TransmittedBPDUs	Specifies the number of BPDUs transmitted on this port for this spanning tree instance.
InvalidBPDUsRcvd	Specifies the number of invalid BPDUs received on this port for this spanning tree instance.

SPB-PIM Gateway configuration

	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.0
	VSP 8400 Series	VOSS 6.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

SPB-PIM Gateway configuration includes controller and gateway nodes, and Multicast Source Discovery Protocol (MSDP) configuration.

The following topics provide necessary concepts and procedures to configure SPB-PIM Gateway.

SPB-PIM Gateway fundamentals

This section provides conceptual content to help you configure and customize SPB-PIM Gateway (SPB-PIM GW) on the switch.

IP Multicast over Fabric Connect in Protocol Independent Multicast networks

IP Multicast over Fabric Connect provides simplicity in provisioning and deploying IP multicast bridging and routing. Also, due to the fact that only one control plane protocol (IS-IS) exists, convergence times in the event of a network failure, are typically sub second.

IP Multicast over Fabric Connect

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. IP Multicast over Fabric Connect uses these extensions, along with the Internet Group Management Protocol (IGMP) Snooping and Querier functions at the edge of the SPBM cloud, to create sub-trees of the VSN SPB for each multicast group to transport IP multicast data.

With IP Multicast over Fabric Connect, the switch supports the following:

- Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network (Layer 2 VSN with IP Multicast over Fabric Connect). Example application: Multicast in data centers.
- IP multicast routing support for IP Shortcuts using SPBM in the core and IGMP on the access (IP Shortcuts with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.
- Layer 3 Virtual Services Network with VRF based routing support for IP Multicast over Fabric Connect in the core and IGMP on the access (Layer 3 VSN with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image Distribution, VXLAN, Multi-tenant IP multicast.

Important

Sources must be IGMP enabled to support discovery functions specific to the multicast applications in use.

IP Multicast over Fabric Connect restrictions

- IP Multicast over Fabric Connect cannot connect to an IP Multicast router outside the SPB network.
- You can only deploy IP Multicast over Fabric Connect in environments where there are no multicast routers between the edge of the SPB network and the IP Multicast hosts that connect to the network.
- An existing network which is Protocol Independent Multicast (PIM) based cannot participate in the SPB network either by connecting to SPB originated streams or by injecting PIM network streams into the SPB network.
- In certain environments it is not possible to deploy an SPB network all the way to the point where the SPB network directly connects to an IGMP edge.

You encounter these restrictions during the following typical deployment scenarios:

- **Scenario 1:** You deployed IP Multicast using PIM and want to expand the network by deploying SPB for the new portion of the network. You want multicast applications to work across the old and new portion of the network.
- **Scenario 2:** Multicast traffic is exchanged between independent network operators at the boundary between their networks. PIM is the multicast routing protocol. A network operator wants to upgrade or replace the existing network to an SPB network. The inter-domain multicast traffic exchanges with other networks should not be disrupted.

The following figure shows the traditional Multicast over Fabric Connect environment with no PIM routers.

Figure 243: IP Multicast over Fabric Connect streams

In the above figure, sources and receivers on the edges of the SPB network are IGMP hosts and sources of multicast data. Hence, the traditional Multicast over Fabric Connect host-to-host deployment works.

The following figure shows the traditional Multicast over Fabric Connect environment with PIM routers.

Figure 244: IP Multicast over Fabric Connect Streams

In the above figure, sources and receivers on the edges of the SPB network, which are IGMP or source hosts can communicate over the SPB network. Sources and receivers connected to PIM routers cannot participate in the SPB network.

SPB-PIM Gateway

Multicast over Fabric Connect cannot connect to a PIM router that is external to the SPB network. When a receiver joins the SPB network for a specific group, the receiver must receive multicast streams in the neighboring multicast domains (PIM network). Similarly, a receiver in the neighboring multicast domain (PIM network) must receive multicast streams from sources in the SPB network. SPB-PIM Gateway (SPB-PIM GW) provides multicast inter-domain communication between an SPB network and a PIM network. SPB-PIM GW accomplishes this inter-domain communication across a special gateway VLAN. The gateway VLAN communicates with the PIM network through a subset of the full protocol messaging required for RFC 4601 compliance of a PIM interface, and translates the PIM network requirements into SPB language and vice versa.

SPB-PIM GW provides the following functionality:

- One or more SPB domains can share streams with one or more PIM domains.
- SPB-PIM GW can connect two independent SPB domains. The independent SPB domains connected by SPB-PIM GW share a subset of multicast streams without a PIM network in between.

SPB-PIM GW is supported in the GRT and in VRFs.

Multicast over Fabric Connect with SPB-PIM GW

In a Multicast over Fabric Connect environment with SPB-PIM GW, the SPB network connects sources and receivers from one or more PIM networks. The multicast traffic is then delivered across the domain boundaries through a path that transports the multicast traffic.

Multicast over Fabric Connect with SPB-PIM GW functionality consists of SPB nodes, which act as SPB-PIM Controller nodes and SPB-PIM Gateway nodes. The SPB Controller uses the Multicast Source Discovery Protocol (MSDP) to discover foreign sources.

The following figure shows the Multicast over Fabric Connect environment with SPB-PIM GW.

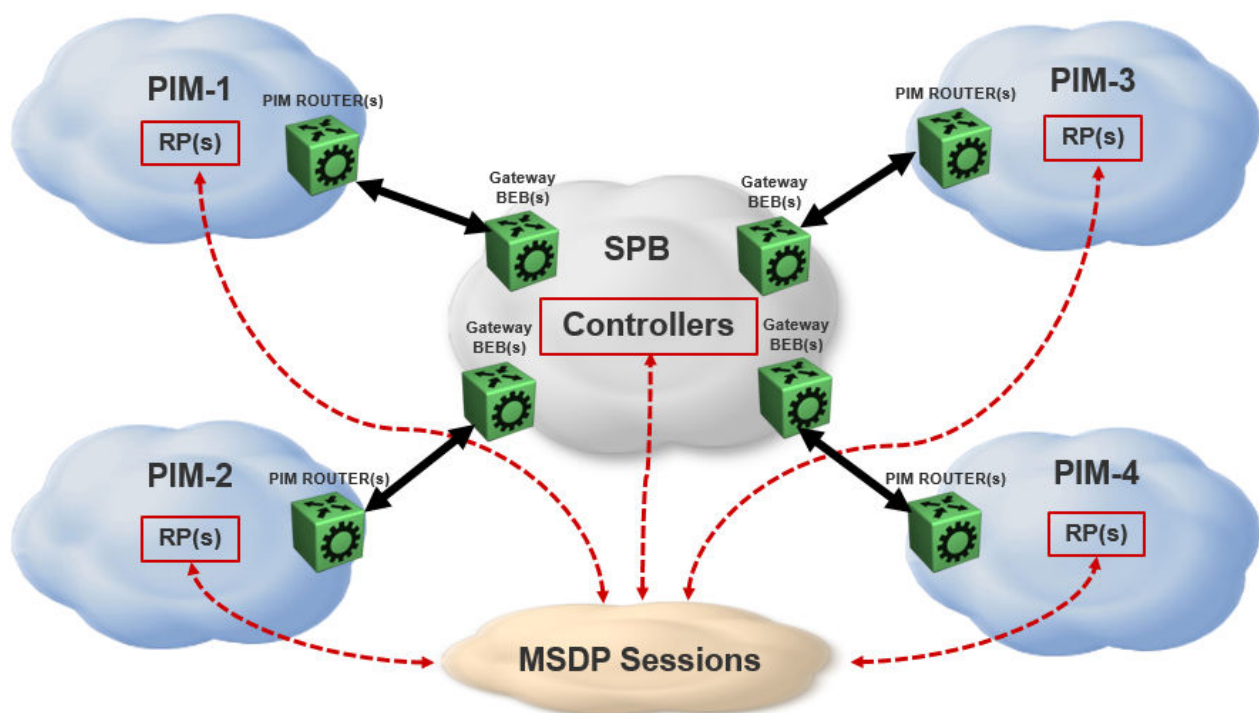

Figure 245: Multicast over Fabric Connect with SPB-PIM GW

SPB-PIM GW components

SPB-PIM GW has two functional components:

- SPB-PIM Gateway Controller Nodes (Controller), which are used for multicast source discovery.
- SPB-PIM Gateway Nodes (Gateway), on which the SPB-PIM Gateway interfaces reside.

Note

The Controller and Gateway can reside in a single node.

The following figure shows the SPB-PIM GW components.

Figure 246: SPB-PIM GW components

SPB-PIM Gateway Controller Node

SPB-PIM Gateway Controller Node (Controller) shares stream information between the local SPB domain and a foreign domain. The foreign domain is the PIM network Rendezvous point (RP) or another SPB domain Controller.

The Controller functionality is outlined below:

- The Controller discovers PIM sources for a specific multicast group and distributes them to the Gateways.

Note

PIM source discovery is either through MSDP or static configuration of foreign streams at the Controller.

- The Controller advertises local SPB originated streams through MSDP to another PIM domain or another SPB domain.
- The Controller references the Unicast IP route table to determine which Gateway has the best route to the PIM source. The Controller then assigns the stream to the selected Gateway.

The Controller Node has the following components:

- Source Discovery (MSDP and static configuration)
- Gateway Selection Controller

Source Discovery (MSDP and static configuration)

MSDP resides in the Controller BEB or Controller BCB and PIM network RP that wish to advertise multicast source information between domains.

You can implement SPB-PIM GW under the following scenarios:

- The multicast source resides in the Protocol Independent Sparse Module (PIM-SM) domain. The multicast source must be discovered by MSDP residing on the Gateway Controller in the SPB domain.
- The multicast source resides in the SPB domain. The multicast source must be advertised to the neighboring PIM domain through MSDP peers.

For more information on MSDP, see [MSDP overview](#) on page 3194.

Note

You can also configure multicast sources statically on the Controller. Static configuration is useful for SSM multicast group range streams in the foreign domain, which are not advertised by MSDP. Static configuration is also useful for when two SPB domains are connected through a PIM Gateway, and want to only advertise a subset of streams to each other, without enabling MSDP.

Gateway Selection Controller

The Gateway Selection Controller resides in the Controller BEB or Controller BCB node in the SPB network. The Gateway Selection Controller receives source information from MSDP or through static configuration. The source information consists of the following components:

- Sender IP address (S)
- Group IP address (G)
- VRF ID of the stream
- RP of the source (optional)

Gateway Selection Controller finds the best BEB (Gateway Node) in the SPB network through which the sender sends traffic to group G. The Gateway Selection Controller performs the following tasks:

- The Gateway Selection Controller uses Layer 3 reachability information to reach S, which is retrieved from the ISIS IP Shortcuts (IPSC) database.
- The VSN identifier (I-SID) is determined by using the VRF ID provided by MSDP.
- The Gateway Selection Controller uses the VRF ID and searches the IP shortcut database to determine which Gateway is closest to S.

Note

If multiple BEBs have a route to S, the BEB with the lowest Layer 3 metric is selected as the Gateway.

Note

If a Gateway link fails or the cost of the route changes, the selection process identifies the link failure as a route change and selects another best Gateway BEB.

The selected Gateway BEB for a stream must satisfy the following criteria:

- The selected Gateway BEB for a stream must announce a route to the source of the foreign stream through ISIS.

**Note**

Among all the routes to the source of the foreign stream announced by different BEBs through ISIS, the route announced by the selected Gateway has the longest prefix match and has the lowest external route metric.

- If multiple BEBs meet the Gateway selection criteria, a deterministic hash function of system ID, source IP address, and group IP address is used. The deterministic hash function is computed for each of the BEBs that meet the Gateway selection criteria. The BEB that generates the lowest hash value is selected as the Gateway for the stream.

The result of the Gateway selection process is saved in the Gateway assignment table. The Gateway assignment table consists of VSN identifier or I-SID, S, G, and the selected Gateway BEB. Having only one selected Gateway BEB ensures that traffic from source S is drawn into the SPB network by only one BEB, the selected Gateway BEB. The selection Controller then distributes the Gateway assignment table information to all the Gateway nodes.

SPB-PIM Gateway Node

The SPB-PIM Gateway Node (Gateway) has the following components:

- Gateway Selection Agent
- SPB-PIM Gateway interface

Gateway Selection Agent

The Gateway Selection Agent (Agent) resides in the Gateway BEB Node in the SPB network. The Gateway BEB has connections into the foreign network over SPB-PIM Gateway Interfaces. The Agent receives foreign network source information from the Controller BEB or the Controller BCB Node. The source information consists of the following components:

- Sender IP address (S)
- Group IP address (G)
- VSN identifier (I-SID)
- Gateway assigned to the stream

The Agent interacts with SPB-PIM Gateway interface and creates the multicast path. The Agent receives foreign source information from the Controller and creates a foreign source address (SA) cache after validating the reachability to S. The Agent interacts with the SPB-PIM Gateway interface to validate that the next-hop ip address toward the source is a valid PIM adjacency. The foreign SA cache includes the following components:

- Source IP address (information received from the Gateway Controller)
- Group IP address (information received from the Gateway Controller)
- Ingress port (The port through which S is accessible)
- Upstream IP address (The next-hop IP address, which is also the PIM neighbor across the SPB-PIM Gateway interface which is used to reach S as indicated by the unicast routing entry)
- Ingress VLAN ID

If multiple next-hops are available, then the first valid PIM neighbor next-hop is used for the upstream.

Note

If the Agent receives the same source information from multiple Controllers, then the Agent takes action only for the information received from the preferred Controller. The Controller with the lowest system ID is the preferred Controller.

SPB-PIM Gateway interface

The SPB-PIM Gateway interface provides inter-domain multicast services. The SPB-PIM Gateway interface connects senders and receivers of multicast streams across a PIM Domain and a SPB network boundary over a Gateway interface. The SPB-PIM Gateway interface provides the following functionality:

- PIM HELLO exchanges
- Issuing Joins and Leaves
- Process received Joins and Leaves
- Implements the Gateway assignment table by acting as the Ingress BEB for streams for which the SPB-PIM Gateway interface is the selected Gateway
- Enforces the Gateway assignment table and does not forward streams for which the SPB-PIM Gateway interface is not the selected Gateway
- Forwards local and remote SPB streams to satisfy stream requests from neighboring multicast domains
- SPB-PIM Gateway Interfaces supports both SM and SSM multicast group range joins and prunes. *G joins are only supported in SM group range.

The PIM Gateway interface resides in the SPB-PIM Gateway Node (Gateway). The SPB-PIM Gateway interface connects to a PIM router in a PIM network or to another Gateway BEB in an SPB network. Local hosts (IGMP member hosts and multicast data source hosts) are not supported on SPB-PIM Gateway interfaces, only PIM Routers or another SPB BEB with SPB-PIM Gateway interface configured. Multicast data from local source hosts and IGMP reports from local hosts are dropped. An SPB Node must be configured as a SPB-PIM Gateway Node if the SPB Node is connected to a foreign PIM network or a foreign SPB network. A single Gateway Node can have multiple SPB-PIM Gateway interfaces. The SPB-PIM Gateway interface can be a VLAN or a brouter port, can reside on an MLT and is fully virtualized. The SPB-PIM Gateway interface is a translation mechanism between the PIM protocol and SPB TLVs.

Note

- Only PIM protocol messages are communicated over the SPB-PIM Gateway interface
- Only SPB TLVs are communicated over Fabric Connect over SPB
- The SPB-PIM Gateway interface is the only component that handles the translation mechanism

The SPB-PIM Gateway interface communicates with the PIM router through the standard PIM protocol messaging HELLO, JOIN, and PRUNE. The SPB-PIM Gateway interface then forms a normal PIM adjacency with the PIM router or another SPB Gateway Node. The SPB-PIM Gateway Interface processes received SG joins and prunes, *G joins and prunes, and SG-RPT joins and prunes. The SPB-PIM Gateway interface transmits SG joins and prunes, but never *G joins. The SPB-PIM Gateway Interface does not have RP capabilities, and therefore has no need for group-to-RP mapping configurations. A *G

JOIN received on a SPB-PIM Gateway Interface is accepted if the destination IP is the IP address of the interface or of a neighbor on the interface if the neighbor is learned on another port in the interface. However, the RP address within the *G JOIN message is ignored by the SPB-PIM Gateway Interface.

MSDP overview

MSDP enables advertisement of multicast source information between different PIM-SM domains. This function of MSDP in SPB-PIM GW topologies is to advertise multicast source information between SPB domains and PIM domains. MSDP routers in a PIM-SM or SPB domain have a peering relationship with MSDP peers in another domain. The peering relationship is a TCP connection in which the control information is exchanged. The TCP connection between peers uses the underlying unicast routing system.

Source Active messages

In a PIM domain, MSDP enabled routers are RPs. MSDP routers form adjacencies through TCP port 639 to share multicast source information. This functionality is similar to the Border Gateway Protocol (BGP). When an MSDP router receives multicast source information, the routers use reachability information to perform Reverse Path Forwarding (RPF) checks. The reachability information is exchanged through BGP or any other unicast routing protocol.

When a RP router learns of a new (S,G), the RP router saves the (S,G) information and the RP address in the MSDP Source Active (SA) local cache. The RP router learns the new (S,G) through a directly connected source or PIM register message. The RP router then sends an SA update message which contains (S,G,RP) information to the MSDP peers. The MSDP peers broadcast the SA to RPs in their local domains and to their MSDP peers in other PIM-SM domains.

Note

A PIM domain is a set of routers in a single Autonomous System (AS), which uses the same RP for any given multicast group.

When an SPB-PIM Gateway Controller in the SPB domain learns of a new (S,G) in its own domain, the Controller saves the (S,G) information in the local SA cache. The Controller learns the new (S,G) through a directly connected source or Intermediate-System-to-Intermediate-System (IS-IS). The controller sends an SA update message to the MSDP peers in the PIM domain. SA uses the CLIP address configured on the controller as the RP address.

Note

Configure CLIP before you enable MSDP. Peer connections use the CLIP address as the local address.

Reverse Path Forwarding check

When an MSDP peer receives the SA from a peer, the MSDP performs an RPF check. The RPF check ensures that the SA received from the MSDP peer is the closest to the originating RP. An RPF check prevents SA loops.

Note

This RPF check is different from the multicast routing RPF check.

If the RPF checks pass, then the receiving MSDP enabled router saves the SA information in the SA foreign cache and makes it available to the local domain. Each MSDP peer floods the SA information away from the originating RP. The flooding process is called peer RPF flooding.

SA redistribution and filtering

Redistribution and filtering is used to control SA flooding. The MSDP redistribute policy is applied on the MSDP node that originates the SAs to control which SAs are advertised on all MSDP peers. An SA filter is applied to a specific MSDP peer in the inbound direction or outbound directions or both inbound and outbound direction on any MSDP router. Filtering is multicast group based.

When configuring MSDP redistribution, use prefix lists to create the route policies. When a route policy is created it must match the group prefix with the name of the prefix list created for the group address. If deny action is set for the lists in the route-policy, the policy blocks the matching groups from all the sources. If permit action is set for the lists in the route-policy, the policy accepts the matching groups from all the sources. MSDP redistribution does not refer to the redistribution of SPB domain sources to MSDP. MSDP redistribution refers to SAs which needs to be redistributed to other MSDP peers.

Note

MSDP redistribution is applied globally to all MSDP peers. SA filtering is used to filter SAs on a peer-to-peer level.

MSDP and SPB-PIM GW

The SPB-PIM GW functional component for MSDP resides in the SPB-PIM Gateway Controller node (Controller).

Overview

Controllers from an SPB network discover sources through MSDP sessions with RPs from a PIM network. Once the SA packed is received at the MSDP module of the Controller, the IP routing table is examined to determine which peer is the next hop towards the originating RP of the SA message. Once the SA RPF test passes, the SA packet is saved in the foreign cache and passed to the Controller.

The Controller nodes also distribute the sources from an SPB domain to a PIM domain through an MSDP session with RPs in the PIM network. Similar to RP, when a Controller in the SPB domain learns of a new (S,G), through a directly connected source or ISIS, the Controller saves the new (S,G) in its local SA cache. The Controller then transmits an SA update message for this source to its MSDP peers in the PIM domain. The Controller that sends the SA to the MSDP is viewed as the RP (circuitless IP interface is used).

MSDP as part of SPB-PIM GW

MSDP does not work with the traditional PIM implementation. MSDP communicates only with the Controller and should be configured as an IP endpoint.

MSDP configuration considerations:

- A circuitless IP interface (CLIP) is used in the context of global router or VRF, hence at least one CLIP in each VRF should be configured.
- MSDP should use a single CLIP address as the source for establishing all MSDP connections in the same VRF.
- For SPB sources, this CLIP is used as the RP in all SA messages advertised.

- MSDP source IP address should be one of the CLIP interfaces pre-configured on the global router or VRF.
- The originator-id should be configured before enabling MSDP.

**Note**

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers.

The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

For more information on MSDP configuration, see [Multicast Source Discovery Protocol configuration](#) on page 3197.

Full mesh group

MSDP mesh groups are full mesh of MSDP peers and is a subset of MSDP speakers. MSDP mesh groups are used for SA flooding which is similar to the BGP route reflector concept. MSDP floods the SA to all the members of the mesh group when:

- The MSDP peers are fully meshed
- The MSDP enabled router learns a new SA from a non-member of its mesh group
- The SA passes the RPF check

The receiving routers accept the SA and forwards it only to any non-mesh Group MSDP peers.

The SPB-PIM Gateway is deployed in two models:

- Model 1: All multicast networks have peering agreements with one another. The full mesh MSDP is setup.
- Model 2 : An inter-domain multicast provider exists. All multicast networks setup MSDP peering with the provider.

The controllers relay SA messages between individual networks.

**Note**

Consider the following when you deploy SPB-PIM Gateway:

- Use mesh group of MSDP peers (PIM RP's and SPB-PIM Gateway Controller nodes) to avoid flooding and RPF failure.

**Note**

Since MSDP uses CLIP interface in its peering relation, the MSDP peer may not fall in any of the RFC rules and the MSDP SA messages will be rejected.

- Controllers from the same SPB network must not have MSDP sessions with each other, regardless of whether mesh groups are used or not.
- When using mesh groups, all Controllers within one SPB domain should peer with the same set of RPs and Controllers in adjacent domains, ie, one Controller should not peer with an RP that the other Controllers do not peer with.

Multicast Source Discovery Protocol configuration

This section provides procedures to configure Multicast Source Discovery Protocol (MSDP) using the Command Line Interface (CLI) and Enterprise Device Manager (EDM).

Basic MSPD configuration using the CLI

This section provides procedures to configure Basic MSDP using the command line interface (CLI).

Configuring the MSDP originator ID

Configure the originator ID to set the Rendezvous Point (RP) address inside the Source Active (SA) message. The RP address must be a pre-configured CLIP interface on the global router or a VRF. The RP address is also the local IP address in all peer relations.

**Note**

To delete the originator ID, you must first disable MSDP.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Configure the MSDP originator ID:

```
ip msdp originator-id {A.B.C.D}
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp originator-id 2.0.2.2
```

Variable definitions

The following table defines parameters for the **ip msdp originator-id** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP source IP address. The IP address must be one of the CLIP interfaces configured on the global router or a VRF.

Configuring MSDP on a VRF

Create an MSDP instance on a user defined VRF to allow further configuration to take place. This command does not exist in the Global Configuration mode because the MSDP instance for a default VRF is created by default.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```
2. Create the MSDP instance:

```
ip msdp
```

Enabling MSDP globally

Enable or disable MSDP globally on the device to allow further configuration to take place.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable MSDP globally on the switch:

```
ip msdp enable
```

Creating an MSDP peer

Create an MSDP peer to establish a peer relationship between the local MSDP enabled router and a peer in another domain.

**Important**

Do not enable more than 20 active peers.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Create an MSDP peer:

```
ip msdp peer {A.B.C.D}
```

3. Enable an MSDP peer:

```
ip msdp peer {A.B.C.D} enable
```

**Note**

MSDP peer is disabled by default.

4. (Optional) Specify the remote autonomous system (AS) number of the MSDP peer:

```
ip msdp peer {A.B.C.D} remote-as WORD<0-11>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp peer 21.0.0.2
Switch:1(config)#ip msdp peer 21.0.0.2 enable
Switch:1(config)#ip msdp peer remote-as 1
```

Variable definitions

The following table defines parameters for the **ip msdp peer** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
WORD<0-11>	Specifies the AS number of the MSDP peer, 0-65535 (2-Byte AS) 0-4294967295 (4-Byte AS).

MSDP Peer Configuration using the CLI

This section provides procedures to configure MSDP peer using the command line interface (CLI).

Configuring a peer description

Configure a peer description to add descriptive text to an MSDP peer for easy identification of a peer.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the peer description:

```
ip msdp description {A.B.C.D} WORD<1-255>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp peer 21.0.0.2 primary
```

Variable definitions

The following table defines parameters for the **ip msdp description** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
WORD<1-255>	Specifies a descriptive text to a MSDP peer in the range of 1-255 characters. To include spaces in the peer description, enclose the text string in quotation marks.

Securing control messages

Configure Message Digest (MD) 5 authentication to secure control messages on the TCP connection between MSDP peers.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Enable MD5 authentication:

```
ip msdp md5-authentication {A.B.C.D} [enable]
```

3. Specify the case sensitive password for MD5 authentication:

```
ip msdp password peer {A.B.C.D} WORD<1-80>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp md5-authentication 21.0.0.2 enable
Switch:1(config)#ip msdp password peer 21.0.0.2 helloworld
```

Variable definitions

The following table defines parameters for the **ip msdp** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.
<i>WORD<1-80></i>	Specifies the MD5 authentication password.

Configuring the MSDP peer SA limit

Configure the SA limit to limit the number of SA messages from an MSDP peer that the router saves in the SA cache. The default value is 6,144 messages.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```
2. Configure the SA limit:

```
ip msdp sa-limit {A.B.C.D} <0-6144>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp sa-limit 21.0.0.2 6100
```

Variable definitions

The following table defines parameters for the **ip msdp sa-limit** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.
<i><0-6144></i>	Specifies the maximum number of SA messages to keep in SA cache.

Limiting which packets the router sends

Configure the time-to-live (TTL) threshold to limit which multicast data packets the router encapsulated in SA Messages forwarded to an MSDP peer. The TTL limits the number of hops a packet can take before the router drops the packet. The router sends out SA Messages with encapsulated data only if

TTL equals or exceeds the value you configure. If the TTL is lower than the value you configure, the router drops the data packet and forwards the SA Message without the encapsulated data.

Note

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers.

The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Configure the MSDP peer TTL threshold:

```
ip msdp ttl-threshold {A.B.C.D} <1-255>
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp ttl-threshold 21.0.0.2 10
```

Variable definitions

The following table defines parameters for the **ip msdp ttl-threshold** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
<1-255>	Specifies the TTL value. Default value is 1.

Configuring the MSDP peer keep alive messages

Configure keepalive messages to adjust the interval in seconds at which an MSDP peer sends keep alive messages (default is 60 seconds) and the interval at which the MSDP peer waits for keep alive messages from other peers before it declares them down (default is 75 seconds).

**Note**

In a peer relationship, the keep alive interval configured on one peer must be at least 1 second less than the hold time configured on the other side of the peer relationship. This is not applicable when the hold time is set to 0 seconds.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the MSDP peer keep alive interval:

```
ip msdp keepalive {A.B.C.D} <0-21845> <0-65535>
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp keepalive 21.0.0.2 70 71
```

Variable definitions

The following table defines parameters for the **ip msdp keepalive** command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code><0-21845></code>	Specifies the keep alive interval in seconds. The default is 60 seconds.
<code><0-65535></code>	Specifies the hold time interval in seconds. The default is 75 seconds. Note: 0 seconds means the peer never expires. Values 1 and 2 are not allowed.

Configuring the MSDP peer connect-retry period

Configure the connect-retry period to specify the amount of time, in seconds, between connection attempts for peering sessions. The default is 30 seconds.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the MSDP peer connect-retry period:

```
ip msdp connect-retry {A.B.C.D} <1-65535>
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp connect-retry 21.0.0.2 40
```

Variable definitions

The following table defines parameters for the **ip msdp connect-retry** command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code><1-65535></code>	Specifies the connect-retry interval in seconds. The default is 30 seconds.

Clearing the peer connection

Clear the peer connection to clear the TCP connection to the specified MSDP peer, and reset all MSDP message counters.

**Note**

This procedure does not clear the SA cache entries the router learns from the peer.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear the peer connection:

```
clear ip msdp peer {A.B.C.D} [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#clear ip msdp peer 21.0.0.2
```

Variable definitions

The following table defines parameters for the `clear ip msdp peer` command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code>vrf WORD<0-16></code>	Specifies the VRF name.
<code>vrfids WORD<0-512></code>	Specifies the VRF ID.

Deleting an MSDP peer

Use this procedure to delete an MSDP peer.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Clear the peer connection:

```
no ip msdp peer {A.B.C.D}
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#no ip msdp peer 21.0.0.2
```

MSDP Message Control using the CLI

Filtering PIM routes

Filter SPB routes to filter which (S,G,RP) entries sent out to all MSDP peers. This procedure applies only to the rendezvous point (RP) that originates the MSDP SA messages and not the intermediate MSDP peers that forward the received SA messages.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```
2. Create the MSDP filter:

```
ip msdp redistribute
```
3. Create the route policy name:

```
ip msdp redistribute route-policy WORD<1-64>
```

4. Apply the redistribution filters:

```
ip msdp apply redistribute
```

Example

```
Switch:1>enable

Switch:1#configure terminal

Switch:1(config)#ip msdp redistribute

Switch:1(config)#ip msdp redistribute route-policy helloworld

Switch:1(config)#ip msdp apply redistribute
```

Variable definitions

The following table defines parameters for the **clear ip redistribute** command.

Variable	Value
<i>WORD</i> <1-64>	Specifies the route policy name.

Filtering SA messages

Filter SA messages to determine which SA messages to accept from a peer and which SA messages to send to a peer. By default, no inbound or outbound filter exists.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`
2. Create the inbound filter:

```
ip msdp sa-filter in {A.B.C.D}
```
3. Create the inbound filter route policy name:

```
ip msdp sa-filter in {A.B.C.D} route-policy WORD<1-64>
```
4. Create the outbound filter:

```
ip msdp sa-filter out {A.B.C.D}
```
5. Create the outbound filter route policy name:

```
ip msdp sa-filter out {A.B.C.D} route-policy WORD<1-64>
```

Example

```
Switch:1>enable

Switch:1#configure terminal

Switch:1(config)#ip msdp sa-filter in 21.0.0.2 route-policy helloworld
```

Variable definitions

The following table defines parameters for the **ip msdp sa-filter** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.
<i>route-policy WORD<1-64></i>	Specifies the route policy name for an inbound or outbound filter.

Configuring MSDP mesh groups

Configure mesh groups to reduce SA flooding. A mesh group does not forward SA messages to other group members. The originator, which is also a mesh group member, forwards SA messages to all group members. Create MSDP mesh groups from a group of meshed MSDP speakers from a domain.

Note

The MSDP router does not belong to any mesh group by default.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the MSDP mesh group:

```
ip msdp mesh-group WORD<1-64> {A.B.C.D}
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp mesh-group helloworld 21.0.0.2
```

Variable definitions

The following table defines parameters for the **ip msdp mesh-group** command.

Variable	Value
<i>WORD<1-64></i>	Specifies the mesh group name.
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.

Clearing the MSDP SA cache

Clear the SA cache to clear the SA entries the router learns from all peers or a specific peer.

**Note**

This procedure clears the foreign cache. This procedure does not clear the local cache.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Clear the SA cache for all peers:
`clear ip msdp sa-cache [vrf WORD<0-16>] [vrfids WORD<0-512>]`
3. Clear the SA cache for a specific peer:
`clear ip msdp sa-cache peer {A.B.C.D} [vrf WORD<0-16>] [vrfids WORD<0-512>]`
4. Clear the SA cache for a specific group range, source range, and RP.
`clear ip msdp sa-cache [source prefix/len] [group prefix/len] [rp {A.B.C.D}] [vrf WORD<0-16>] [vrfids WORD<0-512>]`

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#clear ip msdp sa-cache peer 21.0.0.2
```

Variable definitions

The following table defines parameters for the **clear ip msdp sa-cache** command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code>vrf WORD<0-16></code>	Specifies the VRF names.
<code>vrfids WORD<0-512></code>	Specifies the VRF ID.

MSDP Verification using the CLI

This section provides procedures to verify MSDP using the command line interface (CLI).

Displaying the peer information

Use the following procedure to display the peer configuration and SA message information.

Procedure

1. Enter Privileged EXEC mode:
`enable`

2. Display the peer information:

```
show ip msdp peer {A.B.C.D} [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

Example

```
Switch:#enable
Switch:1#show ip msdp peer 2.2.2.2
=====
                        MSDP Peer - GlobalRouter

```

Variable definitions

The following table defines parameters for the **show ip msdp peer** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
vrf WORD<0-16>	Displays configuration info for a particular VRF.
vrfids WORD<0-512>	Displays configuration info for a particular VRF ID.

Displaying the SA cache

Use the following procedure to display the (S,G) state learned from MSDP peers and the local (S,G) state. The local (S,G) is the SPB (S,G) sent to MSDP.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display the SA cache:

```
show ip msdp sa-cache [local] [vrf WORD<0-16>] [vrfids WORD<0-512>]
[group {A.B.C.D}] [rp {A.B.C.D}] [source {A.B.C.D}]
```

Example

```

```

Variable definitions

The following table defines parameters for the **show ip msdp show-all** command.

Variable	Value
<code>file WORD<1-99></code>	Specifies the file name to save the display output.
<code>vrf WORD<0-16></code>	Displays configuration information for a particular VRF.
<code>vrfids WORD<0-512></code>	Displays configuration information for a particular VRF ID.

Clearing IPv4 MSDP Statistics

Use the following procedure to clear all IPv4 Multicast Source Discovery Protocol (MSDP) statistics for all peers or a specific peer.

About This Task

The switch supports this command for local management VRF or global routing table (GRT). If you do not specify a VRF or VRF ID, the switch defaults to GRT.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Clear IPv4 MSDP statistics for all peers:

```
clear ip msdp statistics [vrf WORD<0-16>] [vrfids WORD<0-512>]
```
3. Clear IPv4 MSDP statistics for a specific peer:

```
clear ip msdp statistics {A.B.C.D.} [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

Variable Definitions

Use the data in the following table to use the **clear ip msdp statistics** command.

Variable	Value
<code>vrf WORD<0-16></code>	Specifies a VRF instance by VRF name.
<code>vrfids WORD<0-512></code>	Specifies the ID of the VRF.
<code>{A.B.C.D.}</code>	Specifies the IPv4 MSDP address for a specific peer.

Basic MSDP configuration using the EDM

This section provides procedures to configure basic MSDP using the EDM.

Configuring the MSDP originator ID

Configure the originator ID to set the RP address inside the SA message. The RP address must be a pre-configured CLIP interface on the global router or a VRF. The RP address is also the local IP address in all peer relations.

**Note**

Originator ID cannot be deleted if MSDP is enabled.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Globals** tab.
4. In the **RPAddress** box, type the IP address to use as the originator ID.
5. Click **Apply**.

Global field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
Enabled	Enables MSDP. If you clear this check box, you disable MSDP. The default setting is clear (disabled).
CacheLifetime	Configures the lifetime given to SA cache entries when created or refreshed.
NumSACacheEntries	Displays the total number of entries in the SA cache.
RPAddress	Specifies the IP address to use as the originator ID. If the address is not a system local address, the system rejects the configuration.
RouteMapName	Specifies the name of the optional route policy to create or modify. You do not need to create a route policy to use the redistribution filter. Note: To delete the route map name, clear the field and click Apply .
RedistributeFilterEnabled	Filters the (S,G,RP) entries provided by PIM to MSDP. The default is clear (disabled).
RedistruteFilterApply	Applies the changes made to the redistribute filter.
StatsClear	Clears MSDP statistics.

Enabling MSDP

Enable or disable MSDP globally on the switch to allow further configuration to take place.

Before You Begin

You must configure the originator ID before you enable MSDP.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Globals** tab.
4. Select the **Enabled** check box to enable MSDP.
5. Click **Apply**.

Global field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
Enabled	Enables MSDP. If you clear this check box, you disable MSDP. The default setting is clear (disabled).
CacheLifetime	Configures the lifetime given to SA cache entries when created or refreshed.
NumSACacheEntries	Displays the total number of entries in the SA cache.
RPAddress	Specifies the IP address to use as the originator ID. If the address is not a system local address, the system rejects the configuration.
RouteMapName	Specifies the name of the optional route policy to create or modify. You do not need to create a route policy to use the redistribution filter. Note: To delete the route map name, clear the field and click Apply .
RedistributeFilterEnabled	Filters the (S,G,RP) entries provided by PIM to MSDP. The default is clear (disabled).
RedistruteFilterApply	Applies the changes made to the redistribute filter.
StatsClear	Clears MSDP statistics.

Creating an MSDP peer

Create an MSDP peer to establish a peer relationship between the local MSDP enabled router and a peer in another domain.

Important

Do not enable more than 20 active peers.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. Click **Insert**.
5. In the **RemoteAddress** box, type the IP address of the peer.
6. Click **Insert**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.

Name	Description
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.

Name	Description
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

MSDP Peer Configuration using the EDM

This section provides procedures to configure MSDP peer using the EDM.

Securing control messages

Configure Message Digest (MD) 5 authentication to secure control messages on the TCP connection between MSDP peers.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **Md5AuthEnabled** field, and then select true.
5. In the row for the peer, double-click the **Md5AuthPassword** field, and then type a password.
6. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.

Name	Description
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.

Name	Description
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Configuring the MSDP peer SA limit

Configure the SA limit to limit the number of SA messages from an MSDP peer. The router saves the SA messages in the local cache.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **SALimit** field, and then type a value.
5. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.

Name	Description
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.

Name	Description
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Configuring a peer description

About This Task

Configure a peer description to add a descriptive text to an MSDP peer, for easy identification of a peer.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **Description** field, and then type a description for the peer.
5. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.

Name	Description
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.

Name	Description
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Configuring the MSDP peer time to live threshold

Configure the time-to-live (TTL) threshold to limit which multicast data packets the router encapsulated in SA Message forwarded to an MSDP peer. The TTL limits the number of hops a packet can take before the router drops the packet. The router sends out SA Messages with encapsulated data only if TTL equals or exceeds the value you configure. If the TTL is lower than the value you configure, the router drops the data packet and forwards the SA Message without the encapsulated data.

Note

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers.

The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **Md5AuthEnabled** field, and then select true.
5. In the row for the peer, double-click the **DataTtl** field, and then type a value.
6. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.

Name	Description
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.

Name	Description
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Configuring the MSDP peer keepalive messages

Configure keepalive messages to adjust the interval in seconds at which an MSDP peer sends keep alive messages (default is 60 seconds) and the interval at which the MSDP peer waits for keep alive messages from other peers before it declares them down (default is 75 seconds).

Note

In a peer relationship, the keep alive interval configured on one peer must be at least 1 second less than the hold time configured on the other side of the peer relationship. This is not applicable when the hold time is set to 0 seconds.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **KeepAliveConfigured** field, and then type the interval at which to send keepalive messages.
5. In the row for the peer, double-click the **HoldTimeConfigured** field, and then type the interval at which to wait for keepalive messages.
6. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).

Name	Description
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.

Name	Description
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Configuring the MSDP peer connect-retry period

Configure the connect-retry period to specify the amount of time, in seconds, between connection attempts for peering sessions. The default is 30 seconds.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **ConnectRetryInterval** field, and then type the interval.
5. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.

Name	Description
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.

Name	Description
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Changing the MSDP peer status

Change the peer status to administratively enable or disable a configured peer. Disable the peer to stop the peering relationship.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **AdminEnabled** field, and then select true.
5. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.

Name	Description
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARquests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARquests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.

Name	Description
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Clearing the MSDP peer connection

Clear the TCP connection to the specified MSDP peer, and reset all MSDP message counters.

The default is disabled (false).

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **ClearPeer** field, and then select true.
5. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.

Name	Description
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
InSARquests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARquests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.

Name	Description
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Deleting an MSDP peer

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. Select a row from the peer to delete.
5. Click **Delete**.
6. Click **Yes**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.

Name	Description
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.

Name	Description
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

MSDP Message Control using the EDM

This section provides procedures to configure MSDP message control using the EDM.

Filtering PIM routes

Configure MSDP global filter for which the SA local cache are distributed to all MSDP peers. All SA local cache entries generate SA messages.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Globals** tab.
4. Select the **RedistributeFilterEnabled** check box.
5. Type the name of the route policy in the **RouteMapName** field.
6. Select the **RedistributeFilterApply** check box to apply the changes to the redistribute filter.

You do not need to apply the changes in the following situations:

- You create the redistribute filter without a route policy.
- You disable the redistribute filter.
- You remove a route policy from the redistribute filter.

7. Click **Apply**.

Global field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
Enabled	Enables MSDP. If you clear this check box, you disable MSDP. The default setting is clear (disabled).
CacheLifetime	Configures the lifetime given to SA cache entries when created or refreshed.
NumSACacheEntries	Displays the total number of entries in the SA cache.
RPAddress	Specifies the IP address to use as the originator ID. If the address is not a system local address, the system rejects the configuration.

Name	Description
RouteMapName	Specifies the name of the optional route policy to create or modify. You do not need to create a route policy to use the redistribution filter. Note: To delete the route map name, clear the field and click Apply .
RedistributeFilterEnabled	Filters the (S,G,RP) entries provided by PIM to MSDP. The default is clear (disabled).
RedistruteFilterApply	Applies the changes made to the redistribute filter.
StatsClear	Clears MSDP statistics.

Filtering SA messages

Filter SA messages to determine which SA messages to accept from a peer and which SA messages to send to a peer. By default, no inbound or outbound filter exists.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **InSAFilterEnabled** field, and then select true.
5. In the row for the peer, double-click the **InSAFilterRouteMapName** field, and then type the route map name for the IN SA Filter of the peer.
6. In the row for the peer, double-click the **OutSAFilterEnabled** field, and then select true.
7. In the row for the peer, double-click the **OutSAFilterRouteMapName** field, and then type the route map name for the OUT SA Filter of the peer.
8. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).

Name	Description
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.

Name	Description
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Configuring the MSDP mesh groups

Configure mesh groups to reduce SA flooding. A mesh group does not forward SA messages to other group members in the same mesh group. The originator, which is also a mesh group member, forwards SA messages to all group members. Create MSDP mesh groups from a group of meshed MSDP

speakers from a domain. Do not create MSDP peerings between Controllers within the same SPB domain.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Mesh Group** tab.
4. Click **Insert**.
5. In the **Name** field, type a name for the mesh group.
6. In the **PeerAddress** field, type the IP address of the peer to add the mesh group.
7. Click **Insert**.

Mesh Group field descriptions

Use the data in the following table to use the **Mesh Group** tab.

Name	Description
Name	Specifies the mesh group ID; the name of the mesh group from 1-64 characters.
PeerAddress	Specifies the IP address of the MSDP router that is the peer.

Clearing the MSDP SA cache

Clear the SA cache to clear the SA entries the router learns from all the peers or a specific peer.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **SA-Cache** tab.
4. Click **Clear SA-Cache**.

SA-Cache field descriptions

Use the data in the following table to use the **SA-Cache** tab.

Name	Description
GroupAddr	Shows the group IP address of the SA cache entry.
SourceAddr	Shows the source IP address of the SA cache entry.
OriginRP	Shows the RP address of the SA cache entry.
PeerLearnedFrom	Shows the peer from which this SA cache entry was accepted.
RPFPeer	Shows the peer from which an SA message corresponding to the cache entry is accepted.

Name	Description
InSAs	Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the number of MSDP encapsulated data packets received that are relevant to this cache entry.
UpTime	Shows the time since this entry was first placed in the SA cache.
ExpiryTime	Shows the time remaining before this entry expires from the SA cache.

MSDP Verification using the EDM

This section provides procedures to verify MSDP using the EDM.

Viewing peer information

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.

Name	Description
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.

Name	Description
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Viewing the local SA cache

View the local SA cache to display the (S, G) state the router learns from local Protocol Independent Multicast - Sparse Mode (PIM-SM) entries.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **SA-Cache-Records** tab.

SA-Cache-Records field descriptions

Use the data in the following table to use the **SA-Cache-Records** tab.

Name	Description
TypeInformation	Shows the SA cache type. The SA cache type can be local or foreign cache.
GroupAddr	Shows the group IP address of the SA cache entry.
SourceAddr	Shows the source IP address of the SA cache entry.
OriginRP	Shows the RP address of the SA cache entry.
OriginatorAsNumber	Shows the AS number of the originator.
RouteType	Shows the type of route used for Reverse Path Forwarding checking. The value can be rip (1), ospf (2), static (3), bgp (4), isis(5) or none (6).

Viewing the foreign SA cache

View the foreign SA cache to display the (S, G) state the router learns from SA messages.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **SA-Cache-Records** tab.

SA-Cache-Records field descriptions

Use the data in the following table to use the **SA-Cache-Records** tab.

Name	Description
TypeInformation	Shows the SA cache type. The SA cache type can be local or foreign cache.
GroupAddr	Shows the group IP address of the SA cache entry.
SourceAddr	Shows the source IP address of the SA cache entry.
OriginRP	Shows the RP address of the SA cache entry.
OriginatorAsNumber	Shows the AS number of the originator.
RouteType	Shows the type of route used for Reverse Path Forwarding checking. The value can be rip (1), ospf (2), static (3), bgp (4), isis(5) or none (6).

Viewing the mesh group

Configure Message Digest (MD) 5 authentication to secure control messages on the TCP connection between MSDP peers.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Mesh Group** tab.

Mesh Group field descriptions

Use the data in the following table to use the **Mesh Group** tab.

Name	Description
Name	Specifies the mesh group ID; the name of the mesh group from 1-64 characters.
PeerAddress	Specifies the IP address of the MSDP router that is the peer.

Controller configuration

This section provides procedures to configure the Controller using Command Line Interface (CLI) and Enterprise Device Manager (EDM).

The Controller functionality is configured at the global (switch-wide) level.

Controller Configuration using the CLI

This section provides procedures to configure controller using the command line interface (CLI).

Enabling the Controller

Enable the Controller globally.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable
configure terminal
router isis
```
2. Enable the Controller globally:

```
spbm <1-100> multicast spb-pim-gw controller enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast spb-pim-gw controller enable
```

Variable definitions

The following table defines parameters for the **spb** command.

Variable	Value
<1-100>	Specifies the isis spbm instance-id to create the spbm instance.
<i>controller enable</i>	Enables the SPB-PIM Gateway Controller.

Displaying the Controller admin status

Use the following procedure to display the admin status of the Controller.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Controller Status:

```
show isis spbm
```

Example

Note

The SPB-PIM-GW column displays either Controller, Gateway, or Controller/Gateway if the Controller and or Gateway functionality is configured.

```
Switch:1>show isis spbm

Displaying the active Controller and Gateway Nodes

Use the following procedure to display the active Controllers and Gateways in the SPBM domain.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway active Controller and Gateway Nodes:

```
show ip spb-pim-gw node [controller | gateway] [spb-node-as-mac]
```

Example

Display all node lists:

```
Switch:1>show ip spb-pim-gw node
=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role
-----
BEB3-4037      Gateway
BEB5-4011      Controller

Total Number of Nodes = 2/2
=====
```

Display Controller node lists only:

```
Switch:1>show ip spb-pim-gw node controller
=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role
-----
BEB5-4011      Controller

Total Number of Nodes = 1/2
=====
```

Display Gateway node lists only:

```
Switch:1>show ip spb-pim-gw node gateway
=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role
-----
BEB3-4037      Gateway

Total Number of Nodes = 1/2
=====
```

Display all node lists with MAC address:

```
Switch:1>show ip spb-pim-gw node spb-node-as-mac
```

```

=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role           Mac Address
-----
BEB3-4037      Gateway        00:37:00:37:00:37
BEB5-4011      Controller     00:11:00:11:00:11
Total Number of Nodes = 2/2
=====

```

Display Controller node lists with MAC address:

```

Switch:1>show ip spb-pim-gw node controller spb-node-as-mac

=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role           Mac Address
-----
BEB5-4011      Controller     00:11:00:11:00:11
Total Number of Nodes = 1/2
=====

```

Display Gateway node lists with MAC address:

```

Switch:1>show ip spb-pim-gw node gateway spb-node-as-mac

=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role           Mac Address
-----
BEB3-4037      Gateway        00:37:00:37:00:37
Total Number of Nodes = 1/2
=====

```

Configuring a static foreign source on the global router

Configure a static foreign source on the global router. Configuration is done at the Controller. Statically configure foreign sources, such as streams in a Source Specific Multicast (SSM) group range that are not advertised by the foreign network through MSDP. Non-SSM range group multicast address streams are advertised by MSDP and do not need to be statically configured.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure a static foreign source:

```
ip spb-pim-gw foreign-source {A.B.C.D} group {A.B.C.D}
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip spb-pim-gw foreign-source 10.0.0.1 group 240.0.0.1
```

Variable definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<i>foreign-source</i> {A.B.C.D}	Specifies the multicast foreign source IP address.
<i>group</i> {A.B.C.D}	Specifies the group IP address.

Configuring a static foreign source on a VRF

Configure a static foreign source on a VRF, configuration is done at the Controller.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Configure a static foreign source:

```
ip spb-pim-gw foreign-source {A.B.C.D} group {A.B.C.D}
```

Example

In the following example, vrf-10 is configured with vrf id 10.

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#router vrf vrf-10
```

```
Switch:1(router-vrf)#ip spb-pim-gw foreign-source 10.0.0.1 group
240.0.0.1
```

Variable definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<i>foreign-source</i> {A.B.C.D}	Specifies the multicast foreign source IP address.
<i>group</i> {A.B.C.D}	Specifies the group IP address.

Displaying foreign sources

Use the following procedure to display the foreign sources learned from MSDP or statically configured at the Controller.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the foreign source information:

```
show ip spb-pim-gw foreign-source [all] [controller | gateway] [vrf
WORD<0-16>] [vrfids WORD<0-512>] [source {A.B.C.D}] [group {A.B.C.D}]
[static | msdp] [spb-node-as-mac]
```

Example

Note

The command **show ip spb-pim-gw**, which specifies the parameter *controller*, the OWNER column displays the RP address of the MSDP peer from which the foreign source was learned. If the *gateway* parameter is specified, then the OWNER column displays MSDP rather than the actual RP address.

```
Switch:1>show ip spb-pim-gw foreign-source controller
=====
==
SPB-PIM-GW Controller Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      OWNER
-----
--
10.0.0.1    240.0.0.1  beb-1           GlobalRouter 47.17.0.1
10.0.0.2    240.0.0.2  beb-1           GlobalRouter static
10.0.0.3    240.0.0.3  -               GlobalRouter 47.17.0.2
-----
--
```

Display the foreign sources from a specific VRF:

```
Switch:1>show ip spb-pim-gw foreign-source controller vrf green
=====
==
SPB-PIM-GW Controller Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      OWNER
-----
--
10.0.0.1    240.0.0.1  beb-1           green     47.17.0.1
10.0.0.2    240.0.0.2  beb-1           green     static
10.0.0.3    240.0.0.3  -               green     47.17.0.2
-----
--
```

Display all the foreign sources at the Controller with the Gateway in the SPB-PIM-GW shown as a mac address rather than a nickname:

```
Switch:1>show ip spb-pim-gw foreign-source controller vrf green spb-node-as-mac
=====
==
SPB-PIM-GW Controller Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      OWNER
-----
```

```

-----
--
10.0.0.1 240.0.0.1 00:0b:eb:00:00:a1 green      47.17.0.1
10.0.0.2 240.0.0.2 00:0b:eb:00:00:a1 green      static
10.0.0.3 240.0.0.3 -                green      47.17.0.2
-----
--

```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw foreign source** command.

Variable	Value
<i>all</i>	Displays information for all the VRF IDs from the Controller and Gateway foreign source database.
<i>controller</i>	Displays information from the Controller foreign source database. Only displays information on nodes configured as Controller.
<i>gateway</i>	Displays information from the Gateway foreign source database. Only displays information on nodes configured as Gateway.
<i>vrf WORD<0-16></i>	Displays information from the Controller foreign source database for a specific VRF name.
<i>vrfids WORD<0-512></i>	Displays information from the Controller foreign source database for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.
<i>source {A.B.C.D}</i>	Displays information for the specific source IP address from the Controller foreign source database.
<i>group {A.B.C.D}</i>	Displays information for the specific multicast group IP address from the Controller foreign source database.
<i>static</i>	Displays information from the Controller foreign source database that is configured statically.
<i>msdp</i>	Displays information from the Controller foreign source database that is learned through MSDP.
<i>spb-node-as-mac</i>	Displays the MAC address for the assigned SPB-PIM Gateway.

Displaying Multicast over Fabric Connect sources

Use the following procedure to display all the SPB Multicast over Fabric Connect sources distributed to MSDP. This procedure is only valid on a Controller node.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB source information:

```
show ip spb-pim-gw spbmc-source [vrf WORD<1-32>] [vrffids WORD<0-512>]
[source {A.B.C.D}] [group {A.B.C.D}] [originator WORD<1-32>] [spb-
node-as-mac]
```

Example

```
Switch:1>show ip spb-pim-gw spbmc-source
```

```
=====
SPB-PIM-GW SPB Source
=====
SOURCE          GROUP          VRF          ORIGINATOR
-----
10.0.0.1        240.0.0.1     GlobalRouter bcb-1
10.0.0.2        240.0.0.2     GlobalRouter bcb-2
10.0.0.3        240.0.0.3     GlobalRouter bcb-2
-----
--
```

Display the SPB Multicast over Fabric Connect from a specific VRF:

```
Switch:1>show ip spb-pim-gw spbmc-source vrf green
```

```
=====
SPB-PIM-GW Foreign Source
=====
SOURCE  GROUP    SPB-PIM-GW  VRF    OWNER    CONTROLLER

---
```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw spbmc-source** command.

Variable	Value
<i>vrf WORD<1-32></i>	Displays SPB originated sources for a specific VRF.
<i>vrfids WORD<0-512></i>	Displays SPB originated sources for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.
<i>source {A.B.C.D}</i>	Displays information for a specific source IP address from SPB originated sources database.
<i>group {A.B.C.D}</i>	Displays information for a specific multicast group IP address from SPB originated sources database.
<i>originator WORD<0-32></i>	Displays information for a specific originator host name from SPB originated sources database.
<i>spb-node-as-mac</i>	Displays the originator of SPB originated sources as a MAC address rather than a nickname.

Controller Configuration using the EDM

This section provides procedures to configure controller using the EDM.

Enabling the Controller

Enable the Controller globally.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. In the row for the SPBM, double click the **McastSpbPimGwControllerEnable** field, and then select true.
4. Select **Apply**.

SPBM field descriptions

Use the data in the following table to use the **SPBM** tab.

Name	Description
McastSpbPimGwControllerEnable	Enables or disables the ISIS multicast SPM-PIM Gateway Controller node.
McastSpbPimGWGatewayEnable	Enables or disables the ISIS multicast SPM-PIM Gateway node.

Displaying the Controller and Gateway admin status

Use the following procedure to display the admin status of the Controller and Gateway.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **SPBM** tab.

Displaying active Controller and Gateway nodes

Use the following procedure to display the active Controllers and Gateways in the SPBM domain.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Node** tab.

Node field descriptions

Use the data in the following table to use the **Node** tab.

Name	Description
MacAddress	Shows the MAC address of the active node.
HostName	Shows the host name of the active node.
RoleType	Shows the role of the active node: either gateway, controller, or both.

Configuring a static foreign source globally

Configure a static foreign source on the global router. Configuration is done at the Controller.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Controller-Foreign-Source** tab.
4. Click **Insert**.
5. In the **SourceAddress** box, type the multicast foreign source IP address.
6. In the **GroupAddress** box, type the group IP address.
7. Click **Insert**.

Controller-Foreign-Source field descriptions

Use the data in the following table to use the **Controller-Foreign-Source** tab.

Name	Description
SourceAddress	Specifies the source IP address from a foreign multicast domain.
GroupAddress	Specifies the multicast group IP address associated with the foreign source.
GatewaySysId	Displays the system ID of the node selected as the Gateway for this foreign source. GatewaySysId field will have a valid value if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is 0.
GatewayHostName	Displays the host name of the node selected as the Gateway for this foreign source. GatewayHostName field will have valid values if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is NULL.
Type	Displays the owner type for this source.
Owner	Displays the IP address of the MSDP peer if the foreign source is MSDP.

Configuring a static foreign source on a VRF

Configure a static foreign source on a VRF. Configuration is done at the Controller.

Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Click **Set VRF Context view**.
3. Select a row and click **Launch VRF Context view**.
4. Select a switch port in the **Device Physical View** tab.
5. In the navigation pane, expand **Configuration > IP**.
6. Click **SPB-PIM-GW**.
7. Click the **Controller-Foreign-Source** tab.
8. Click **Insert**.
9. In the **SourceAddress** box, type the multicast foreign source IP address.
10. In the **GroupAddress** box, type the group IP address.
11. Click **Insert**.

Controller-Foreign-Source field descriptions

Use the data in the following table to use the **Controller-Foreign-Source** tab.

Name	Description
SourceAddress	Specifies the source IP address from a foreign multicast domain.
GroupAddress	Specifies the multicast group IP address associated with the foreign source.
GatewaySysId	Displays the system ID of the node selected as the Gateway for this foreign source. GatewaySysId field will have a valid value if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is 0.
GatewayHostName	Displays the host name of the node selected as the Gateway for this foreign source. GatewayHostName field will have valid values if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is NULL.
Type	Displays the owner type for this source.
Owner	Displays the IP address of the MSDP peer if the foreign source is MSDP.

Displaying foreign sources

Use the following procedure to display the foreign sources learned from MSDP or statically configured at the Controller.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Controller-Foreign-Source** tab.

Controller-Foreign-Source field descriptions

Use the data in the following table to use the **Controller-Foreign-Source** tab.

Name	Description
SourceAddress	Specifies the source IP address from a foreign multicast domain.
GroupAddress	Specifies the multicast group IP address associated with the foreign source.
GatewaySysId	Displays the system ID of the node selected as the Gateway for this foreign source. GatewaySysId field will have a valid value if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is 0.

Name	Description
GatewayHostName	Displays the host name of the node selected as the Gateway for this foreign source. GatewayHostName field will have valid values if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is NULL.
Type	Displays the owner type for this source.
Owner	Displays the IP address of the MSDP peer if the foreign source is MSDP.

Displaying Multicast over Fabric Connect sources

Use the following procedure to display all the SPB Multicast over Fabric Connect sources distributed to MSDP.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **spbm-source** tab.

Spbmc-Source field descriptions

Use the data in the following table to use the **Spbmc-Source** tab.

Name	Description
SourceAddress	Displays the source IP address from SPBM multicast domain.
GroupAddress	Displays the multicast group IP address associated with the SPBM source.
OriginatorSysId	Displays the system ID of the node from which the source originates.
OriginatorHostName	Displays the host name of the node from which the source originates.

Gateway configuration

This section provides procedures to configure the Gateway using Command Line Interface (CLI) and Enterprise Device Manager (EDM).

The Gateway functionality is configured at the global (switch-wide) level. SPB-PIM Gateway Interfaces are configured at the interface level. For more information on SPB-PIM Gateway Interfaces configuration, see [SPB-PIM Gateway interface configuration](#) on page 3286.

Gateway Configuration using the CLI

This section provides procedures to configure gateway using the command line interface (CLI).

Enabling the Gateway

Enable the Gateway at the global (switch-wide) level.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Enable the Gateway globally:

```
spbm <1-100> multicast spb-pim-gw gateway enable
```

Example

```
Switch:1>enable

Switch:1#configure terminal

Switch:1(config)#router isis

Switch:1(config-isis)#spbm 1 multicast spb-pim-gw gateway enable
```

Variable definitions

The following table defines parameters for the **spb** command.

Variable	Value
<1-100>	Specifies the isis spbm instance-id to create the spbm instance.
<i>gateway enable</i>	Enables the SPB-PIM Gateway.

Displaying the Gateway admin status

Use the following procedure to display the admin status of the Gateway.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Gateway admin status:

```
show isis spbm
```

Example

```
Switch:1>show isis spbm

```

Displaying foreign sources information

Use the following procedure to display the Gateway foreign sources database. If executed on a Gateway node, it displays the foreign sources assigned to the Gateway by the Controller. Foreign sources are originally learned from MSDP or statically configured on the Controller.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the foreign sources information:

```
show ip spb-pim-gw foreign-source [all] [controller | gateway] [vrf
WORD<0-16>] [vrfids WORD<0-512>] [source {A.B.C.D}] [group {A.B.C.D}]
[from-controller <0x00:0x00:0x00:0x00:0x00:0x00> | preferred][static |
msdp] [spb-node-as-mac]
```

Example

```
Switch:1>show ip spb-pim-gw foreign-source gateway
=====
==
SPB-PIM-GW Gateway Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      PORT  VLAN  CONTROLLER      OWNER
-----
--
10.0.0.1    240.0.0.1  beb-2           GlobalRouter 1/1    200   bcb-2           msdp
10.0.0.2    240.0.0.2  beb-2           GlobalRouter 1/1    200   bcb-2           static
10.0.0.3    240.0.0.3  beb-2           GlobalRouter -      -     bcb-2           msdp
-----
--
```

**Note**

The SPB-PIM-GW column displays the node that is selected as the Gateway for the particular source or group stream. The OWNER column displays either msdp or static depending on how the source was originally learned at the assigning Controller. The PORT and VLAN columns represent the port or VLAN toward the source.

Display the foreign sources from a specific VRF:

```
Switch:1>show ip spb-pim-gw foreign-source gateway vrf green
=====
==
SPB-PIM-GW Gateway Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      PORT  VLAN  CONTROLLER      OWNER
-----
--
10.0.0.1    240.0.0.1  beb-2           green     1/1    200   bcb-2           msdp
10.0.0.2    240.0.0.2  beb-2           green     1/1    200   bcb-2           static
10.0.0.3    240.0.0.3  beb-2           green     -      -     bcb-2           msdp
-----
--
```

Display all the foreign sources available at the Gateway with SPB-PIM-GW and Controller as mac:

```
Switch:1>show ip spb-pim-gw foreign-source gateway vrf green spb-node-as-mac
=====
==
SPB-PIM-GW Gateway Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      PORT  VLAN  CONTROLLER      OWNER
-----
--
10.0.0.1    240.0.0.1  00:0b:eb:00:00:a2 green    1/1    200   00:0b:cb:00:00:c2 msdp
10.0.0.2    240.0.0.2  00:0b:eb:00:00:a2 green    1/1    200   00:0b:cb:00:00:c2 static
10.0.0.3    240.0.0.3  00:0b:eb:00:00:a2 green    -      -     00:0b:cb:00:00:c2 msdp
-----
--
```

Display all the foreign sources available at the Gateway which are statically configured at the Controller:

```
Switch:1>show ip spb-pim-gw foreign-source gateway vrf green static
=====
==
SPB-PIM-GW Gateway Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      PORT  VLAN  CONTROLLER      OWNER
-----
--
10.0.0.2    240.0.0.2  beb-2           green    1/1    200   bcb-2           static
-----
--
```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw foreign source** command.

Variable	Value
<i>all</i>	Displays information for all the VRF IDs from the Controller and Gateway foreign source database.
<i>controller</i>	Displays information from the Controller foreign source database. Only displays information on nodes configured as Controller.
<i>gateway</i>	Displays information from the Gateway foreign source database. Only displays information on nodes configured as Gateway.
<i>vrf WORD<0-16></i>	Displays information from the Gateway foreign source database for a specific VRF name.
<i>vrfids WORD<0-512></i>	Displays information from the Gateway foreign source database for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

Variable	Value
<i>source {A.B.C.D}</i>	Displays information for the specific source IP address from the Gateway foreign source database.
<i>group {A.B.C.D}</i>	Displays information for the specific multicast group IP address from the Gateway foreign source database.
<i>from-controller 0x00:0x00:0x00:0x00:0x00:0x00</i>	Displays information filtering on a specific Controllers assignments, where the Controller is specified as a mac address.
<i>from-controller preferred</i>	Displays information from Gateway source database filtering on a preferred Controller or chosen by the Gateway.
<i>static</i>	Displays information from the Gateway foreign source database that is configured statically at the assigning Controller.
<i>msdp</i>	Displays information from the Gateway foreign source database that is learned through MSDP.
<i>spb-node-as-mac</i>	Displays the MAC address for the assigned PIM-GW.

Gateway Configuration using the EDM

This section provides procedures to configure gateway using the EDM.

Enabling the Gateway globally

Use this procedure to enable the Gateway at the global (switch-wide) level.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. In the row for the SPBM, double click the **McastSpbPimGwGatewayEnable** field, and then select true.
4. Select **Apply**.

SPBM field descriptions

Use the data in the following table to use the **SPBM** tab.

Name	Description
McastSpbPimGwControllerEnable	Enables or disables the ISIS multicast SPM-PIM Gateway Controller node.
McastSpbPimGWGatewayEnable	Enables or disables the ISIS multicast SPM-PIM Gateway node.

Displaying foreign sources

Use the following procedure to display the Gateway foreign source database. Foreign sources are originally learned from MSDP or statically configured on the Controller.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Gateway-Foreign-Source** tab.

Gateway-Foreign-Source field descriptions

Use the data in the following table to use the **Gateway-Foreign-Source** tab.

Name	Description
SourceAddress	Displays the foreign source IP address.
GroupAddress	Displays the multicast group IP address associated with the foreign source.
ControllerSysId	Displays the system ID of the controller node that sends this foreign source.
ControllerHostName	Displays the host name of the controller node that sends this foreign source.
GatewaySysId	Displays the system ID of the node selected as the gateway for this foreign source.
GatewayHostName	Displays the host name of the node selected as the gateway for this foreign source.
InVid	Displays the VLAN ID of the SPB-PIM Gateway interface through which the source of this source is reachable.
InPort	Displays the physical interface through which the source of this source is reachable.
OwnerType	Displays if the owner is MSDP or static.

SPB-PIM Gateway interface configuration

This section provides procedures to configure the SPB-PIM Gateway interface using the Command Line Interface (CLI) and Enterprise Device Manager (EDM).

The SPB-PIM Gateway interface is either a VLAN or a Brouter port interface. An SPB-PIM Gateway interface is configured separately from the global (switch-wide) Gateway functionality. The global Gateway configuration does not affect the administrative or the operational state of the SPB-PIM Gateway interfaces which function independently. However, the Gateway node functionality works in conjunction with the Gateway Interface functionality. Configure SPB-PIM Gateway on an interface that connects to a router in a foreign PIM or SPB multicast domain.

SPB-PIM Gateway Interface Configuration using the CLI

This section provides procedures to configure SPB-PIM gateway interface using the command line interface (CLI).

Enabling SPB-PIM Gateway on a VLAN

Enable SPB-PIM Gateway on a VLAN interface.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable SPB-PIM Gateway on a VLAN:

```
ip spb-pim-gw enable
```

**Note**

SPB-PIM Gateway cannot be enabled under the following circumstances:

- If the IP interface does not exist on the VLAN. An IP Address must first be configured on the VLAN.
- If the **spbm_config_mode** boot flag is set to false.
- If the VLAN is configured with a circuitless IP.
- If the interface is a management VLAN.
- If **ip igmp snooping** is enabled.
- If the spb-multicast is enabled on the VLAN.
- If the VLAN has SMLT ports.
- If the VLAN has an i-sid configured.
- If the VLAN is a vIST VLAN.

Enabling SPB-PIM Gateway on a brouter port interface

Enable SPB-PIM Gateway on a brouter port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[, ...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable SPB-PIM Gateway on a brouter port:

```
ip spb-pim-gw enable
```

**Note**

SPB-PIM Gateway cannot be enabled under the following circumstances:

- If the IP interface is not configured using the **brouter** command
- If the IP interface does not exist on the brouter port
- If the **spbm_config_mode** boot flag is set to false
- If **ip igmp snooping** is enabled
- If the spb-multicast is enabled on the brouter port
- If the brouter port is part of an SMLT or vIST Vlan
- If the brouter port has an i-sid configured

Configuring the SPB-PIM Gateway VLAN optional parameters

Configure the SPB-PIM Gateway interface parameters on a VLAN.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```
2. Configure the SPB-PIM Gateway VLAN HELLO interval:

```
ip spb-pim-gw hello-interval <0-18724>
```
3. Configure the SPB-PIM Gateway VLAN JOIN PRUNE interval:

```
ip spb-pim-gw ip join-prune-interval <1-18724>
```

Variable definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<i>hello-interval<0-18724></i>	Specifies the HELLO interval in seconds. The default value is 30 seconds.
<i>join-prune-interval<1-18724></i>	Specifies the JOIN PRUNE interval in seconds. The default value is 60 seconds.

Configuring the SPB-PIM Gateway brouter port optional parameters

Configure the SPB-PIM Gateway interface parameters on a brouter port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the SPB-PIM Gateway router port HELLO interval:

```
ip spb-pim-gw hello-interval <0-18724>
```

3. Configure the SPB-PIM Gateway router port JOIN PRUNE interval:

```
ip spb-pim-gw join-prune-interval <1-18724>
```

Variable definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<code>hello-interval<0-18724></code>	Specifies the HELLO interval in seconds. The default value is 30 seconds.
<code>join-prune-interval<1-18724></code>	Specifies the JOIN PRUNE interval in seconds. The default value is 60 seconds.

Displaying the SPB-PIM Gateway interface default values

Use the following procedure to display the default values used for the SPB-PIM Gateway interface HELLO and JOIN PRUNE intervals unless specifically configured on the individual interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway interface default values:

```
show ip spb-pim-gw
```

Example

```
Switch:1>show ip spb-pim-gw
=====
                               Spb-pim-gw General Group
=====
Hello Interval                  : 30
Join-Prune Interval            : 60
```

Displaying the SPB-PIM Gateway router port information

Use the following procedure to display the SPB-PIM Gateway router port information. This procedure displays the administrative (configured) state of the interface as well as the operational state, and the HELLO and JOIN PRUNE intervals. An interface can be administratively ENABLED but operationally

DISABLED if, for example, mvpn is not enabled on the VRF, or **spbm <spbm-instance> multicast enable** is not configured.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway interface information:

```
show ip spb-pim-gw interface [gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

```
Switch:1#show ip spb-pim-gw interface gigabitethernet 1/2

=====
Port Ip Spb-pim-gw
=====
ORT-NUM  OPSTATE    ADMINSTATE  HELLOINT  JPINT
=====
1/2      Disabled   Enabled     30         60
=====
```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw interface** gigabit command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vrf WORD<1-16>	Displays SPB-PIM Gateway interface information for a specific VRF.
vrfids WORD<0-512>	Displays SPB-PIM Gateway interface information for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

Displaying the SPB-PIM Gateway VLAN information

Use the following procedure to display the SPB-PIM Gateway VLAN interface information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway VLAN interface information:

```
show ip spb-pim-gw interface [vlan]
```

Example

```
Switch:1>show ip spb-pim-gw interface
=====
===
                               Spb-pim-gw Interface - GlobalRouter
=====
===

IF          ADDR          MASK          JPINT    HELLOINT  OPSTATE  ADMINSTATE
Vlan50     50.1.1.1      255.255.255.0  60      30        Disabled Enabled
Vlan123    123.1.1.1     255.255.255.0  60      30        Disabled Disabled
Vlan142    142.1.1.1     255.255.255.0  60      30        Enabled  Enabled
Vlan400    100.1.1.2     255.255.255.0  60      30        Disabled Disabled

Total spb-pim-gw Interfaces Displayed 4/4
```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw interface** command.

Variable	Value
vlan-id	The VLAN ID of an interface to display.

Displaying the SPB-PIM Gateway neighbor information

Use the following procedure to display the SPB-PIM Gateway interfaces neighbor information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway neighbor information:

```
show ip spb-pim-gw neighbor [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

```
Switch:1>show ip spb-pim-gw neighbor
=====
                               Spb-pim-gw Neighbor - GlobalRouter
=====
=====
INTERFACE ADDRESS          UPTIME          EXPIRE
Vlan26     26.1.1.10      0 day(s), 00:11:36  0 day(s), 00:01:28

Total SPB-PIM-GW Neighbors Displayed = 1/1
=====
```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw neighbor** command.

Variable	Value
<code>vrf WORD<1-16></code>	Displays the SPB-PIM Gateway interface neighbor information for a specific VRF name.
<code>vrfids WORD<0-512></code>	Displays the SPB-PIM Gateway interface neighbor information for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

Displaying the SPB-PIM Gateway multicast routes

Use the following procedure to display the SPB-PIM Gateway multicast routes. This procedure displays upstream (toward the foreign source) information and downstream (receiver) information on the SPB-PIM Gateway interfaces. This command does not display the following information:

- Upstream information for streams ingressing on spb-multicast interfaces
- Upstream information for streams ingressing from a remote SPB node
- Receivers in spb-multicast interfaces

Use the **show isis spbm ip-multicast-route** command to display information on all multicast streams and the multicast streams ingress interfaces and egress interfaces.

Use the **show ip spb-pim-gw mroute** command to display information only on SPB-PIM Gateway interfaces.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway multicast routes:

```
show ip spb-pim-rw mroute [source {A.B.C.D}] [group {A.B.C.D}] [vrf
WORD<1-16>] [vrfids WORD<0-512>]
```

Example

Note

The **show ip spb-pim-gw mroute** command displays active upstream information and active downstream information per (*,g) and (s,g) per port, which includes *G Join or Prune pending state, SG join or prune pending state, and SG Rpt PRUNE or PRUNE pending state.. There can be upstream information for a specific SG and no downstream, and vice-versa, as the information in the command **show ip spb-pim-gw mroute** reflects only information known on the SPB-PIM Gateway interfaces. For example, there might be downstream receivers on a SPB-PIM Gateway Interface for a particular stream which is ingressing on an spb-multicast interface; thus, the upstream information will not be displayed using this command.

```
Switch:1>show ip spb-pim-gw mroute
=====
```

```

```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw mroute** command.

Variable	Value
<i>vrf WORD<1-16></i>	Displays the SPB-PIM Gateway mroute information for a specific VRF name.
<i>vrfids WORD<0-512></i>	Displays the SPB-PIM Gateway interface mroute information for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

Variable	Value
<i>group {A.B.C.D}</i>	Displays mroute information specific to a group IP address.
<i>source {A.B.C.D}</i>	Displays mroute information specific to a source IP address.

Display the IP mroute Routes

Use the following procedure to display multicast routes ingressing on either SPB-PIM Gateway interfaces or SPB multicast interfaces.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the multicast routes:

```
show ip mroute mroute
```

Example

Note

The UPSTREAM_NBR field is populated only if the stream was learned across a spb-pim-gw interface, and the upstream neighbor is the PIM neighbor IP address toward the source. The PROT field equals spb-pim-gw when the stream’s source is learned on a VLAN configured for protocol spb-pim-gw. If the stream’s source is learned on a VLAN configured for spb-multicast, the PROT field equals spb.

```
Switch:1>show ip mroute route

=====

Variable definitions

The following table defines parameters for the **show ip mroute route** command.

Variable	Value
<code>vrf WORD<1-32></code>	Displays the multicast mroute information for a specific VRF name.
<code>vrfids WORD<0-512></code>	Displays the multicast mroute information for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

SPB-PIM Gateway Interface Configuration using the EDM

This section provides procedures to configure SPB-PIM gateway interface using the EDM.

Enabling SPB-PIM Gateway on a VLAN

Enable SPB-PIM Gateway on a VLAN interface.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Advanced** tab.
4. In the row for the VLANs, double click the **SpbPimGatewayMulticast** field, and then select enable from the drop down menu.
5. Click **Apply**.

Enabling SPB-PIM Gateway on a Brouter port interface

Enable SPB-PIM Gateway on a Brouter port.

Procedure

1. In the Device Physical View tab, select the port you need to configure.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **SPB-PIM-GW** tab.
5. Select the **Enable** check box to enable SPB-PIM Gateway on a Brouter port interface.
6. Click **Apply**.

SPB-PIM-GW field descriptions

Use the data in the following table to use the **SPB-PIM-GW** tab.

Name	Description
Enable	Enables SPB-PIM Gateway on the interface. The default is disabled.
OperState	Displays the current operational state of this SPB-PIM Gateway interface.
Address	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
AddressMask	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
HelloInterval	Configures the PIM HELLO transmission interval.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval.

Configuring SPB-PIM Gateway VLAN optional parameters

Configure the SPB-PIM Gateway interface parameters on a VLAN.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANS**.
3. Select a row from the VLAN and click the **IP** tab.
4. Click the **SPB-PIM-GW** tab.
5. In the **HelloInterval** field, type the hello transmission interval.
6. In the **JoinPruneInterval** field, type the join prune transmission interval.
7. Click **Apply**.

SPB-PIM-GW field descriptions

Use the data in the following table to use the **SPB-PIM-GW** tab.

Name	Description
OperState	Displays the current operational state of this SPB-PIM Gateway interface.
Address	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
AddressMask	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.

Name	Description
HelloInterval	Configures the PIM HELLO transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global SPB-PIM Gateway HELLO interval setting. Setting the HELLO Interval to 0 causes the neighbors to never expire its neighborhood with this local SPB-PIM Gateway interface.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global level JOIN PRUNE transmission interval setting.

Configuring the SPB-PIM Gateway optional parameters

Perform this procedure to configure the optional parameters on existing SPB-PIM Gateway interfaces.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Interfaces** tab.
4. In the row for the interfaces, double-click the **HelloInterval** box, and then type the hello interval in seconds.
5. In the row for the interfaces, double-click the **JoinPruneInterval** box, and then type the join prune interval in seconds.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
IfIndex	Shows the interface index.
OperState	Shows the operational state of the interface.
AddressType	Shows the address type of the interface.
Address	Shows the address assigned to the interface.
AddressMask	Shows the address mask associated with the interface address.
HelloInterval	Configures the PIM HELLO transmission interval. The default is 30 seconds.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval. The default is 60 seconds.

Displaying the SPB-PIM Gateway interface default values

Use the following procedure to display the default values used for the SPB-PIM Gateway interface HELLO and JOIN PRUNE intervals unless specifically configured on the individual interface.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Globals** tab.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
HelloInterval	Displays the PIM HELLO transmission interval.
JoinPruneInterval	Displays the PIM JOIN PRUNE transmission interval.

Displaying the SPB-PIM Gateway router port information

Use the following procedure to display the SPB-PIM Gateway interface information.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Interfaces** tab.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
IfIndex	Displays the VLAN ID.
OperState	Displays the current operational state of this SPB-PIM Gateway interface.
AddressType	Displays the address type of this SPB-PIM Gateway interface.
Address	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
AddressMask	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
HelloInterval	Configures the PIM HELLO transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global SPB-PIM Gateway HELLO interval setting. Setting the HELLO Interval to 0 causes the neighbors to never expire its neighborship with this local SPB-PIM Gateway interface.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global level JOIN PRUNE transmission interval setting.

Displaying the SPB-PIM Gateway VLAN information

Use the following procedure to display the SPB-PIM Gateway VLAN information.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Select a row from the VLAN and click the **IP** tab.
4. Click the **SPB-PIM-GW** tab.

SPB-PIM-GW field descriptions

Use the data in the following table to use the **SPB-PIM-GW** tab.

Name	Description
OperState	Displays the current operational state of this SPB-PIM Gateway interface.
Address	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
AddressMask	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
HelloInterval	Configures the PIM HELLO transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global SPB-PIM Gateway HELLO interval setting. Setting the HELLO Interval to 0 causes the neighbors to never expire its neighborship with this local SPB-PIM Gateway interface.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global level JOIN PRUNE transmission interval setting.

*Displaying the SPB-PIM Gateway neighbor information***About This Task**

Use the following procedure to display the SPB-PIM Gateway neighbor information

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Neighbors** tab.

Neighbors field descriptions

Use the data in the following table to use the **Neighbors** tab.

Name	Description
IfIndex	Specifies the IfIndex for the interface which is used to reach this SPB-PIM Gateway neighbor.
AddressType	Specifies the address type of this SPB-PIM Gateway neighbor.
Address	Specifies the primary IP address of this router on this SPB-PIM Gateway neighbor.
UpTime	Specifies the time since this SPB-PIM Gateway neighbor last became a neighbor of the local router.
ExpiryTime	Specifies the minimum time remaining before this SPB-PIM Gateway neighbor times out.

Displaying the IP mroute routes

Use the following procedure to display multicast routes ingressing on either SPB-PIM Gateway interfaces or SPB multicast interfaces.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Routes** tab.

Routes field descriptions

Use the data in the following table to use the **Routes** tab.

Name	Description
Group	Displays the IP multicast group address for this entry that contains multicast routing information.
Source	Displays the network address that, when combined with the corresponding route SourceMask value, identifies the source that contains multicast routing information.
SourceMask	Displays the network mask that, when combined with the corresponding route Source value, identifies the multicast source.
UpstreamNeighbor	Shows the address of the upstream neighbor from which the IP datagrams from these sources are received. The address is 0.0.0.0 if the network is local.
Interface	Displays the interface, slot and portnumber, or VLAN ID where IP datagrams sent by these multicast sources to this multicast address are received.

Name	Description
ExpiryTime	Displays the amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.
Protocol	Displays the protocol as one of the following: <ul style="list-style-type: none"> • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb (12) • spbpimgw(13)

SPB-PIM Gateway Interface Deployment Scenarios

This section provides information about different deployment scenarios for SPB-PIM gateway interface.

SPB-PIM Gateway Base Case Deployment Scenario

There are several different customer topology scenarios for the SPB-PIM Gateway (SPB-PIM GW) feature deployment . One of these scenarios, shown in [Figure 5](#), is fully described here, along with configuration details, and display information.

The deployment scenario described here has two domains:

- SPB domain
- PIM domain

The PIM network has 5 PIM routers:

- RP
- PIM-A1
- PIM-A2
- PIM-B
- PIM-C

The RP router is the PIM-SM rendezvous point. PIM router PIM-B has receiver host R2 attached to it and source S1 is connected to PIM router PIM-C.

The SPB domain has the following components:

- SPB-PIM Gateway Controller node
- Two Gateway nodes, BEB-A1 and BEB-A2
- BEB-A1 is connected to the PIM network through a SPB-PIM Gateway interface to the PIM router PIM-A1

- BEB-A2 is connected to the PIM network through a SPB-PIM Gateway interface to the PIM router PIM-A2

**Note**

PIM-A1 and PIM-A2 routers attached to the BEBs SPB-PIM Gateway interface have standard PIM configured on their side of the interface.

- The SPB cloud has a BEB-B to which the source S2 is connected
- The SPB cloud has a BEB-C to which a receiver R1 is connected

**Note**

You can place the controller anywhere in the SPB cloud. The controller can be in the boundary or the core. Anywhere there is a connection into the PIM network from the SPB network, there must be a Gateway node(s) and Gateway interface(s).

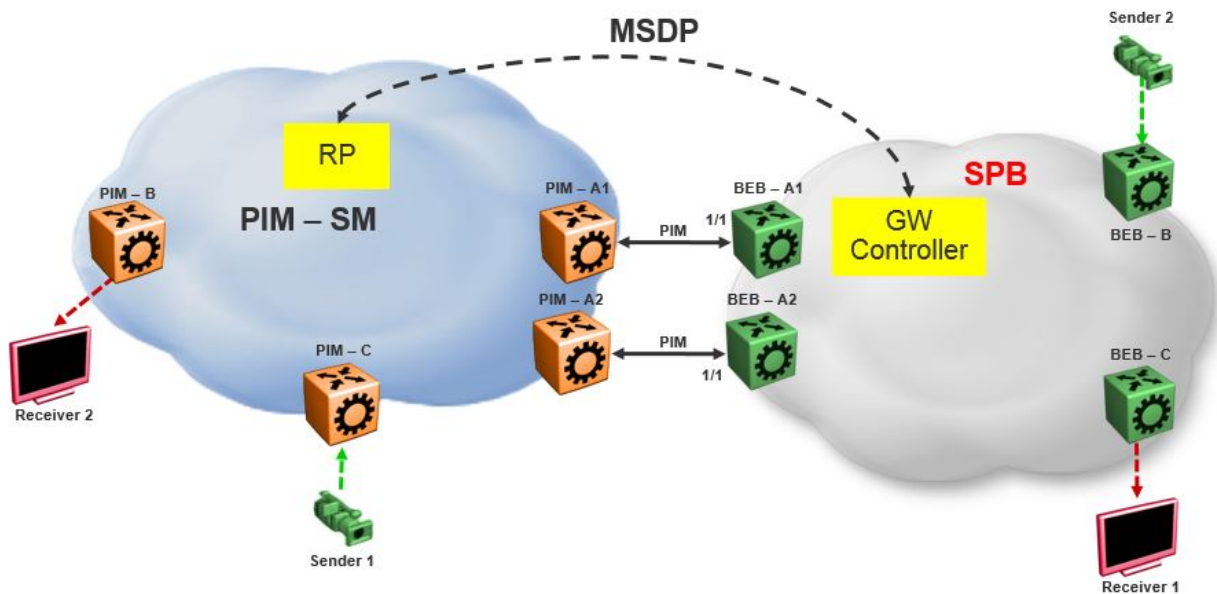

Figure 247: SPB-PIM Gateway base case configuration

The SPB-PIM Gateway nodes BEB-A1 and BEB-A2 from the SPB cloud are connected to the PIM network. The connection is established by SPB-PIM Gateway interface connections to PIM routers PIM-A1 and PIM-A2. A MSDP connection is established between the RP from the PIM domain and the SPB-PIM Gateway Controller from the SPB domain. A MSDP connection is established to exchange the multicast source information between the RP and the SPB Controller. Unicast routing or reachability is setup before establishing the MSDP connection between the RP and the Gateway controller. The Unicast setup is not shown in the above figure.

SPB-PIM Gateway base case configuration example

Before You Begin

- The Shortest Path Bridging (SPB) infrastructure must be configured and setup in the SPB domain (not shown in this example)
- Protocol Independent Multicast (PIM) infrastructure must be configured and setup in the PIM domain (not shown in this example)
- Unicast routing table must be setup in the PIM domain to ensure reachability of the Multicast Source Discovery Protocol (MSDP) peer and source S2 from the SPB network
- Unicast routing table must be setup in the SPB domain to ensure reachability of the MSDP peer and source S1 from the PIM network

Example**Node: Gateway controller**

Configure ISIS and SPBM:

```
Switch:1#configure terminal
Switch:1(config)#spbm
Switch:1(config)#router isis
Switch:1(config-isis)#system-id 0026.0026.0026
Switch:1(config-isis)#manual-area 01.0202.0303.04
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 nick-name 0.00.26
Switch:1(config-isis)#spbm 1 b-vid 10,20 primary 10
Switch:1(config-isis)#vlan create 10 name bvlan1 type spbm-bvlan
Switch:1(config)#vlan create 20 name bvlan2 type spbm-bvlan
Switch:1(config)#router isis enable
```

NNI Configuration:

```
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-if)#no shutdown
```

- Enable IPSC to setup Unicast route table. This setup ensures reachability of Rendezvous Point (RP) in the PIM network
- Create a loopback interface 2.0.2.2 to enable IPSC and MSDP originator-id
- Enable Multicast over Fabric Connect
- Configure static route and direct route redistribution
- Apply the static route and direct route redistribution

**Note**

Static route is used to reach RP for the below sample configuration.

```
Switch:1(config)#interface loopback 1
Switch:1(config-if)#ip address 2.0.2.2/32
Switch:1(config)#router isis
Switch:1(config-isis)#ip-source-address 2.0.2.2
Switch:1(config-isis)#spbm 1 ip enable
Switch:1(config-isis)#spbm 1 multicast enable
Switch:1(config-isis)#
Switch:1(config-isis)#redistribute static
Switch:1(config-isis)#redistribute static enable
Switch:1(config-isis)#redistribute direct
Switch:1(config-isis)#redistribute direct enable
```

```
Switch:1(config-isis)#
Switch:1(config-isis)#end
Switch:1#isis apply redistribute static
Switch:1#isis apply redistribute direct
```

MSDP Configuration:

Create an instance for the MSDP session. This IP interface is used for establishing an MSDP session with an RP in the PIM network. The source IP address used for the MSDP session must not be the newly created IP interface. The originator-id specifically configured for MSDP is used as the source IP address to establish the MSDP session. The originator-id is also used by the RP in the source active (SA) messages sent to the MSDP peers. The CLIP configured earlier is used as the originator-id.

```
Switch:1#configure terminal
Switch:1(config)#vlan create 2100 type port-mstprstp 0
Switch:1(config)#vlan members add 2100 1/3 portmember
Switch:1(config)#interface vlan 2100
Switch:1(config-if)#ip address 21.0.0.1/24
Switch:1(config-if)#exit

Switch:1(config)#ip msdp originator-id 2.0.2.2
Switch:1(config)#ip msdp enable
Switch:1(config)#ip msdp peer 21.0.0.2
Switch:1(config)#ip msdp peer 21.0.0.2 enable
```

SPB-PIM Gateway Controller configuration:

Enable SPB-PIM Gateway Controller

```
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast spb-pim-gw controller enable
```

Node: BEB-A1 (SPB-PIM Gateway)

Configure ISIS and SPBM:

```
Switch:1#configure terminal
Switch:1(config)#spbm
Switch:1(config)#
Switch:1(config)#router isis
Switch:1(config-isis)#system-id 0015.0015.0015
Switch:1(config-isis)#manual-area 01.0202.0303.04
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 nick-name 0.00.15
Switch:1(config-isis)#spbm 1 b-vid 10,20 primary 10
Switch:1(config-isis)#
Switch:1(config-isis)#vlan create 10 name bvlan1 type spbm-bvlan
Switch:1(config)#vlan create 20 name bvlan2 type spbm-bvlan
Switch:1(config)#router isis enable
```

NNI Configuration:

```
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
```

```
Switch:1(config-if)#isis enable
Switch:1(config-if)#no shutdown
```

- Enable IP Shortcuts (IPSC) to setup Unicast route table. This setup ensures reachability of sources in the PIM network
- Create a loopback interface 1.0.1.1 to enable IPSC
- Enable Multicast over Fabric Connect
- Configure static route and direct route redistribution
- Apply the static route and direct route redistribution

Note

Static route is used to reach sources in the PIM network for the below sample configuration.

```
Switch:1(config)#interface loopback 1
Switch:1(config-if)#ip address 1.0.1.1/32
Switch:1(config-if)#router isis
Switch:1(config-isis)#ip-source-address 1.0.1.1
Switch:1(config-isis)#spbm 1 ip enable
Switch:1(config-isis)#spbm 1 multicast enable
Switch:1(config-isis)#
Switch:1(config-if)#router isis
Switch:1(config-isis)#redistribute static
Switch:1(config-isis)#redistribute static enable
Switch:1(config-isis)#redistribute direct
Switch:1(config-isis)#redistribute direct enable
Switch:1(config-isis)#
Switch:1(config-isis)#end
Switch:1#isis apply redistribute static
Switch:1#isis apply redistribute direct
```

SPB-PIM Gateway interface configuration:

- Create an IP interface
- Enable SPB-PIM Gateway on the IP interface

Note

For the sample configuration below, the SPB-PIM Gateway interface is on VLAN 2000 with IP address 20.0.0.1

```
Switch:1#configure terminal
Switch:1(config)#vlan create 2000 type port-mstprstp 0
Switch:1(config)#vlan members add 2000 1/1 portmember
Switch:1(config)#interface vlan 2000
Switch:1(config-if)#ip address 20.0.0.1/24
Switch:1(config-if)#ip spb-pim-gw enable
```

Enable SPB-PIM Gateway node functionality:

```
Switch:1(config-if)#router isis
Switch:1(config-isis)#spbm 1 multicast spb-pim-gw gateway enable
```

Similar configuration is done for the SPB-PIM Gateway node BEB-A2.

PIM Sparse Mode (PIM-SM) is enabled at the PIM routers PIM-A1 and PIM-A2 on the interfaces connecting SPB-PIM Gateway nodes BEB-A1 and BEB-A2. The SPB-PIM Gateway nodes BEB-A1 and BEB-A2 see the PIM routers PIM-A1 and PIM-A2 as PIM neighbors. The PIM routers PIM-A1 and PIM-A2 see the SPB-PIM Gateway nodes as PIM neighbors. The SPB-PIM Gateway nodes BEB-A1 and BEB-A2 have IP reachability to the PIM source S1 with PIM neighbors as the next hop.

The route to reach source S1 is distributed to the Gateway controller through IPSC. The Gateway controller uses this route information to select only one of the Gateways to which the source S1 will be assigned for a specific group. The Gateway node is the only node that can draw the source S1 stream into the SPB network on behalf of SPB receivers, by sending an SG Join across a Gateway Interface to the nexthop toward the source S1. This ensures that the data is not duplicated from multiple ingress interfaces from the PIM network. Other Gateway nodes that are not assigned as the Gateway to the source S1 will not establish multicast path.

When S1 from the PIM network sends traffic to G1, RP from the PIM network sends MSDP SA message for (S1,G1) to the Gateway Controller. If the Gateway Controller selects BEB-A1 as the Gateway for the foreign source S1 and group G1, the Gateway Controller assigns BEB-A1 to (S1,G1). The Gateway Controller then sends the Gateway assignment information to all the nodes. When BEB-A1 receives the assignment information, it sees that it is assigned as the Gateway to (S1,G1). The BEB-A1 then checks if the next hop to reach S1 is a valid PIM neighbor. If the next hop is a valid PIM neighbor, the BEB-A1 interacts with Multicast over Fabric Connect and advertises a sender TLV for the (S1,G1) into the SPB cloud. The BEB-A2 also receives the Gateway assignment information but silently saves the received Gateway assignment information since it is not the selected Gateway. If the interested receiver R1 is found at BEB-C, as part of Multicast over Fabric Connect processing, BEB-C sends receiver TLV for the group G1 to the advertising node, BEB-A1. Upon receiving this receiver TLV, BEB-A1 establishes the multicast stream through its Gateway interface which is upstream towards the PIM neighbor, by sending out a PIM SG Join message toward the source S1. This causes PIM-A1 node to forward multicast data from S1 to BEB-A1.

When the local source S2 (local to the SPB network) at BEB-B in the SPB network sends traffic to group G1, BEB-B advertises a sender TLV for (S1,G1). The controller sees this sender TLV and sends an MSDP SA message for (S2,G1) to the RP in the PIM network.

**Note**

The controller does not send SA messages for (S1,G1) to the PIM network since S1 is a foreign source.

When PIM network receiver R2 is interested in group G1, the PIM router PIM-B sends PIM a (*,G) Join message to the RP. RP in turn sends (S2,G1) Join towards the source S2. The unicast IP reachability to source S2 which is setup in the RP is used for sending (S2,G1) joins hop-by-hop towards the source. From the RP point of view, the next hop to reach the source S2 is one of the PIM routers PIM-A1 or PIM-A2 (depending on the unicast route table next hop address). For this example, the next hop is PIM-A1. The RP sends the (S2,G1) Join message towards the PIM-A1. PIM-A1 then sends an SG Join to BEB-A1. Upon receiving the Join for (S2,G1) from the PIM network, BEB-A1 sends a receiver TLV into the SPB network to the S2 advertising router BEB-B. When the BEB-B receives the receiver TLV, the BEB-B establishes the multicast stream from source S2 toward the receiver.

Source Specific Multicast

PIM-SSM does not use a Rendezvous Point to centralize the receivers and sources. A PIM-SSM router which has a receiver for a group multicast address in the SSM address range joins directly to a source for that group by sending an SG join toward the source, not a *G join toward the RP for the group. Because of this, MSDP is not required in order for the PIM Network to learn of an SSM range stream in the SPB network. However, in order for the SPB network to know where a PIM SSM source resides, it must statically configure S1,SSM-G1 at the controllers. In this way, a Gateway can be chosen for the stream, even in the absence of MSDP.

The following figure shows a non-MSDP SSM environment where stream PIM network source S1, for an SSM group, must be statically configured at the SPB Controllers:

Figure 248: Static configuration of SSM groups in Controllers

Peer Mesh Group

The following figure shows the Peer Mesh Group configuration:

Note

Controllers within a single SPB network must never peer with each other, regardless of whether mesh groups exist. In addition, both Controllers must have the same peerings configured with other networks RPs.

Figure 249: Peer Mesh Group

MSDP Peer Mesh Group configuration example

Example

Configure MSDP:

If the MSDP speakers are fully meshed, the speakers can be configured into a mesh group in order to prevent excessive SA forwarding and RPF checks. To configure a mesh group, specify a name along with the MSDP peer. For example, on router RP1, configure a mesh group which includes RP2, RP3, and both Gateway controllers. On RP2, configure the same mesh group with members RP1, RP3, and both Gateway controllers. On RP3, configure the same mesh group with members RP1, RP2, and both Gateway controllers. On each Gateway controller, configure the same mesh group with members RP1, RP2, and RP3, but never with another Gateway controller in the same SPB domain.

```
Switch:1(config)#ip msdp originator-id 2.0.2.2
Switch:1(config)#ip msdp enable
Switch:1(config)#ip msdp peer 21.0.0.2 enable
Switch:1(config)#ip msdp mesh-group mgTest 21.0.0.2
```

Multi domain

The following figure shows a multi domain scenario, where two PIM domains and one SPB domain share multicast streams:

Figure 250: Multi domain configuration

SPB domain interconnect

The following figure shows the SPB domain interconnect configuration. In this scenario, two SPB domains are connected by PIM Gateway interfaces, and there is no traditional PIM Network involved. The Controllers from each SPB domain form MSDP adjacencies the Controllers in the other domain (but not within the same domain) other to share their multicast sources. The SPB-PIM Gateway nodes see the other SPB-PIM Gateway nodes as PIM neighbors on the SPB-PIM Gateway interfaces.

Figure 251: SPB domain interconnect

System Access

[System access fundamentals](#) on page 3311

[System access configuration using CLI](#) on page 3324

[System access configuration using EDM](#) on page 3349

The following sections describe how to access the switch, create users, and user passwords.

System access fundamentals

This section contains conceptual information about how to access the switch and create users and user passwords for access.

Logging On to the System

After the startup sequence is complete, the system opens the login prompt.

Note

With enhanced secure mode enabled, the person in the role-based authentication level of administrator configures the login and password values for the other role-based authentication levels. The administrator initially logs on to the switch using the default login of `admin` and the default password of `admin`. After the initial login, the switch prompts the administrator to create a new password.

The administrator then configures default logins and passwords for the other users based on the role-based authentication levels of the user. For more information on enhanced secure mode, see [System access security enhancements](#) on page 3336.

The following table shows the default values for login and password for the console and Telnet sessions.

Table 236: Access levels and default logon values

Access level	Description	Default logon	Default password
Read-only	Permits view only configuration and status information. This access level is equivalent to Simple Network Management Protocol (SNMP) read-only community access.	ro	ro
Layer 1 read-write	View most switch configuration and status information and change physical port settings.	l1	l1

Table 236: Access levels and default logon values (continued)

Access level	Description	Default logon	Default password
Layer 2 read-write	View and change configuration and status information for Layer 2 (bridging and switching) functions.	l2	l2
Layer 3 read-write	View and change configuration and status information for Layer 2 and Layer 3 (routing) functions.	l3	l3
Read-write	View and change configuration and status information across the switch. Read-write access does not allow you to change security and password settings. This access level is equivalent to SNMP read-write community access.	rw	rw
Read-write-all	Permits all the rights of read-write access and the ability to change security settings. This access level allows you to change the command line interface (CLI) and web-based management user names and passwords and the SNMP community strings.	rwa	rwa

You can enable or disable users with particular access levels, eliminating the need to maintain large numbers of access levels and passwords for each user.

The system denies access to a user with a disabled access level who attempts to log on. The system displays the following error message after a user attempts to log on with a blocked access level:

```
CPU1 [mm/dd/yy hh:mm:ss] 0x0019bfff GlobalRouter CLI WARNING Slot 1: Blocked unauthorized cli access
```

The system logs the following message to the log file:

```
User <user-name> tried to connect with blocked access level <access-level> from <src-ipaddress> via <login type>.
```

The system logs the following message for the console port:

```
User <user-name> tried to connect with blocked access level <access-level> from console port.
```

RADIUS authentication

Remote Authentication Dial-in User Service (RADIUS) authentication takes precedence over the local configuration. If you enable RADIUS authentication on the switch, the user can access the switch even if you block an access level on the switch.

Important

When you enable RADIUS on the switch and configure a RADIUS server to be used by CLI or EDM, the server authenticates the connection, whether it is FTP, HTTPS, SSH, or TELNET. However, in the event that the RADIUS server is unresponsive or is unreachable, the switch will fall back to the local authentication, so that you can access the switch using your local login credentials.

If you disable an access level, all running sessions, except FTP sessions, with that access level to the switch terminate.

Important

Only the RWA user can disable an access level on the switch. You cannot disable the RWA access level on the switch.

The system preserves these configurations across restarts.

hsecure mode boot configuration flag

The switch supports a configurable flag called high secure (hsecure). Use the hsecure flag to enable the following password features:

- 10 character enforcement
- aging time
- limitation of failed login attempts
- protection mechanism to filter designated IP addresses

If you activate the **hsecure** flag, the software enforces the 10-character rule for all passwords. The password must contain a minimum of two uppercase characters, two lowercase characters, two numbers, and two special characters.

If you enable hsecure for the first time and the password file does not exist, then the device creates a normal default username (rwa) and password (rwa). In this case, the password does not meet the minimum requirements for hsecure and as a result the system prompts you to change the password.

For more information about the hsecure flag, see [hsecure Mode](#) on page 2993.

Enhanced secure mode

If you enable enhanced secure mode, the system uses different authentication levels. Enhanced secure mode allows the system to:

- Provide role-based access levels
- Stronger password requirements
- Stronger rules on password length
- Stronger rules on password complexity
- Stronger rules on password change intervals

- Stronger rules on password reuse
- Stronger password maximum age use

For more information on enhanced secure mode, see [System access security enhancements](#) on page 3336.

Default Web-Server Behavior

The default switch configuration enforces the following restrictions for web-server access:

- The web-server password must be a minimum of 8 characters.
- Secure communications with the web server use Transport Layer Security (TLS) version 1.2 and above.
- The switch does not support the RC4 cipher. The switch supports the following ciphers:
 - TLS_RSA_WITH_AES_128_CBC_SHA
 - TLS_RSA_WITH_AES_256_CBC_SHA
 - TLS_RSA_WITH_AES_128_CBC_SHA256
 - TLS_RSA_WITH_AES_256_CBC_SHA256

For information about how to enable and configure the web server, see [Configure the Web Server](#) on page 254 or [Configure the Web Management Interface](#) on page 269. For information about supported browser versions, see [Supported Browsers](#) on page 262.

Managing the System using Different VRF Contexts

You can use the Enterprise Device Manager (EDM) to manage the system using different Virtual Router Forwarding (VRF) contexts.

- Using the GlobalRouter (VRF 0), you can manage the entire system. GlobalRouter is the default view at log in
- Using a VRF context other than the GlobalRouter (VRF 0), you have limited functionality to manage the system. For instance you can only manage the ports assigned to the specified VRF instance

Specify the VRF instance name on the EDM screen when you launch a VRF context view. You can use the context names (SNMPv3) and community strings (SNMPv1/v2) to assign different VRFs to manage selected components, such as ports and VLANs. For more information about context names and community strings, see [Simple Network Management Protocol \(SNMP\)](#) on page 3104.

CLI Passwords

The switch ships with default passwords configured for access to CLI through a console or Telnet session. If you possess read-write-all access authority, and you use SNMPv3, then you can change passwords in encrypted format. If you use Enterprise Device Manager (EDM), then you can also specify the number of allowed Telnet sessions and Remote login (rlogin) sessions.

Note

Rlogin is only supported on VSP 8600 Series.

**Important**

Be aware that the default passwords and community strings are documented and well known. Change the default passwords and community strings immediately after the first login.

For security, if you fail to log on correctly in three consecutive instances, then the device locks for 60 seconds.

The switch stores passwords in encrypted format and not in the configuration file.

Subscriber or administrative interaction

As a network administrator, you can configure the RADIUS server for user authentication to override user access to commands. You must still provide access based on the existing access levels in the switch, but you can customize user access by allowing and denying specific commands.

You must configure the following three returnable attributes for each user:

- Access priority (single instance)—the access levels currently available on the switch (ro, l1, l2, l3, rw, rwa)
- Command access (single instance)—indicates whether the user has access to the commands on the RADIUS server
- CLI commands (multiple instances)—the list of commands that the user can or cannot use

Access Policies for Services

You can control access to the switch by creating an access policy. An access policy specifies the hosts or networks that can access the switch through various services, such as Telnet, Simple Network Management Protocol (SNMP), Hypertext Transfer Protocol (HTTP), Secure Shell version 2 (SSHv2), and remote login (rlogin). You can enable or disable access services by configuring flags.

**Note**

Rlogin is only supported on VSP 8600 Series.

Use access policies for in-band management to secure access to the switch. When configuring an access policy, a lower precedence takes higher priority if you use multiple policies. For example, preference 120 has priority over preference 128.

You can define network stations that can access the switch or stations that cannot access the switch. For each service you can also specify the level of access, such as read-only or read-write-all.

When you configure access policies, you can perform either of the following actions:

- Globally enable the access policy feature, and then create and enable individual policies. Each policy takes effect immediately after you enable it.
- Create and enable individual access policies, and then globally enable the access policy feature to activate all the policies at the same time.

HTTP, SSH and rlogin support IPv4 and IPv6 with no difference in configuration or functionality.

Web interface passwords

The switch includes a web-management interface, Enterprise Device Manager (EDM), that you can use to monitor and manage the device through a supported web browser from anywhere on the network. For more information on supported web browsers, see [Supported Browsers](#) on page 262.

A security mechanism protects EDM and requires you to log on to the device using a user name and password. The default user name is `admin` and the default password is `password`.

Important

For security reasons, EDM is disabled by default.

By default, the minimum password length for the web server is 8 characters but you can override this value. For more information about how to enable and configure the web server, see [Configure the Web Server](#) on page 254 or [Configure the Web Management Interface](#) on page 269.

Password encryption

The switch handles password encryption in the following manner:

- After the device starts, the system restores the web-server passwords and community strings from the hidden file.
- After you modify the web-server username and password or SNMP community strings, the system makes the modifications to the hidden file.

Multiple CLI Users for Each Role

Table 237: Multiple CLI Users product support

Feature	Product	Release introduced
Multiple CLI users per role	VSP 4450 Series	VOSS 7.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 7.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 7.0
	VSP 8400 Series	VOSS 7.0
	VSP 8600 Series	VSP 8600 8.0 demonstration feature
	XA1400 Series	VOSS 8.0.50

Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

You can create up to a maximum of 10 CLI users for each role, which includes:

- 3 default users (rwa, rw, and ro)—User Type = default
- 7 user defined users (rwa or rw or ro)—User Type = userDefined

Usernames for default users (rwa, rw, and ro) can be changed; however, usernames for user defined users cannot be changed.

Users require a username and password to connect to the switch. Users can log on through the local serial port, Telnet, SSH, remote login (rlogin), or ftp. When a user is created, authentication is enabled, by default.

Note

Rlogin is only supported on VSP 8600 Series.

For security reasons, if a login attempt fails, the error feedback does not indicate if the failed login is due to an invalid user name or an invalid password. Response times for invalid user name and invalid user name/password pair are identical to prevent identification of which of the two failed.

Note

Multiple CLI users for each role does not apply in enhanced secure mode.

Enhanced Secure Mode

Table 238: Enhanced Secure Mode product support

Feature	Product	Release introduced
Enhanced Secure mode	VSP 4450 Series	VOSS 4.2
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 4.2
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50
Enhanced Secure mode for JITC and non-JITC sub-modes.	VSP 4450 Series	VOSS 5.1
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.1
	VSP 8400 Series	VOSS 5.1
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	Not Supported

Table 238: Enhanced Secure Mode product support (continued)

Feature	Product	Release introduced

	VSP 4900 Series	VOSS 8.5
	VSP 7200 Series	VOSS 8.5
	VSP 7400 Series	VOSS 8.5
	VSP 8200 Series	VOSS 8.5
	VSP 8400 Series	VOSS 8.5
	VSP 8600 Series	Not supported
	XA1400 Series	VOSS 8.5

Authentication Levels

After you enable enhanced secure mode with the **boot config flags enhancedsecure-mode** command, the switch supports role-based authentication levels. With enhanced secure mode enabled, the switch supports the following authentication access levels for local authentication, Remote Authentication Dial-In User Service (RADIUS), and Terminal Access Controller Access Control System Plus (TACACS+) authentication:

- Administrator
- Privilege
- Operator
- Auditor
- Security

Each username is associated with a certain role in the product and appropriate authorization rights for viewing and executing commands are available for that role.

With enhanced secure mode enabled, the person in the role-based authentication level of administrator configures the login and password values for the other role-based authentication levels. The administrator access level cannot be disabled on VOSS switches.

The administrator initially logs on to the switch using the default login of `admin` and the default password of `admin`. After the initial login, the switch prompts the administrator to create a new password.

The following displays an example of the initial login to the switch by the administrator after enhanced secure mode is enabled.

```

Login: admin
Password: ****
      This is an initial attempt using the default user name and password.
      Please change the user name and password to continue.
Enter the new name : rwa
Enter the New password : *****
Re-enter the New password : *****
Password changed successfully
      Last Successful Login:Wed Oct 14 12:20:42 2015
      Unsuccessful Login attempts from last login is: 0

```

The administrator then configures default logins and passwords for the other users based on the role-based authentication levels of the user.

Access Level and Login Details

Access level	Description	Login location
Administrator	The administrator access level permits all read-write access, and can change security settings. The administrator access level can configure CLI and web-based management user names, passwords, and the SNMP community strings. The administrator access level can also view audit logs. The administrator access level can be disabled on VSP 8600 Series only.	SSH/Telnet (in band/mgmt)/ console
Privilege	The privilege access level has the same access permission as the administrator; however, the privilege access level cannot use RADIUS or TACACS+ authentication. The privilege access level is known as the emergency-admin on VSP 8600 Series only.	SSH/Telnet(in band/mgmt)/ console/
Operator	The operator access level can view most switch configurations and status information. The operator access level can change physical port settings at layer 2 and layer 3. The operator access level cannot access audit logs or security settings.	SSH/Telnet(in band/mgmt)/ console/
Auditor	The auditor access level can view configuration information, status information, and audit logs.	SSH/Telnet(in band/mgmt)/ console/
Security	The security access level can change security settings only. The security access level also has permission to view configuration and status information.	SSH/Telnet(in band/mgmt)/ console/

Password Requirements

After you enable enhanced secure mode on the switch, the password requirements are stronger. The individual in the administrator access level role configures and provides a temporary user name and password. After you log in for the first time with the temporary user name and temporary password, the system forces you to change the temporary password. After you change the temporary password, you cannot use the password again in subsequent sessions.

The following topics discuss the enhanced password requirements.

Password Complexity Rule

After you enable enhanced secure mode, the system checks each password change request to ensure the new password meets the password complexity required.

The default for the password complexity rule includes the following:

- Two uppercase characters, from the range: ABCDEFGHIJKLMNOPQRSTUVWXYZ
- Two lowercase characters, from the range: abcdefghijklmnopqrstuvwxyz
- Two numeric characters, from the range: 1234567890
- Two special characters, from the range: `~!@#\$%^&*()_+=[]\|;:'<>.,?/

Password Length Rule

The system enforces a minimum password length of 15 characters after you enable enhanced secure mode.

If the password is not long enough, the system displays the following message:

```
Password change aborted. The new password does not meet the minimum complexity requirement. Please select another password that meets the change interval, length, complexity, no consecutive repeating characters or history requirements of the domain.
```

Password Change Interval Rule

The system enforces a minimum password change interval, which defines the minimum amount of time before you can change to a new password. By default, the minimum change interval is 24 hours between changing from one password to a new password. When you attempt to change your password, the system checks the timestamp for your password to determine if enough time has passed to enable you to change the password.

If you attempt to change the password and not enough time has passed, the system rejects the request, and the system informs you that the password was recently changed. Any password change outside of the enforced interval requires the Administrator to approve the change.

If you try to change the password before the change interval allows, the system displays the following message:

```
Password change aborted. The new password does not meet the minimum complexity requirement. Please select another password that meets the change interval, length, complexity, no consecutive repeating characters or history requirements of the domain.
```

Minimum Password Change

Note

Product Notice: This section does not apply to VSP 8600 Series.

The system enforces a minimum password change requirement, which defines that 8 characters must differ within the same position from the old password.

If the new password does not have at least 8 characters changed within the same position from the old password, the system rejects the password and displays the following message:

```
The password change failed, less than eight characters were changed.
```

Password Reuse Rule

After you enable enhanced secure mode, the administrator access level can define the number of old passwords that cannot be reused. The password reuse rule ensures that recently used passwords are not reused immediately, which reduces the risk of someone unlawfully gaining access to the system. The default number of prohibited recently used passwords is 3, but you can define up to 99.

The system saves the password history and stores the history in an encrypted format, along with the user name and date of change. If a particular user attempts to change a password, the system checks

the new password against the stored passwords the user has previously used. If the password is on the list of previously used passwords, the system rejects the password change, and displays the following message:

```
Old password not allowed.
```

Password Maximum Age Rule

The system enforces automatic password renewal and password lockout after the expiration period because long-term usage of the same password can cause the system to be vulnerable to hacking.

You can configure the password expiration period to a range of 1 to 365 days. The default password expiration period is 90 days.

Password Max-Session

The password max-sessions value indicates the maximum number of times a particular type of role-based user can log in to the switch through the SSH session at the same time. The max-sessions value applies only for SSH sessions, and only with enhanced secure mode enabled.

After the maximum session number is reached that particular type of user cannot login. For example, if the max-sessions for an auditor user is configured as 5, then the auditor user can log in to only five SSH sessions at the same time. The default is 3.

Password Pre-Notification Interval and Post-Notification Interval Rule

After enhanced secure mode is enabled, the switch enforces password expiry. To ensure a user does not lose access, the switch offers pre- and post-notification messages explaining when the password will expire.

The administrator can define pre- and post-notification intervals to between one to 99 days.

The system maintains the password with a time stamp for when the password expiration. When you log in, the system checks the password time stamp and the notification timer values. If the administrator configures the pre-notification to 30 days, when you log in, the system checks the time stamp and notification timer values, and if the password expiry is due in 30 days, the system displays the first notification.

The pre-notification intervals provide messages to warn users that their passwords will expire within a particular timeframe:

- interval 1—By default, interval 1 is 30 days.
- interval 2—By default, interval 2 is 7 days.
- interval 3—By default, interval 3 is 1 day.

The post-notification intervals provide notification to users that their passwords have expired within a particular timeframe:

- interval 1—By default, interval 1 is 1 day.
- interval 2—By default, interval 2 is 7 days.
- interval 3—By default, interval 3 is 30 days.

If you do not change the password before the expiry date, the system locks your account. When your account is locked, only the administrator can unlock the account. The administrator creates a temporary

password, and then you can login with the temporary password. If the administrator password expires and the configured notification interval lapses, access to SSH/Telnet/FTP connections is denied. The administrator must connect to the console port using a serial connection to change the password.

Sensitive File Protection

Note

Sensitive file protection does not apply to VSP 8600 Series.

For certain switches in enhanced secure mode, sensitive files and paths are protected. The home directory for enhanced secure mode is `/intflash/shared`. You cannot access sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. You cannot access sensitive files using CLI commands. Files transferred on the switch through the default path are saved in `/intflash/shared`.

The following sensitive files and paths are protected in enhanced secure mode:

- `/intflash/.cert`
- `/intflash/.ike_psk.txt`
- `/intflash/ospf_key.txt`
- `/intflash/ospf_vrfif_key.txt`
- `/intflash/ospf_vrfvif_key.txt`
- `/intflash/ospf_vrfif_md5key.txt`
- `/intflash/ospf_vrfvif_md5key.txt`
- `/intflash/ospf_md5key.txt`
- `/intflash/.isis_md5key.txt`
- `/intflash/.isis_sha2key.txt`
- `/intflash/.isis_simplekey.txt`
- `/intflash/.shadovfedmoc.txt`
- `/intflash/snmp_usm_moc.txt`
- `/intflash/snmp_usm_moc_fed.txt`
- `/intflash/snmp_comm_moc.txt`
- `/intflash/snmp_comm_moc_fed.txt`
- `/intflash/.radsec/profile`
- `/intflash/.ssh/ssh_rsa.key`
- `/intflash/.ssh/ssh_dss.key`
- `/intflash/.ssh/moc_sshc_rsa_file`
- `/intflash/.ssh/moc_sshc_dsa_file`
- `/intflash/.ssh/id_dsa_*`
- `/intflash/.ssh/id_rsa_*`
- `/intflash/server.pem`
- `/intflash/app/server.pem`
- `/intflash/app/restweb/certs/privkey.pem`
- `/intflash/app/restweb/certs/server.pem`
- `/intflash/app/restweb/certs/cert.pem`

- /intflash/app/slamon/certs/trustcerts.txt
- /intflash/ovsdb/keys/privatekey.pem
- /intflash/ovsdb/keys/sc-cert.pem
- /intflash/.shadov.txt
- /intflash/.ntp_keys.txt

Sensitive files cannot be accessed using the following CLI commands:

- **cd**
- **copy**
- **move**
- **move**
- **rename**
- **remove**
- **delete**
- **more**
- **edit**
- **dir**
- **mkdir**

Operational Considerations

- If you attempt to change the value of the enhancedsecure-mode flag when the system is running, you are prompted to continue or to cancel the action. If you decide to continue, all sensitive files are deleted. You must save the current configuration and then reset the switch for the change to take effect.
- When you upgrade the software from releases versions earlier than VOSS 8.5, even if the enhancedsecure-mode flag is changed, no sensitive files are deleted.

If you upgrade the software to VOSS 8.5, if the enhancedsecure-mode flag is changed, all sensitive files are deleted.

- If you enable the **boot config flags factorydefaults** configuration flag to return an existing switch to factory default configuration, in enhanced secure mode, all sensitive files are deleted.
- When the switch resets after you enable enhanced secure mode or you upgrade the switch software, all configuration files, such as the runtime, primary, and backup configuration files are copied to /intflash/shared. The system displays the following message:

```
GlobalRouter SW INFO The runtime config file /intflash/config.cfg is
copied to /intflash/shared/config.cfg due to changing ESM mode/upgrade
version.
```

When the switch resets after you disable enhanced secure mode or after you downgrade the switch software, the switch uses the same configuration files as it used before the switch reset, either from /intflash/shared or from /intflash.

System access configuration using CLI

The section provides procedures to manage system access through configurations such as usernames, passwords, and access policies.

Change the Default Username

You can change usernames for default users (rwa, rw, and ro) for the specified access level. You cannot change usernames for user-defined users.

Before You Begin

Only the rwa user can change the default username.

About This Task

Perform this procedure to change the default username for the specified access level.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Change the default username:
`username WORD <1-20> level {l1|l2|l3|ro|rw|rwa}`

The system displays the following message:

```
Do you want to change username for the default RO user ?
```

3. Type `y`.
4. Enter the old password.
5. Enter the new password.
6. Re-enter the new password.

Example

Change the default username:

```
Switch:1>enable
Switch:1#config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#username EXUser ?
  level  Which access level
Switch:1(config)#username EXUser level ?
  l1  Change Layer 1 read write enable password
  l2  Change Layer 2 read write enable password
  l3  Change Layer 3 read write enable password
  ro  Change read only enable password
  rw  Change read write enable password
  rwa Change read write all enable password

Switch:1(config)#username EXUser level ro
```

```

Do you want to change username for the default RO user ? (y/n) ? y

Enter the old password : **
Enter the New password : *****
Re-enter the New password : *****

```

Variable Definitions

The following table defines parameters for the **username** command.

Table 239:

Variable	Value
<i>WORD</i> <1-20>	Specifies the user logon name.
<i>level</i> 11 12 13 ro rw rwa	Specifies the access level.

Enabling CLI access levels

Enable CLI access levels to control the configuration actions of various users.

About This Task

Important

Only the RWA user can disable an access level on the switch. You cannot disable the RWA access level on the switch.

The system preserves these configurations across restarts.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable an access level:

```
password access-level WORD<2-8>
```

Example

Block CLI access to Layer 1:

```

Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no password access-level 11

```

Variable Definitions

The following table defines parameters for the **password access-level** command.

Variable	Value
<code>WORD<2-8></code>	<p>Permits or blocks this access level. The available access level values are as follows:</p> <ul style="list-style-type: none"> • l1 — Specifies Layer 1. • l2 — Specifies Layer 2. • l3 — Specifies Layer 3. • ro — Specifies read-only. • rw — Specifies read-write. • rwa — Specifies read-write-all. <p>To set this option to the default value, use the default operator with the command. By default, the system permits all access levels. To block an access level, use the no operator with the command.</p>

Changing passwords

Configure new passwords for each access level, or change the logon or password for the different access levels of the switch. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change encrypted passwords.

Before You Begin

- You must use an account with read-write-all privileges to change passwords. For security, the switch saves passwords to a hidden file.

About This Task

If you enable the hsecure flag, after the aging time expires, the system prompts you to change your password. If you do not configure the aging time, the default is 90 days.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Change a password:

```
cli password WORD<1-20> {layer1|layer2|layer3|read-only|read-write|
read-write-all}
```
3. Enter the old password.
4. Enter the new password.
5. Enter the new password a second time.

6. Configure password options:

```
password [access-level WORD<2-8>] [aging-time <1-365>] [default-
lockout-time <60-65000>] [lockout WORD<0-46> time <60-65000>] [min-
passwd-len <10-20>] [password-history <3-32>]
```

Example

Change a password, and then set the password to an access level of read-write-all and the expiration period for the password to 60 days:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#cli password smith read-write-all
Switch:1(config)#Enter the old password : winter
Switch:1(config)#Enter the New password : summer
Switch:1(config)#Re-enter the New password : summer
Switch:1(config)#password access-level rwa aging-time 60
```

Variable Definitions

The following table defines parameters for the **cli password** command.

Variable	Value
<i>layer1 layer2 layer3 read-only read-write read-write-all</i>	Changes the password for the specific access level.
<i>WORD<1-20></i>	Specifies the user logon name.

Use the data in the following table to use the **password** command.

Variable	Value
<i>access level WORD<2-8></i>	Permits or blocks this access level. The available access level values are as follows: <ul style="list-style-type: none"> • l1 • l2 • l3 • ro • rw • rwa
<i>aging-time <1-365></i>	Configures the expiration period for passwords in days, from 1-365. The default is 90 days.
<i>default-lockout-time <60-65000></i>	Changes the default lockout time after three invalid attempts. Configures the lockout time, in seconds, and is in the 60-65000 range. The default is 60 seconds. To configure this option to the default value, use the default operator with the command.

Variable	Value
<code>lockout WORD<0-46> time <60-65000></code>	Configures the host lockout time. <ul style="list-style-type: none"> <code>WORD<0-46></code> is the host IP address in the format a.b.c.d. <code><60-65000></code> is the lockout-out time, in seconds, in the 60-65000 range. The default is 60 seconds.
<code>min-passwd-len <10-20></code>	Configures the minimum length for passwords in high-secure mode. The default is 10 characters. To configure this option to the default value, use the default operator with the command.
<code>password-history <3-32></code>	Specifies the number of previous passwords the switch stores. You cannot reuse a password that is stored in the password history. The default is 3. To configure this option to the default value, use the default operator with the command.

Configure an Access Policy

About This Task

Configure an access policy to control access to the switch.

You can permit network stations to access the switch or forbid network stations to access the switch.

For each service, you can also specify the level of access; for example, read-only or read-write-all.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Create an access policy by assigning it a number:

```
access-policy <1-65535>
```
- Restrict the access to a specific level:

```
access-policy <1-65535> access-strict
```
- Configure access for an access policy:

```
access-policy <1-65535> accesslevel <ro|rwa|rw>
```
- Configure the access policy mode, network, and precedence:

```
access-policy <1-65535> [mode <allow|deny>] [precedence <1-128>]
[network <A.B.C.D> <A.B.C.D>]
```

If you configure the access policy mode to **deny**, the system checks the mode and service, and if they match the system denies the connection. With the access policy mode configured to **deny**, the system does not check **accesslevel** and **access-strict** information. If you configure the access policy mode to allow, the system continues to check the **accesslevel** and **access-strict** information.

6. (Optional) Configure access protocols for an access policy:

```
access-policy <1-65535> [ftp] [http] [ssh] [telnet] [tftp]
```
7. (Optional) Configure trusted username access for an access policy:

```
access-policy <1-65535> host WORD<0-46> [username WORD<0-30>]
```
8. (Optional) Configure SNMP parameters for an access policy:

```
access-policy <1-65535> [snmp-group WORD<1-32> <snmpv1|snmpv2c|usm>]
```

OR

```
access-policy <1-65535> [snmpv3]
```
9. Enable the access policy:

```
access-policy <1-65535> enable
```
10. Enable access policies globally:

```
access-policy
```

Example

Assuming no access policies exist, start with policy 3 and name the policy policy3. Add the read-write-all access level and the usm group group_example. Enable access strict, and finally, enable the policy.

```
Switch:1(config)#access-policy 3
Switch:1(config)#access-policy 3 name policy3
Switch:1(config)#access-policy 3 accesslevel rwa
Switch:1(config)#access-policy 3 snmp-group group_example usm
Switch:1(config)#access-policy 3 access-strict
Switch:1(config)#access-policy 3 enable
```

Variable Definitions

The following table defines parameters for the **access-policy** command.

Variable	Value
<i>access-strict</i>	Restrains access to criteria specified in the access policy. <ul style="list-style-type: none"> • true—The system accepts only the currently configured access level. • false—The system accepts access up to the configured level. Use the no operator to remove this configuration.
<i>accesslevel</i> <ro rwa rw>	Specifies the level of access if you configure the policy to allow access.
<i>enable</i>	Enables the access policy.
<i>ftp</i>	Activates or disables FTP for the specified policy. Because FTP derives its login and password from the CLI management filters, FTP works for read-write-all (rwa) and read-write (rw) access, but not for the read-only (ro) access. Use the no operator to remove this configuration.

Variable	Value
<i>host</i> WORD<0-46>	For remote login access, specifies the trusted host address as an IP address. The switch supports access-policies over IPv4 and IPv6 with no difference in functionality or configuration. Use the no operator to remove this configuration.
<i>http</i>	Activates the HTTP for this access policy. Use the no operator to remove this configuration.
<i>mode</i> <allow deny>	Specifies whether the designated network address is allowed access to the system through the specified access service. The default is allow. If you configure the access policy mode to <i>deny</i> , the system checks the mode and service, and if they match, the system denies the connection. With the access policy mode configured to <i>deny</i> , the system does not check <i>accesslevel</i> and <i>access-strict</i> information. If you configure the access policy mode to allow, the system continues to check the <i>accesslevel</i> and <i>access-strict</i> information.
<i>name</i> WORD<0-15>	Specifies the access policy name.
<i>network</i> <A.B.C.D> <A.B.C.D>	Specifies the IP address and subnet mask for IPv4, or the IP address and prefix for IPv6, that can access the system through the specified access service. The switch supports access-policies over IPv4 and IPv6 with no difference in functionality or configuration. Use the no operator to remove this configuration.
<i>precedence</i> <1-128>	Specifies a precedence value for a policy, expressed as a number from 1-128. The precedence value determines which policy the system uses if multiple policies apply. Lower numbers take higher precedence. The default value is 10.
<i>rlogin</i> Note: Exception: only supported on VSP 8600 Series.	Enables rlogin for the access policy.
<i>snmp-group</i> WORD<1-32> <snmpv1 snmpv2c usm>	Adds an SNMP version 3 group under the access policy. WORD<1-32> is the SNMP version 3 group name consisting of 1-32 characters. <snmpv1 snmpv2c usm> is the security model; either snmpv1, snmpv2c, or usm. Use the no operator to remove this configuration.
<i>snmpv3</i>	Activates SNMP version 3 for the access policy. Use the no operator to remove this configuration.

Variable	Value
<i>ssh</i>	Activates SSH for the access policy. Use the no operator to remove this configuration.
<i>telnet</i>	Activates Telnet for the access policy. Use the no operator to remove this configuration.
<i>tftp</i>	Activates the Trivial File Transfer Protocol (TFTP) for this access policy. Use the no operator to remove this configuration.
<i>username WORD<0-30></i>	Specifies the trusted host user name for remote login access.

Specifying a name for an access policy

Before You Begin

The policy must exist before you can name it.

About This Task

Assign a name to an existing access policy to uniquely identify the policy.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- Assign a name to the access policy:

```
access-policy <1-65535> name WORD<0-15>
```

Example

Assign a name to an access policy:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#access-policy 10 name useraccounts
```

Variable Definitions

The following table defines parameters for the **access-policy** command.

Variable	Value
<i>name WORD<0-15></i>	Specifies a name expressed as a string from 0-15 characters.

Allowing a network access to the switch

About This Task

Specify the network to which you want to allow access.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Specify the network:

```
access-policy <1-65535> [mode <allow|deny>] [network <A.B.C.D>  

<A.B.C.D>]
```

Example

Specify the network to which you want to allow access:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#access-policy 5 mode allow network 192.192.192.0 24
```

Variable Definitions

The following table defines parameters for the **access-policy** command.

Variable	Value
<i>mode</i> <allow deny>	Specifies whether a designated network address is allowed or denied access through the specified access service. The default is allow.
<i>network</i> <A.B.C.D> <A.B.C.D>	Specifies the IPv4 address and subnet mask, or the IPv6 address and prefix-length, permitted or denied access through the specified access service.

Configuring access policies by MAC address

About This Task

Configure access-policies by MAC address to allow or deny local MAC addresses on the network management port after an access policy is activated. If the source MAC does not match a configured entry, the default action is taken. For connections coming in from a different subnet, the source MAC of the last hop is used in decision making. Configuring access-policies by MAC address does not perform MAC or Forwarding Database (FDB) filtering on data ports.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add the MAC address and configure the action for the policy:

```
access-policy by-mac <0x00:0x00:0x00:0x00:0x00:0x00> <allow|deny>
```
3. Specify the action for a MAC address that does not match the policy:

```
access-policy by-mac action <allow|deny>
```

Example

Add the MAC address:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#access-policy by-mac 00-C0-D0-86-BB-E7 allow
```

Variable Definitions

The following table defines parameters for the **access-policy by-mac** command.

Variable	Value
<0x00:0x00:0x00:0x00:0x00:0x00>	Adds a MAC address to the policy. Enter the MAC address in hexadecimal format.
<allow deny>	Specifies the action to take for the MAC address.

Creating multiple CLI users

Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

You can create up to seven new CLI users on the switch, in addition to the three default CLI users. The username must be unique. If you enable the hsecure flag, password complexity rules apply to all users.

Before You Begin

You must use an account with read-write-all privileges to create new CLI users.

About This Task

Note

When a new CLI user is created, the specified username and access level cannot be changed later.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a new CLI user:
`username add {<WORD 1-20> level [ro|rw|rwa] enable}`
3. Enter a password.
4. Enter the password a second time.

Example

Create a new CLI user:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#username add smith level rwa enable
Enter password : *****
Re-enter password : *****
Switch:1(config)#
```

Variable Definitions

The following table defines parameters for the **username** command.

Variable	Value
<code>add WORD<1-20></code>	Specifies the username to create.
<code>enable</code>	Enables the new CLI user.
<code>level <ro rw rwa></code>	Specifies the level assigned to the new CLI user: <ul style="list-style-type: none"> • ro: Read-only level • rw: Read-write level • rwa: Read-write-all level

Deleting a username

About This Task

Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Use this task to delete a username. Default ro, rw, and rwa users cannot be deleted.

Before You Begin

You must use an account with read-write-all privileges to delete a user.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`

2. Delete the username:

```
no username <WORD 1-20>
```

Example

Delete a user:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no username smith
The specified username will be deleted! Continue (y/n) ? Y
Switch:1(config)#show cli username smith
Username does not exist
```

Variable Definitions

The following table defines parameters for the **no username** command.

Variable	Value
<i>WORD <1-20></i>	Specifies the username to delete.
<i>enable</i>	Disables the username.

Displaying CLI usernames and roles

About This Task

Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Use this task to display CLI usernames and roles.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display CLI usernames and roles:

```
show cli username
```

Example

```
Switch:1>show cli username

=====
UserName          AccessLevel   State         Type
=====
ro                 ro            enable        default
rw                 rw            enable        default
rwa                rwa           NA            default
smith              rw            enable        userDefined
```

System access security enhancements

The section provides information on security enhancements after you enable enhanced secure mode.

Display the Boot Config Flags Status

Use the following procedure to display the boot config flags status.

If enhanced secure mode is enabled, the status displays whether the JITC or non-JITC sub-mode is enabled. If enhanced secure mode is disabled, the status displays as false.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. View the boot flags status:

```
show boot config flags
```

Example

In the following example, the status displays that enhanced secure mode is disabled.

Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags ha-cpu true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags linerate-directed-broadcast false
flags logging true
flags nni-mstp false
flags reboot true
flags rlogind false
flags savetostandby true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
flags vxlan-gw-full-interworking-mode false
```

Enabling enhanced secure mode

Use the following procedure to enable enhanced secure mode. Enhanced secure mode is disabled by default.

About This Task

Note

When you migrate your switch from enhanced secure mode enabled to disabled, or from disabled to enabled, you must build a new configuration. Do not use a configuration created in either enhanced secure mode disabled or enabled, and expect it to transfer over to the new mode.

The configuration file cannot be guaranteed if you transfer between enhanced secure mode enabled to disabled, or from enhanced secure mode disabled to enabled.

After you enable the enhanced secure mode, the system provides role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use. The enhanced secure mode boot flag supports two sub-modes namely JITC and non-JITC.

After you disable enhanced secure mode, the authentication, access-level, and password requirements work similarly to any of the existing commercial releases.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable enhanced secure mode:

```
boot config flags enhancedsecure-mode [jitc | non-jitc]
```

Note

As a best practice, enable the enhanced secure mode in the non-JITC sub-mode, because the JITC sub-mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting.

3. (Optional) Disable enhanced secure mode:

```
no boot config flags enhancedsecure-mode
```

4. (Optional) Configure the enhanced secure mode to the default value:

```
default boot config flags enhancedsecure-mode
```

5. Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

6. Restart the switch:

```
boot [config WORD<1-99>] [-y]
```

Note

If you enter the **boot** command with no arguments, you cause the switch to start using the current boot choices defined by the **boot config choice** command.

If you enter a boot command and the configuration filename without the directory, the device uses the configuration file from /intflash/.

Example

Enable the enhanced secure non-JITC sub-mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags enhancedsecure-mode non-jitc
Switch:1(config)#save config
Switch:1(config)#exit
Switch:1(config)#boot config /intflash/config.cfg -y
```

Enable the enhanced secure JITC sub-mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags enhancedsecure-mode jitc
Switch:1(config)#save config
Switch:1(config)#exit
Switch:1(config)#boot config /intflash/config.cfg -y
```

Variable definitions

Use the data in the following table to use the **boot config flags enhancedsecure-mode** command.

Variable	Value
<i>jitc</i>	Enables the JITC enhanced secure mode. The JITC mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting.
<i>non-jitc</i>	Enables the non-JITC enhanced secure mode.

Create Accounts for Different Access Levels

Use the following procedure to create accounts for different access levels in enhanced secure mode. You must be the administrator to configure the different access levels.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Create accounts on the switch for different access levels:
password create-user {auditor|operator|privilege|security} WORD<1-255>
3. Save the configuration:
save config

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Create an account at the auditor level for jsmith:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password create-user auditor jsmith
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password create-user** command.

Variable	Value
{auditor operator privilege security}	Specifies the access level for the user.
WORD<1-255>	Specifies the user name.

Deleting Accounts in Enhanced Secure Mode

Use the following procedure to delete accounts in enhanced secure mode.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.
- You must be an admin or privilege user to delete accounts.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Delete an account on the switch:
password delete-user username WORD<1-255>

3. Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Delete an account for jsmith:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password delete-user user-name jsmith
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password delete-user** command.

Variable	Value
<i>user-name</i> <i>WORD</i> <1-255>	Specifies the user name.

Configuring a password for a specific user

Configure a new password for a user if the password has expired or locked. Only the administrator can configure a password for a user.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Create accounts on the switch for different access levels:

```
password set-password user-name WORD<1-255>
```
3. Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure a password for jsmith:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password set-password user-name jsmith
Enter the New password : *****
Switch:1(config)#Password modified for user jsmith
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password set-password** command.

Variable	Value
<i>user-name</i> WORD<1-255>	Specifies the user for which to configure the password.

Return the System to the Factory Defaults

To return the system to factory defaults, run the **boot config flags factorydefaults** command.

For more information about the factorydefaults boot flag, see [Boot Sequence](#) on page 145.

Configuring the Password Complexity Rule

About This Task

Use the following procedure to configure the password complexity rule.

The password complexity rule default is to use at least two uppercase, two lowercase, two numeric, and two special character to meet the password criteria.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Configure the password complexity rule:

```
password password-rule <1-2> <1-2> <1-2> <1-2>
```
- (Optional) Configure the password complexity rule to the default:

```
default password password-rule
```

4. Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the password complexity rule to require two uppercase, two lowercase, two numeric and two special characters in each password:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password password-rule 2 2 2 2
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password password-rule** command.

Variable	Value
<1-2> <1-2> <1-2> <1-2>	Configures the minimum password rule. The first variable defines the number of uppercase characters required. The second <1-2> variable defines the number of lowercase characters required. The third <1-2> variable defines the number of numeric characters required. The fourth <1-2> variable defines the number of special characters required. The default for each of these is 2.

Configuring the password length rule

About This Task

Configure the password length rule after you enable enhanced secure mode. By default, the minimum password length is 15.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the password length rule option:

```
password min-passwd-len <8-32>
```
3. (Optional) Configure the password length rule to the default:

```
default password min-passwd-len
```

- Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the password length rule to 20:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password min-passwd-len 20
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password min-passwd-len** command.

Variable	Value
<8-32>	Configures the minimum character length required. The default is 15.

Configuring the change interval rule

About This Task

Use the following procedure to configure the change interval rule. The system enforces a minimum password change interval, which defines the minimum amount of time before you can change to a new password. By default, the minimum change interval is 24 hours between changing from one password to a new password.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Configure the change interval rule option:

```
password change-interval <1-999 hours>
```
- (Optional) Configures the change interval rule to the default:

```
default password change-interval
```

4. Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the change interval rule to 72 hours:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password change-interval 72
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password change-interval** command.

Variable	Value
<1-999>	Configures the minimum interval between consecutive password changes. The default is 24 hours.

Configuring the reuse rule

Use the following procedure to configure the password reuse rule. The default password reuse rule is 3.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the password reuse rule option:

```
password password-history <3-32>
```
3. (Optional) Configure the password reuse rule to the default:

```
default password password-history
```

4. Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the reuse rule to 30:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password password-history 30
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password password-history** command.

Variable	Value
<3-32>	Configures the minimum number of previous passwords to remember. The default is 3.

Configuring the maximum number of sessions

Use the following procedure to configure the maximum number of sessions on the switch. The max-sessions value configures the number of times a particular role-based user can log in to the switch through the SSH session at the same time. The default max-sessions value is 3.

The max-sessions value applies only for SSH sessions, and only with enhanced secure mode enabled.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the maximum number of sessions:

```
password max-sessions <1-8> user-name WORD<1-255>
```
3. (Optional) Configure the password reuse rule to the default:

```
default password max-sessions
```

4. Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the reuse rule to 5:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password max-sessions 5 user-name jsmith
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password max-sessions** command.

Variable	Value
<1-8>	Specifies the maximum number of sessions. The default is 3.
user-name <i>WORD</i> <1-255>	Specifies the user-name.

Configuring the maximum age rule

Use the following procedure to configure the maximum age rule.

If enhanced secure mode is enabled, the individual with the administrator access level role can configure the aging-time for each user. If you configure the aging time for each user, the aging time must be more than the global change interval value. The default is 90 days.

If you do not enable enhanced secure mode, the aging time is a global value for all users.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the maximum age rule option:

```
password aging-time day <1-365> [user WORD<1-255>]
```
3. (Optional) Configure the maximum age rule to the default:

```
default password aging-time [user WORD<1-255>]
```

4. Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the maximum age rule option to 100 days for user jsmith:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password aging-time day 100 user jsmith
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password aging-time** command.

Variable	Value
<i>day</i> <1-365>	Configures the password aging time in days. The default is 90 days.
<i>user WORD</i> <1-255>	Specifies a particular user.

Configuring the Pre-notification and Post-notification Rule

Use the following procedure to configure the pre-notification and post-notification rule.

After enhanced secure mode is enabled, the switch enforces password expiry. To ensure a user does not lose access, the switch offers pre- and post-notification messages explaining when the password will expire.

The administrator can define pre- and post-notification intervals to between one to 99 days.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

About This Task

The pre-notification intervals provide messages to warn users that their passwords will expire within a particular timeframe:

The post-notification intervals provide notification to users that their passwords have expired within a particular timeframe:

- interval 1—By default, interval 1 is 1 day.
- interval 2—By default, interval 2 is 7 days.
- interval 3—By default, interval 3 is 30 days.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the pre-notification rule option:

```
password pre-expiry-notification-interval <1-99> <1-99> <1-99>
```
3. Configure post-notification rule option:

```
password post-expiry-notification-interval <1-99> <1-99> <1-99>
```
4. Configure the pre-notification rule to the default:

```
default password pre-expiry-notification-interval
```
5. Configure the post-notification rule to the default:

```
default password post-expiry-notification-interval
```
6. Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the pre- and post-notification rules to the default:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#default password pre-expiry-notification-interval
Switch:1(config)#default password post-expiry-notification-interval
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **pre-expiry-notification-interval** command.

Variable	Value
<1-99> <1-99> <1-99>	Configure the pre-notification intervals to provide messages to warn the users that their passwords will expire within a particular timeframe. The first <1-99> variable specifies the first notification, the second <1-99> specifies the second notification, and the third <1-99> variable specifies the third interval. By default, the first interval is 30 days, the second interval is 7 days, and the third interval is 1 day.

Use the data in the following table to use the **post-expiry-notification-interval** command.

Variable	Value
<1-99> <1-99> <1-99>	Configure the post-notification intervals to provide notification to the users that their passwords have expired within a particular timeframe. The first <1-99> variable specifies the first notification, the second <1-99> specifies the second notification, and the third <1-99> variable specifies the third interval. By default, the first interval is 1 day, the second interval is 7 days, and the third interval is 30 days.

System access configuration using EDM

The section provides procedures you can use to manage system access by using Enterprise Device Manager (EDM). Procedures include configurations for usernames, passwords, and access policies.

Configuring CLI Access using EDM

Use the following procedures to perform CLI access configuration tasks such as:

- Enable access levels
- Change passwords
- Configure the logon banner

Enable Access Levels

About This Task

Enable access levels to control the configuration actions of various users.

Important

Only the RWA user can disable an access level on the switch. You cannot disable the RWA access level on the switch.

The system preserves these configurations across restarts.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **CLI** tab.
4. Select the enable check box for the required access level.
5. Click **Apply**.

Change Passwords

About This Task

Configure new passwords for each access level, or change the logon or password for the different access levels of the system to prevent unauthorized access. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change passwords in encrypted format.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **CLI** tab.
4. Specify the username and password for the appropriate access level.
5. Click **Apply**.

*Configure the Logon Banner***About This Task**

Configure the logon banner using EDM to display a warning message to users on the CLI before authentication.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **CLI** tab.
4. Enter the banner text in the **CustomBannerText** field.
5. Check the **CustomBannerEnable** check box.
6. Click **Apply**.

CLI Field Descriptions

The following table defines parameters for the **CLI** tab.

Name	Description
RWAUserName	Specifies the user name for the read-write-all CLI account.
RWAPassword	Specifies the password for the read-write-all CLI account.
RWEnable	Activates the read-write access. The default is enabled.
RWUserName	Specifies the user name for the read-write CLI account.
RWPassword	Specifies the password for the read-write CLI account.
RWL3Enable	Activates the read-write Layer 3 access. The default is enabled.
RWL3UserName	Specifies the user name for the Layer 3 read-write CLI account.
RWL3Password	Specifies the password for the Layer 3 read-write CLI account.
RWL2Enable	Activates the read-write Layer 2 access. The default is enabled.
RWL2UserName	Specifies the user name for the Layer 2 read-write CLI account.
RWL2Password	Specifies the password for the Layer 2 read-write CLI account.

Name	Description
RWL1Enable	Activates the read-write Layer 1 access. The default is enabled.
RWL1UserName	Specifies the user name for the Layer 1 read-write CLI account.
RWL1Password	Specifies the password for the Layer 1 read-write CLI account.
ROEnable	Activates the read-only CLI account. The default is enabled.
ROUserName	Specifies the user name for the read-only CLI account.
ROPassword	Specifies the password for the read-only CLI account.
MaxTelnetSessions	Specifies the maximum number of concurrent Telnet sessions in a range from 0-8. The default is 8.
MaxRloginSessions Note: Exception: only supported on VSP 8600 Series.	Specifies the maximum number of concurrent rlogin sessions in a range from 0-8. The default is 8.
Timeout	Specifies the number of seconds of inactivity for a Telnet or Rlogin session before the system initiates automatic timeout and disconnect, expressed in a range from 30-65535. The default is 900 seconds. Note: rlogin is supported only on the VSP 8600 Series.
NumAccessViolations	Indicates the number of CLI access violations detected by the system. This variable is a read-only field.
CustomBannerText Note: Exception: not supported on VSP 8600 Series.	Specifies the text message that is displayed to users on the CLI before authentication. The message can be company information, such as company name and contact, or a warning message for the users of CLI. With character limitation from 1-1800, the text box displays 79 characters per line.
CustomBannerEnable Note: Exception: not supported on VSP 8600 Series.	Specifies whether custom logon banner is enabled or disabled. The default is enabled.

Create an Access Policy

About This Task

Create an access policy to control access to the switch. An access policy specifies the hosts or networks that can access the switch through various services, such as Telnet, SNMP, HTTP, SSH, and rlogin.

Note

Rlogin is only supported on VSP 8600 Series.

You can allow network stations access the switch or forbid network stations to access the switch. For each service, you can also specify the level of access, such as read-only or read-write-all.

HTTP and HTTPS support IPv4 and IPv6 addresses.

Important

EDM does not provide SNMPv3 support for an access policy. If you modify an access policy with EDM, SNMPV3 is disabled.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Access Policies**.
3. Select the **Access Policies** tab.
4. Select **Insert**.
5. In **ID**, type the policy ID.
6. In **Name**, type the policy name.
7. Select **PolicyEnable**.
8. Select the **Mode** option to allow or deny a service.

If you configure the access policy mode to **deny**, the system checks the mode and service, and if they match the system denies the connection. With the access policy mode configured to **deny**, the system does not check **AccessLevel** and **AccessStrict** information. If you configure the access policy mode to allow, the system continues to check the **AccessLevel** and **AccessStrict** information.
9. From the **Service** options, select a service.
10. In **Precedence**, type a precedence number for the service (lower numbers mean higher precedence).
11. Select the **NetInetAddrType**.
12. In **NetInetAddress**, type an IP address.
13. In **NetInetAddrPrefixLen**, type the prefix length.
14. In **TrustedHostInet Address**, type an IP address for the trusted host.
15. In **TrustedHostUserName**, type a user name for the trusted host.
16. Select an **AccessLevel** for the service.
17. Select **AccessStrict**, if required.

Important

If you select **AccessStrict**, you specify that a user must use an access level identical to the one you select.

18. Select **Insert**.

Access Policies Field Descriptions

Use the data in the following table to use the **Access Policies** tab.

Name	Description
Id	Specifies the policy ID.
Name	Specifies the name of the policy.
PolicyEnable	Activates the access policy. The default is enabled.
Mode	Indicates whether a packet with a source IP address matching this entry is permitted to enter the device or is denied access. The default is allow. If you configure the access policy mode to deny , the system checks the mode and service, and if they match the system denies the connection. With the access policy mode configured to deny , the system does not check AccessLevel and AccessStrict information. If you configure the access policy mode to allow, the system continues to check the AccessLevel and AccessStrict information.
Service	Indicates the protocol to which this entry applies. The default is no service enabled.
Precedence	Indicates the precedence of the policy expressed in a range from 1-128. The lower the number, the higher the precedence. The default is 10.
NetInetAddrType	Indicates the source network Internet address type as one of the following. <ul style="list-style-type: none"> any IPv4 IPv6 IPv4 is expressed in the format a.b.c.d. Express IPv6 in the format x:x:x:x:x:x.
NetInetAddress	Indicates the source network Inet address (prefix/network). If the address type is IPv4, you must enter an IPv4 address and its mask length. You do not need to provide this information if you select the NetInetAddrType of any. If the type is IPv6, you must enter an IPv6 address. You do not need to provide this information if you select the NetInetAddrType of any.
NetInetAddrPrefixLen	Indicates the source network Inet address prefix-length/mask. If the type is IPv4, you must enter an IPv4 address and mask length. If the type is IPv6, you must enter an IPv6 address and prefix length. You do not need to provide this information if you select the NetInetAddrType of any.

Name	Description
<p>TrustedHostInetAddr</p> <p>Note: Exception: rlogin and rsh are only supported on VSP 8600 Series.</p>	<p>Indicates the trusted Inet address of a host performing a remote login to the device. You do not need to provide this information if you select the NetInetAddrType of any. TrustedHostInetAddr applies only to rlogin and rsh.</p> <p>Important: You cannot use wildcard entries in the TrustedHostInetAddr field.</p> <p>If the type is IPv4, you must enter an IPv4 address and mask length. If the type is IPv6, you must enter an IPv6 address and prefix length.</p>
<p>TrustedHostUserName</p> <p>Note: Exception: rlogin and rsh are only supported on VSP 8600 Series.</p>	<p>Specifies the user name assigned to the trusted host. The trusted host name applies only to rlogin and rsh. Ensure that the trusted host user name is the same as your network logon user name; do not use the switch user name, for example, rwa.</p> <p>Important: You cannot use wildcard entries. The user must already be logged in with the user name to be assigned to the trusted host. For example, using "rlogin -l newusername xx.xx.xx.xx" does not work from a UNIX workstation.</p>
<p>AccessLevel</p>	<p>Specifies the access level of the trusted host as one of the following:</p> <ul style="list-style-type: none"> • readOnly • readWrite • readWriteAll <p>The default is readOnly.</p>
<p>Usage</p>	<p>Counts the number of times this access policy applies.</p>
<p>AccessStrict</p>	<p>Activates or disables strict access criteria for remote users. If selected, a user must use an access level identical to the one you selected in the dialog box to use this service.</p> <ul style="list-style-type: none"> • selected: remote login users can use only the currently configured access level • cleared: remote users can use all access levels <p>Note: If Mode is configured as allow the system checks AccessStrict information. If Mode is configured as deny, the system does not check AccessStrict information.</p> <p>Important: If you do not select true or false, user access is governed by criteria specified in the policy table. For example, a user with an rw access level specified for a policy ID in the policy table is allowed rw access, and ro is denied access.</p> <p>The default is false (cleared).</p>

Enable an Access Policy

About This Task

Enable the access policy feature globally to control access across the switch.

You can create an access policy to control access to the switch. An access policy specifies the hosts or networks that can access the switch through access services; for example Telnet, SNMP, Hypertext Transfer Protocol (HTTP), and remote login (rlogin).

Note

Rlogin is only supported only on VSP 8600 Series.

Procedure

1. In the Device Physical View tab, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **System Flags** tab.
5. Select the **EnableAccessPolicy** check box.
6. Click **Apply**.

Creating Multiple Users

Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

You can create up to seven new CLI user roles on the switch, in addition to the three default CLI user roles. The username must be unique. If you enable the hsecure flag, password complexity rules apply to all users.

Before You Begin

You must use an EDM account with read-write-all privileges to create new CLI users.

About This Task

Use this task to create multiple CLI users on the switch using EDM.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Multiple Users** tab.
4. Click **Insert**.
5. Type the ID.
6. Type a unique user name.

7. Type a password.
8. Select the access level.
9. Select **Enable** to activate the user account.
10. Click **Insert**.

Multiple Users field descriptions

Use the data in the following table to use the **Multiple Users** tab.

Name	Description
Id	Specifies the unique ID.
Name	Specifies the username.
Password	Specifies the password.
Level	Specifies the user access level. <ul style="list-style-type: none"> • ro • rw • rwa
Enable	Enables the user access on the switch.
Type	Specifies the user type.

Modify User Passwords

About This Task

Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Use this task to modify user account passwords using EDM.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Multiple Users** tab.
4. To change the user account password, double-click the **Password** field.
5. Click **Apply**.

Disable a User Account

About This Task

Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Use this task to disable a user account using EDM.

Note

Users with rwa access rights cannot be disabled. Only users with ro and rw access rights can be disabled.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Multiple Users** tab.
4. View whether the user account is enabled. To modify, double-click on the cell and select false from the list.
5. Click **Apply**.

Delete a User Account

About This Task

Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Use this task to delete a user account using EDM. You cannot delete default ro, rw, and rwa users.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Multiple Users** tab.
4. Select the row with the user account to delete and click **Delete**.
5. Click **Yes** to confirm.

System access security enhancements using EDM

The section provides information to enable enhanced secure mode.

Enable Enhanced Secure Mode

Use the following procedure to enable enhanced secure mode in either the JITC or non-JITC sub-modes.

The enhanced secure mode is disabled by default.

About This Task

After you enable enhanced secure mode, the system can provide role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use.

After you disable enhanced secure mode, the authentication, access-level, and password requirements work similarly to any of the existing commercial releases.

Note

You can use EDM to enable or disable enhanced secure mode. To configure the security enhancements this feature provides, you must use CLI.

Procedure

1. On the Device Physical View, select the device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **Boot Config** tab.
5. In the **EnableEnhancedsecureMode** option box, select either **jitc** or **non-jitc** to enable the enhanced secure mode in one of these sub-modes. Select **disable** to disable the enhanced secure mode.

Note

As a best practice, enable the non-JITC sub-mode. The JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

6. Click **Apply**.
7. Save the configuration, and restart the switch.

TACACS+

- [TACACS+ Fundamentals on page 3360](#)

Table 240: TACACS+ product support

Feature	Product	Release introduced
TACACS+	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 4.1
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50
TACACS+ secure communication using IPSec for IPv4 Note: VOSS Releases 6.0 and 6.0.1 do not support this feature.	VSP 4450 Series	VOSS 5.1.2
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.1.2
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.1.2
	VSP 8400 Series	VOSS 5.1.2
	VSP 8600 Series	VSP 8600 8.0 demonstration feature
	XA1400 Series	VOSS 8.0.50

Note

DEMO FEATURE - Secure AAA server communication, which includes TACACS+ secure communication for IPv4, is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

TACACS+ Fundamentals

The switch supports the TACACS+ client. TACACS+ is a remote authentication protocol that provides centralized validation of users who attempt to gain access to a router or Network Access Server (NAS).

The TACACS+ feature is a client and server-based protocol that allows the switch to accept a user name and password and send a query to a TACACS+ authentication server, sometimes called a TACACS+ daemon. The TACACS+ server allows access or denies access based on the response by the client.

The TACACS+ feature facilitates the following services:

- Login authentication and authorization for CLI access through rlogin, Secure Shell (SSH), Telnet, or serial port.
- Login authentication for web access through EDM.
- Command authorization for CLI through rlogin, SSH, Telnet, or serial port.
- Accounting of CLI through rlogin, SSH, Telnet, and serial port.

Note

rlogin is only supported on VSP 8600 Series.

The following figure displays the basic layout of the switch and the TACACS+ server.

Figure 252: Switch and TACACS+ server

The TACACS+ feature uses Transmission Control Protocol (TCP) for its transport to ensure reliable delivery of packets. TACACS+ provides security by encrypting all traffic between the switch, which acts as the Network Access Server, and the TACACS+ server.

TACACS+ is a newer version of TACACS and provides separate authentication, authorization, and accounting (AAA) services. TACACS+ does not support earlier versions of TACACS.

TACACS+ is a base license feature. The TACACS+ feature is disabled by default.

TACACS+ Operation

The switch acts as an NAS to provide a connection to a single user, to a network, subnetwork or interconnected networks. The switch acts as a gateway to guard access to the TACACS+ server and network. Encryption relies on a secret key that is known to the client and the TACACS+ server.

Similar to the Remote Access Dial-In User Services (RADIUS) protocol, TACACS+ provides the ability to centrally manage the users who want to access a remote device. TACACS+ provides management of remote and local users who try to access a device through:

- rlogin
- Secure Shell (SSHv2)
- Telnet
- serial port
- web management

**Note**

Rlogin is only supported on VSP 8600 Series.

A TACACS+ daemon, which typically runs on a UNIX or Windows NT workstation, maintains the TACACS+ authentication, authorization, and accounting services.

Extreme Networks Identity Engines supports the TACACS+ daemon.

As a best practice, use the Identity Engines Ignition Server as your TACACS+ server.

You configure users in the TACACS+ server. If you enable authentication, authorization, and accounting services, the following occurs:

- During the logon process, the TACACS+ client initiates the TACACS+ authentication session with the TACACS+ server.
- After successful authentication the TACACS+ client initiates the TACACS+ authorization session with the TACACS+ server. This is transparent to the user. The switch receives the user access level after a successful TACACS+ authorization. The TACACS+ server authorizes every command the user issues if TACACS + command authorization is enabled for that user access level.
- After successful authorization, if you enable TACACS+ accounting, the TACACS+ client sends accounting information to the TACACS+ server.

A TACACS+ session establishes with the server in one of two ways:

- Multi-connection mode (also known as per-session): For every authentication, authorization, and accounting (AAA) request the switch establishes a session with the TACACS+ server, and then after the request finishes, the session is torn down. Multi-connection mode is the default mode.
- Single-connection mode: The first AAA request establishes the session, which is only torn down if TACACS+ is disabled or due to inactivity.

TACACS+ Architecture

You can connect the TACACS+ server to the switch:

- In-band through one of the data ports.
- Out-of-band through the management port.

Connect the TACACS+ server through a local interface. Management PCs can reside on an out-of-band management Ethernet port, or on the corporate network. Place the TACACS+ server on the corporate network so you can route it to the switch.

Before you configure the switch, you must configure at least one TACACS+ server and a key.

The TACACS+ server and the switch must have the same:

- Encryption key
- Connection mode (single connection or per-session connection. Per-session connection is the same as multi-connection mode.)
- TCP port number

You can configure a secondary TACACS+ server for backup authentication. You specify the primary authentication server when you configure the switch.

Authentication, authorization, and accounting

A fundamental feature of TACACS+ is the separation of authentication, authorization, and accounting (AAA) services, which allows you to selectively implement one or more TACACS+ services.

TACACS+ authentication

TACACS+ authentication provides control of authentication through login and password.

Authentication uses a database of users and passwords to determine:

- who a user is
- whether to allow the user access to the NAS

Important

Prompts for log on and password occur prior to the authentication process. If TACACS+ fails because no valid servers exist, the device uses the user name and password from the local database. If TACACS+ or the local database returns an access denied packet, the authentication process stops. The device attempts no other authentication methods.

The following figure illustrates the authentication process.

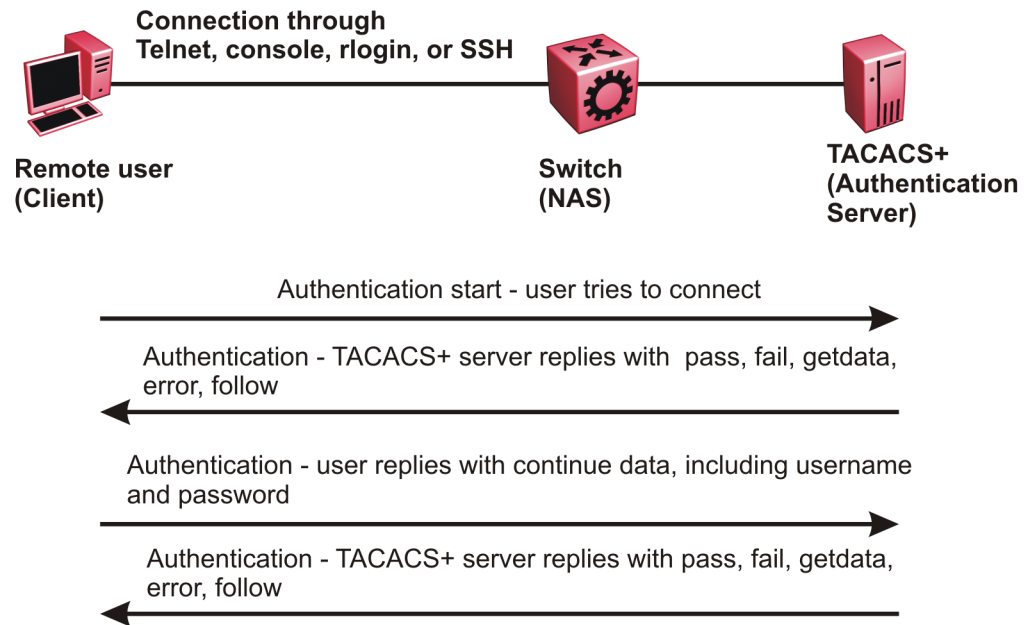

Figure 253: Authentication process

TACACS+ authorization

The transition from TACACS+ authentication to the authorization phase is transparent to the user. After successful completion of the authentication session, an authorization session starts with the authenticated user name. The authorization session provides access level functionality.

Authorization cannot occur without authentication.

Authorization:

- determines what a user can do
- allows administrators fine-grained control over the capabilities of users during sessions

The following figure illustrates the authorization process.

Figure 254: Authorization process

Authorization determines what a user can do. Authorization gives you the ability to limit network services to certain users and to limit the use of certain commands to certain users. The TACACS+ feature enhances the security by tightly policing the command execution for a particular user. After you enable command authorization, all commands, no matter the access level to which they belong, are sent to the TACACS+ server for authorization. Authorization cannot occur without first enabling authentication. You must configure command authorization globally and at individual access levels.

Two kinds of authorization requests exist:

1. Login authorization: Login authorization happens immediately after authentication and is transparent to the user. When the user logs on to the device, authorization provides the user access level. With log on, the device does not send a command to the TACACS+ server. You cannot configure login authorization.
2. Command authorization: When you configure command authorization for a particular level, all commands that you issue are sent to the TACACS+ server for authorization. The device can only issue the commands the TACACS+ server authorizes. You need to configure command authorization globally and at individual access levels, which are visible to the users.

Note

You must verify that the switch can reach the TACACS+ server and that you configure TACACS+ properly before you enable command authorization.

If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not allow the user to issue any command that has privilege level command authorization enabled. In such a case, the user can only issue logout and exit commands.

If a user tries to log in and the TACACS+ server does not exist or is not reachable, then, as discussed before, a local database in the switch authenticates the user. The switch authorizes a locally authenticated user and a locally authenticated user is not eligible for TACACS+ command authorization.

After the switch requests authorization, the logon credentials are sent to the TACACS+ daemon for authorization. If logon authorization fails, the user receives a permission denied message.

If TACACS+ logon authorization succeeds, the switch uses information from the user profile, which exists in the local user database or on the TACACS+ server, to configure the session for the user.

After you enable TACACS+ command authorization all commands are visible to all users; however, the user can only issue those commands that the TACACS+ server configuration allows.

The switch cannot enforce command access level. The TACACS+ server returns an access level to the switch. The switch allows the user to access the switch according to the access level. The device grants the user access to a command only if the profile for the user allows the access level.

You preconfigure command authorization on the TACACS+ server. You specify a list of regular expressions that match command arguments, and you associate each command with an action to deny or permit.

All members in a group have the same authorization. If you place a user in a group, the daemon looks in the group for authorization parameters if it cannot find them in the user profile.

TACACS+ Accounting

TACACS+ accounting enables you to track the services users access and the amount of network resources users consume.

TACACS+ accounting allows you to track:

- what a user does
- when a user does certain actions

The accounting record includes the following information:

- User name
- Date
- Start/stop/elapsed time
- Access server IP address
- Reason

You can use accounting for an audit trail, to bill for connection time or resources used, or for network management. TACACS+ accounting provides information about user sessions using the following connection types: Telnet, rlogin, SSH, and web-based management.

Note

rlogin is only supported on VSP 8600 Series.

With separation of AAA, accounting can occur independently from authentication and authorization.

The following figure illustrates the accounting process.

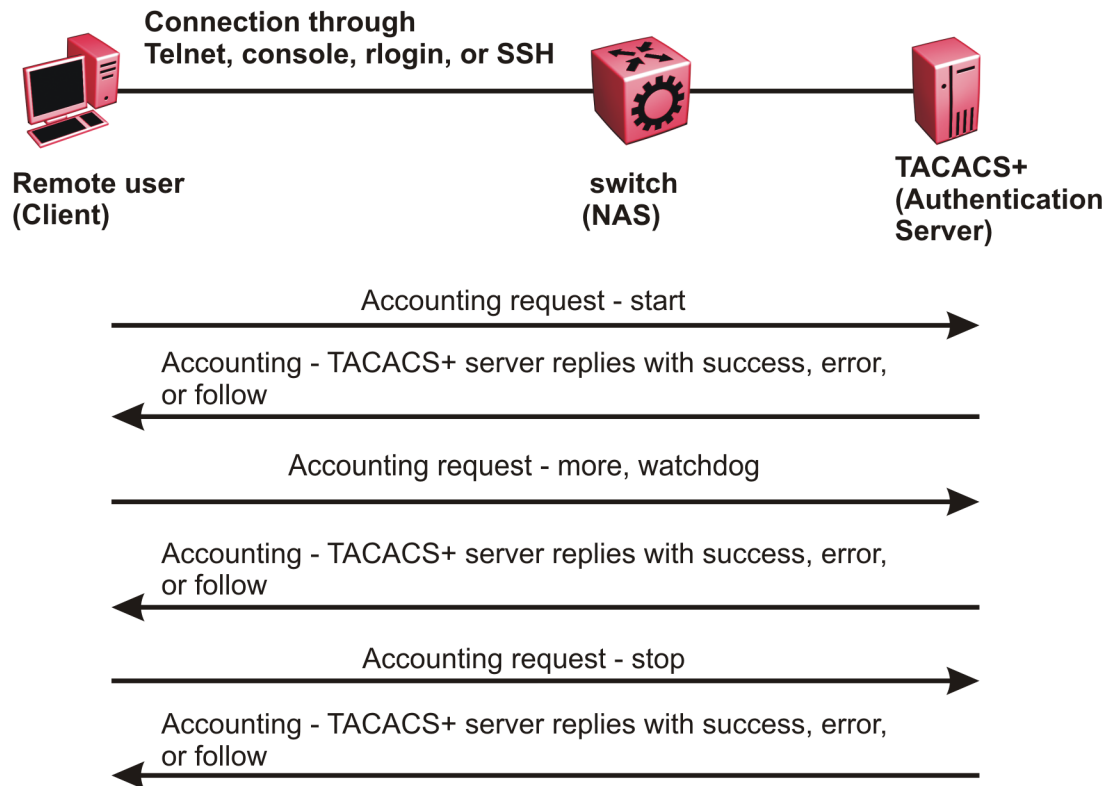

Figure 255: Accounting process

After you enable accounting, the switch reports user activity to the TACACS+ server in the form of accounting records. Each accounting record contains accounting attribute value (AV) pairs. AV pairs are strings of text in the form “attribute-value” sent between the switch and a TACACS+ daemon as part of the TACACS+ protocol. The TACACS+ server stores the accounting records.

You cannot customize the set of events the switch monitors and logs with TACACS+ accounting. TACACS+ accounting logs the following events:

- User logon and logoff
- Logoff generated because of activity timeout
- Unauthorized command
- Telnet session closed (not logged off)

Privilege Level Changes at Runtime

You can change your privilege level at runtime with the **tacacs switch level** command.

You need to configure separate profiles in the TACACS+ server configuration file for the switch level. The switch supports only levels 1 to 6 and level 15. The switch uses the profile when you issue the command **tacacs switch level <1-15>**. As part of the profile, you specify a user name, level, and password. To preconfigure a dummy user for that level on the TACACS+ daemon, the format of the user

name for the dummy user is **\$enab<n>\$**, where **<n>** is the privilege level to which you want to allow access.

The following is an example of a TACACS+ server profile, which you configure on the TACACS+ server:

```
user = $enab6$ {
member = level6
login = cleartext get-me-on-6
}
```

The following table maps user accounts to TACACS+ privilege level.

Switch access level	TACACS+ privilege level	Description
NONE	0	If the TACACS+ server returns an access level of 0, the user is denied access. You cannot log into the device if you have an access level of 0.
READ ONLY	1	Permits you to view only configuration and status information.
LAYER 1 READ WRITE	2	Permits you to view most of the switch configuration and status information and change physical port settings.
LAYER 2 READ WRITE	3	Permits you to view and change configuration and status information for Layer 2 (bridging and switching) functions.
LAYER 3 READ WRITE	4	Permits you to view and change configuration and status information for Layer 2 and Layer 3 (routing) functions.
READ WRITE	5	Permits you to view and change configuration and status information across the switch. This level does not allow you to change security and password settings.
READ WRITE ALL	6	Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings.

Switch access level	TACACS+ privilege level	Description
NONE	7 to 14	If the TACACS+ server returns an access level of 7 to 14, the user is denied access. You cannot log into the device if you have an access level of 7 to 14.
READ WRITE ALL	15	Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings. Note: Access level 15 is internally mapped to access level 6, which ensures consistency with other vendor implementations. The switch does not differentiate between an access level of 6 and an access level of 15.

Note

If you enable enhanced secure mode with the **boot config flags enhancedsecure-mode** command, you enable different access levels, along with stronger password complexity, length, and minimum change intervals. With enhanced secure mode enabled, the switch supports the following access levels for RADIUS authentication:

- Administrator
- Privilege
- Operator
- Auditor
- Security

The switch associates each username with a certain role and appropriate authorization rights to view and configure commands. For more information, see [Enhanced Secure Mode](#) on page 3317.

TACACS+ command authorization

After you enable TACACS+ authorization, the current privilege-level to command mapping on the switch is no longer relevant because the TACACS+ server has complete responsibility for command authorization. TACACS+ authorization provides access to the system based on username, not based on privilege level.

After you enable TACACS+ command authorization for a particular privilege level, and a user with that privilege level logs on, the user can access commands based on his user name.

TACACS+ switch level and TACACS+ switch back commands

The user can only issue the **tacacs switch level** command after TACACS+ authenticates the user. Locally authenticated users, which means users authenticated only by the switch and not by the TACACS+ server, cannot use the **tacacs switch level** command.

Consider a user, called X, with a privilege level of 4, who uses the **tacacs switch level <1-15>** command to change the privilege level from 4 to 6.

If user X successfully changes the switch level to 6, the user name changes from X to "\$enab6\$", and the privilege level changes from 4 to 6. If TACACS+ command authorization is enabled for privilege level 6, then the TACACS+ server authorizes commands issued based on the rules defined for (dummy) user "\$enab6\$".

If TACACS+ command authorization is not enabled for privilege level 6, then the switch locally authorizes the user X based on the privilege level of the user.

The user can return to his previous privilege level using the **tacacs switch back** command. In the preceding scenario, if the user issues the **tacacs switch back** command, the user name changes for user X from "\$enab6\$" to X, and the privilege level changes from 6 to 4.

TACACS+ switch level supports up to eight levels, and TACACS+ switch level allows a user to switch level up to eight times from his original privilege level. The switch stores all of the previous privilege levels in the same order in which the user switches levels. After switching eight times, if the user tries to switch a level the ninth time, the following error message displays:

```
Only allowed to switch level 8 times!
```

The user can switch back to his previous privilege levels using the **tacacs switch back** command. The **tacacs switch back** command switches back in the reverse order in which you issued the **tacacs switch level** command. Consider a user who switched levels from 4 to 5, and then to 6. If the user used the **tacacs switch back** command, the user first moves from 6 to 5, and then using the **tacacs switch back** command again moves from 5 to 4.

**Note**

If you want to switch to a privilege level 'X' using **tacacs switch level <1-15>** command, you must create a user "\$enabX\$" on the TACACS+ server. X is the privilege level that you want to change.

TACACS+ switch level functionality:

The following table explains TACACS+ switch level functionality.

User logs in with	TACACS+ server available	Result
TACACS+ authentication	Yes	The user can issue the tacacs switch level <1-15> command.
Local authentication	No	The user cannot issue the tacacs switch level <1-15> command.
Local authentication	Yes	Even if a TACACS+ server becomes reachable, the user remains locally authenticated and cannot issue the tacacs switch level <1-15> command.

TACACS+ command authorization functionality:

The following table explains TACACS+ command authorization functionality.

User logs in with	Command authorization	Result
Local authentication	—	The switch authorizes the user locally.
TACACS+ authentication	Not enabled for the logged-in level.	The switch authorizes the user locally. If the server connection is lost, the switch authorizes the user locally.
TACACS+ authentication	Enabled for the logged-in level.	The TACACS+ server authorizes the user. If the server connection is lost, the user can only issue exit and logout commands.

**Note**

A user who configures TACACS+ is locally authenticated and authorized by the switch, so even after the user configures TACACS+, the switch continues to locally authorize the user.

TACACS+ and RADIUS differences

TACACS+ and RADIUS are security protocols that you can use on network devices.

You can enable TACACS+ and RADIUS together. However, TACACS+ has a higher priority. If the TACACS+ server is not available the authentication is sent to RADIUS, if RADIUS is enabled. However, if TACACS+ authentication fails, then requests are not sent to RADIUS.

Following is a list of differences between TACACS+ and RADIUS.

TACACS+	RADIUS
Separates Authorization, Authentication and Accounting (AAA). As a result, you can selectively implement one or more TACACS+ services. With TACACS+ you can use different servers for each service.	Combines authentication and authorization.
Uses TCP. TCP is connection-oriented. TCP immediately indicates if a server crashes or is not running. TCP offers an acknowledgement that a request has been received.	Uses UDP. UDP is best-effort delivery. RADIUS uses re-transmit attempts and timeouts to make up for the support TCP has.
Encrypts the entire body of the packet, which includes the password and username.	Encrypts only the password from the client to the server.
Used for administrator access. Usually used for administrator access to network devices.	Used for subscriber access. Usually used to authenticate remote users to a network.
Can control which access level of commands a user or group can access.	Cannot control which access level of commands can be used.

TACACS+ Feature Limitations

TACACS+ does not support the following features:

- Point-to-Point Protocol (PPP) authentication and accounting
- IPv6 for TACACS+
- S/KEY (One Time Password) authentication
- PAP/CHAP/MSCHAP authentication methods
- The FOLLOW response of a TACACS+ server, in which the AAA services are redirected to another server. The response is interpreted as an authentication failure.
- User capability to change passwords at runtime over the network. The system administrator must change user passwords locally, on the server.
- TACACS+ command authorization when the user accesses the switch through EDM and SNMP.
- Restriction of command authorization for a specific kind of access. After you enable command authorization, command authorization applies for Telnet, SSH, rlogin, and serial-port access. You cannot restrict command authorization to just one kind of access.

Note

Rlogin is only supported on VSP 8600 Series.

If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not permit the user to execute any command that has privilege level command authorization enabled.

TACACS+ configuration using CLI

Enabling TACACS+

Enable TACACS+ globally on the switch.

The switch supports the TACACS+ client. TACACS+ is a security application implemented as a client and server-based protocol that provides centralized validation of users who attempt to gain access to a router or network access server (the switch).

By default, TACACS+ is disabled.

Before You Begin

- You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch are available.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable TACACS+ globally:
`tacacs protocol enable`
3. Disable TACACS+ globally:
`no tacacs protocol enable`

`default tacacs protocol enable`

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs protocol enable
```

Add a TACACS+ Server

Add a primary and secondary TACACS+ server and specify the authentication process.

If you have a backup server configured, the AAA request goes to the backup server if the primary server is not available.

As a best practice, use the Identity Engines Ignition server as your TACACS+ server.

About This Task

The TACACS+ server and the switch must have the same:

- Encryption key
- Connection mode (single connection or per-session connection. Per-session connection is the same as multi-connection mode)

- TCP port number

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add a primary TACACS+ server with an encryption key:

```
tacacs server host {A.B.C.D} key WORD<0-128>
```

3. (Optional) Configure the parameters for the primary TACACS+ server as required.

- a. (Optional) Specify a single connection to maintain a constant connection between the switch and the TACACS+ daemon:

```
tacacs server host {A.B.C.D} single-connection
```

Note

The TACACS+ daemon must also support this mode. If you do not configure this, the switch uses the default connection type, which is the per-session connection. Per-session is the same as multi-connection mode.

- b. (Optional) Specify the TCP port to use when the switch connects to the TACACS+ daemon:

```
tacacs server host {A.B.C.D} port <1-65535>
```

The default port is 49.

- c. (Optional) Specify the period of time (in seconds) the switch waits for a response from the TACACS+ daemon before it times out and shows an error:

```
tacacs server host {A.B.C.D} timeout <10-30>
```

- d. (Optional) Designate a fixed source IP address for all outgoing TACACS+ packets and enable this option:

```
tacacs server host {A.B.C.D} source {A.B.C.D}source-ip-interface  
enable
```

Note

This step applies to VSP 8600 Series only.

4. Specify the IP address of the secondary TACACS+ server and specify an encryption key:

```
tacacs server secondary-host {A.B.C.D} key WORD<0-128>
```

5. (Optional) Configure the optional parameters on the secondary TACACS+ server as required.
 - a. (Optional) Specify a single connection for the secondary TACACS+ server to maintain a constant connection between the switch and the TACACS+ daemon:

```
tacacs server secondary-host {A.B.C.D} single-connection
```

Note

The TACACS+ daemon must also support this mode. If you do not configure this, the switch uses the default connection type, which is the per-session connection. Per-session is the same as multi-connection mode.

- b. (Optional) Specify the TCP port to use when the switch connects to the TACACS+ daemon:

```
tacacs server secondary-host {A.B.C.D} port <1-65535>
```
 - c. (Optional) Specify the period of time (in seconds) the switch waits for a response from the TACACS+ daemon before it times out and shows an error:

```
tacacs server secondary-host {A.B.C.D} timeout<10-30>
```
 - d. (Optional) Designate a fixed source IP address for all outgoing TACACS+ packets and enable this option:

```
tacacs server secondary-host {A.B.C.D} source {A.B.C.D} source-ip-interface enable
```

Note

This step applies to VSP 8600 Series only.

6. Display the status of the TACACS+ configuration:

```
show tacacs
```

7. (Optional) Delete a primary TACACS+ server:

```
no tacacs server host {A.B.C.D} [single-connection] [source source-ip-interface enable]
```

8. (Optional) Delete a backup TACACS+ server:

```
no tacacs server secondary-host {A.B.C.D} [single-connection] [source source-ip-interface enable]
```

9. (Optional) Configure a primary TACACS+ server or secondary TACACS+ server to the default settings:

```
default tacacs server {A.B.C.D} [port] [single-connection] [source source-ip-interface enable] [timeout]
```

Example

Configure the primary server with the IP address 192.0.2.1 and the encryption key 1dt41y. Configure the secondary server with the IP address 198.51.100.2 with the same encryption key 1dt41y. Display the configuration to ensure proper configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs server host 192.0.2.1 key 1dt41y
Switch:1(config)#tacacs server secondary-host 198.51.100.2 key 1dt41y
Switch:1(config)#show tacacs
```

```
Global Status:
```

```

global enable : true

authentication enabled for : cli

accounting enabled for : none

authorization : disabled

User privilege levels set for command authorization : None

Server:
        create :

Prio      Status  Key      Port  IP address      Timeout Single Source
SourceEnabled
Primary   Conn    *****  49    192.0.2.1      10     false  0.0.0.0
false
Backup   NotConn *****  49    198.51.100.2   10     false  0.0.0.0
false

Switch:1(config)#no tacacs server host 192.0.2.1
Switch:1(config)#no tacacs server secondary-host 198.51.100.2

```

Variable Definitions

The following table defines parameters for the **tacacs server host** and the **tacacs server secondary-host** commands.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the IP address of the TACACS+ server you want to add. Only IPv4 addresses are valid.
<i>key WORD <0-128></i>	Configures the authentication and encryption key for all TACACS+ communications between the device and the TACACS+ server. If the key length is zero, that indicates no encryption is used. You must configure the same encryption key for the TACACS+ server and the switch.
<i>port <1-65535></i>	Configures the TCP port, on which the client establishes a connection to the server. A value of 0 indicates the system specified default value is used. The default is 49. You must configure the same TCP port for the TACACS+ server and the switch.
<i>single-connection</i>	Specifies if the TCP connection between the device and the TACACS+ server is a single connection. If you specify the single connection parameter, the connection between the switch and the TACACS+ daemon remains open, which is more efficient because it allows the daemon to handle a higher number of TACACS+ operations. The single-connection is torn down if TACACS+ is disabled due to inactivity. If you do not configure this, the switch uses the default connection type, which is the multi-connection. With the multi-connection, the connection opens and closes each time the switch and TACACS+ daemon communicate. Note: You must configure the same connection mode for the TACACS+ server and the switch. To enable single-connection, the TACACS+ daemon has to support this mode as well.

Variable	Value
<i>source {A.B.C.D}</i> Note: Exception: only supported on VSP 8600 Series only.	Designates a fixed source IP address for all outgoing TACACS+ packets, which is useful if the router has many interfaces and you want to make sure all TACACS+ packets from a certain router have the same IP address. If you do not configure an address, the system uses 0.0.0.0 as the default. Only IPv4 addresses are valid. Note: If you configure a valid source IP address that is not 0.0.0.0 without enabling source-ip-interface, the source IP address returns to 0.0.0.0.
<i>source-ip-interface enable</i> Note: Exception: only supported on VSP 8600 Series only.	Enables the source address. You must enable this parameter if you configure a valid source IP address. The default is disabled.
<i>timeout <10-30></i>	Configures the maximum time, in seconds, to wait for this TACACS+ server to reply before it times out. The default value is 10 seconds.

Configuring TACACS+ authentication

Configure what application TACACS+ authenticates: CLI, web, or all.

TACACS+ authentication provides control of authentication through login and password.

By default, CLI authentication is enabled.

Before You Begin

- You must enable TACACS+ globally for TACACS+ authentication to function.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- Configure TACACS+ authentication:

```
tacacs authentication <all/cli/web>
```
- (Optional) Disable TACACS+ authentication:

```
no tacacs authentication <all/web>
```
- (Optional) Configure TACACS+ authentication to the default settings (default is cli authentication enabled):

```
default tacacs authentication <all/cli/web>
```
- Display the configuration:

```
show tacacs
```

Example

Configure TACACS+ to authenticate CLI and display the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs authentication cli
Switch:1(config)#show tacacs
Global Status:

    global enable : true

    authentication enabled for : cli

    accounting enabled for : none

Server:

    create :

Prio   Status  Key      Port  IP address  Timeout  SingleSource  Source  Enabled
Primary Conn   *****  49    192.0.2.1   10      false        0.0.0.0  false
Backup NotConn *****  49    198.51.100.2 10      false        0.0.0.0  false
```

Variable Definitions

The following table defines parameters for the **tacacs authentication** command.

Variable	Value
<i>all</i>	Specifies TACACS+ authentication for all applications. By default, CLI authentication is enabled.
<i>cli</i>	Specifies TACACS+ authentication for command line connections. By default, CLI authentication is enabled.
<i>web</i>	Specifies TACACS+ authentication for web connections. By default, CLI authentication is enabled.

Configuring TACACS+ accounting

Determines for which applications TACACS+ collects accounting information. Use TACACS+ accounting to track the services that users access and the amount of network resources that users consume. If unassigned, TACACS+ does not perform the accounting function.

If enabled, TACACS+ accounting logs the following events:

- User log on and log off
- Log off generated because of activity timeout
- Unauthorized command
- Telnet session closed (not logged off)

If unassigned, TACACS+ does not perform the accounting function. No default value exists.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable TACACS+ accounting:
`tacacs accounting enable cli`
3. (Optional) Disable TACACS+ accounting:
`no tacacs accounting cli`

`tacacs accounting disable [cli]`

Example

Enable TACACS+ accounting:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs accounting enable cli
```

Configuring command authorization with TACACS+

Use this procedure to enable TACACS+ authorization for a particular privilege level. Use this option to limit the use of certain commands to certain users.

If command authorization fails, the following log message displays: `Command <command> not authorized for user <username>`.

By default, command authorization is disabled on the switch. The default for the command authorization level is none.

Before You Begin

- You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch are available. You must verify that the switch can reach the TACACS+ server and that you configure TACACS+ properly before you enable command authorization. If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not allow you to issue any command that has privilege level command authorization enabled. If the switch cannot reach the TACACS+ server, you can only issue logout and exit commands.
- To use TACACS+ authorization, you must enable TACACS+ authentication.

About This Task

Two kinds of authorization requests exist:

1. Login authorization: Login authorization happens immediately after authentication when the user logs on to the device, authorization provides the user access level. You cannot configure login authorization.
2. Command authorization: When you configure command authorization for a particular level, all commands that you issue are sent to the TACACS+ server for authorization. You need to configure command authorization globally and at individual access levels.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable TACACS+ authorization:

```
tacacs authorization enable
```
3. Configure TACACS+ privilege level for TACACS+ command authorization:

```
tacacs authorization level <1-6>

tacacs authorization level all

tacacs authorization level none
```
4. (Optional) Disable TACACS+ authorization:

```
tacacs authorization disable

default tacacs authorization
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs authorization enable
Switch:1(config)#tacacs authorization level 6
```

Variable Definitions

The following table defines parameters for the **tacacs authorization** command.

Variable	Value
<i>level <1-6></i>	Enables command authorization for a specific privilege level. The default for the command authorization level is none.
<i>level all</i>	Enables command authorization for all privilege levels. The default for the command authorization level is none.
<i>level none</i>	Disables command authorization for all privilege levels. The default for the command authorization level is none.

Changing privilege levels at runtime

Users can change their privilege levels at runtime. The privilege level determines what commands a user can access through TACACS+ server authorization.

A user can only use the **tacacs switch level** command, after TACACS+ authenticates the user. Locally authenticated users, which means users authenticated only by the switch and not by the TACACS+ server, cannot use the **tacacs switch level** command.

Before You Begin

- You need to configure separate profiles in the TACACS+ server configuration file for switch level. As part of the profile, you specify a user name, level, and password.

About This Task

After you enable TACACS+ authorization, the current privilege-level to command mapping on the switch is no longer relevant because the TACACS+ server has complete responsibility for command authorization. TACACS+ authorization provides access to the system based on username, not based on privilege level.

After you enable TACACS+ command authorization for a particular privilege level, and a user with that privilege level logs on, the user can access commands based on his user name.

Note

If you want to switch to a privilege level 'X' using **tacacs switch level <1-15>** command, you must create a user "\$enabX\$" on the TACACS+ server. X is the privilege level to which you want to change.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Change the privilege level for a user at runtime:
`tacacs switch level <1-15>`
3. Return to the original privilege level:
`tacacs switch back`

Example

Change the privilege level for a user at runtime. Return to the original privilege level:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs protocol enable
Switch:1(config)#tacacs switch level 5
Password:*****
```

Return to the original privilege level:

```
Switch:1(config)#tacacs switch back
```

Variable Definitions

The following table defines parameters for the **tacacs switch** command.

Variable	Value
<code>level <1-15></code>	<p>Specifies the privilege level you want to access. You can change your privilege level at runtime by using this parameter. You are prompted to provide the required password. If you do not specify a level in the command, the administration level is selected by default.</p> <p>Note: For switch level, you need to configure separate profiles in the TACACS+ server configuration file. As part of the profile, you specify a username, level, and password. To preconfigure a dummy user for that level on the TACACS+ daemon, the format of the username for the dummy user is <code>\$enab<n>\$</code>, where <code><n></code> is the privilege level to which you want to allow access.</p>
<code>back</code>	Specifies that you want to return to the original privilege level.

TACACS+ configuration using EDM

Configure TACACS+ Globally

Enable TACACS+ globally on the switch. TACACS+ is a security application implemented as a client and server-based protocol that provides centralized validation of users. By default, TACACS+ is disabled.

Before You Begin

- You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch (network access server) are available.

You must verify that the switch can reach the TACACS+ server and that you configure TACACS+ properly before you enable command authorization.

- If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not allow the user to issue any command that has privilege level command authorization enabled. In such a case, the user can only issue logout and exit commands.
- You must enable TACACS+ globally for TACACS+ authentication to function.
- You must enable TACACS+ authentication for TACACS+ authorization to function.

About This Task

Configure what application TACACS+ authenticates. TACACS+ authentication provides control of authentication through login and password dialog, challenge and response. By default, CLI authentication is enabled.

After authentication is complete, the switch starts the authorization process. By default, command authorization is disabled on the switch. The default for the command authorization level is none. If command authorization fails, the following log message displays: `Command <command> not authorized for user <username>`.

Two kinds of authorization requests exist:

1. Login authorization: Login authorization happens immediately after authentication when the user logs on to the device, authorization provides the user access level. You cannot configure login authorization.
2. Command authorization: When you configure command authorization for a particular level, all commands that you issue are sent to the TACACS+ server for authorization. You need to configure command authorization globally and at individual access levels.

Enable TACACS+ accounting function and determine which application TACACS+ accounts. After you enable accounting, the switch reports user activity to the TACACS+ server in the form of accounting records. The default for accounting is none.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **TACACS+**.
3. Click the **TACACS+ Globals** tab.
4. Select the **GlobalEnable** check box to enable TACACS+ globally.
5. Select the **cli** check box to enable the **Accounting** option.
6. Select the **cli** or **web** check box to enable the **Authentication** option.
7. Click the **CliCommandAuthorizationEnabled** box to enable TACACS+ authorization.
8. Select the level in the **CliCommandAuthorizationLevels** box.
9. Click **Apply**.

TACACS+ Globals field descriptions

Use the data in the following table to use the **TACACS+ Globals** tab.

Name	Description
GlobalEnable	Enables or disables the TACACS+ feature globally.
Accounting	<p>Determines for which applications TACACS+ collects accounting information. Use TACACS+ accounting to track the services that users access and the amount of network resources that users consume. If unassigned, TACACS+ does not perform the accounting function. The default is none.</p> <p>If enabled, TACACS+ accounting logs the following events:</p> <ul style="list-style-type: none"> • User log on and log off • Log off generated because of activity timeout • Unauthorized command • Telnet session closed (not logged off)

Name	Description
Authentication	Configures what application TACACS+ authenticates. The options include: <ul style="list-style-type: none"> cli web TACACS + authentication provides control of authentication through login and password dialog, challenge and response. By default, CLI authentication is enabled.
LastUserName	Displays the last user for which the system attempted authentication.
LastAddressType	Displays the type of address to access the TACACS+ server.
LastAddress	Displays the last address to access the TACACS+ server.
CliCommandAuthorizationEnabled	Enables TACACS+ authorization for a particular privilege level. Use this option to limit the use of certain commands to certain users. To use TACACS+ authorization, you must also use TACACS+ authentication. The switch allows the user to access the switch according to the access level. The default is disabled.
CliCommandAuthorizationLevels	Enables command authorization for a specific privilege level. The default for the command authorization level is none.

Add a TACACS+ Server

Add a TACACS+ server, configure the TACACS+ server, and specify the authentication process.

If you have a secondary server configured, the AAA request goes to the backup server if the primary server is not available.

As a best practice, use the Identity Engines Ignition Server as your TACACS+ server.

Before You Begin

You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch are available.

About This Task

The TACACS+ server and the switch must have the same:

- Encryption key
- Connection mode (single connection or per-session connection. Per-session is the same as multi-connection mode.)
- TCP port number

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **TACACS+**.
3. Select the **TACACS+ Servers** tab.
4. Select **Insert**.
5. In the **AddressType** box, select **ipv4**.
6. In the **Address** field, type the IP address of the TACACS+ server.
7. (Optional) In the **PortNumber** field, type the TCP port on which the client establishes a connection to the TACACS+ server.
8. (Optional) In the **ConnectionType** box, select either **singleConnection** or **perSessionConnection** to specify the TCP connection type between the switch and TACACS+ server.
9. (Optional) In the **Timeout** field, type the period of time (in seconds) the switch waits for a response from the TACACS+ server.
10. In the **Key** field, enter the key that the switch and the TACACS+ server share.
11. (Optional) Select **SourceIPInterfaceEnabled**, if you want to enable the switch to designate a fixed source IP address for all outgoing TACACS+ packets.

Note

This step applies to VSP 8600 Series only.

12. In the **SourceIPInterfaceType** box, select **ipv4**.

Note

This step applies to VSP 8600 Series only.

13. (Optional) In the **SourceIPInterface** field, type a fixed source IP address if you want to designate a fixed source IP address for all outgoing TACACS+ packets.

Note

This step applies to VSP 8600 Series only.

14. In the **Priority** box, select either **primary** or **backup** to determine the order the switch uses the TACACS+ servers.
15. Select **Insert**.

TACACS+ Servers field descriptions

Use the data in the following table to use the **TACACS+ Servers** tab.

Name	Description
AddressType	Specifies the type of IP address to use on the TACACS+ server. You must set the value to IPv4.
Address	Specifies the IP address of the TACACS+ server.

Name	Description
PortNumber	Configures the TCP port on which the client establishes a connection to the server. The default is 49. A value of 0 indicates that the system specified default value is used. You must configure the same TCP port for the TACACS+ server and the switch.
ConnectionType	Specifies if the TCP connection between the device and the TACACS+ server is a single connection. If you specify the single connection parameter, the connection between the switch and the TACACS+ daemon remains open, which is more efficient because it allows the daemon to handle a higher number of TACACS+ operations. The single-connection session is torn down if TACACS+ is disabled due to inactivity. If you do not configure this parameter, the switch uses the default connection type, which is the multi-connection. With the multi-connection, the connection opens and closes each time the switch and TACACS+ daemon communicate. Note: You must configure the same connection mode for the TACACS+ server and the switch. To enable single-connection, the TACACS+ daemon has to support this mode as well.
ConnectionStatus	Specifies if the TCP connection between the device and TACACS+ server is connected or not connected.
Timeout	Configures the maximum time, in seconds, to wait for this TACACS+ server to reply before it times out. The default value is 10 seconds.
Key	Configures the authentication and encryption key for all TACACS+ communications between the device and the TACACS+ server. If the key length is zero, that indicates no encryption is used. You must configure the same encryption key for the TACACS+ server and the switch.
SourceInterfaceEnabled Note: Exception: only supported on VSP 8600 Series	Enables the source address specification. If SourceInterfaceEnabled is true (the check box is selected), and you change SourceInterfaceEnabled to false (the check box is cleared), the SourceInterface is reset to 0.0.0.0. The default is disabled. You must enable this parameter if you configure a valid source IP address

Name	Description
SourceInterfaceType Note: Exception: only supported on VSP 8600 Series	Specifies the type of IP address to use on the interface that connects to the TACACS+ server. Note: You must set the value to IPv4.
SourceInterface Note: Exception: only supported on VSP 8600 Series	Designates a fixed source IP address for all outgoing TACACS+ packets, which is useful if the router has many interfaces and you want to make sure all TACACS+ packets from a certain router have the same IP address. If you do not configure an address, the system uses 0.0.0.0 as the default. Only IPv4 addresses are valid. Note: If you configure a valid source IP address that is not 0.0.0.0 without enabling source-ip-interface, the source IP address returns to 0.0.0.0.
Priority	Determines the order in which the switch uses the TACACS+ servers, where 1 is the highest priority. The priority values are primary and backup. If more than one server shares the same priority, the device uses the servers in the order they exist in the table.

Modify a TACACS+ Configuration

Modify an existing TACACS+ configuration to customize the server.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **TACACS+**.
3. Click **TACACS+ Servers** tab.
4. Double-click in the fields that you want to modify.

In some of the fields, the text becomes bold, which indicates that you can edit them. In other fields, the system displays a list.

5. In the fields that you can edit, type the desired values.
6. In the fields with lists, select the desired option.
7. Click **Apply**.

TACACS+ Configuration Examples

This section provides configuration examples to configure the switch and Identity Engines Ignition Server to use TACACS+.

Figure 256: Switch connects to the TACACS+ server

TACACS+ Configuration on the Switch

The following section shows the steps required to configure TACACS+ on the switch.

The example displays how to:

- Configure a key to be used by the TACACS+ server and the switch. In the example, the key is configured to the word `secret`.
- Configure an IP address for the TACACS+ server. In the example the IP address for the primary server is 192.0.2.8, which is accessible by the Management Router VRF.
- Configure the TACACS+ server to authenticate CLI sessions.
- Enable TACACS+.

Switch

```
TACACS CONFIGURATION

tacacs server host 192.0.2.8 key *****
tacacs protocol enable
tacacs accounting enable cli
tacacs authorization enable
tacacs authorization level 6
```

Verify your configuration

The **show tacacs** output must show as `global enable: true` to confirm TACACS is enabled.

The output for the **show tacacs** command must display the IP addresses for the TACACS+ server. The IP addresses must be accessible to the Management Router VRF on the switch.

If you want to use the TACACS+ server to authenticate sessions in CLI, the output must display as `authentication enabled for: cli`. If you want to authenticate EDM sessions, the output must display as `authentication enabled for: web`.

Ensure the other parameters match what you have configured.

```
Global Status:

global enable : true

authentication enabled for : cli
```

```
accounting enabled for : cli

authorization : enabled

User privilege levels set for command authorization : rwa

Server:
      create :

Prio      Status  Key      Port  IP address  Timeout Single Source
SourceEnabled
Primary  Conn  *      49    192.0.2.8   10     false  0.0.0.0
false
```

Identity Engines Ignition Server TACACS+ Configuration Example

The following section shows the steps required to configure TACACS+ on Identity Engines Ignition Server, Release 8.0. Use the preceding information to configure the switch.

A TACACS+ server responds to and audits network access requests. In an installation, the Identity Engines Ignition Server is the TACACS+ server.

The example displays how to do the following:

- Enable TACACS+
- Configure a user
- Create a command set
- Configure the authentication protocol policy
- Create the authorization policy
- Configure TACACS+ authenticators

For more information on the Ignition Server, see *Identity Engines Ignition Server Administration*.

Before You Begin

- Configure the Ignition Server appliance and set up its network settings. For more information, see *Identity Engines Ignition Server Getting Started*.
- Install the Ignition Dashboard on your Windows OS.
- Configure each authenticator (switch) to recognize the Ignition Server appliance as its TACACS+ server.
- Configure your switch to send packets to the Ignition Server appliance with the appropriate IP address and port.
- Ensure licenses are up-to-date.

Procedure

1. If the Ignition Server Dashboard is not connected to your Ignition Server, select **Administration: Login** to connect.
 - a. The default login credentials for **User Name** and **Password** are admin/admin. change the default values.
 - b. In the **Connect to** field enter the IP address of the Ignition Server for TACACS+. In this example, the IP address for the TACACS+ server is 192.0.2.8.

2. Enable TACACS+.
 - a. In the Ignition Server Dashboard, select **Site 0**.
 - b. In the Sites window, select the **Services** tab.
 - c. Under the Services tab, select the **TACACS+** tab.
 - d. Click the **Edit** button in the TACACS+ tab.
 - e. In the **Edit TACACS+ Configuration** dialog box, select the **Protocol is enabled** box.
 - f. In the **Bound Interface** field, select **Admin Port**.
 - g. In the **Port** field, enter 49.
 - h. Select **Accept Requests from Any Authenticator**.

Select this option if you want to create a global TACACS+ authenticator that sets policy for all authenticators that do not match a specific TACACS+-enabled authentication in your Ignition Server configuration.
 - i. In the **Access Policy** field, select **default-tacacs-admin**.

Use this configuration in the case of a global TACACS+ authenticator. Choose your global TACACS+ policy that you want applied if the device finds no better matching authenticator.
 - j. In **TACACS+ Shared Secret** field, enter the secret that the switch and TACACS+ Ignition Server share. In this example, the shared secret is `secret`.
 - k. Click **OK**.
3. Configure a user recognized by the TACACS + server.
 - a. In the Ignition Server Dashboard, expand the Configuration tree: **Site Configuration > Directories > Internal Store > Internal Users**.
 - b. Click **New**.
 - c. Fill in the appropriate fields.

As an example:

User Name: jsmith

First Name: John

Last Name: Smith

Password: test

Confirm password: test
4. If your TACACS+ policy uses per-command authorization, create a command set.
 - a. In the Ignition Server Dashboard, expand the Configuration tree: **Site Configuration > Access Policies > TACACS+**.
 - b. Click **Define Command Sets**.
 - c. Click **New**.
 - d. In the New Device Command Set window, type a **Name** and **Description** for the command set; for instance, level5.

In this window you build your command set by adding commands to the list. You can build the command list manually or you can import a list. For more information on importing a command list, see *Identity Engines Ignition Server Administration*.
 - e. To manually add the commands, click **Add** in the New/Edit Device Command Set window.

- f. Click the **Simple Command Using Keywords and Arguments** box.
 - g. In the **Command** field, type the command, and optionally its arguments.
 - h. To allow the command to be used with any argument, select the **Allow** box.
 - i. To allow only the specific command and arguments you have types, tick the **Deny** box.
 - j. Click **OK** to add the command to the list.
 - k. Continue to add the commands that you want.
5. If your TACACS+ policy uses privilege-level authorization, create the TACACS+ access policy to allow the TACACS+ Ignition Server to communicate with the switch.
- a. In the Ignition Server Dashboard, expand the Configuration tree: **Site Configuration > Access Policies > TACACS+**.
 - b. Select **default-tacacs-admin**.
 - c. Click on the **Authorization Policy** tab and select the name of the policy you want to edit.
 - d. Click **Edit** and the **Edit Authorization Policy** window opens.
 - e. In the **Rules** section, select the rule you want to edit. In this case select level5, to which you have already added commands.

The **Rules** list at the left lets you browse and sort the rules in your policy. Use the up and down arrow buttons at the right to set the rule sequence, and click a rule name in the list to edit that rule. The Selected Rule Details section lets you edit the rule you have selected.
 - f. In the Selected Rule Details section, under **Rule Name**, for this example, it reads `level5`.
 - g. Select **Rule Enabled**.
 - h. With level5 selected in the Rules list, go to the buttons to the right of the **Constraint** list and click **New**.
 - i. In the Action section, select **Allow**.
 - j. Select the **Command Sets** tab, in the Action section. Allow Commands in Set should read level-5, in this example, and under All Command Sets all the commands that are accessible under level5 should be listed.
 - k. Click **OK**.

For this example to function properly, the summary window must display:

IF User: user-id = level5 THEN Allow

Permit commands in Command Set: level-5
6. Configure the Ignition Server to connect to authenticators, which is the switch:
- a. In the Ignition Server Dashboard, expand **Site Configuration > Authenticators > default** and the Authenticator Summary window opens.
 - b. Click **New**, and the Authenticator Details window appears.
 - c. For this example, type `switch1` under name.
 - d. To the right select **Enable Authenticator**.
 - e. Type the IP address for the switch, which is the authenticator. Use the primary CPU address or the management virtual address.
 - f. In the **Vendor** field, select **Nortel**.
 - g. In the **Device template** field, select **ers-switches-nortel**.
 - h. Select the **TACACS+ Settings** tab.
 - i. Select **Enable TACACS+ Access**.

- j. In the **TACACS+ Shared Secret** field, type the key value you entered into the switch. In this example, the key is the word `secret`.

To connect using TACACS+, you must use the shared secret for each device. In your switch documentation, the shared secret can also be referred to as a specific key string or an encryption string.

- k. Under **Access Policy**, select **default-tacacs-user**.
- l. Click **OK**.

Traffic Filtering

[Traffic filtering fundamentals on page 3392](#)

[Access control list configuration using CLI on page 3417](#)

[Access control list configuration using EDM on page 3430](#)

[Access Control Entry Configuration using CLI on page 3439](#)

[Access Control Entry Configuration using EDM on page 3465](#)

Traffic filtering can generally provide a mechanism to accurately manage and secure network flows or prioritize crucial information over other network traffic.

The following topics provide necessary concepts and procedures to configure an access control list (ACL) and access control entry (ACE) to filter traffic.

Traffic filtering fundamentals

Use the information in this section to help you understand filtering. This section describes a range of features that you can use with the switch to allocate network resources to apply filters.

In a large and busy network, traffic management is very important and can be complex. Traffic filtering can generally provide a mechanism to accurately manage and secure network flows or prioritize crucial information over other network traffic. Some of the primary uses of filtering are:

- Manage traffic flows.
- Implement security permissions on network traffic.
- Prioritize mission critical traffic flows.
- Redirect traffic to firewalls or other devices to efficiently manage bandwidth.

Overview of Traffic Filtering

Traffic filtering on the switch is based on ACL filter implementation. Access Control List (ACL) based filters are a means to provide predictable and flexible traffic filtering. ACL Traffic filters can be configured using the Command Line Interface (CLI) or the Enterprise Device Manager (EDM). ACL filters set a list of criteria for the network traffic to be matched against, performing a predefined set of actions. Access Control Lists and Action Control Entries provide traffic filtering services on the switch.

Traffic filtering supports IPv6 ingress and egress port/vlan security and QoS ACL/filters. IPv6 egress QoS ACL/filters are not supported.

QoS and Filters

The switch has functions you can use to provide appropriate QoS levels to traffic for each customer, application, or packet. These functions include port-based shapers, DiffServ access or core port settings, and ingress port-rate limiting or policing. The switch also provides access control list (ACL)-based filters. You do not need to use filters to provide QoS; however, filters aid in prioritizing customer traffic. Filters also provide protection by blocking unwanted traffic.

Port rate limiting or policing apply at ingress; shapers apply at egress. ACL-based filters apply at ingress and egress.

There are four ingress filter groups:

- Port-based Security ACEs
- Port-based QoS ACEs
- VLAN-based Security ACEs
- VLAN-based QoS ACEs

Filters help you provide QoS by permitting or dropping traffic based on the parameters you configure. You can use filters to mark packets for specific treatment.

Typically, filters act as firewalls or are used for Layer 3 redirection. In more advanced cases, traffic filters can identify Layer 3 and Layer 4 traffic streams. The filters cause the streams to be re-marked and classified to attain a specific QoS level at both Layer 2 (802.1p) and Layer 3 (DSCP).

Traffic filtering is a key QoS feature. The switch, by default, determines incoming packet 802.1p or DiffServ markings, and forwards traffic based on their assigned QoS levels. However, situations exist where the markings are incorrect, or the originating user application does not have 802.1p or DiffServ marking capabilities. Also, you can give a higher priority to select users (executive class). In these situations, use filters to prioritize specific traffic streams.

You can use filters to assign QoS levels to devices and applications. To help you decide whether to use a filter, key questions include:

1. Does the user or application have the ability to mark QoS information on data packets?
2. Is the traffic source trusted? Are the QoS levels configured appropriately for each data source?

Users can maliciously configure QoS levels on their devices to take advantage of higher priority levels.

3. Do you want to prioritize traffic streams?

This decision-making process is outlined in the following figure.

Figure 257: Filter decision-making process

Configure filters through the use of Access Control Lists (ACL) and Access Control Entries (ACE), which are implemented in hardware. An ACL can include both security and QoS type ACEs.

The following steps summarize the filter configuration process:

1. Determine your desired match fields.
2. Create an ACL.
3. Create an ACE within the ACL.
4. Configure the desired precedence, traffic type, and action.

You determine the traffic type by creating an ingress or egress ACL.

5. Modify the parameters for the ACE.

Apply rules to incoming and outgoing traffic. The total number of ACLs that you can configure differs depending on the switch.

An ACL can filter either IPv6 or non-IPv6 packets. By default, an ACL filters non-IPv6 packets. You must specify the packet type as IPv6 at the ACL level to enable IPv6 filtering. You cannot change the packet type for the ACL after you configure it. If you need a different packet type, you must delete the ACL, and then re-create it with the other packet type.

You can associate an ACL with the following interfaces:

- Ingress port (inPort)
- Ingress VLAN (inVLAN)
- Ingress VSN (inVSN)
- Egress port (outPort)

**Note**

VLAN-based ACL filters are not supported on a DvR Leaf node.

**Note**

All ACLs are enabled when a DvR Leaf node is created. When creating the DvR Leaf node, or when you enable IS-IS globally, the message `dvr leaf [x]` displays in CLI. If the DvR Leaf node is reset or reconnects to the DvR domain, this message does not display but the same principle applies. As a best practice, delete ACLs not used on DvR Leaf nodes, rather than disable them, because the ACLs re-enable without warning after a DvR domain transition caused by reset, or protocol or link bounce.

**Note**

The VSP 8600 Series Segmented Management Instance does not support ACL based filters or use of ping with -Q option to change the internal priority of management traffic.

The ingress VLAN ACL associations apply to all active port members of a VLAN. An ACL is created in the enabled state by default.

The InVSN Filter is an Access Control List (ACL) that can be used with MAC-in-MAC (MIM) encapsulated packets that are received on the Network Node Interface (NNI) ingress ports and are routed or bridged to UNI ports or terminated on the fabric node. The InVSN Filter matches and filters IPv4 and IPv6 packet headers coming on UNI ports only, NNI ports only, or both UNI and NNI ports. The InVSN Filter does not filter packets that arrive on NNI ingress ports but are bridged to other NNI ports or are for transit traffic.

An ACL can contain multiple filter rules called Access Control Entries (ACE). ACEs provide match criteria and rules for ACL-based filters. An ACE can provide actions such as dropping a packet, monitoring a packet, or remarking QoS on a packet. Complete lists of actions are provided in the Access Control Entries section. After an ingress or egress packet meets the match criteria specified in ACEs within an ACL, the system executes the predefined action.

ACLs provide the ability to configure default and global actions. A default action is applied when no filter rule (ACE) matches on a packet flow. The global action is executed when any filter rule (ACE) matches on a packet flow. The default action mode for ACLs is permit. ACL global actions are:

- monitor-dst-mlt

- monitor-dst-ports

The following figure shows the relationships between ACEs and VLAN- and port-based ACLs.

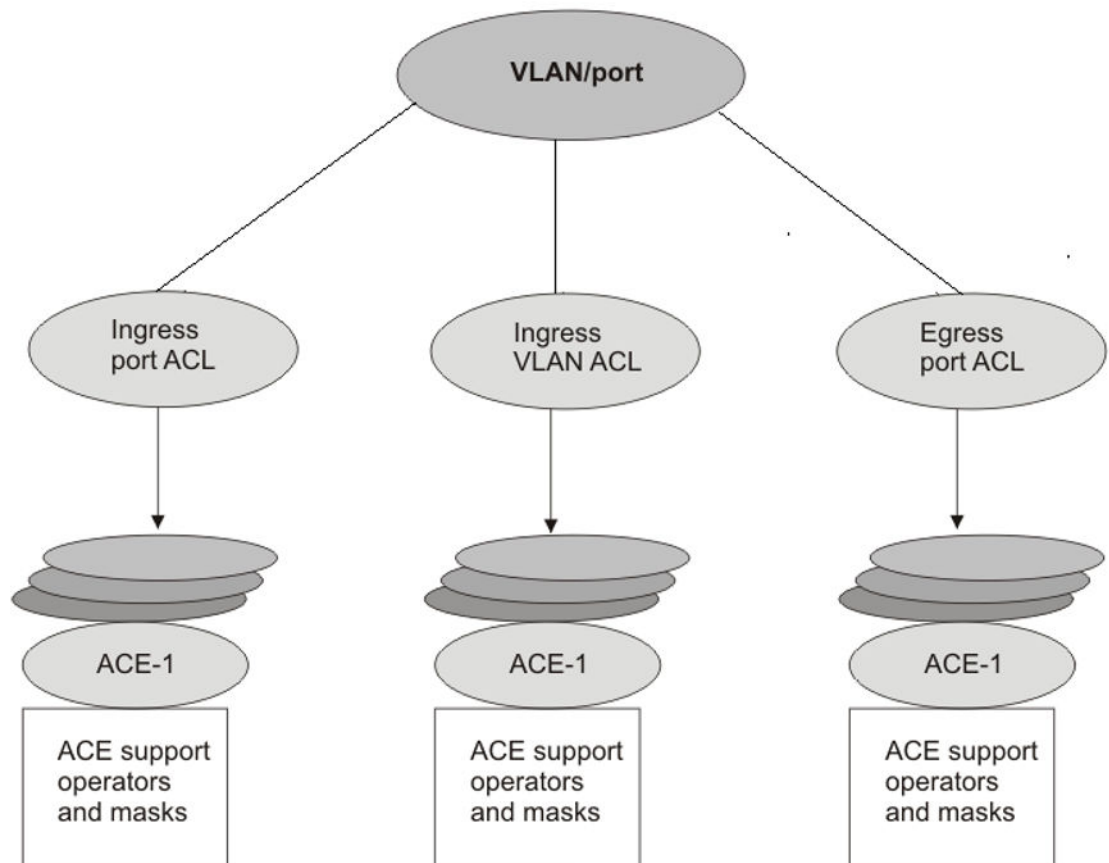

Figure 258: ACE and ACL relationships

The switch filter rules are defined using Access Control Entries (ACE). An ACE is an ordered set of filter rules contained in an Access Control List (ACL). ACE rules are divided into the following three components:

- Operators
- Attributes
- Actions

An ACE generally operates on fields in a packet. If a packet field matches an ACE rule, the system executes the action specified. As each packet enters through an interface with an associated ACL, the system scans the ACE list configured on that ACL and matches on the packet fields. If multiple ACE rules are associated with the ACL, the lower ACE ID will have a higher precedence.

Operators

ACEs use operators to match on packet fields. The switch supports the following operators:

- Equal-to

This rule operator looks for an exact match with the field defined. If the field matches exactly with the rule, the system will return a match (hit). If the rule does not match, the search continues and at the end of the search a miss is returned.

- Mask

ACL-based filters provide the mask operator to match on Layer 2, Layer 3, and Layer 4 packet fields. The mask operator is used to mask bits in packet fields during a search or to match on a partial value of a packet field. This section provides examples of the mask operator.

If a mask bit is set to 1, it means it is not part of the match criteria (treated as do not care), and a mask bit of 0 means that the value represented is part of the match criteria. You can use the mask operator for the following attributes:

- source MAC address
- destination MAC address
- VLAN ID
- Dot1p
- IPv4/IPv6 source address
- IPv4/IPv6 destination address
- destination IP address
- DSCP
- Layer 4 source port
- Layer 4 destination port
- TCP flags

**Note**

MAC Address cannot be configured as attributes for IPv6 filters.

The syntax for ACL and ACE configuration of a mask is similar to the use of equal operator, except that you provide the mask value. You can specify a mask value (number) to represent the bits to mask in the attribute. You can define a mask in different ways depending on the attribute you need to mask:

- If you use a decimal number for an IP address mask, it specifies the most significant bits of the provided IP address to match on. For example, a mask of 24 used with an IP address is the same as a mask of 0.0.0.255, and a mask of 8 used with an IP address is the same as a mask of 0.255.255.255.
- If you use a decimal number for a MAC address mask, it specifies the least significant bits of the provided MAC address to ignore. For example, a mask of 32 used with a MAC address is the same as a mask of 0x0000ffffff, and a mask of 16 used with a MAC address is the same as a mask of 0x00000000ffff.

**Note**

Unlike the standard convention, for ACL filter configuration, a mask bit value of '1' specifies a do-not-care bit, and value of '0' signifies must-match bit.

The following table explains the mask operator for MAC addresses.

Table 243: Mask operator for MAC address

Rule	Result
<pre>filter acl ace ethernet 10 10 dst- mac mask 01:00:5e:00:00:01 0x000000FFFFFF</pre>	The rule matches only on the most significant 24 bits as they are not masked, for example, 01:00:5e, and does not care about the least significant 24 bits because they are masked; the least significant 24 bits can have a value of 00:00:00 - FF:FF:FF.
<pre>filter acl ace ethernet 10 10 dst- mac mask 0x01:00:5e:00:00:01 0xFFFFFFFF0000</pre>	The rule matches only on the least significant 16 bits because they are not masked, for example, 00:01, and does not care about the most significant 32 bits because they are masked; the most significant 32 bits can have a value of 00:00:00:00 - FF:FF:FF:FF.
<pre>filter acl ace ethernet 10 10 dst- mac mask 0x01:00:5e:00:00:01 0xFF00FF0000FF</pre>	The rule matches only on the unmasked bits, for example, 0xXX:00:XX:00:00:XX. The rule matches only on the bits not masked, for example, all the zeroes and the x represents a do not care (0xXX:00:XX:00:00:XX)

The following table explains the mask operator for IP addresses.

Table 244: Mask operator for IP address

Rule	Result
<pre>filter acl ace ip 10 10 src-ip mask 2.10.10.12 0.255.255.255</pre>	The rule matches only the most significant 8 bits, and does not care about the value of the remaining 24 bits as they are considered masked. For example, 10.10.12. Packets with a source IP address of 2.15.16.122 or 2.3.4.5 match on the filter rule while packets with a source IP address of 3.10.10.12 and 4.10.10.12 do not match on the filter rule.
<pre>filter acl ace ip 10 10 src-ip mask 3.4.5.6 255.255.255.0</pre>	The rule matches only the least significant 8 bits, for example, 6, and does not care about the most significant 24 bits, 3.4.5. Packets with a source IP address of 17.16.5.6 or 192.168.1.6 match on the filter rule while packets with a source IP address of 3.4.5.4 or 3.4.5.7 do not match on the filter rule.

The following table explains the mask operator for Layer 4 source port.

Table 245: Mask operator for Layer 4 source port

Rule	Result
<pre>filter acl ace protocol 10 10 src- port mask 80 0xF</pre>	The filter rule matches on Layer 4 source port 80 (1010000). The mask value 0xF (1111) masks the least significant 4 bits, which means source port 81 (1010001) through 95 (1011111) also match this filter rule. This means the range 80–95 is a match on this rule.

The following table demonstrates the resulting action based on mask configuration and example packets.

Table 246: Mask operator configuration examples

Filter configuration	Address examples that match the filter	Address examples that do not match the filter
<pre>Ethernet mask: filter acl 1000 type inport filter acl port 1000 6/5,9/11 filter acl ace 1000 12 filter acl ace ethernet 1000 12 src- mac mask 00:00:11:11:16:00 0x00ff000000f0 filter acl ace action 1000 12 permit count filter acl ace 1000 12 enable</pre>	<pre>Source MAC: 00:01:11:11:16:10 00:10:11:11:16:f0 00:1f:11:11:16:10 00:ff:11:11:16:f0 00:00:11:11:16:60 00:e6:11:11:16:e0</pre>	<pre>Source MAC: 00:00:11:11:16:01 00:ff:11:11:16:f1</pre>

Attributes

Attributes are fields in a packet (Layer 2, Layer 3, Layer 4) or other information related to the packet on which an ACE rule is applied like slot/port. The list of all the attributes and the operators that could be applied on them are listed below.

If you want to configure IPv6 attributes, you must configure an ACL to filter either IPv6 or non-IPv6 traffic. You can only configure IPv6 attributes for IPv6 packets. You cannot configure IPv6 attributes for non-IPv6 packets.

Table 247: Attribute list

Attribute Name	Operator
Slot/Port	Equal
Destination MAC (IPv4 filters only)	Equal, Mask
Source MAC (IPv4 filters only)	Equal, Mask
VLAN ID	Equal, Mask
.Ip bits	Equal, Mask
Ether Type	Equal
ARP Opcode	Equal
Source IP	Equal, Mask
Destination IP	Equal, Mask
Protocol Type	Equal
Type of Service	Equal, Mask
IP Fragmentation	Equal
IP Options	Equal
Layer 4 Destination Port	Equal, Mask
Layer 4 Source Port	Equal, Mask
TCP Flags	Equal, Mask
ICMP Message Type	Equal
Source IPv6 (IPv6 only)	Equal, Mask
Destination IPv6 (IPv6 only)	Equal, Mask
Next header (IPv6 only)	Equal
Traffic class (IPv6 only)	Equal
Routed only	Equal

Actions

Actions occur when the filter rule is hit or missed. The types of actions that the filter configuration can execute are split into two categories:

- security actions supported by the ACE IDs.
- QoS actions supported by the ACE IDs.

Note

- Ingress ACLs support security and QoS ACE actions. Egress ACLs do not support QoS ACEs.

Filter rules that support Security actions and QoS actions are stored separately. If an ACL filter is applied to a traffic flow, the switch performs a parallel search, if supported, on both Security and QoS ACE lists, which results in distinct and non-conflicting actions.

Note

The ACE ID range for both security and QoS actions is different for different hardware platforms. Parallel search is not supported on all hardware platforms. For more information, see [ACL Filters Behavior Differences](#) on page 3414.

The following tables show the supported switch actions:

Table 248: Security ACE Actions

Security ACE Actions	User supplied parameters	Comments
mode	Permit or Deny	Applies to both Ingress and Egress ACLs.
redirect-next-hop	IP address, Mode	<p>Redirects the packet to the user supplied IP address. If the switch cannot resolve ARP for the user-specified next-hop, packets that match the filter are dropped.</p> <p>Note: The filter does not redirect packets with a time-to-live (TTL) of 1 nor does it send them to the CPU where the CPU would generate ICMP TTL expired messages. IP Traceroute reports a timeout for the hop.</p> <p>Note: The filter with policer only redirects the traffic that passes the policer. For instance, if the stream is 100 Mbps and the policer peak rate is 50 Mbps, only 50 Mbps is redirected.</p> <p>Applies to ingress IPv4 ACLs only (routed and Layer 2).</p>
count	None	Collect ACE statistics. Applies to Ingress and Egress ACLs.
monitor-dst-mlt	mlt-id	Applies to Ingress ACLs only.

Table 248: Security ACE Actions (continued)

Security ACE Actions	User supplied parameters	Comments
monitor-dst-ports	Port	Applies to Ingress ACLs only.
monitor I-SID offset	None	The actual monitor I-SID value to which packets are mirrored. Note: This action is not supported on all hardware platforms.

Table 249: QoS ACE Actions

QoS ACE Actions	User supplied parameters	Comments
<ul style="list-style-type: none"> • remark-dscp • remark-dot1p • internal-qos 	<ul style="list-style-type: none"> • DSCP • dot1p (ingress only) • Internal-qos 	<p>Applies to Ingress ACLs.</p> <p>Note: remark-dot1p and internal-qos do not apply to IPv6 filtering.</p> <p>Each QoS action has its own user-supplied parameters.</p> <p>Note: Some hardware platforms do not support remark-dot1p and supports remark-DSCP for Layer 3 routed packets only.</p>
count	None	Applies to Ingress and Egress ACLs.

When you configure an IPv6 ACL with an ACE action of remark DSCP for a mirrored packet, the mirrored copy does not include the remark DSCP value. Because of port-mirroring functionality on VSP 4900 Series, VSP 7400 Series, and VSP 8400 Series, the mirrored copy does not reflect the changes that occur in the switch to the outgoing packet. As a result, the mirrored copy is not identical to the outgoing packet. For more information, see [Port Mirroring](#) on page 3581.

Internal QoS Level and Remarking

Setting the internal QoS level is an ingress action. Remarking is an egress action.

The internal-qos action assigns a new value to the packet internal-qos. It determines the packet egress queue, outgoing packet dot1p value and egress-DSCP value.

The remark-dot1p action assigns a new dot1p value to the outgoing packet. The remark-DSCP action assigns a new DSCP value to the outgoing packet.

If a packet is filtered by a rule set to internal-qos action only, then the packet internal qos, egress queue, egress dot1p and egress DSCP will be derived from the filter internal-qos value.

If a packet is filtered by a rule set to remark-dot1p only or remark-DSCP only or both remark actions, then the packet will be remarked with the new dot1p or DSCP, or both. However, these remarked values

will not have any impact on the internal-qos packet. It will be based on the native packet coming into the switch.

If a packet is filtered by a rule set with all three qos actions, then the internal-qos will determine the egress queue, but the remark-dot1p determines the egress dot1p and the remark-DSCP determines the egress DSCP.

If you want to change the internal QoS for remarked incoming packets, you have to add the **permit internal-qos** command as shown in the following ACL filter example.

```
filter acl 10 type inPort name "ACL-CTI"  
filter acl port 10 1/2-1/50  
filter acl ace 10 1302 name "CIFS-SCCM Source"  
filter acl ace action 10 1302 permit remark-dscp phbaf11 remark-dot1p 1 count  
filter acl ace action 10 1302 permit internal-qos 0  
filter acl ace ethernet 10 1302 ether-type eq ip  
filter acl ace ip 10 1302 src-ip mask 0.0.0.0 255.255.255.255  
filter acl ace ip 10 1302 ip-protocol-type eq tcp  
filter acl ace protocol 10 1302 src-port mask 0 0xffff
```

When a packet goes through the switch, the internal QoS level governs which queue the packet uses on egress. To verify which queue the packets are egressing on, use the **show qos cosq-stats interface [value]** command. For more information, see [View Port Egress CoS Queue Statistics](#) on page 2696 or [Viewing port egress CoS queue statistics](#) on page 2713.

Conflict and Precedence

The switch supports both port-based and VLAN-based ACLs. A port can be associated with both Port-based ACL and a VLAN-based ACL, as shown in [Access control lists](#) on page 3394. Within an ACL, a rule match can generate security actions and QoS actions. The system goes through a set of precedence levels to resolve any conflicting actions between port-based ACL and VLAN-based ACL lookup. The

following table provides a list of search results and actions for all possible conflicts between port and VLAN-based ACLs and security and QoS ACE for each ACL.

Table 250: Conflict and Precedence resolution

Port-based ACL look up		Actions performed on Port-based ACL		If VLAN-based ACL is enabled		Actions performed on VLAN-based ACL search	
Security	QoS	Security action	QoS action	Security	QoS	Security action	QoS action
Security ACE search is a Miss and ACL mode is Permit.	QoS ACE search is a Miss	Default security statistics collected	Default QoS statistics collected	Security ACE search is a Miss and mode is set to Permit	QoS ACE search is a Miss	Collect default Miss statistics	Collect default Miss statistics
				Security ACE search is a Miss and mode is set to Permit	QoS ACE search returns a Hit	Collect default Miss statistics	Execute configured ACE and default ACL actions
				Security ACE search is a Miss and mode is set to Deny	Search result is invalid, since security mode is set to Deny	Drop packet and collect default Miss statistics	No action is executed
				Security ACE search is a Hit and mode is set to Permit	QoS ACE search returns a Miss	Execute configured ACE and default ACL actions	Collect default Miss statistics
				Security ACE search is a Hit and mode is set to Permit	QoS ACE search is a Hit	Execute configured ACE and default ACL actions	Execute configured ACE and default ACL actions
				Security ACE search is a Hit and mode is set to Deny	QoS ACE search returns a Hit	Discard the packet and execute configured ACE and global actions	No action is executed
Security ACE is Miss and ACL mode is Deny	Search result is invalid since security mode is set to Deny	Discard the packet and collect default statistics	No action is executed	VLAN-based ACL is not configured	VLAN-based ACL is not configured	No action is executed	No action is executed

Table 250: Conflict and Precedence resolution (continued)

Port-based ACL look up		Actions performed on Port-based ACL		If VLAN-based ACL is enabled		Actions performed on VLAN-based ACL search	
Security	QoS	Security action	QoS action	Security	QoS	Security action	QoS action
Security ACE search is a Miss and ACL mode is set to Permit	QoS ACE search is a Hit	Default search statistics collected	Execute configured ACE and default ACL actions	Security ACE search is a Miss and mode is set to Permit	Port-based ACL's QoS action take precedence. QoS search result invalid.	Collect default Miss statistics	No action is executed
				Security ACE search is a Miss and mode is set to Deny	Port-based ACL's QoS action take precedence. QoS search result invalid.	Drop packet and collect default Miss statistics	No action is executed
				Security ACE search is a Hit and mode is set to Permit	Port-based ACL's QoS action take precedence. QoS search result invalid.	Execute configured ACE and default ACL actions	No action is executed
				Security ACE search is a Hit and mode is set to Deny	Port-based ACL's QoS action take precedence. QoS search result invalid.	Discard the packet and execute configured ACE and global Actions	No action is executed
Security ACE search is a Hit and ACE mode is Permit	QoS ACE search is a Miss	Execute configured ACE and default ACL actions	Collect default Miss statistics	Port-based ACL's Security action take precedence. Security search result invalid	QoS ACE search returns a Miss	No action is executed	Collect default Miss statistics
				Port-based ACL's Security action take precedence. Security search result invalid.	QoS ACE search returns a Hit	No action is executed	Execute configured ACE and default ACL actions

Table 250: Conflict and Precedence resolution (continued)

Port-based ACL look up		Actions performed on Port-based ACL		If VLAN-based ACL is enabled		Actions performed on VLAN-based ACL search	
Security	QoS	Security action	QoS action	Security	QoS	Security action	QoS action
Security ACE search is a Hit and ACE mode is Permit	QoS ACE search is a Hit	Execute configured ACE and default ACL actions	Execute configured ACE and default ACL actions.	Port-based ACL's Security action take precedence. Security search result invalid	Port-based ACL's QoS action take precedence. QoS search result invalid.	No action is executed	No action is executed
Security ACE search is a Hit and ACE mode is Deny	Search result is invalid since Security mode is set to Deny	Discard the packet and collect default statistics	No action is executed	Port-based ACL's Security action take precedence. Security search result invalid	Port-based ACL's QoS action take precedence. QoS search result invalid.	No action is executed	No action is executed

Common ACE uses and configuration

The following table describes configurations you can use to perform common actions.

Table 251: Common ACE uses and configurations

Function	ACE configuration
Permit a specific host to access the network	<ul style="list-style-type: none"> Use action permit. Configure the source IP address to be the host IP address. <pre>filter acl ace 1 5 name "Permit_access_to_198.51.100.0" filter acl ace action 1 5 permit filter acl ace ethernet 1 5 ether-type eq ip filter acl ace ip 1 5 src-ip eq 198.51.100.0 filter acl ace 1 5 enable</pre>
Deny a specific host from accessing the network	<ul style="list-style-type: none"> Use action deny. Configure the source IP address to be the host IP address. <pre>filter acl ace 1 5 name "Deny_access_to_198.51.100.0" filter acl ace action 1 5 deny filter acl ace ethernet 1 5 ether-type eq ip filter acl ace ip 1 5 src-ip eq 198.51.100.0 filter acl ace 1 5 enable</pre>

Table 251: Common ACE uses and configurations (continued)

Function	ACE configuration
Permit a specific range of hosts to access the network	<ul style="list-style-type: none"> Use action permit. Configure the source IP address to be the range of host IP addresses. <pre>filter acl ace 1 5 name "Permit_access_to_1.2.3.4-1.2.3.7" filter acl ace action 1 5 permit filter acl ace ethernet 1 5 ether-type eq ip filter acl ace ip 1 5 src-ip mask 1.2.3.4 0.0.0.3 filter acl ace 1 5 enable</pre>
Deny Telnet traffic	<ul style="list-style-type: none"> Use action deny. Configure the protocol as TCP and the TCP destination port to be 23. <pre>filter acl ace 1 5 name "Deny_telnet" filter acl ace action 1 5 deny filter acl ace ethernet 1 5 ethertype eq ip filter acl ace ip 1 5 ip-protocol-type eq tcp filter acl ace protocol 1 5 dst-port eq 23 filter acl ace 1 5 enable</pre>
Deny FTP traffic	<ul style="list-style-type: none"> Use action deny. Configure the protocol as TCP and the TCP destination port to be 21. <pre>filter acl ace 1 5 name "Deny_ftp" filter acl ace action 1 5 deny filter acl ace ethernet 1 5 ethertype eq ip filter acl ace ip 1 5 ip-protocoltype eq tcp filter acl ace protocol 1 5 dst-port eq 21 filter acl ace 1 5 enable</pre>

Switched UNI ACL Filters

InPort and OutPort filters are supported on Switched UNI (S-UNI) and Fabric Attach ports.

Note

InPort and outPort filters are supported on S-UNI and Fabric Attach ports for the traffic mapped to an I-SID which does not have platform VLAN associated. The Customer VLAN-ID (CVID) can be applied as VLAN-ID qualifier in inPort and outPort filters.

Note

InPort, outPort, and inVLAN filters are supported on S-UNI and Fabric Attach ports for the traffic mapped to an I-SID which has platform VLAN associated. The platform VLAN should be used as VLAN-ID in inPort and inVLAN filters, and the CVID as VLAN-ID in the outPort filter.

Traffic filter configuration

Traffic filtering manages traffic by defining filtering conditions and associating these conditions with specific actions. The following steps summarize the filtering configuration process:

1. Determine your desired match fields.
2. Configure an ACL and associate it with Ingress or Egress traffic flow.
3. Configure an ACE within the ACL.
4. Configure the desired precedence, attributes, and action.
5. Enable the ACE.

Ingress Bandwidth Rate Limiter

Ingress bandwidth rate limiter functionality handles congestion, meters traffic, and takes action based on the ACL filter rules. A policer can be attached directly to an ACL ACE entry to perform flow-based rate limiting. You can configure the service rate and peak rate. All traffic that qualifies for a filter is metered. Every packet that exceeds the service rate is marked as yellow, and every packet that exceeds the peak rate is marked as red and is dropped.

The ingress flow-based policer limits the traffic rate accepted by the specified ingress port. The port drops or re-marks violating traffic. The line rate of the port is the maximum rate that can be configured.

The ingress flow-based policer is available on the following interfaces:

- Ingress port (inPort)
- Ingress VLAN (inVLAN)
- Ingress VSN (inVSN)

Operation Considerations

The following section describes operational considerations for ingress bandwidth rate limiter functionality:

- If you configure ingress policer/port rate limiter and QoS port rate limiter on VSP 4900 Series, and a flow matches both of them, then green marked packets can be dropped.
- IPv4 policer statistics for red, yellow, and green packets and bytes are available on VSP 7400 Series.
- Only IPv4 policer statistics for red packets and bytes are available on VSP 4900 Series. Yellow and green packet counters are not supported on VSP 4900 Series.

- Egress port (outPort) interface is not supported.
- Policers are not supported on IPv6 ACLs.
- Supports QoS ACEs only.
- You can configure the default action policer within an ACL for permit action mode only.
- Drop action mode is not supported.
- **monitor-dst-ports**, **monitor-dst-mlt**, or **monitor-isid-offset** actions are supported. All traffic received is mirrored.
- The filter with policer and redirect-next-hop actions redirect only the traffic that passes the policer (if the stream is 100 Mbps, and the policer peak-rate is 50 Mbps, only 50 Mbps is redirected).
- Ingress policer/port rate limiter and QoS port rate limiter features are partially incompatible. Configuring both of these features together that can affect the same traffic can result in more traffic drop than expected. The best practices are as follows:
 - If ACL type is inPort, do not configure Qos port limiter on any of the ports that are part of ACL
 - If ACL type is inVlan, do not configure Qos port limiter on ports that are part of any VLAN in the ACL
 - If ACL type is inVsn, do not configure Qos port limiter on ports that are part of any VSN in the ACL

ACL and ACE configuration guidelines

To find the maximum number of ACLs and ACEs that the switch supports, see the [VOSS Release Notes](#).

ACL Filters Behavior Differences

The implementation of ACL filters is similar in all switches but there are some differences as summarized in the following tables.

Note

The InVSN Filter shares the port-based groups in the following table.

Table 253: Hardware filter engine resources

VSP 4450 Series	VSP 4900 Series VSP 7200 Series VSP 8200 Series VSP 8400 Series	VSP 7400 Series	VSP 8600 Series	XA1400 Series
If you enable Application Telemetry, IPv6 security filter commands and configurations are blocked and not available.	If you enable Application Telemetry, IPv6 security filter commands and configurations are blocked and not available.	If you enable Application Telemetry, IPv6 security filter commands and configurations are supported.	If you enable Application Telemetry, IPv6 security filter commands and configurations are supported.	Application Telemetry and IPv6 filters are not supported
All switches use a filter group as memory to store filter rules. The number of filter groups used can differ:				

Table 253: Hardware filter engine resources (continued)

VSP 4450 Series	VSP 4900 Series VSP 7200 Series VSP 8200 Series VSP 8400 Series	VSP 7400 Series	VSP 8600 Series	XA1400 Series
<p>The switch supports four separate ingress filter groups:</p> <ol style="list-style-type: none"> port-based Security ACEs port-based QoS ACEs VLAN-based Security ACEs VLAN-based QoS ACEs 	<p>The switch supports two ingress filter groups, where each group is shared by two filter types:</p> <ol style="list-style-type: none"> port-based and VLAN-based Security ACEs port-based and VLAN-based QoS ACEs 	<p>The switch supports two ingress filter groups, where each group is shared by two filter types:</p> <ol style="list-style-type: none"> port-based and VLAN-based Security ACEs port-based and VLAN-based QoS ACEs 	<p>The switch supports the following ingress filter group:</p> <ul style="list-style-type: none"> port-based and VLAN-based ACEs 	<p>The switch supports one ingress filter group with two filter types:</p> <ol style="list-style-type: none"> port-based and VLAN-based Security ACEs port-based and VLAN-based QoS ACEs
For each ingress packet, a parallel search is performed on each of the four filter groups.	For each ingress packet, a parallel search is performed on each of the two filter groups.	For each ingress packet, a parallel search is performed on each of the two filter groups.	For each ingress packet, a search is performed on the filter group.	For each ingress packet, a search is performed on the filter group.

Table 254: Incoming packet behavior

Filter	VSP 4450 Series	VSP 4900 Series VSP 7200 Series VSP 8200 Series VSP 8400 Series	VSP 7400 Series	VSP 8600 Series	XA1400 Series
Can match both port-based and VLAN-based ACL/ACE	Regardless of the type of matching ACEs (Security or QoS), the action of either the highest priority matching ACE or the default action will be performed.	Port-based ACLs have precedence over VLAN-based ACLs. If the matching ACEs are of the same type (both Security or both QoS), then the VLAN-based ACL/ACE is ignored.	Port-based ACLs have precedence over VLAN-based ACLs. If the matching ACEs are of the same type (both Security or both QoS), then the VLAN-based ACL/ACE is ignored.	Port-based ACLs have precedence over VLAN-based ACLs. If a packet matches both a Port-based and a VLAN-based ACL, then the VLAN-based ACL is ignored.	Port-based ACLs have precedence over VLAN-based ACLs. If a packet matches both a Port-based and a VLAN-based ACL, then the VLAN-based ACL is ignored. Security ACEs have precedence over QoS ACEs.

is supported for OutPort ACLs.	is supported for OutPort ACLs.	is not supported for OutPort ACLs.	is supported for OutPort ACLs.	is supported for OutPort ACLs The Egress filters do not apply to the mirrored packets.

Table 257: ACL statistics behavior

VSP 4450 Series	VSP 4900 Series VSP 7200 Series VSP 8200 Series VSP 8400 Series	VSP 7400 Series	VSP 8600 Series	XA1400 Series
Supports Viewing ACL Statistics by the ACE type Security and QoS.	Supports Viewing ACL Statistics by the ACE type Security and QoS.	Supports Viewing ACL Statistics by the ACE type Security and QoS.	Supports Viewing ACL Statistics by the ACE type QoS.	Supports Viewing ACL Statistics by the ACE type Security and QoS.

For QoS scaling and filter scaling information, see [VOSS Release Notes](#).

Access control list configuration using CLI

Use an access control list (ACL) to specify an ordered list of access control entries (ACEs), or filter rules. The ACEs provide specific actions that you want the filter to perform.

Creating an IPv4 ACL

Create an ACL to specify an ordered list of ACEs, or filter rules.

About This Task

Do not configure IPv4 egress ACL filters on NNI ports because the system-generated egress vIST filter rules and the user-created IPv4 egress rules use the same filter hardware.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Create an ACL:

```
filter acl <acl-id> type <inVlan|inPort|outPort|inVsn> [matchType
<both|terminatingNNIOnly|uniOnly> ] [name WORD<0-32>] [enable]
```
- Enable an ACL:

```
filter acl [enable]
```

4. Ensure the configuration is correct:

```
show filter acl [<acl-id>]
```

Variable definitions

Use the data in the following table to use **filter acl** command.

Variable	Value
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
enable	Enables the ACL state, and all associated ACEs. Enabled is the default state.
matchType <both terminatingNNIOnly uniOnly>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> • <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node • <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node • <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .
name WORD<0-32>	Specifies an optional descriptive name for the ACL.
type <inVlan inPort outPort inVsn>	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Create an IPv6 ACL

Create an IPv6 ACL to specify an ordered list of ACEs, or filter rules.

You must specify the packet type as IPv6 at the ACL level to enable IPv6 filtering. By default, an ACL filters non IPv6 packets.

Note

You cannot change packet type for the ACL after you have configured it. If you want a different packet type, you must delete the ACL and re-create it using the other packet type.

Before You Begin

- Application Telemetry must be disabled on VSP 4450 Series, VSP 7200 Series, VSP 8200 Series, and VSP 8400 Series.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create an IPv6 ACL:

```
filter acl <acl-id> type <inVlan|inPort|outPort|inVsn> [matchType
<both|terminatingNNIOnly|uniOnly> ] [name WORD<0-32>] [pktType ipv6]
[name <0-32>]
```

Note

IPv6 egress QoS ACL/Filters are not supported.

3. Enable the ACL:

```
filter acl <acl-id> enable
```

4. Ensure the configuration is correct:

```
show filter acl [<acl-id>]
```

Variable definitions

Use the data in the following table to use the **filter acl** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>enable</code>	Enables the ACL state, and all associated ACEs. Enabled is the default state.
<code>matchType <both terminatingNNIOnly uniOnly></code>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> • <code>both</code> for traffic ingressing on both UNI ports and NNI ports terminating on this node • <code>terminatingNNIOnly</code> for traffic ingressing on NNI ports only and terminating on this node • <code>uniOnly</code> for traffic ingressing on UNI ports only The default value is <code>both</code> .
<code>name WORD<0-32></code>	Specifies an optional descriptive name for the ACL.
<code>type <inVlan inPort outPort inVsn></code>	Specifies the ACL type. The values <code>inVlan</code> , <code>inPort</code> , and <code>inVsn</code> are ingress ACLs. The value <code>outPort</code> configures IPv6 egress filters. A port-based ACL has precedence over a VLAN-based ACL.
<code>pktType <ipv6></code>	Specifies the IP version as IPv6. The default is nonipv6. <p>Note: You cannot change packet type for the ACL once you have configured it. If you want a different packet type, you must delete the ACL and re-create it using the other packet type.</p>

Associating VLANs with an ACL

Associate VLANs with an ACL to apply filters to VLAN traffic.

A VLAN can be part of two different ACLs of different types: IPv6 and non-IPv6.

Before You Begin

- The ACL exists.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Add VLAN interfaces to an ACL:

```
filter acl vlan <acl-id> <1-4059>
```
3. Remove specified VLAN interfaces from an ACL:

```
no filter acl vlan <acl-id> <1-4059>
```

Variable definitions

Use the data in the following table to use the **filter acl vlan** command.

Variable	Value
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Associating ports with an ACL

Associate ports with an ACL to apply filters to port traffic.

A port can be part of two different ACLs of different types: IPv6 and non-IPv6.

Before You Begin

- The ACL exists.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Associate port interfaces with a particular ACL:

```
filter acl port <acl-id> {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

- Remove port interfaces from a particular ACL:

```
no filter acl port <acl-id> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

Variable definitions

Use the data in the following table to use the **filter acl port** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Associate an I-SID with an ACL

Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

Before You Begin

- The inVsn ACL exists.
- This I-SID is already configured on the fabric node.

About This Task

For inVsn ACL types, specify the I-SID associated with the customer VLAN (Layer 2 VSN), the customer VRF (Layer 3 VSN), or the IP Shortcut.

Note

For IP Shortcut traffic, the inVsn ACL match type must be *both*. In this case, the I-SID is zero (0).

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Specify the I-SID.

```
filter acl i-sid <acl-id> <0-15999999>
```

Variable definitions

Use the data in the following table to use the **filter acl i-sid** command.

Variable	Value
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<0-15999999>	Specifies the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN). This I-SID must already be configured on the fabric node. The InVSN Filter supports IP Shortcut traffic if the inVsn ACL match type is <i>both</i> . In this case, the I-SID is zero (0). Important: You can specify a Switched UNI I-SID if the I-SID is associated with a platform VLAN.

Configure Global and Default Actions for an ACL

Configure the default action to specify packet treatment if a packet does not match any ACE.

Configure the global action to specify packet treatment if a packet does match an ACE.

Global action can only be configured for Ingress ACLs.

Before You Begin

Ensure that the ACL exists.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Configure the global action for an ACL:

```
filter acl set <acl-id> global-action [monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}] [monitor-dst-mlt <1-512>]
```
- Configure an ACL to the default global action settings:

```
default filter acl set <acl-id> global-action [monitor-dst-ports]
```
- Configure the default action for an ACL:

```
filter acl set <acl-id> default-action <permit|deny>
```
- Configure an ACL default policer.

```
filter acl set <acl-id> default-action permit policer svc-rate <0-4000000000> peak-rate <8-4000000000>
```
- Configure an ACL to the default action settings:

```
default filter acl set <acl-id> default-action
```

Variable Definitions

The following table defines parameters for the **filter acl set** commands.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>default-action <permit deny></code>	Specifies the default action to take when none of the ACEs match. Options are <code><permit deny></code> . The default is permit.
<code>monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the global action to take for matching ACEs: <ul style="list-style-type: none"> monitor destination ports—Configures mirroring to a destination port or ports. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>monitor-dst-mlt <1-512></code>	Configures mirroring to a destination MLT in the range of 1 to 512.
<code>policer svc-rate <0-4000000000> peak-rate <8-4000000000></code> Note: Exception: only supported on VSP 4900 Series and VSP 7400 Series.	Specifies the policer for filter with service rate and peak transfer rate of packets. The service rate value specifies the rate of traffic committed to be delivered. Packets above the specified peak rate value are dropped on ingress.

Renaming an ACL

Perform this procedure to change the name of an existing ACL.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Rename an ACL:

```
filter acl <acl-id> name WORD<0-32>
```
- Reset the ACL name to the default name:

```
default filter acl <acl-id> name
```

Variable definitions

Use the data in the following table to use **filter acl** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>enable</code>	Enables the ACL state, and all associated ACEs. Enabled is the default state.
<code>matchType <both terminatingNNIOnly uniOnly></code>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <code>both</code> for traffic ingressing on both UNI ports and NNI ports terminating on this node <code>terminatingNNIOnly</code> for traffic ingressing on NNI ports only and terminating on this node <code>uniOnly</code> for traffic ingressing on UNI ports only The default value is <code>both</code> .
<code>name WORD<0-32></code>	Specifies an optional descriptive name for the ACL.
<code>type <inVlan inPort outPort inVsn></code>	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Disabling an ACL

Perform this procedure to disable an ACL and all ACEs that belong to it.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Disable an ACL:

```
no filter acl <acl-id> enable
```

Variable definitions

Use the data in the following table to use **filter acl** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>enable</code>	Enables the ACL state, and all associated ACEs. Enabled is the default state.

Variable	Value
matchType <both terminatingNNIOnly uniOnly>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .
name WORD<0-32>	Specifies an optional descriptive name for the ACL.
type <inVlan inPort outPort inVsn>	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Resetting an ACL to default values

Reset an ACL to change the ACL name to the default name and the filter ACL mode to a default of enable.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Reset an ACL to default values:

```
default filter acl <acl-id>
```

Variable definitions

Use the data in the following table to use **filter acl** command.

Variable	Value
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
enable	Enables the ACL state, and all associated ACEs. Enabled is the default state.
matchType <both terminatingNNIOnly uniOnly>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .

Variable	Value
<i>name</i> WORD<0-32>	Specifies an optional descriptive name for the ACL.
<i>type</i> <inVlan inPort outPort inVsn>	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Deleting an ACL

Delete an ACL to remove an ordered list of filter rules.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Delete an ACL:

```
no filter acl <acl-id>
```

The system displays the following message:

```
WARNING: All ACE entries under this ACL will be Deleted.
Do you wish to delete this ACL? (y/n)?
```

3. Enter *y*.

Variable definitions

Use the data in the following table to use **filter acl** command.

Variable	Value
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<i>enable</i>	Enables the ACL state, and all associated ACEs. Enabled is the default state.
matchType <both terminatingNNIOnly uniOnly>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> • <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node • <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node • <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .
<i>name</i> WORD<0-32>	Specifies an optional descriptive name for the ACL.
<i>type</i> <inVlan inPort outPort inVsn>	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Clear ACL Statistics

Clear default ACL statistics if you no longer require previous statistics.

Note

The ACL statistics do not support security action on some hardware platforms.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Enter the following command to clear default ACL statistics:
clear filter acl statistics default <acl-id>
3. Enter the following command to clear global ACL statistics:
clear filter acl statistics global <acl-id>
4. Enter the following command to clear all ACL statistics:
clear filter acl statistics all
5. Enter the following command to clear statistics associated with a particular ACL, ACE, or ACE type:
clear filter acl statistics <acl-id> <ace-id> [qos] [security]

Variable Definitions

Use the information in the following table to use the **clear filter acl statistics** command.

Variable	Value
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<ace-id>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.

Enable IPv6 Egress Filters

Use the **boot config flags** command to enable IPv6 egress filters and to add IPv6 egress qualifiers at startup.

About This Task

This flag is disabled by default.

For 5320 Series and 5420 Series platforms, the **boot config flags ipv6-egress-filter** and **boot config flags macsec** commands are mutually exclusive.

Before You Begin

If more than 200 IPv4 egress entries exist in the configuration file, make a backup of the configuration file before you enable IPv6 egress filters. Only a maximum of 200 IPv4 egress entries are saved in the configuration file after you use the **save config** command.

For example, you can enter more than 200 IPv4 egress entries in the configuration file prior to enabling IPv6 egress filters. However, the entries are stored in ascending numerical order with ACL ID and ACE ID

respectively, and not in the order in which they were added. Therefore, after you enable IPv6 egress filters and restart, and because the configuration file is read in ascending order, you receive an error message after the 200 maximum has been reached, such as:

```
CP1 [2017-09-28T00:44:24.077+05:30] 7K-Fi-94-I6:1 0x001049d4 00000000
GlobalRouter FILTER ERROR Unable to allocate data path resources for ACL
ID 12.
```

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable the IPv6-egress-filter boot config flag:

```
boot config flags ipv6-egress-filter
```
3. Save the configuration, and then restart the switch for the change to take effect.
4. After you restart the switch, verify that the IPv6-egress-filter boot config flag is configured to true:

```
show boot config flags
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags ipv6-egress-filter
Warning: Please save the configuration and reboot the switch
for this configuration to take effect.
```

Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags ha-cpu true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags linerate-directed-broadcast false
flags logging true
flags nni-mstp false
flags reboot true
flags rlogind false
flags savetostandby true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
```

```

flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
flags vxlan-gw-full-interworking-mode false

```

Display Filter Access Control List Configuration

About This Task

Perform this procedure to display the filter Access Control List (ACL) configuration on the switch.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display filter ACL configuration:
show filter acl

Example

```
Switch:1(config)#show filter acl
```

```

Access control list configuration using EDM

Use traffic filtering to provide security by blocking unwanted traffic and prioritizing other traffic.

Configuring an access control list

Use an access control list (ACL) to specify an ordered list of access control entries (ACE), or filter rules. The ACEs provide specific actions for the filter to perform.

About This Task

Do not configure IPv4 egress ACL filters on NNI ports because the system-generated egress vIST filter rules and the user-created IPv4 egress rules use the same filter hardware.

To modify an ACL parameter, double-click the parameter you wish to change. Change the value, and then click Apply. You cannot change a parameter that the system displays it dimmed; in this case, delete the ACL, and then configure a new one.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Click **Insert**.
5. In the **AcId** field, type an ACL ID, or accept the default value .
6. In **Type**, specify the type of ACL.
7. In the **Name** field, specify a name for the ACL.
8. Perform one of the following if the ACL is VLAN-based or port-based:
 - a. If the ACL is VLAN-based, click the **VlanList** ellipsis, and then choose a VLAN list.
 - b. If the ACL is port-based, click the **PortList** ellipsis, and then choose a port list.
9. Select the desired ports, and then click **Ok**.
10. Configure the **DefaultAction**.
11. Configure the **ControlPktAction**.

Note

There is no control packet action support for the InVSN Filter. Control packets go to the CPU after termination.

12. Enable or disable the **State**, as required.
13. In the **PktType** field, select the packet type to create either IPv4 or IPv6 ACLs.

14. If the ACL type is inVsn, do the following:
 - a. In the **MatchType** field, select the match type to associate with the ACL that the traffic is ingressing on.
 - b. In the **Isid** field, enter the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN) or enter 0 for IP shortcut.
15. Configure the remaining fields, as appropriate.
16. Click **Insert**.
17. To delete an ACL, select the ACL, and then click **Delete**.

ACL field descriptions

Use the data in the following table to use the **ACL** tab.

Name	Description
AcId	Specifies a unique identifier for the ACL.
Type	<p>Specifies the ACL type. Valid options are</p> <ul style="list-style-type: none"> • inVlan • inPort • outPort • inVsn <p>Important: The inVlan ACLs drop packets if you add a VLAN after ACE creation.</p> <p>Important: You can insert an inVsn ACL type for a Switched UNI only if the Switched UNI I-SID is associated with a platform VLAN.</p>
Name	Specifies a descriptive user-defined name for the ACL.
VlanList	For inVlan ACL types, specifies all VLANs to associate with the ACL.
PortList	For inPort and outPort ACL types, specifies the ports to associate with the ACL.
DefaultAction	Specifies the action taken when no ACEs in the ACL match. Valid options are deny and permit, with permit as the default. Deny means the system drops the packets; permit means the system forwards packets.
ControlPktAction	Specifies the action taken for control packets. Valid options are deny and permit.
State	Enables or disables all of the ACEs in the ACL. The default value is enable.
PktType	Indicates the packet type to which this ACL applies.
MirrorMltd	Configures mirroring to a destination MLT.
MirrorDstPortList	Configures mirroring to a destination port or ports.

Name	Description
MatchType	<p>For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are:</p> <ul style="list-style-type: none"> <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node <i>uniOnly</i> for traffic ingressing on UNI ports only <p>The default value is <i>both</i></p>
Isid	<p>For inVsn ACL types, specifies the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN). This I-SID should already be configured on the fabric node. The InVSN Filter supports IP Shortcut traffic if the inVsn ACL match type is <i>both</i>. In this case, the I-SID is zero (0).</p> <p>Important: You can specify a Switched UNI I-SID if the I-SID is associated with a platform VLAN.</p>
Origin	<p>Indicates the origin of the ACL:</p> <ul style="list-style-type: none"> <i>config</i> - ACL created by the user. <i>eap</i> - ACL created by Extensible Authentication Protocol (EAP) through Remote Authentication Dial-In User Service (RADIUS) response.
DefaultSvcRate Note: Exception: Only supported on VSP 4900 Series, VSP 7400 Series.	<p>Specifies the service rate limit in kbps {8-4000000000}.The granularity is 8 kbps.</p>
DefaultPeakRate Note: Exception: Only supported on VSP 4900 Series, VSP 7400 Series.	<p>Specifies the value when exceeded causes packets to drop on ingress. Peak rate limit in kbps {8-4000000000}.The granularity is 8 kbps.</p>

Viewing ACL Statistics

About This Task

Graph statistics for a specific ACL ID to view default statistics.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.

4. Select an ACL.
5. Click **Graph**.
6. You can click **Clear Counters** to clear the **Statistics** fields.

Statistics Field Descriptions

Use the data in the following table to use the **Statistics** tab.

Name	Description
AcId	Specifies the ACL ID.
MatchDefaultSecurityPkts	Shows a security packet count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchDefaultSecurityOctets	Shows a security byte count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchDefaultQosPkts	Shows a QoS packet count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchDefaultQosOctets	Shows a QoS byte count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalSecurityPkts	Shows a security packet count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalSecurityOctets	Shows a security byte count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalQosPkts	Shows a QoS packet count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalQosOctets	Shows a QoS byte count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
DefaultGreenBytes Note: Exception: Only supported on VSP 4900 Series, VSP 7400 Series.	Shows byte count of traffic sent with a rate lower than committed-rate matching any of the ACE rules or hits on Default Action.
DefaultGreenPackets Note: Exception: Only supported on VSP 4900 Series, VSP 7400 Series.	Shows packet count of traffic sent with a rate lower than committed-rate matching any of the ACE rules or hits on Default Action.

Name	Description
DefaultYellowBytes Note: Exception: Only supported on VSP 4900 Series, VSP 7400 Series.	Shows byte count of traffic sent with a rate lower than peak-rate and higher than committed-rate matching any of the ACE rules or hits on Default Action.
DefaultYellowPackets Note: Exception: Only supported on VSP 4900 Series, VSP 7400 Series.	Shows packet count of traffic sent with a rate lower than peak-rate and higher than committed-rate matching any of the ACE rules or hits on Default Action.
DefaultRedBytes Note: Exception: Only supported on VSP 4900 Series, VSP 7400 Series.	Shows byte count of traffic sent with a rate higher than peak-rate matching any of the ACE rules or hits on Default Action.
DefaultRedPackets Note: Exception: Only supported on VSP 4900 Series, VSP 7400 Series.	Shows packet count of traffic sent with a rate higher than peak-rate matching any of the ACE rules or hits on Default Action.

Clearing ACL Statistics

About This Task

Clear ACL statistics when you want to gather a new set of statistics.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select a field.
5. Click **ClearStats**.

Enable IPv6 Egress Filters

Enable IPv6 egress filters to add IPv6 egress qualifiers at startup.

About This Task

This flag is disabled by default.

Before You Begin

If more than 200 IPv4 egress entries exist in the configuration file, make a backup of the configuration file before you enable IPv6 egress filters. Only a maximum of 200 IPv4 egress entries are saved in the configuration file after you save the configuration.

For example, you can enter more than 200 IPv4 egress entries in the configuration file prior to enabling IPv6 egress filters. However, the entries are stored in ascending numerical order with ACL ID and ACE ID respectively, and not in the order in which they were added. Therefore, after you enable IPv6 egress filters and restart, and because the configuration file is read in ascending order, you receive an error message after the 200 maximum has been reached, such as:

```
CP1 [2017-09-28T00:44:24.077+05:30] 7K-Fi-94-I6:1 0x001049d4 00000000
GlobalRouter FILTER ERROR Unable to allocate data path resources for ACL
ID 12.
```

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **Chassis**.
3. Click the **Boot Config** tab.
4. Select the **EnableIpv6EgressFilterMode** check box.
5. Click **Apply**.
6. Save the configuration, and then restart the switch for the change to take effect.

Boot Config Field Descriptions

Use the data in the following table to use the **Boot Config** tab.

Name	Description
SwVersion	Specifies the software version that currently runs on the chassis.
LastRuntimeConfigSource	Specifies the last source for the run-time image.
PrimaryConfigSource	Specifies the primary configuration source.
PrimaryBackupConfigSource	Specifies the backup configuration source to use if the primary does not exist.

Name	Description
EnableFactoryDefaultsMode	<p>Specifies whether the switch uses the factory default settings at startup.</p> <ul style="list-style-type: none"> • false: The node does not use factory default settings at startup. • fabric: This mode is not supported. • noFabric: The node uses the factory default mode settings at startup. <p>The default value is false. This flag is automatically reset to the default setting after the switch restarts. If you change this parameter, you must restart the switch for the change to take effect.</p> <p>Note: The factorydefaults flag deletes the runtime, primary and backup configuration files, local password files, authentication keys, and certificates. After a factory default, you must change the password on first login.</p>
EnableDebugMode	<p>Enabling the debugmode allows a user to enable TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. It only works on console connection. The default value is disabled.</p> <p>Important: Do not change this parameter.</p>
EnableRebootOnError	<p>Activates or disables automatic reboot on a fatal error. The default value is activated.</p> <p>Important: Do not change this parameter.</p>
EnableTelnetServer	<p>Activates or disables the Telnet server service. The default value is disabled.</p>
EnableRloginServer	<p>Activates or disables the rlogin and rsh server. The default value is disabled.</p> <p>Note: Exception: only supported on VSP 8600 Series.</p>
EnableFtpServer	<p>Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the TFTPD flag is disabled.</p>
EnableTftpServer	<p>Activates or disables Trivial File Transfer Protocol server service. The default value is disabled.</p>
EnableSshServer	<p>Activates or disables the SSH server service. The default value is disabled.</p>

Name	Description
EnableSpbmConfigMode	Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. The boot flag is enabled by default.
EnableIpv6Mode Note: Exception: not supported on VSP 4450 Series or XA1400 Series .	Enable this flag to support IPv6 routes with prefix-lengths greater than 64 bits. This flag is disabled by default.
EnableEnhancedsecureMode	Enables or disables the enhanced secure mode. Select either jtc or non-jtc to enable the enhanced secure mode in one of these sub-modes. The default is disabled. Note: As a best practice, enable the enhanced secure mode in the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.
EnableUrpMode	Enables Unicast Reverse Path Forwarding (uRPF) globally. You must enable uRPF globally before you configure it on a port or VLAN. The default is disabled.
EnableVxlanGwFullInterworkingMode Note: Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.	Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vST. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag. In Base Interworking Mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments.
EnableFlowControlMode Note: Exception: not supported on VSP 8600 Series.	Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames. The default is disabled.

Name	Description
<p>AdvancedFeatureBwReservation</p> <p>Note: Exception: only supported on VSP 7400 Series and XA1480.</p>	<p>Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work.</p> <ul style="list-style-type: none"> The high level means that the switch reserves the maximum bandwidth for the advanced features. The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features. <p>The default is enabled with low level. If you change this parameter, you must restart the switch.</p>
<p>EnableDvrLeafMode</p>	<p>Enables the switch to be configured as a DVR Leaf. When enabled, you cannot configure the switch to operate as a DvR Controller.</p>
<p>EnablevrfScaling</p>	<p>Changes the maximum number of VRFs and Layer 3 VSNs that the switch supports. If you select this check box, the maximum number increases. The default is disabled.</p> <p>Important: If you select both this check box and the EnableSpbmConfigMode check box, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see VOSS Release Notes.</p>
<p>EnableSyslogRfc5424Format</p>	<p>Enables or disables the RFC 5424 syslog format. The default is enabled. If the pre-existing configuration file is for a release prior to this enhancement, then the flag is disabled automatically.</p>
<p>NniMstp</p>	<p>Enables MSTP, and allows non SPBM B-VLAN configuration on SPBM NNI ports. The default is disabled.</p> <p>Note: Spanning Tree is disabled on all SPBM NNIs.</p> <p>You cannot add an SPBM NNI port or MLT port to any non SPBM B-VLAN.</p>
<p>EnableIpv6EgressFilterMode</p>	<p>Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch.</p>
<p>MasterCPUSlot</p> <p>Note: Exception: only supported on VSP 8600 Series.</p>	<p>Specifies the slot number, either 1 or 2, for the master CPU. The default value is 1.</p>

Name	Description
EnableHaCpu Note: Exception: only supported on VSP 8600 Series.	Enables or disables the CPU High Availability feature. If you enable or disable HA mode, the secondary CPU automatically resets to load settings from the previously-saved configuration file. The default is enabled.
EnableSavetoStandby Note: Exception: only supported on VSP 8600 Series.	Enables or disables automatic save of the configuration file to the standby CPU. The default value is enabled.
Slot	Specifies the slot number.
TftpHash	Enables TFTP hashing.
TftpRetransmit	Set TFTP retransmit timeout counter.
TftpTimeout	Set TFTP timeout counter.
User	Configure host user.
Password	Configure host password.

Access Control Entry Configuration using CLI

Use an access control entry (ACE) to provide an ordered list of traffic filtering rules.

Note

Some hardware platforms support ACE IDs from the range 1-1000 for both security and QoS rules. For more information, see [ACL Filters Behavior Differences](#) on page 3414.

Configure ACEs

Use an ACE to define packet attributes and the desired behavior for packets that carry the attribute or list of attributes.

Before You Begin

- The ACL exists. If you want to use IPv6 filters, you must specify the packet type as IPv6 at the ACL level to enable IPv6 filtering.

About This Task

ACLs are by default created in enabled state while ACEs are by default created in disabled state. Use CLI commands to enable an ACE.

Procedure

- Enter Global Configuration mode:

```
enable
configure terminal
```

2. Create and name an ACE:

```
filter acl ace <acl-id> <ace-id> [name WORD<0-32>]
```

The ACE ID determines ACE precedence (that is, the lower the ID, the higher the precedence).

Note

For some hardware platforms, the ACE ID range is from 1 to 1000. If you try to create an ACE ID outside the range, the device displays the following error message:

```
Invalid input detected at '^' marker
```

3. Configure the mode as deny or permit:

```
filter acl ace action <acl-id> <ace-id> <deny|permit>
```

Note

For VSP 8600 Series, the filter ACL ACE deny action does not apply to the Extensible Authentication Protocol (MKPDU), Link Layer Discovery Protocol, Virtual Link Aggregation Control Protocol, Link Aggregation Control Protocol, Topology Discovery Protocol, and Bridge Protocol Data Unit (BPDU) Guard frames. The system still snoops these packets to the Central Processing Unit (CPU) for processing.

4. Configure ACE actions as required.

5. Ensure the configuration is correct:

```
show filter acl ace <acl-id> <ace-id>
```

6. Ensure the filter is enabled:

```
filter acl ace <acl-id> <ace-id> enable
```

7. Optionally, reset an ACE to default values (reset the ACE name to the default name and the administrative state to the default value of disable):

```
default filter acl ace <acl-id> <ace-id>
```

8. Optionally, delete an ACE ID:

```
no filter acl ace <acl-id> <ace-id>
```

Variable Definitions

Use the data in the following table to use the **filter acl ace** and the **filter acl ace action** commands.

Variable	Value
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<ace-id>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.

Variable	Value
<code><deny permit></code>	Configures the action mode for security ACEs. Note: For each Security ACE, you must define one or more actions as well as the associated action mode (permit or deny). Otherwise, the security ACE cannot be enabled. There is no default configuration for Security ACEs. With QoS ACE, the action mode is not configurable. QoS ACEs are always set to action mode permit.
<code>enable</code>	Enables an ACE within an ACL. After you enable an ACE, to make changes, first disable it.
<code>name WORD<0-32></code>	Specifies an optional descriptive name for the ACE that uses 0-32 characters.

Configure ACE actions

Note

DEMO FEATURE - Policy Based Routing (Redirect Next Hop) per VRF is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

Configure ACE actions to determine the process that occurs after a packet matches an ACE.

Before You Begin

- Create ACE and ACL.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure ACE actions:

```
filter acl ace action <acl-id> <ace-id> <permit | deny>
```

Note

For VSP 8600 Series, the filter ACL ACE deny action does not apply to the Extensible Authentication Protocol (MKPDU), Link Layer Discovery Protocol, Virtual Link Aggregation Control Protocol, Link Aggregation Control Protocol, Topology Discovery Protocol, and Bridge Protocol Data Unit (BPDU) Guard frames. The system still snoops these packets to the Central Processing Unit (CPU) for processing.

3. (Optional) Configure ACE actions to count matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> count
```

4. (Optional) Configure the QoS level for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> internal-qos
<0-7>
```

Note

This step does not apply to IPv6 filtering.

5. (Optional) Enable mirroring on destination MLT for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> monitor-dst-
mlt <1-512>
```

6. (Optional) Enable mirroring on a port for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> monitor-dst-
ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. (Optional) Enable mirroring on destination I-SID for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> monitor-isid-
offset <1-1000>
```

8. (Optional) Configure the next hop IPv4 or IPv6 address for redirect mode for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> redirect-next-
hop WORD<1-45> [count | unreachable | vrf {WORD <1-16>}]
```

Important

Ensure you configure the ACE match rules so that you only collect the desired traffic. For example, routed packets.

9. (Optional) Configure the next hop IPv4 or IPv6 address for redirect mode for matching packets for a VRF:

Note

If the next hop is unreachable, you can also configure ACE actions to permit or deny packet dropping within the VRF.

```
filter acl ace action <acl-id> <ace-id> <permit | deny> redirect-next-
hop WORD<1-45> vrf WORD <1-16> unreachable <permit | deny>
```

10. (Optional) Configure the next hop IPv4 or IPv6 address for redirect mode for matching packets for a VRF:

Note

If the next hop is unreachable, you can also configure ACE actions to count matching packets, or to permit or deny packet dropping within the VRF

```
filter acl ace action <acl-id> <ace-id> <permit | deny> redirect-next-
hop WORD<1-45> vrf WORD <1-16> unreachable <permit | deny> count
```

11. (Optional) Configure the QoS dot1p priority for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> remark-dot1p
<0-7>
```

Note

This step does not apply to IPv6 filtering.

12. (Optional) Configure the QoS phb and dscp for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> remark-dscp
[phbcs0 | phbcs1 | phbaf11 | phbaf12 | phbaf13 | phbcs2 | phbaf21 |
phbaf22 | phbaf23 | phbcs3 | phbaf31 | phbaf32 | phbaf33 | phbcs4 |
phbaf41 | phbaf42 | phbaf43 | phbcs5 | phbef | phbcs6 | phbcs7]
```

13. (Optional) Configure the mode when next hop is unreachable:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> unreachable
[permit | deny]
```

14. Ensure the configuration is correct:

- `show filter acl action <acl-id> <ace-id>`
- `show filter acl config`
- `show filter acl ace`

Example

Configure ACE actions:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#filter acl ace action 1 47 permit redirect-next-hop 192.0.2.5
unreachable deny count
```

Display the configuration using the **show filter ace action** command:

```
Switch:1(config)#show filter acl action

Variable Definitions

Use the data in the following table to use the **filter acl ace action** command.

-

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code><ace-id></code>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<code>count</code>	Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.

Variable	Value
<code><deny permit></code>	Configures the action mode for security ACEs. Note: For each Security ACE, you must define one or more actions as well as the associated action mode (permit or deny). Otherwise, the security ACE cannot be enabled. There is no default configuration for Security ACEs. With QoS ACEs, the action mode is not configurable. QoS ACEs are always set to action mode permit.
<code>monitor-isid-offset <1-1000></code>	Specifies the offset ID which will be mapped to the actual monitor I-SID where packets are mirrored. Monitor I-SID = base monitor I-SID + offset ID. The base monitor I-SID is 16776000.
<code>internal-qos <0-7></code>	This variable is a QoS action. The default value is 1. Note: This does not apply to IPv6 filtering.
<code>monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Configures mirroring to a destination port or ports. This action is a security action. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>monitor-dst-mlt <1-512></code>	Configures mirroring to a destination MLT in the range of 1 to 512.
<code>redirect-next-hop WORD <1-45></code>	Specifies the nexthop IPv4 or IPv6 address for redirect node. This action is a security action. Note: redirect-next-hop is available for demonstration purposes on some products. For more information, see VOSS Feature Support Matrix .
<code>unreachable <permit deny></code>	Denies or permits packet dropping when the next hop for the packet is unreachable. The default value is deny. This action is a security action. Note: unreachable is available for demonstration purposes on some products. For more information, see VOSS Feature Support Matrix .
<code>vrf WORD<1-16></code>	Specifies the direct next hop VRF name. The name must be in the range of 1 to 16 characters. Note: vrf is available for demonstration purposes on some products. For more information, see VOSS Feature Support Matrix .

Variable	Value
<code>remark-dscp <phbcs0 phbcs1 phbaf11 phbaf12 phbaf13 phbcs2 phbaf21 phbaf22 phbaf23 phbcs3 phbaf31 phbaf32 phbaf33 phbcs4 phbaf41 phbaf42 phbaf43 phbcs5 phbcs6 phbef phbcs7></code>	<p>Specifies the new Per-Hop Behavior (PHB) for matching packets: phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, phbcs7. This action is a QoS action.</p> <p>Note: This action applies to IPv6 filtering.</p>
<code>remark-dot1p <0-7></code>	<p>Specifies the new 802.1 priority bit for matching packets: zero, one, two, three, four, five, six, or seven. This action is a QoS action.</p> <p>Note: This does not apply to IPv6 filtering.</p>

Configuring ARP ACEs

Use ACE Address Resolution Protocol (ARP) entries to ensure the filter looks for ARP requests or responses.

You cannot configure ARP attributes for IPv6 filters.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. Enter Global Configuration mode:

```
enable
configure terminal
```
2. Configure an ACE for ARP packets:

```
filter acl ace arp <acl-id> <ace-id> operation eq <arprequest|
arpresponse>
```
3. Ensure the configuration is correct:

```
show filter acl arp <acl-id> <ace-id>
```
4. Optionally, delete the individual attributes from the ARP portion of the ACE:

```
no filter acl ace arp <acl-id> <ace-id> [operation]
```
5. Optionally, delete all the attributes from the ARP portion of the ACE:

```
default filter acl ace arp <acl-id> <ace-id>
```

Variable Definitions

Use the data in the following table to use the **filter acl ace arp** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code><ace-id></code>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<code>operation eq</code> <code><arprequest </code> <code>arpresponse></code>	Specifies the type of ARP operation to filter: arpRequest or arpResponse.

Configuring an Ethernet ACE

Configure an Ethernet ACE to filter on Ethernet parameters.

You do not need to configure Ethertype for IPv6 filters. If you try to configure an Ethertype other than 0x86dd or IPv6 the device displays an error.

Before You Begin

- The ACL exists.
- The ACE exists.

About This Task

The `eq` and `mask` parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an ACE for the destination or source MAC address attribute:

```
filter acl ace ethernet <acl-id> <ace-id> <dst-mac|src-mac> eq WORD<1-1024>
```

OR

```
filter acl ace ethernet <acl-id> <ace-id> <dst-mac|src-mac> mask WORD<1-1024> WORD<1-1024>
```

Note

This is supported only for IPv4 filters.

3. Configure an ACE for an Ethernet type attribute:

```
filter acl ace ethernet <acl-id> <ace-id> ether-type eq WORD<1-200>
```

4. Configure an ACE for a port attribute:

```
filter acl ace ethernet <acl-id> <ace-id> port eq {slot/port[sub-
port]}
```

5. Configure an ACE for a VLAN attribute:

```
filter acl ace ethernet <acl-id> <ace-id> vlan-id eq <1-4059>
```

OR

```
filter acl ace ethernet <acl-id> <ace-id> vlan-id mask <1-4059>
<0-0xFFF>
```

6. Configure an ACE for a VLAN tagged priority attribute:

```
filter acl ace ethernet <acl-id> <ace-id> vlan-tag-prio eq <0-7>
```

OR

```
filter acl ace ethernet <acl-id> <ace-id> vlan-tag-prio mask <0-7> <0-
0x7>
```

7. Ensure the configuration is correct:

```
show filter acl ethernet <acl-id> <ace-id>
```

8. Optionally, delete the individual attributes from the Ethernet portion of the ACE:

```
no filter acl ace ethernet <acl-id> <ace-id>
```

9. Optionally, delete all the attributes from the Ethernet portion of the ACE:

```
default filter acl ace ethernet <acl-id> <ace-id>
```

Variable definitions

Use the data in the following table to use the **filter acl ace ethernet** command.

Variable	Value
<0-7>	Specifies the priority bits (3-bit field) from the 802.1Q/p tag.
<0-0x7>	Specifies the mask value for VLAN tagged priority attribute.
<0-0xFFF>	Specifies the mask value for a VLAN attribute. For example: filter acl ace ethernet 10 10 vlan-id eq 10 filter acl ace ethernet 10 10 vlan-id mask 1025 0xF
<ace-id>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Variable	Value
<code>{slot/port[/sub-port]}</code>	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>WORD<1-200></code>	<p>Specifies an ether-type name or number:</p> <ul style="list-style-type: none"> • 0x0-0xffff • ip, arp, ipx802dot3, ipx802dot2, ipxSnap, ipxEthernet2, appleTalk, decLat, decOther, sna802dot2, snaEthernet2, netBios, xns, vines, ipv6, rarp, or PPPoE <p>Note:</p> <p>Ethernet ACE filter configured with ether-type eq ipx802dot3 does not match the packet with format destination MAC address, source MAC address, length, 0xFFFF, payload and FCS.</p> <p>Ethernet ACE filter configured with ether-type eq ipx802dot2 does not match the packet with format destination MAC address, source MAC address, length, 0xE0E0, payload and FCS.</p>
<code>WORD<1-1024></code>	<p>If the operator is mask, the <code>WORD<1-1024></code> parameter is {"" 1..48 , mac address mask 0x0..FFFFFFFFFFFF}</p> <p>If the operator is eq, the <code>WORD<1-1024></code> parameter is the destination or source MAC address: AA:BB:CC:DD:EE:FF</p> <p>For example:</p> <pre>filter acl ace ethernet 10 10 dst-mac eq 0x01:00:5:00:00:01 filter acl ace ethernet 10 10 dst-mac mask 0x01:00:5:00:00:01 24 filter acl ace ethernet 10 10 src-mac mask 0x01:00:5:00:00:01 0xFFFFFFFF0000</pre>

Configure an IP ACE

Configure an IP ACE to filter on the source IP address, destination IP address, DiffServ Code Point (DSCP), protocol, IP options, IP fragmentation, and routed packets only.

Before You Begin

- The ACL exists.
- The ACE exists.

About This Task

The `eq` and `mask` parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```

2. Configure an ACE for the DSCP attribute:

```
filter acl ace ip <acl-id> <ace-id> dscp eq {<0..63>|<0x00..0x3f>|
phbcs0|phbcs1|phbaf11|phbaf12|phbaf13|phbcs2|phbaf21|phbaf22|phbaf23|
phbcs3|phbaf31|phbaf32|phbaf33|phbcs4|phbaf41|phbaf42|phbaf43|phbcs5|
phbef|phbcs6|phbcs7}
```

OR

```
filter acl ace ip <acl-id> <ace-id> dscp mask {<0..63>|<0x00..0x3f>|
phbcs0|phbcs1|phbaf11|phbaf12|phbaf13|phbcs2|phbaf21|phbaf22|phbaf23|
phbcs3|phbaf31|phbaf32|phbaf33|phbcs4|phbaf41|phbaf42|phbaf43|phbcs5|
phbef|phbcs6|phbcs7} WORD<0x0-0x40>
```

3. Configure an ACE for the destination or source IP address attribute:

```
filter acl ace ip <acl-id> <ace-id> <dst-ip|src-ip> eq WORD<1-1024>
```

OR

```
filter acl ace ip <acl-id> <ace-id> <dst-ip|src-ip> mask WORD<1-1024>
{<0-32>|null|<A.B.C.D>}
```

4. Configure an ACE for the IP fragmentation attribute:

```
filter acl ace ip <acl-id> <ace-id> ip-frag-flag eq <noFragment|
anyFragment>
```

5. Configure an ACE for the IP options attribute:

```
filter acl ace ip <acl-id> <ace-id> ip-options any
```

6. Configure an ACE for the protocol type attribute:

```
filter acl ace ip <acl-id> <ace-id> ip-protocol-type eq WORD<1-256>
```

7. Configure an ACE for routed packets only:

```
filter acl ace ip <acl-id> <ace-id> routed-only
```

Note

This step does not apply to VSP 8600 Series or XA1400 Series.

8. Ensure the configuration is correct:

```
show filter acl ip <acl-id> <ace-id>
```

9. (Optional) Delete all the attributes from the IP (Layer 3) portion of the ACE:

```
default filter acl ace ip <acl-id> <ace-id>
```

Example

```
Switch:1(config)#filter acl ace ip 1 12 dst-ip eq 198.51.100.0
```

Variable definitions

Use the data in the following table to use the **filter acl ace ip** command.

Variable	Value
<code><ace-id></code>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>{<0-32> null <A.B.C.D>}</code>	Specifies the mask value for the destination or source IP address For example: <pre>filter acl ace ip 10 10 dst-ip mask 198.51.100.0 25 filter acl ace ip 10 10 dst-ip mask 198.51.100.1 203.0.113.0 filter acl ace ip 10 10 src-ip mask 198.51.100.2 22 filter acl ace ip 10 10 src-ip mask 198.51.100.3 203.0.113.1</pre>
<code><noFragment anyFragment></code>	Specifies a match option for IP fragments noFragment or anyFragment.
<code>{<0..63> <0x00..0x3f> phbcs0 phbcs1 phbaf11 phbaf12 phbaf13 phbcs2 phbaf21 phbaf22 phbaf23 phbcs3 phbaf31 phbaf32 phbaf33 phbcs4 phbaf41 phbaf42 phbaf43 phbcs5 phbcs6 phbef phbcs7}</code>	Specifies the DSCP value using one of the following formats: <ul style="list-style-type: none"> Enter as an integer (0-63) or hex (0x00-0x3f), or as a string: <ul style="list-style-type: none"> phbcs0 — Enter as string “phbcs0”, integer 0 or hex 0x00 phbcs1 — Enter as string “phbcs1”, integer 8 or hex 0x08 phbaf11 — Enter as string “phbaf11”, integer 10 or hex 0x0a phbaf12 — Enter as string “phbaf12”, integer 12 or hex 0x0c phbaf13 — Enter as string “phbaf13”, integer 14 or hex 0x0e phbcs2 — Enter as string “phbcs2”, integer 16 or hex 0x10 phbaf21 — Enter as string “phbaf21”, integer 18 or hex 0x12 phbaf22 — Enter as string “phbaf22”, integer 20 or hex 0x14 phbaf23 — Enter as string “phbaf23”, integer 22 or hex 0x16 phbcs3 — Enter as string “phbcs3”, integer 24 or hex 0x18 phbaf31 — Enter as string “phbaf31”, integer 26 or hex 0x1a phbaf32 — Enter as string “phbaf32”, integer 28 or hex 0x1c phbaf33 — Enter as string “phbaf33”, integer 30 or hex 0x1e phbcs4 — Enter as string “phbcs4”, integer 32 or hex 0x20 phbaf41 — Enter as string “phbaf41”, integer 34 or hex 0x22 phbaf42 — Enter as string “phbaf42”, integer 36 or hex 0x24 phbaf43 — Enter as string “phbaf43”, integer 38 or hex 0x26 phbcs5 — Enter as string “phbcs5”, integer 40 or hex 0x28 phbef — Enter as string “phbef”, integer 46 or hex 0x2e phbcs6 — Enter as string “phbcs6”, integer 48 or hex 0x30 phbcs7 — Enter as string “phbcs7”, integer 56 or hex 0x38
<code>WORD<0x0-0x40></code>	Specifies the mask value, for example, <pre>filter acl ace ip 10 10 dscp mask 129 0x40</pre>

Variable	Value
<i>WORD</i> <1-256>	Specifies one or more IP protocol types: (1-256), or tcp, udp, ipsecesp, vrrp, snmp or undefined.
<i>WORD</i> <1-1024>	Specifies the destination or source IP address (a.b.c.d).

Configure an IPv6 ACE

Configure an IPv6 ACE to filter traffic based on Source IPv6 address, Destination IPv6 address, IPv6 next header, and IPv6 traffic class, and routed packets only.

Source IPv6 and destination IPv6 support equal (eq) and mask operators. Next header and traffic class attributes support the equal (eq) operator. The equal to rule operator looks for an exact match with the field defined. If the field matches exactly with the rule, the system will return a match (hit). ACL-based filters provide the mask operator to match on Layer 2, Layer 3, and Layer 4 packet fields. The mask operator is used to mask bits in packet fields during a search or to match on a partial value of a packet field.

Before You Begin

- Application Telemetry must be disabled on VSP 4450 Series, VSP 7200 Series, VSP 8200 Series, and VSP 8400 Series.
- The ACL exists. The ACL exists with the IPv6 packet type. You can only configure ACE IPv6 attributes to filter on an IPv6 packet.
- The ACE exists.

About This Task

The *eq* and *mask* parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Create and name an ACE:

```
filter acl ace <acl-id> <ace-id> [name Word<1-32>]
```
3. Configure an ACE for the destination IPv6 address attribute:

```
filter acl ace ipv6 <acl-id> <ace-id> dst-ipv6 eq WORD<0-255>
```

OR

```
filter acl ace ipv6 <acl-id> <ace-id> dst-ipv6 mask WORD<1-128>
WORD<0-255>
```

- Configure an ACE for the source IP address attribute:

```
filter acl ace ipv6 <acl-id> <ace-id> src-ipv6 eq WORD<0-255>
```

OR

```
filter acl ace ipv6 src-ipv6 <acl-id> <ace-id> mask WORD<1-128>  
WORD<0-255>
```

- Specify the next header of the IP header:

```
filter acl ace ipv6 <acl-id> <ace-id> nxt-hdr eq {fragment|hop-by-hop|  
icmpv6|ipsecah|ipsecesp|noHdr|routing|tcp|udp|undefined}
```

You must configure next header to configure the protocol attributes.

- Specify the traffic class attribute of the IPv6 header:

```
filter acl ace ipv6 <acl-id> <ace-id> traffic-class eq WORD<0-255>
```

- Configure an ACE for routed packets only:

```
filter acl ace ipv6 <acl-id> <ace-id> routed-only
```

Note

This step does not apply to VSP 8600 Series or XA1400 Series.

- Ensure that your configuration is correct:

```
show filter acl ipv6 <acl-id> <ace-id>
```

Example

```
Switch:1(config)#filter acl ace ipv6 15 15 dst-ipv6 eq 30:0:0:0:0:0:ffff/64
```

Configuring a protocol ACE

Configure a protocol ACE to filter on the source port, destination port, ICMP and ICMPv6 message type, or TCP flags.

Note

For IPv6 filters, you must configure next header to configure the protocol attributes.

Before You Begin

- The ACL exists.
- The ACE exists.

About This Task

The *eq* and *mask* parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an ACE for destination port attributes:

```
filter acl ace protocol <acl-id> <ace-id> dst-port eq WORD<1-60>
```

OR

```
filter acl ace protocol <acl-id> <ace-id> dst-port mask WORD<1-60>
WORD<1-256>
```

3. Configure an ACE for source port attributes:

```
filter acl ace protocol <acl-id> <ace-id> src-port eq WORD<1-65535>
```

OR

```
filter acl ace protocol <acl-id> <ace-id> src-port mask WORD<1-65535>
WORD<1-256>
```

4. Configure an ACE for ICMP message type attributes:

```
filter acl ace protocol <acl-id> <ace-id> icmp-msg-type eq WORD<1-200>
```

5. Configure an ACE for TCP flags attributes:

```
filter acl ace protocol <acl-id> <ace-id> tcp-flags eq WORD<1-50>
```

OR

```
filter acl ace protocol <acl-id> <ace-id> tcp-flags mask {0-0x3F|
0-0x3F}
```

6. Ensure the configuration is correct:

```
show filter acl protocol <acl-id> <ace-id>
```

7. (Optional) Delete the individual attributes from the protocol portion of the ACE:

```
no filter acl ace protocol <acl-id> <ace-id> [dst-port] [icmp-msg-
type] [icmpv6-msg-type] [routing-type] [src-port] [tcp-flags]
```

8. (Optional) Delete all the attributes from the protocol portion of the ACE:

```
default filter acl ace protocol <acl-id> <ace-id>
```

Specify ICMP packets:

```
Switch:1(config)#filter acl ace protocol 1 12 icmpv6-msg-type eq echoRequest
```

Table 258: TCP Flags Order in Packet

32 (decimal)	16 (decimal)	8 (decimal)	4 (decimal)	2 (decimal)	1 (decimal)
Urgent	Ack	Push	Reset	Syn	Fin

Configure an ACE for TCP flags attributes: Example 1

The mask is set for an 'ack' tcp flag bit regardless of whether any other tcp flag bits are also set:

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask ack ?
<0-0x3F | 0-63> Mask value <Hex | Decimal>: This six bit mask is a reverse mask where
0:care
about, 1:do not care about
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask ack 0x2f
Hex Value 20 10 8 4 2 1
```

```
TCP Flags _ ack _ _ _ _
Binary Value 1 0 1 1 1 1 or in hex = 0x2F
```

Configure an ACE for TCP flags attributes: Example 2

A packet will match this filter if the 3 tcpflag bits are set in the tcp header (and only those 3 bits).

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags eq ?
WORD<1-50> Tcp flags
{none | fin | syn | rst | push | ack | urg | undefined}
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags eq syn,push,urg
```

You can configure a functionally equivalent filter with the mask operator as follows:

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask syn,push,urg 0x0
```

Configure an ACE for TCP flags attributes: Example 3

The mask operator provides more flexibility. For example a packet will match the following filter if the 'syn,push,urg' tcpflag bits are set, regardless of whether any other tcpflag bits are also set:

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask syn,push,urg ?
<0-0x3F | 0-63> Mask value <Hex | Decimal>: This six bit mask is a reverse mask where
0:care
          about, 1:do not care about
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask syn,push,urg 0x15
```

Configure an ACE for ICMP message type: Example 4

```
filter acl 1 type inPort name "ICMP_TRAFFIC_FILTER"
filter acl port 1 1/3
filter acl ace 1 1
filter acl ace action 1 1 deny count
filter acl ace ethernet 1 1 ether-type eq ip
filter acl ace ip 1 1 src-ip mask 194.183.100.64 0.0.0.15
filter acl ace ip 1 1 dst-ip eq 146.97.137.42
filter acl ace ip 1 1 ip-protocol-type eq icmp
filter acl ace protocol 1 1 icmp-msg-type eq echo-request
filter acl ace 1 1 enable
filter acl ace 1 2
filter acl ace action 1 2 deny count
filter acl ace ethernet 1 2 ether-type eq ip
filter acl ace ip 1 2 src-ip mask 194.183.100.64 0.0.0.15
filter acl ace ip 1 2 dst-ip eq 146.97.137.42
filter acl ace ip 1 2 ip-protocol-type eq icmp
filter acl ace protocol 1 2 icmp-msg-type eq echoreply
filter acl ace 1 2 enable
```

Variable Definitions

Use the data in the following table to use the **filter acl ace protocol** command.

Variable	Value
{0-0x3F}	Specifies the mask value.
<ace-id>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>WORD<1-50></code>	Specifies one or more TCP flags—none, fin (finish connection), syn (synchronize), rst (reset connection), push, ack (acknowledge), urg (urgent), and undefined.
<code>WORD<1-60></code>	Specifies the destination port: (0-65535), or echo, ftpdata, ftpcontrol, ssh, telnet, dns, http, hdot323, bootpServer, bootpClient, tftp, rtp, rtcp, or undefined.
<code>WORD<1-200></code>	Specifies the ICMP message type: Icmpmsg type (0-255), or echoreply, destunreach, sourcequench, redirect, echo-request, routeradv, routerselect, time-exceeded, param-problem, timestamp-request, timestamp-reply, addressmask-request, addressmask-reply, or traceroute.
<code>WORD<1-200></code>	Specifies the ICMPv6 message type: Icmpmsg type (0-255), or destUnreach, pktTooBig, timeExceeded, paramProblem, echoRequest, echoReply, mcastListenReq, mcastListenRpt, mcastListenDone, routerSolicit, routerAdvert, neighborSolicit, neighborAdvert, redirectMsg, nodeInfoReq, nodeInfoRsp, or v2McastListenRpt.
<code>WORD<1-256></code>	Specifies the mask parameter, {0-0xFFFF}.
<code>WORD<0-65535></code>	Specifies the source port (0-65535).

Configure Ingress Policer and Port Rate Limiter

Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series.

Before You Begin

Ensure that both the ACL and the ACE exist.

About This Task

Perform this procedure to limit the number of packets that can be attached to an ACL ACE. If you want to modify the ingress bandwidth rate limiter values, you must first disable the ACE.

Note

You can attach one policer to ACL and ACE. Every policer is independent.

Procedure

1. Enter the Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an ACL and ACE policer:

```
filter acl ace policer <acl-id> <ace-id> svc-rate <0-4000000000> peak-
rate <8-4000000000>
```

Note

You must configure both svc-rate and peak-rate.

3. Ensure the configuration is correct:

```
show filter acl policer <acl-id> <ace-id>
```

Variable Definitions

The following table defines parameters for the **filter acl ace policer** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code><ace-id></code>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<code>svc-rate <0-4000000000></code> Note: Exception: only supported on VSP 4900 Series and VSP 7400 Series.	Specifies the rate of the traffic committed to be delivered. Service rate limit in kbps {0-4000000000}.The granularity is 8 kbps.
<code>peak-rate <8-4000000000></code> Note: Exception: only supported on VSP 4900 Series and VSP 7400 Series.	Specifies the value when exceeded causes packets to drop on ingress. Peak rate limit in kbps {8-4000000000}.The granularity is 8 kbps.

Viewing ACL and ACE configuration data

View your configuration to review the information and ensure it is correct.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View ACL information:

```
show filter acl <acl-id>
```

3. View IPv6 ACL information:

```
show filter acl ipv6 <acl-id> <ace-id>
```

4. View the running configuration for an ACL and corresponding ACE:

```
show filter acl config <acl-id> <ace-id>
```

Variable Definitions

Use the data in the following table to use the **show filter acl** and **show filter acl config** commands.

Variable	Value
<ace-id>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.

View ACE Statistics

View ACE statistics to ensure that the filter operates correctly.

Note

The ACL statistics do not support security action on some hardware platforms.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View ACE statistics for a specific ACL, ACE, or ACE type:
show filter acl statistics <acl-id> <ace-id> [qos] [security]
3. View all ACE statistics:
show filter acl statistics all
4. View default ACE statistics:
show filter acl statistics default [<acl-id>]
5. View global statistics for ACEs:
show filter acl statistics global [<acl-id>]
6. View filter policer statistics for ACL and ACE:
show filter acl statistics <acl-id> <ace-id> policer

Examples

View ACE statistics:

Note

Based on your hardware platform, the output can display all the ACL packets or segregate them as QoS and security ACL packets.

```
Switch:1>enable
Switch:1#show filter acl statistics all
```

```

Variable Definitions

The following table defines parameters for the **show filter acl statistics** command.

Variable	Value
<i><acl-id></i>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<i><ace-id></i>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<i>policer</i>	Specifies the policer parameter for the command.
Note: Exception: only supported on VSP 4900 Series and VSP 7400 Series.	

Access Control Entry Configuration using EDM

Use an access control entry (ACE) to define a pattern (found in a packet) and the desired behavior for packets that carry the pattern.

As a best practice, create access control lists (ACL) with a default action of permit, and with an ACE mode of deny. For deny or permit ACLs or ACEs, the default action and the mode must be opposite for the ACE (filter) to have meaning.

Note

Some hardware platforms support ACE IDs from the range 1-1000 for both security and QoS rules.

Configure an ACE

Note

DEMO FEATURE - Policy Based Routing (Redirect Next Hop) per VRF is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

Before You Begin

- The ACL exists.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the ACL to which to add an ACE.
5. Click **ACE**.
6. Click the **ACE Common** tab.
7. Click **Insert**.
8. Configure the ACE ID.
9. Name the ACE.
10. Choose the mode: **deny** (drop packets) or **permit** (forward packets).
11. Configure the ACE actions as required.
12. Click **Insert**.
13. Configure the ACE attributes as required.
14. To enable the ACE, in the **ACE Common** tab, configure **AdminState** to enable, and then click **Apply**.
15. To delete an ACE Common entry, select the entry, and then click **Delete**.

ACE Common field descriptions

Use the data in the following table to use the **ACE Common** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Name	Specifies a descriptive user-defined name for the ACE. The system automatically assigns a name if you do not type one.
AdminState	Indicates the status of the ACE as enabled or disabled. You can modify an ACE only if you disable it.
OperState	Indicates the current operational state of the ACE.
Mode	Indicates the operating mode for this ACE. Valid options are deny and permit, with deny as the default.
RedirectNextHop	Redirects matching IPv4/IPv6 traffic to IPv4/IPv6 nexthop.
RedirectNextHopVrfname	Specifies the direct next hop VRF name. The name must be in the range of 1 to 16 characters.
RedirectUnreach	Denies or permits packet dropping when the next hop for the packet is unreachable. The default value is deny. This action is a security action.
InternalQos	This variable is a QoS action. The default value is 1.
RemarkDscp	Specifies whether the DSCP parameter marks nonstandard traffic classes and local-use Per-Hop Behavior. The default is disable. Use this option to create a QoS ACE.
RemarkDot1Priority	Specifies whether Dot1 Priority, as described by Layer 2 standards (802.1Q and 802.1p) is enabled. The default is disable. Use this option to create a QoS ACE.

Configure ACE Actions

Configure ACE actions to determine the process that occurs after a packet matches (or does not match) an ACE. Use debug actions (flags) to use filters for troubleshooting and monitoring procedures.

Before You Begin

- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select an **AcId**.
7. Select **Action**.

8. Configure the actions as required, and then select **Apply**.

Action field descriptions

Use the data in the following table to use the **Action** tab.

Note

The table lists the options for both Security ACEs and QoS ACEs. Dependent upon the ACE, the system displays different options on the EDM interface.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Mode	Configures the action mode for security ACEs. The default value is deny.
RemarkDscp	Specifies the new Per-Hop Behavior (PHB) for matching packets: phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, phbcs7. This action is a QoS action.
RemarkDot1Priority	Specifies the new 802.1 priority bit for matching packets: zero, one, two, three, four, five, six, or seven. This action is a QoS action. Note: This does not apply to IPv6 filtering.
InternalQoS	This variable is a QoS action. The default value is 1. Note: This does not apply to IPv6 filtering.
RedirectNextHop	Specifies the next-hop IPv4 address (a.b.c.d) or IPv6 address (aaaa:bbbb:cccc:dddd:eeee:ffff:gggg:hhhh) for redirect mode. Applies to ingress ACLs (routed and Layer 2 packets).
Count	Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.
DstPortList	Configures mirroring to a destination port or ports. This action is a security action.
DstMlId	Configures mirroring to a destination MLT. This action is a security action.

Name	Description
MonitoringIsidOffset	Configures the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored.
MirroringQoS	Defines the Quality of Service (QoS) profiles for the mirrored packet into monitoring I-SID.

Configuring ACE ARP entries

Use ACE Address Resolution Protocol (ARP) entries so that the filter looks for ARP request or response packets.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select a parameter for the appropriate ACL.
5. Click **ACE**.
6. Select a parameter for the appropriate ACE.
7. Click **Arp**.
8. Click **Insert**.
9. Select ARP request or response.
10. Click **Insert**.

ARP field descriptions

Use the data in the following table to use the **ARP** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Type	Specifies the ACE ARP operation. The only option is operation.
Oper	Specifies the operator for the ACE ARP operation. The only option is eq (equal).
Value	Specifies the ARP packet type. Valid options are arpRequest and arpResponse.

Viewing all ACE ARP entries for an ACL

View all of the ACE ARP entries associated with an ACL.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **Arp**.
6. To modify a parameter, double-click the parameter, select the option, and then click **Apply**.

ARP field descriptions

Use the data in the following table to use the **ARP** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Type	Specifies the ACE ARP operation. The only option is operation.
Oper	Specifies the operator for the ACE ARP operation. The only option is eq (equal).
Value	Specifies the ARP packet type. Valid options are arpRequest and arpResponse.

Configuring an ACE Ethernet source address

Perform this procedure to filter on specific Ethernet source addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Eth**.
8. Click the **Source Address** tab.
9. Click **Insert**.
10. Specify the ACE Ethernet operation.
11. In the **List** dialog box, specify the Ethernet source address.
12. Click **Insert**.

Source Address *Field Descriptions*

Use the data in the following table to use the **Source Address** tab.

Variable	Value
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies the MAC address to match.
OperMask	Specifies the MAC Address mask value in hexadecimal format. The value for this variable is empty or 000000000000 if the Oper variable is eq.

Configuring an ACE Ethernet destination address

Perform this procedure to filter on specific Ethernet destination addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Eth**.
8. Click the **Destination Address** tab.
9. Click **Insert**.
10. Specify the ACE Ethernet operation.
11. In the **List** dialog box, specify the Ethernet source address.
12. Click **Insert**.

Destination Address *Field Descriptions*

Use the data in the following table to use the **Destination Address** tab.

Variable	Value
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.

Variable	Value
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies the MAC address to match.
OperMask	Specifies the MAC address mask value in hexadecimal format if the Oper variable is mask. The value of this variable is empty or 000000000000 if Oper is eq.

Configuring an ACE LAN traffic type

Perform this procedure to filter for specific LAN traffic packets.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Eth**.
8. Click the **Ethernet Type** tab.
9. Click **Insert**.
10. Specify the operation type.
11. In the **TypeList** box, type the Ethernet types.
12. Click **Insert**.

Ethernet Type field descriptions

Use the data in the following table to use the **Ethernet Type** tab.

Name	Description
AcId	Specifies the ACL ID.
Aceld	Specifies the ACE ID.

Name	Description
TypeOper	The eq parameter specifies an operator for a field match condition: equal to.
TypeList	Specifies the Ethernet type. Entries include: 0 to 0xffff or ip, arp, ipx802.3, ipx802.2, ipxSnap, ipxEthernet2, appleTalk, appleTalk-ARP, sna802.2, snaEthernet2, netBios, xns, vines, ipv6, rarp, PPPoE-discovery, and PPPoE-session. Note: Ethernet ACE filter configured with Ethernet Type ipx802.3 does not match the packet with format destination MAC address, source MAC address, length, 0xFFFF, payload and FCS. Ethernet ACE filter configured with Ethernet Type ipx802.2 does not match the packet with format destination MAC address, source MAC address, length, 0xE0E0, payload and FCS.

Configuring an ACE Ethernet VLAN tag priority

Perform this procedure to filter for specific VLAN tag priorities.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Eth**.
8. Click the **Vlan Tag Priority** tab.
9. Click **Insert**.
10. Specify the operation type.
11. In the **VlanTagPrio** box, select the priority bits.
12. Click **Insert**.

VLAN Tag Priority field descriptions

Use the data in the following table to use the **Vlan Tag Priority** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.

Name	Description
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
VlanTagPrio	Specifies the priority bits (3-bit field) from the 802.1Q/p tag: <ul style="list-style-type: none"> • zero • one • two • three • four • five • six • seven
OperMask	Specifies the mask value in hexadecimal format if the Oper value is mask.

Configuring an ACE Ethernet port

Use ACE Ethernet port entries so that the filter looks for traffic on specific ports. You can only insert an ACE Common Ethernet port for VLAN ACL types.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Eth**.
8. Click the **Port** tab.
9. Click **Insert**.
10. Specify the operation type.
11. Click the **Port** ellipses (...).
12. Choose the ports.
13. Click **OK**.
14. Click **Insert**.

Port field descriptions

Use the data in the following table to use the **Port** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for a field match condition: equal to.
Port	Specifies the port or port list on which to perform a match.

Configuring an ACE Ethernet VLAN ID

Use ACE Ethernet VLAN ID entries so that the filter looks for traffic on specific VLANs. You can insert an ACE Ethernet VLAN ID only for ACL VLAN types.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Eth**.
8. Click the **Vlan Id** tab.
9. Click **Insert**.
10. Specify the operation type.
11. Enter the VLAN ID or select from a list.
12. Click **Insert**.

VLAN ID field descriptions

Use the data in the following table to use the **Vlan Id** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for a field match condition: equal to.
VlanId	Specifies the VLAN ID on which to perform a match.
OperMask	Specifies the mask value for a VLAN attribute.

Viewing all ACE Ethernet entries for an ACL

View all of the ACE Ethernet entries associated with an ACL.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **Eth**.

Ethernet field descriptions

Use the data in the following table to use the **Ethernet** tab.

Name	Description
AcId	Shows the ACL ID.
AceId	Specifies the ACE ID.
SrcAddrList	Shows the list of Ethernet source addresses to match.
SrcAddrOper	Shows the operators for the ACE Ethernet source MAC address.
SrcAddrOperMask	Shows the source MAC address mask value in hexadecimal format if the SrcAddrOper variable is mask. The value of this field is empty or 000000000000 if the SrcAddrOper field is eq.
DstAddrList	Shows the list of Ethernet destination addresses to match.
DstAddrOper	Shows the operators for the ACE Ethernet destination MAC address.
DstAddrOperMask	Shows the destination MAC address mask value in hexadecimal format if the DstAddrOper variable is mask. The value for this field is empty or 000000000000 if the DstAddrOper field is eq
EtherTypeList	Shows the EtherType value from the Ethernet header. For example, ARP uses 0x0806 and IP uses 0x0800. Platform support determines the behavior for 802.1Q/p tagged packets. The EtherType for 802.1Q tagged frames is 0x8100. The range is 0–65535 and supports lists and ranges of values. An invalid Ether-type of 65536 indicates that you do not want the parameter in the match criteria.
EtherTypeOper	Shows the Ethernet type operators.
VlanTagPrio	Shows the priority bits (3-bit field) from the 802.1Q/p tag.
VlanTagPrioOper	Shows the operators for the ACE Ethernet VLAN tag priority.
VlanTagPrioOperMask	Shows the VLAN tag priority mask value in hexadecimal format if the VlanTagPrioOper field is mask.
Port	Shows the port number or port list to match.
PortOper	Shows the operator for the ACE Ethernet port.

Name	Description
VlanId	Shows the VLAN ID to match.
VlanIdOper	Shows the operator for the ACE Ethernet VLAN ID.
VlanIdOperMask	Shows the VLAN ID mask value in hexadecimal format if the VlanIdOper field is mask.

Configuring an ACE IP source address

Configure ACE IP source address entries to have the filter look for specific source IP addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IP**.
8. Click the Source Address tab.
9. Click **Insert**.
10. Specify the operation type.
11. In the **IPAddr** box, enter the source IP address.
12. Click **Insert**.

Source Address field descriptions

Use the data in the following table to use the **Source Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
IPAddr	Specifies the source IP address.
OperMask	Specifies the mask value for the source IP address.

Configuring an ACE IP destination address

Configure ACE IP destination address entries to have the filter look for specific destination IP addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IP**.
8. Click the **Destination Address** tab.
9. Click **Insert**.
10. Specify the operation type.
11. In the **IPAddr** box, enter the destination IP address.
12. Click **Insert**.

Destination Address field descriptions

Use the data in the following table to use the **Destination Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
IPAddr	Specifies the destination IP address.
OperMask	Specifies the mask value for the destination IP address.

Configuring an ACE IP DSCP

Configure ACE IP DSCP entries to have the filter look for packets with specific DSCP markings.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.

5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IP**.
8. Click the **DSCP** tab.
9. Click **Insert**.
10. Specify the operation type.
11. In the **List** box, enter the count for the DSCP values.
12. Click **Insert**.

DSCP field descriptions

Use the data in the following table to use the **DSCP** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies a count for the number of discrete ranges entered for the DSCP values. Entries include 0–256, disable, phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, and phbcs7.
OperMask	Specifies the mask value.

Configuring an ACE IP protocol

Configure ACE IP protocol entries to have the filter look for packets of specific protocols.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IP**.
8. Click the **Protocol** tab.
9. Click **Insert**.
10. Specify the operation type.

11. In the **List** box, enter the IP protocol type.
12. Click **Insert**.

Protocol field descriptions

Use the data in the following table to use the **Protocol** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for a field match condition: equal to.
List	Specifies the IP protocol type. Entries include 0–256, undefined, tcp, udp, ipsecesp, vrrp, and undefined.

Configuring ACE IP options

Configure ACE IP option entries to have the filter look for packets with an IP option specified.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IP**.
8. Click the **Options** tab.
9. Click **Insert**.
10. Specify the logical operator.
Any is the only choice.
11. Click **Insert**.

Options field descriptions

Use the data in the following table to use the **Options** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	Specifies the logical operator for the ACE IP options. Any is the only option.

Configuring ACE IP fragmentation

Configure ACE IP fragmentation entries to have the filter look for packets with the fragmentation flag.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IP**.
8. Click the **Fragmentation** tab.
9. Click **Insert**.
10. Specify the operator for IP fragmentation.
Eq is the only choice.
11. Specify the fragmentation bits to match from the IP header.
12. Click **Insert**.

Fragmentation field descriptions

Use the data in the following table to use the **Fragmentation** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.

Name	Description
Oper	Specifies the logical operator for the ACE IP options. Any is the only option.
Fragmentation	Specifies the IP fragmentation bits to match from the IP header: <ul style="list-style-type: none"> noFragment anyFragment The default is noFragment.

Viewing all ACE IP entries for an ACL

View all of the ACE IP entries associated with an ACL.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **IP**.

IP field descriptions

Use the data in the following table to use the **IP** tab.

Name	Description
AcId	Shows the ACL IP ID.
AceId	Shows the ACE ID.
SrcAddrOper	Shows the operators for the ACE IP source address.
SrcAddrIpAddr	Shows the IP source address to match from the IP header.
SrcAddrOperMaskRange	Shows the IP mask value if SrcAddrOper is set to mask, or the highest IP address if SrcAddrOper is set to range.
DstAddrOper	Shows the operators for the ACE IP destination address.
DstAddrIpAddr	Shows the IP destination address to match from the IP header.
DstAddrOperMaskRange	Shows the IP mask value if DstAddrIpAddr is set to mask, or the highest IP address if DstAddrIpAddr is set to range.
DscpList	Shows how the 6-bit DSCP parameter from the TOS byte in the IPv4 header encodes PHB information following RFC 2474.
DscpOper	Shows the operators for the ACE IP DSCP.
DscpOperMask	Shows the mask value in hexadecimal format when the mask option is selected in DscpOper .
ProtoList	Shows the IP protocol type from the IP header to match. The range is 0–255.

Name	Description
ProtoOper	Shows the operators for the ACE IP protocols.
Options	Shows the IP options to match from the IP header.
OptionsOper	Shows the logical operator. Any is the only option.
Fragmentation	Shows the IP fragmentation bits to match from the IP header.
FragOper	Shows the operator for IP fragmentation.

Configuring an ACE IPv6 source address

Configure ACE IPv6 source address entries to have the filter look for specific source IP addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **Source Address** tab.
9. Click **Insert**.
10. In the **Oper** field, select the operation type.
11. In the **List** field, enter the source IP address.
12. In the **OperMask** field, enter the operation mask value.
13. Click **Insert**.

Source Address field descriptions

Use the data in the following table to use the **Source Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies the source IP address.
OperMask	Specifies the mask value for the source IP address.

Configuring an ACE IPv6 destination address

Configure ACE IPv6 destination address entries to have the filter look for specific destination IP addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **Destination Address** tab.
9. Click **Insert**.
10. In the **Oper** field, select the operation type.
11. In the **List** field, enter the destination IP address.
12. In the **OperMask** field, enter the operation mask value.
13. Click **Insert**.

Destination Address field descriptions

Use the data in the following table to use the **Destination Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies the destination IP address.
OperMask	Specifies the mask value for the destination IP address.

Configuring an ACE IPv6 next header

Configure ACE IPv6 next header entries to have the filter look for specific next headers.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **Next Hdr** tab.
9. Click **Insert**.
10. In the **Oper** field, select the operation type.
11. In the **NextHdr** field, select the next header type.
12. Click **Insert**.

Next Header field descriptions

Use the data in the following table to use the **Next Hdr** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for an “equal to” field match condition.
NextHdr	Specifies the next header of the IPv6 header. Specifies hop-by-hop, tcp, udp, routing, fragment, ipsecESP, ipsecAH, icmpv6, noNxtHdr, or undefined.

Configuring an ACE IPv6 traffic class

Configure ACE IPv6 traffic class.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **Traffic Class** tab.

9. Click **Insert**.
10. In the **Oper** field, select the operation type.
11. In the **TrafficCls** field, enter the traffic class number.
12. Click **Insert**.

Traffic Class field descriptions

Use the data in the following table to use the **Traffic Class** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for an “equal to” field match condition.
TrafficCls	Specifies the traffic class attribute of the IPv6 header. Traffic class identifies different classes or priorities of IPv6 packets. The range is 0–255.

Viewing all ACE IPv6 entries for an ACL

View all of the ACE IPv6 entries associated with an ACL.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **IPv6** tab.

IPv6 field descriptions

Use the data in the following table to use the **IPv6** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
SrcAddrList	Shows the source IP address.
SrcAddrOper	Shows the operators for the ACE IP source address.

Name	Description
DstAddrList	Shows the destination IP address.
DstAddrOper	Shows the operators for the ACE IP destination address.
NxtHdrNxtHdr	Shows the next header of the IPv6 header.
NxtHdrOper	Shows the operators for the next header.
TrafficClsOper	Shows the operators for the traffic class.
TrafficCls	Shows the traffic class attribute of the IPv6 header.
SrcAddrMask	Shows the mask value for the source IP address.
DstAddrMask	Shows the mask value for the destination IP address.

Configuring an ACE source port

Configure ACE source port entries to have the filter look for packets with a specific source port.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **Source Port** tab.
9. Click **Insert**.
10. Specify the operator for the source port.
11. Specify the port number or port list to match.
12. Click **Insert**.

Source Port field descriptions

Use the data in the following table to use the **Source Port** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Port	Specifies the source port (1–65535).

Name	Description
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
OperMask	Specifies the mask parameter, {0-0xFFFF}.

Configuring an ACE destination port

Configure ACE destination port entries to have the filter look for packets with a specific destination port.

Before You Begin

- The ACE exists.
- The ACL exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **Destination Port** tab.
9. Click **Insert**.
10. Specify the operator for the destination port.
11. Specify the port number or port list to match.
12. Click **Insert**.

Destination Port field descriptions

Use the data in the following table to use the **Destination Port** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
Port	Specifies the port number. As noted at the bottom of the tab, potential entries include 0-65535, echo, ftpdata, ftpcontrol, ssh, telnet, dns, http, h.323, and undefined.
OperMask	Specifies the mask parameter, {0-0xFFFF}.

Configuring an ACE ICMP message type

Configure ACE Internet Control Message Protocol (ICMP) message type entries to have the filter look for packets of a specific ICMP message type.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **Icmp Msg Type** tab.
9. Click **Insert**.
10. Specify the operator for the ICMP message type.
11. In the **List** box, specify the ICMP messages to match.
12. Click **Insert**.

Icmp Msg Type field descriptions

Use the data in the following table to use the **Icmp Msg Type** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	Specifies the operator for the ACE protocol ICMP message type. Equal (eq) is the only option.
List	Specifies the ICMP message type (0-255), or echoreply, destunreach, sourcequench, redirect, echo-request, routeradv, routerselct, time-exceeded, param-problem, timestamp-request, timestamp-reply, addressmask-request, addressmask-reply, or traceroute.

Configuring an ACE ICMPv6 message type

About This Task

Configure ACE Internet Control Message Protocol v6 (ICMPv6) message type entries to have the filter look for packets of a specific ICMPv6 message type.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > Security > Data path**
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **Icmpv6 Msg Type** tab.
9. Click **Insert**.
10. Specify the operator for the ICMPv6 message type.
11. In the **List** field, specify the ICMPv6 messages to match.
12. In the **Count** field, specify 1 through 100.
13. Click **Insert**.

Icmpv6 Msg Type field descriptions

Use the data in the following table to use the **Icmpv6 Msg Type** tab.

Name	Description
AclId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	Specifies the operator for the ACE protocol ICMPv6 message type. Equal (eq) is the only option.
List	Specifies the ICMPv6 message type (0-255), or echoreply, destunreach, sourcequench, redirect, echo-request, routeradv, routerselect, time-exceeded, param-problem, timestamp-request, timestamp-reply, addressmask-request, addressmask-reply, or traceroute.
Count	Specifies 1-100. Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.

Configuring an ACE TCP flag

Configure ACE TCP flag entries to have the filter look for packets with a specific TCP flag.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.

4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **TCP Flags** tab.
9. Click **Insert**.
10. Specify the operator for the TCP flags entry.
11. In the **List** box, specify the TCP flags to match.
12. Click **Insert**.

TCP Flags field descriptions

Use the data in the following table to use the **TCP Flags** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies one or more TCP flags—none, fin (finish connection), syn (synchronize), rst (reset connection), push, ack (acknowledge), urg (urgent), and undefined.
OperMask	Specifies the mask value.

Configure an ACE to Filter IPv4 Routed Packets

Configure an ACE to filter IPv4 routed packets.

Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select **IpRouted** tab.
4. Select **Insert**.
5. In the **AcId** field, type the appropriate ACL ID.
6. In the **AceId** field, type the appropriate ACE ID.
7. **RoutedOnly**
8. Select **Insert**.

IpRouted Field Descriptions

The following table describes values on the **IpRouted** tab.

Name	Description
AcId	Specifies the ACL ID. Value range of 1 to 2048.
AceId	Specifies the ACE ID. Value range of 1 to 2000.

Configure an ACE to Filter IPv6 Routed Packets

Configure an ACE to filter IPv6 routed packets only.

**Note**

This procedure does not apply to VSP 8600 Series or XA1400 Series.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **Ipv6Routed** tab.
4. Select **Insert**.
5. In the **AcId** field, type the appropriate ACL ID.
6. In the **AceId** field, type the appropriate ACE ID.
7. Select **RoutedOnly**.
8. Select **Insert**.

Ipv6Routed Field Descriptions

The following table describes values on the **Ipv6Routed** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
RoutedOnly	Specifies the match for IPv6 routed packets only.

Configure Ingress Policer and Port Rate Limiter

**Note**

This procedure only applies to VSP 4900 Series and VSP 7400 Series switches.

Perform this procedure to limit the number of packets that can be attached to an ACL ACE. If you want to modify the ingress bandwidth rate limiter values, you must first disable the ACE.

Note

You can attach one policer to ACL and ACE. Every policer is independent.

Before You Begin

Ensure that both the ACL and the ACE exist.

Procedure

1. In the navigation tree, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the appropriate ACL.
4. Select the appropriate ACE.
5. Select **Policer**.
6. Select **Insert**.
7. For **SvcRateValue**, type the service rate value.
8. For **PeakRateValue**, type the peak rate value.
9. Select **Insert**.
10. Select **Apply**.

Policer Field Descriptions

Name	Description
AcId	Specifies the ACL identifier numeric value for the filter.
AcId	Specifies the ACE identifier numeric value for the filter.
SvcRateValue	Specifies the service rate in kilobits for the flow of packets from the filter. The range is 8 to 4000000000 and the granularity is 8 kilobits.
PeakRateValue	Specifies peak rate in kilobits for the flow of packets from the filter. The range is 8 to 4000000000 and the granularity is 8 kilobits.
Oper	Specifies the operational status of the policer.

Viewing ACE Port Statistics

About This Task

Use port statistics to ensure that the ACE is operating correctly.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select a field on the **ACL** tab.

5. Click **ACE**.
6. Click the **Statistics** tab.

Statistics Field Descriptions

Use the data in the following table to use the **Statistics** tab.

Name	Description
AcId	Specifies the associated ACL index.
AceId	Specifies the ACE index.
MatchCountPkts	Specifies a packet count of the matching packets.
MatchCountOctets	Specifies the number of octets of the matching packets.
GreenBytes	Specifies the number of bytes sent with a rate lower than the committed-rate of the matching ACE.
GreenPackets	Specifies the number of packets sent with a rate lower than the committed-rate of the matching ACE.
YellowBytes	Specifies the number of bytes sent with a rate lower than peak-rate and higher than the committed-rate of the matching ACE.
YellowPackets	Specifies the number of packets sent with a rate lower than the peak-rate and higher than the committed-rate of the matching ACE.
RedBytes	Specifies the number of bytes sent with a rate higher than the peak-rate of the matching ACE.
RedPackets	Specifies the number of packets sent with a rate higher than the peak-rate of the matching ACE.

Viewing all ACE protocol entries for an ACL

View all of the ACE protocol entries associated with an ACL.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **Proto**.

Protocol field descriptions

Use the data in the following table to use the **Protocol** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.

Name	Description
SrcPort	Specifies the port number or port list to match.
SrcPortOper	Specifies the operator for the ACE protocol source port.
SrcPortOperMaskRange	The value is displayed in hexadecimal format when SrcPortOper is set to mask. When SrcPortOper is set to range, this field is used as the high range value. In this case, the value is displayed in decimal format. When SrcPortOper is set to eq, this field is set to 0.
DstPort	Specifies port number or port list to match.
DstPortOper	Specifies the operator for the ACE protocol destination port.
DstPortOperMaskRange	The value is displayed in hexadecimal format when DstPortOper is set to mask. When DstPortOper is set to range, this field is used as the high range value. In this case, the value is displayed in decimal format. When SrcPortOper is set to eq, this field is set to 0.
IcmpMsgTypeList	Specifies one or a list of ICMP messages to match. The valid range is 0-255 (reserved).
IcmpMsgTypeOper	Specifies the operator for the ACE protocol ICMP message types.
TcpFlagsList	Specifies one or a list of TCP flags to match. The valid range is 0-63.
TcpFlagsOper	Specifies the operator for the ACE protocol TCP flags.
TcpFlagsOperMask	Displays the mask value in hexadecimal format when TcpFlagsOper is set to mask. When TcpFlagsOper is set to eq, this field displays 0x0.

Troubleshooting

[Traps Reference](#) on page 3715

The Troubleshooting section describes common problems and error messages with the techniques to resolve them, as well as information about troubleshooting tools.

The topics in this section provide necessary concepts and procedures to troubleshoot issues with the switch and connectivity issues in the network.

Data Collection Required for Technical Support Cases

Use the following sections to learn about how to gather information before you contact Technical Support.

Data Collection for an Outage

Perform the following data collection procedures when the switch is in an outage condition and you require Technical Support to perform a root cause analysis.

Collecting Data Before You Restart

Perform this procedure before you restart the chassis.

Procedure

1. Capture the current state of the chassis:

```
terminal more disable
```

```
show tech
```

2. Capture Flight Recorder trace information.

```
flight-recorder all {slot[-slot] [, ...]}
```

The **all** command executes three separate commands: `flight-recorder snapshot`, `flight-recorder trace`, and `flight-recorder archive`.

For VSP 8600 Series, you can replace `{slot[-slot] [, ...]}` with `all` to create a snapshot for all slots.

3. Reset the chassis:

- a. Reset the chassis without creating a core file.

```
reset -y
```

- b. For VSP 8600 Series, create a core file of the primary Control Processor (CP):

```
sys action cpu-switch-over -coredump
```

- c. For VSP 8600 Series, create a core file for a particular module:

```
slot reset {<1-8> |SF1 | SF2 | SF3} -coredump
```

- d. For all other platforms, create an ssio core file and a cbc-main.x core file, skip the confirmation question, and then reset the chassis.

```
reset -coredump -y
```

- e. Create an ssio core file and a cbc-main.x core file, prompt for the confirmation question, and then reset the chassis.

```
reset -coredump
```

Note

Create a core file only when there is a need to analyze a problem. If you reset the switch for any other reason the command is `reset -y`.

4. Continue with [Collecting data after you restart](#).

Example

The following example shows output of the `flight-recorder all 1` command.

```
Switch:1#flight-recorder all 1
Processing Flight-recorder snapshot for 1 ....

Flight-recorder snapshot for slot 1 complete, filename is /intflash/PMEM/1/pmem.
20111019114431.1.bin.gz.

Processing Flight-recorder trace for 1 ....

Flight-recorder trace for slot 1 complete, filename is /intflash/flrec/1/trace.2
0111019114434.1.txt.

Processing Flight-recorder archive for slot 1 ....

Flight-recorder archive for slot 1 complete, filename is /intflash/archive/1/arc
hive.20111019114446.1.tar.
```

Collecting Data After You Restart

About This Task

Perform this procedure after you restart the affected chassis.

Procedure

1. Use FTP to transfer the following information:
 - Configuration files from each chassis: Stored on the internal flash at `/intflash/`.
 - Log files from each chassis: Stored on the internal flash at `/intflash/`.
 - Generated archive files for slot: Stored on the internal flash. For example: `/intflash/archive/<slot>`

Note

For , if the core file is not on the primary control processor (CP), you can use FTP to connect to the internal flash of the primary CP. For example, `cp mnt/intflash/archive/<slot>/<filename> /intflash/<filename>`

To copy the file to internal flash or usb device in the primary CP, use the following command: `cp mnt/intflash/archive/<slot>/<filename> {/intflash/<filename> | /usb/<filename>}`

2. Show core information:

```
show core-files
```

If the timestamp for an entry in the command output matches the time the outage first occurred, or is later than that time, transfer that core file to an FTP server. Core files are stored on the internal flash at: `/intflash/coreFiles/`

3. Obtain the network diagram of the relevant nodes, down to the port level.

Data Collection for Non Outage Problems

Use the information in this section to collect data for problems that are less service-impacting than an outage.

Gathering Critical Information

This section identifies the critical information that you must gather before you contact Technical Support.

You must attempt to resolve the problem using this document. Contact Technical Support as a final step taken only after you are unable to resolve the issue using the information and steps provided in this document.

Gather the following information before you contact Technical Support:

- a detailed description of the problem
- the date and time when the problem started
- the frequency of the problem
- if this is a new installation

- if there is relevant information recorded on the support portal — Were related problem solutions found? Is there currently a work around for this issue? For more information, see support on the Extreme Portal at <https://extremeportal.force.com/ExtrSupportHome>.
- if the system was recently upgraded — Have you recently changed or upgraded the system, the network, or a custom application? (For example, has configuration or code been changed?) When were these changes made? Provide the date and time. Who made these changes? Were the changes made by a partner or customer? Provide the names of the individuals who made the changes.

Troubleshooting Planning Fundamentals

You can better troubleshoot the problems on the network by planning for these events in advance. To do this, you must know the following:

- that the system is properly installed and routinely maintained
- the configuration of the network
- the normal behavior of the network

Proper Installation and Routine Maintenance

The following table lists the documents that provide maintenance and installation procedures.

To prevent problems, follow proper maintenance and installation procedures.

Table 259: Maintenance and installation documentation

Subject area	Document
Installation, environmental requirements	Installing the Virtual Services Platform 4450GSX-PWR+ Installing the Virtual Services Platform 4450GTX-HT-PWR+ VSP 4900 Series Switches: Hardware Installation Guide Installing the Virtual Services Platform 7200 Series VSP 7400 Series Switches: Hardware Installation Guide Installing the Virtual Services Platform 8000 Series Installing the Virtual Services Platform 8600 XA1400 Series Switches: Hardware Installation Guide
Transceiver installation and requirements	Extreme Optics website

Network Configuration

To keep track of the network configuration, gather the information described in the following sections. This information, when kept up-to-date, is extremely helpful for locating information if you experience network or device problems.

Site network map

A site network map identifies where each device is physically located on site, which helps locate the users and applications that a problem affects. You can use the map to systematically search each part of the network for problems.

Logical connections

The switch supports virtual LANs (VLAN). With VLANs, you must know how the devices connect logically as well as physically.

Device configuration information

Maintain online and paper copies of the device configuration information. Store all online data with the regular data backup for the site. If the site does not use a backup system, copy the information onto an external storage device, and store the backup at an offsite location.

You can use the File Transfer Protocol (FTP) and Trivial FTP (TFTP) to store configuration files on a remote server.

Other important data about the network

For a complete picture of the network, have the following information available:

- all passwords

Store passwords in a safe place. A good practice is to keep records of previous passwords in case you must restore a device to a previous software version and need to use the old password that was valid for that version.

- device inventory

Maintain a device inventory, which lists all devices and relevant information for the network. The inventory allows you to easily see the device type, IP address, ports, MAC addresses, and attached devices.

- MAC address-to-port number list

If you do not manage the hubs or switches, you must keep a list of the MAC addresses that correlate to the ports on the hubs and switches.

- change control

Maintain a change control system for all critical systems. Permanently store change control records.

- contact details

Store the details of all support contracts, support numbers, engineer details, and telephone and fax numbers.

Normal Behavior on the Network

If you are familiar with the network when it is fully operational, you can be more effective at troubleshooting problems that arise. To understand the normal behavior of the network, monitor the network over a long period of time. During this time you can see a pattern in the traffic flow, such as which devices users access most or when peak usage times occur.

To identify problems, you can use a baseline analysis, which is an important indicator of overall network health. A baseline serves as a useful reference of network traffic during normal operation, which you can then compare to captured network traffic while you troubleshoot network problems. A baseline analysis speeds the process of isolating network problems. By running tests on a healthy network, you compile normal data for your network. You can compare this normal data against the results that you get when the network experiences trouble.

For example, ping each node to discover how long it typically takes to receive a response from devices on your network. Capture and save each response time and you can use these baseline response times to help you troubleshoot. You can also use the **show tech** and **show khi performance {buffer-pool|cpu|memory|process|pthread|slabinfo}** commands to obtain baseline output for normal system behavior.

Note

Depending on the hardware platform, the output of **show khi performance memory** command can differ.

In the following example, the **show khi performance memory** command shows the average memory utilization at various time intervals. The **show khi performance memory history** command shows the VMSize utilization values in kilobytes for each process at various time intervals. After 1 hour elapses, the system stores this information in `/intflash/coreFiles/slot/khi_mem_log`.

```
Switch:1#show khi performance memory
Slot:1Slot:1
  Used: 1609636 (KB)
  Free: 2396068 (KB)
  Current utilization: 40 %
  5-minute average utilization: 40 %
  5-minute high water mark: 40 (%)
  10-minute average utilization: 39 %
  10-minute high water mark: 39 (%)
  1-Hour average utilization: 37 %
  1-Day average utilization: 0 %
  1-Month average utilization: 0 %
  1-Year average utilization: 0 %

Switch:1#show khi performance memory history
Slot:1

Troubleshooting Fundamentals

This section provides conceptual information and helpful tips for common problems.

Connectivity Problems

Use the following general tasks to isolate connectivity problems:

- Check physical connectivity. Verify if an alarm for link or port down exists.
- Check the link state by viewing the **show interface {gigabitEthernet|loopback|vlan}** command output.
- Use tools like ping or trace to verify if the connectivity issue is localized to an individual port or VLAN.
- Try to localize the affected range of ports and slot.

If you contact technical support staff to help troubleshoot connectivity problems, always provide source and destination IP pairs to facilitate in troubleshooting. Be sure to provide both working and non-working pairs for comparison.

```

Switch:1#show interface vlan

Routing Table Problems

Routing table problems include but are not limited to:

- inactive routes
- unnecessary routes
- black hole routes

Note

Only black hole routes that belong to the static type protocol are supported. An inter-VRF black hole route is not installed in the routing table of the destination VRF on the same switch.

- flapping links (links that go up and come down) that cause the routes to flap
- incorrect route tables
- invalid Address Resolution Protocol (ARP) cache that causes incorrect IP to MAC assignment
- problems with administrative distance or other parameters

Important

Do not restart a device to clear a problem. In restarting the device, you also clear the logs. Logs are vital and can help determine many problems.

Cable Connection Problems

You can usually trace port connection problems to a poor cable connection or to an improper connection of the port cables at either end of the link. To remedy such problems, make sure that the cable connections are secure and that the cables connect to the correct ports at both ends of the link. If you use homemade cables, ensure that the cables are wired correctly.

1000BASE-T cables

1 Gb/s ports operate using Category 5 UTP cabling only. Category 5 UTP cable is a two-pair cable. To minimize crosstalk noise, maintain the twist ratio of the cable up to the point of termination; untwist at termination cannot exceed 0.5 in. (1.27 cm).

Pluggable optic cables

Cables for the optical transceivers vary depending on the specific device type.

For more information about the cable requirements for optical transceivers, see [Extreme Optics](#) website.

Alarm Database

The switch contains a local alarms mechanism. Local alarms are raised and cleared by applications running on the switch. View active alarms by using the **show alarm database** command in the CLI. Local alarms are an automatic mechanism run by the system that do not require additional configuration.

The fabric drivers on the I/O and control (IOC) modules or switch fabric (SF) modules can trigger an alarm if the module is not operational. You can view the alarm from the primary control processor (CP) console or from the **show alarm database** output. The message indicates the slot and module that is not operational, and the remote slot and SFI to which it is connected. The alarm clears when the SFI state returns to operational.

Check local alarms regularly to ensure no alarms require additional attention. The raising and clearing of local alarms also creates a log entry for each event. For more information about viewing logs, see [Viewing Logs](#) on page 2283.

View the alarm database regularly to monitor alarm conditions, even if you do not observe a performance problem. Review the alarm messages to determine if the system performs as expected.

Not all alarm conditions indicate a problem so you must be familiar with expected behavior.

The alarm database shows the following alarm text:

```
CP1 [01/01/70 00:03:06.796] 0x00010844 00000000 Global Router HW WARNING
USB found in slot 1 has VendorId 05dc ProductId a01a and Manufacturer
Lexar and did not match supported devices
```

This alarm means that you have tried to insert an unsupported USB device into the USB slot. Only the USB device provided with your system can be inserted into the USB slot.

LED Indications of Problems

For information on LEDs on the chassis, see the hardware installation documentation.

Connectivity Fault Management

Table 260: Connectivity Fault Management product support

Feature	Product	Release introduced

	XA1400 Series	Not Supported

CFM Fundamentals

The Shortest Path Bridging MAC (SPBM) network needs a mechanism to debug connectivity issues and to isolate faults. This is performed at Layer 2, not Layer 3. Connectivity Fault Management (CFM) operates at Layer 2 and provides an equivalent of ping and traceroute. To support troubleshooting of the SPBM cloud, the switch supports a subset of CFM functionality. Configure CFM on all SPBM VLANs.

CFM is based on the IEEE 802.1ag standard.

IEEE 802.1ag Connectivity Fault Management (CFM) provides OAM tools for the service layer, which allows you to monitor and troubleshoot an end-to-end Ethernet service instance. CFM is the standard for Layer 2 ping, Layer 2 traceroute, and the end-to-end connectivity check of the Ethernet network.

The 802.1ag feature divides or separates a network into administrative domains called Maintenance Domains (MD). Each MD is further subdivided into logical groupings called Maintenance Associations (MA). A single MD can contain several MAs.

Each MA is defined by a set of Maintenance Points (MP). An MP is a demarcation point on an interface that participates in CFM within an MD. Two types of MP exist:

- Maintenance End Point (MEP)
- Maintenance Intermediate Point (MIP)

CFM supports three kinds of standard CFM messages: Continuity Check Message (CCM), Loopback Message (LBM), and Linktrace Message (LTM). Messages are sent between Maintenance Points (MP) in the system.

On the switch, CFM is implemented using the LBM and LTM features only to debug SPBM. CCM messages are not required or supported.

You can assign maintenance levels for each CFM SPBM MEP and MIP to each SPBM B-VLAN individually or you can assign maintenance levels and global MEPs for all SPBM VLANs.

Autogenerated CFM and Explicitly Configured CFM

The switch simplifies CFM configuration with autogenerated CFM. With autogenerated CFM, you use the commands **cfm spbm enable** and **cfm cmac enable** and the switch creates default MD, MA, MEPs, and MIPs for SPBM B-VLANs and C-VLANs respectively.

If you choose to configure CFM explicitly, you must configure an MD, MA, MEPs, and MIPs.

- For SPBM B-VLANs, the switch provides two methods to configure CFM, namely, autogenerated and explicitly configured. You cannot use both.
- For C-VLANs, you can only use autogenerated CFM.

Autogenerated CFM

You can use autogenerated CFM at a global level to create a MEP and a MIP at a specified level for every SPBM B-VLAN and C-VLAN on the chassis. If you use autogenerated CFM commands, you do not have to configure explicit MDs, MAs, MEPs, or MIPs, and associate them with multiple VLANs.

If you do not want to use autogenerated CFM commands, you can choose to configure explicit MDs, MAs, MEPs, and MIPs for SPBM B-VLANs. However, you cannot use both an autogenerated CFM configuration and an explicit CFM configuration together.

Note

Previous explicit CFM configurations of MDs, MAs, and MEPs on SPBM B-VLANs continue to be supported. However, if you want to enable the autogenerated commands you must first remove the existing MEP and MIP on the SPBM B-VLANs. The switch only supports one type of MEP or MIP for each SPBM B-VLAN.

For information on autogenerated CFM configuration using CLI see:

- [Configuring Autogenerated CFM on SPBM B-VLANs](#) on page 3515
- [Configure Autogenerated CFM on C-VLANs](#) on page 3517

For information on autogenerated CFM configuration using EDM see:

- [Configure Autogenerated CFM on SPBM B-VLANs](#) on page 3540
- [Configure Autogenerated CFM on C-VLANs](#) on page 3541

Explicitly configured CFM

If you choose to explicitly configure CFM, you must configure an MD, MA, MEPs, and MIPs. You can configure explicit CFM only on SPBM B-VLANs.

For explicit configuration information for CLI see [Configuring Explicit Mode CFM](#) on page 3518.

For explicit configuration information for EDM see [Configuring Explicit CFM](#) on page 3543.

Using CFM

For SPBM B-VLANs, the autogenerated MEPs and MIPs respond to **12 ping**, **12 traceroute**, and **12 tracetest** in the same manner as the MEPs and MIPs created explicitly. For C-VLANs, the autogenerated MEPs and MIPs respond to **12 ping** and **12 traceroute**, but not to **12 tracetest** because no multicast trees exist on C-VLANs. The CFM show commands that display MD, MA, and MEP information work for both autogenerated and explicitly configured CFM MEPs.

You can use CFM to troubleshoot networks and hosts that support the CFM protocol. After you configure CFM, CFM works in the network whether or not SPBM is in use.

You cannot use CFM to troubleshoot networks and hosts that do not support the CFM protocol, such as a customer domain that does not support CFM. Only devices that support the CFM protocol respond to **12 ping** and **12 traceroute** requests.

Maintenance Domain (MD)

A Maintenance Domain (MD) is the part of a network that is controlled by a single administrator. For example, a customer can engage the services of a service provider, who, in turn, can engage the services of several operators. In this scenario, there can be one MD associated with the customer, one MD associated with the service provider, and one MD associated with each of the operators.

You assign one of the following eight levels to the MD:

- 0–2 (operator levels)
- 3–4 (provider levels)
- 5–7 (customer levels)

The levels separate MDs from each other and provide different areas of functionality to different devices using the network. An MD is characterized by a level and an MD name (optional).

A single MD can contain several Maintenance Associations (MA).

Maintenance Association (MA)

An MA represents a logical grouping of monitored entities within its Domain. It can therefore represent a set of Maintenance association End Points (MEPs), each configured with the same Maintenance Association ID (MAID) and MD Level, established to verify the integrity of a single service instance.

The following figure shows MD level assignment in accordance with the 802.1ag standard. As shown in the figure, MIPs can be associated with MEPs. However, MIPs can also function independently of MEPs.

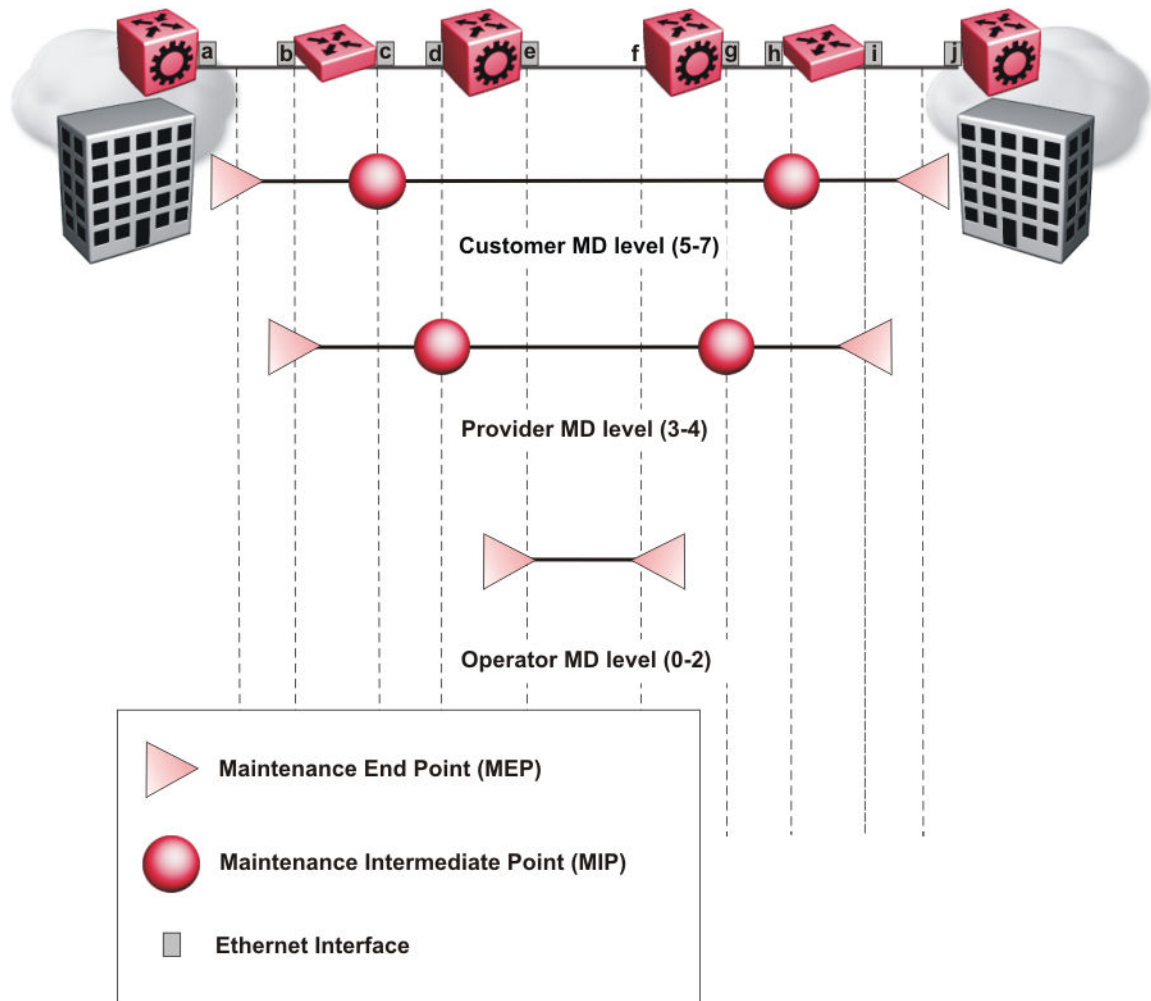

Figure 259: MD level assignment

Maintenance Association Endpoint (MEP)

A Maintenance Endpoint (MEP) represents a managed CFM entity, associated with a specific Domain Service Access Point (DoSAP) of a service instance, which can generate and receive CFM Protocol Data Units (PDU) and track any responses. A MEP is created by MEP ID under the context of an MA. MEP functionality can be divided into the following functions:

- Fault Detection
- Fault Verification
- Fault Isolation
- Fault Notification

Fault detection and notification are achieved through the use of Continuity Check Messages (CCM). CCM messages are not supported.

Fault Verification

Fault verification is achieved through the use of Loopback Messages (LBM). An LBM is a unicast message triggered by the operator issuing an operational command. LBM can be addressed to either a MEP or Maintenance Intermediate Point (MIP) but only a MEP can initiate an LBM. The destination MP can be addressed by its MAC address. The receiving MP responds with a Loopback Response (LBR). LBM can contain an arbitrary amount of data that can be used to diagnose faults as well as performance measurements. The receiving MP copies the data to the LBR.

LBM Message

The LBM packet is often compared to a ping. A MEP transmits the LBM packet. This packet can be addressed to another MEP or to the MAC address of the MP; in the case of SPBM, this is the SPBM system ID or its virtual SMLT MAC. Only the MP for which the packet is addressed responds with an LBR message.

- Provides “ICMP ping like” functionality natively at Layer-2.
- DA is the MAC address of the target.
- Includes a transaction identifier that allows the corresponding LBR to be identified when more than one LBM request is waiting for a response.
- Bridges forward the frame using the normal FDB rules.
- Only the target (MIP or MEP) responds.
- Initiator can choose the size and contents data portion of the LBM frame.
- Can be used to check the ability of the network to forward different sized frames.

L2 Ping

The **l2 ping** command is a proprietary command that allows a user to trigger an LBM message.

For B-VLANs, specify either the destination MAC address or node name.

Note

The virtual node MAC address does not support CFM Layer 2 ping.

This provides a simpler command syntax than the standard LBM commands, which require the user to specify the MD, MA, and MEP ID information. The **l2 ping** command provides a ping equivalent at Layer 2 for use with nodes on the SPBM B-VLAN in the customer domain. SPBM B-VLANs support the SMLT virtual option for the source mode.

Important

CFM CMAC Layer 2 ping and Layer 2 traceroute traversing over Fabric Extend tunnels are not supported when originating from a VSP 4450 Series.

Fault Isolation

Fault isolation is achieved through the use of Linktrace Messages (LTM). LTM is intercepted by all the MPs on the way to the destination MP. The switch supports two types of LTM.

The first type, the unicast LTM, can be addressed to either MEP or MIP MAC address. Each MP on the way decrements the TTL field in the LTM frame, sends Linktrace Reply (LTR), and forwards the original

LTM to the destination. The LTM is forwarded until it reaches its destination or the TTL value is decremented to zero. LTR is a unicast message addressed to the originating MEP.

The second type, the proprietary LTM, is used to map the MAC addresses of the SPBM network; in this case the target MAC is not an MP, but rather a service instance identifier (I-SID).

Link Trace Message

Connectivity Fault Management offers link trace messaging for fast fault detection. Link trace messages allow operators, service providers and customers to verify the connectivity that they provide or use and to debug systems.

Link trace message — unicast

The link trace message (LTM) is often compared to traceroute. A MEP transmits the LTM packet. This packet specifies the target MAC address of an MP which is the SPBM system id or the virtual SMLT MAC. MPs on the path to the target address respond with an LTR.

- Trace the path to any given MAC address.
- DA is unicast
- LTM contains:
 - Time to live (TTL)
 - Transaction Identifier
 - Originator MAC address
 - Target MAC address
- CFM unaware entities forward the frame as is like any other data frame.
- MIP or MEP that is not on the path to the target discards the LTM and does not reply.
- MIP that is on the path to the target
 - Forwards the LTM after decrementing the TTL and replacing the SA with its own address.
 - Sends a reply (LTR) to the originator.
 - Identifies itself in the forwarded LTM and LTR by modifying TLV information.
- If the MIP or MEP is a target
 - Sends an LTR to the originator.
 - Identifies itself in the forwarded LTM and LTR by modifying TLV information.
- A MEP that is not the target but is on the path to the target
 - Generates a reply as described above.
 - It also sets one of the flags fields in the reply to indicate that it is the terminal MEP.

Link trace message — multicast

The multicast link trace message (LTM) can be used to trace the multicast tree from any node on any I-SID using the nickname MAC address and the I-SID multicast address.

Specifying a multicast target address for an LTM allows for the tracing of the multicast tree corresponding to that destination address (DA). With a multicast target every node that is in the active topology for that multicast address responds with a Linktrace reply and also forwards the LTM frame along the multicast path. Missing Linktrace replies (LTRs) from the nodes in the path indicate the point of first failure.

This functionality allows you to better troubleshoot I-SID multicast paths in a SPBM network.

L2 Traceroute

The **12 traceroute** command is a proprietary command that allows you to trigger an LTM message.

Use this command as follows:

- For B-VLANs, specify either the destination MAC address or node name.
- For C-VLANs, specify the destination MAC address.

Note

The virtual node MAC address does not support CFM Layer 2 traceroute.

This command provides a simpler command syntax than the standard LTM commands, which require you to specify the MD, MA, and MEP ID information. The **12 traceroute** command provides a trace equivalent at Layer 2 for use with nodes on the SPBM B-VLAN in the customer domain.

Important

Only the VSP 4450 Series switch supports CFM configuration on C-VLANs.

CFM CMAC Layer 2 ping and Layer 2 traceroute traversing over Fabric Extend tunnels are not supported when originating from a VSP 4450 Series.

You can use CFM to troubleshoot networks and hosts that support the CFM protocol. After you configure CFM, CFM works in the network whether or not SPBM is in use.

You cannot use CFM to troubleshoot networks and hosts that do not support the CFM protocol, such as a customer domain that does not support CFM. Only devices that support the CFM protocol respond to **12 ping** and **12 traceroute** requests.

12 traceroute with IP address

You can specify an IP address as the destination address for the **12 traceroute** command. In this case, the IP address can be either a C-VLAN or a B-VLAN in the SPBM cloud.

The **12 traceroute** command converts Layer 3 IP information to an appropriate Layer 2 VLAN and MAC combination. The system can also target IP addresses that are not SPBM derived routes.

If you enable ECMP, **12 traceroute** runs internally for each of the VLAN paths returned, and displays a summary of the results. If you disable ECMP, the results display only one path.

Note

If you use the **12 traceroute ip-address** command on a DvR Leaf node, the output only shows DvR Controller IP addresses if the IP address or host route specified is unknown in the DvR domain.

Destination addresses for C-VLAN 12 traceroute and linktrace messages

For C-VLANs, CFM uses the following destination MAC addresses for the corresponding maintenance domain (MD) levels for **12 traceroute** and **linktrace** messages.

The switch supports both **12 traceroute** and **linktrace** for C-VLANs, as a best practice, use **12 traceroute**.

Table 261: MD levels and corresponding destination addresses for CFM for C-VLANs

CFM MD Level	Destination MAC address
0	01:80:c2:00:00:38
1	01:80:c2:00:00:39
2	01:80:c2:00:00:3a
3	01:80:c2:00:00:3b
4	01:80:c2:00:00:3c
5	01:80:c2:00:00:3d
6	01:80:c2:00:00:3e
7	01:80:c2:00:00:3f

L2 Tracetree

The **12 tracetree** command is a proprietary command that allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. This command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

Note

The VSP 4450 Series does not support the **12 tracetree** command on C-VLANs because no multicast tree exists on C-VLANs.

L2 Tracetree-fan

The **12 tracetree-fan** command allows a user to trigger an LTM on the internal Fabric Area Network I-SID. This command allows the user to trace the FAN tree.

Maintenance Domain Intermediate Point (MIP)

MIPs do not initialize any CFM messages. MIPs passively receive CFM messages, process the messages received and respond back to the originating MEP. By responding to received CFM messages, MIPs can support discovery of hop-by-hop path among MEPs, allow connection failures to be isolated to smaller segments of the network to help discover location of faults along the paths. MIPs can be created independent of MEPs. MIP functionality can be summarized as:

- Respond to Loopback (ping) messages at the same level as itself and addressed to it.
- Respond to Linktrace (traceroute) messages.
- Forward Linktrace messages after decrementing the TTL.

Layer 2 Tracemroute

The **12tracemroute** command is a proprietary command that allows the user to trace the multicast tree for a certain multicast flow. The user specifies source, group, and service context (either VLAN or VRF) for the multicast flow to trace.

CFM sends a multicast LTM using an internal calculation to map the source, group, and context to the corresponding target address. The LTR comes from all leaves of the multicast tree for that flow, as well as transit nodes. The target MAC used in the LTM is a combination of the data I-SID and the nickname and the packet is sent on the appropriate SPBM B-VLAN. The user can see the generated multicast tree for that flow, which includes the data I-SID and nickname.

Nodal MPs

Nodal MPs provide both MEP and MIP functionality for SPBM deployments. Nodal MPs are associated with a B-VLAN and are VLAN encapsulated packets. The Nodal MEP provides traceability and troubleshooting at the system level for a given B-VLAN. Each node (chassis) has a given MAC address and communicates with other nodes. The SPBM instance MAC address is used as the MAC address of the Nodal MP. The Nodal B-VLAN MPs supports eight levels of CFM and you configure the Nodal B-VLAN MPs on a per B-VLAN basis. Virtual SMLT 10 MAC addresses are also able to respond for LTM and LBM.

Nodal B-VLAN MEPs

The Nodal B-VLAN MEPs created on the CP and function as if they are connected to the virtual interface of the given B-VLAN. Because of this they are supported for both port and MLT based B-VLANs. To support this behavior a MAC Entry is added to the FDB and a new CFM data-path table containing the B-VLAN and MP level are added to direct CFM frames to the CP as required.

Nodal B-VLAN MIPs

The Nodal MIP is associated with a B-VLAN. VLAN and level are sufficient to specify the Nodal MIP entity. The Nodal MIP MAC address is the SPBM system ID for the node on which it resides. If the fastpath sends a message to the CP, the MIP responds if it is not the target and the MEP responds if it is the target.

Nodal B-VLAN MIPs with SMLT

When Nodal MEPs or MIPs are on SPBM B-VLANs the LTM code uses a unicast MAC DA. The LTM DA is the same as the target MAC address, which is the SPBM MAC address or the SMLT MAC address of the target node.

The switch supports SMLT interaction with SPBM. This is accomplished by using two B-VIDs into the core from each pair of SMLT terminating nodes. Both nodes advertise the Nodal B-MAC into the core on both B-VIDS. In addition each node advertises the SMLT virtual B-MAC on one of the two B-VLANs.

The Nodal MEP and MIP are expanded to respond to both the Nodal MAC address as well as the Virtual SMLT MAC address if both MACs are being advertised on its B-VLAN. In addition a source mode is added to the LTM and LBM command to use either the Nodal MAC or the SMLT virtual MAC address as the source MAC in the packet.

Configuration Considerations

When you configure CFM, be aware of the following configuration considerations.

General CFM

- A single switch has a limit of one MEP and one MIP on a C-VLAN or B-VLAN.
- The maintenance level for MEPs and MIPs on a given B-VID (in a network) must be configured to the same level for them to respond to a given CFM command.

- You can configure global CFM at only one MD level for each switch for each VLAN type.
- All nodal MEPs and MIPs are restricted to SPBM B-VLANs.
- SMLT Virtual MAC for C-VLAN does not exist, so the switch does not support this option for the **12 ping** and **12 traceroute** commands.

Autogenerated CFM

- Autogenerated MEPs are not unique across the entire network unless you configure the global MEP ID on each switch to a different value. You must configure a unique MEP ID at a global level, for CFM.
- A single switch can have only one autogenerated MEP or MIP for each B-VLAN or C-VLAN.

Explicit CFM

- Previous explicit CFM configurations of MDs, MAs and MEPs on SPBM B-VLANs continue to be supported. However, if you want to enable autogenerated CFM you must first remove the existing MEP and MIP on the SPBM B-VLAN.
- You can assign maintenance levels for each CFM SPBM MEP and MIP to each SPBM B-VLAN individually or you can assign maintenance levels and global MEPs for all SPBM VLANs by following the appropriate procedure:
 - [Assigning a MEP/MIP Level to an SPBM B-VLAN](#) on page 3522
 - [Assigning MEP/MIP Levels to SPBM B-VLANs Globally](#) on page 3523
 - [Configure CFM Nodal MEP](#) on page 3546

C-VLAN versus SPBM B-VLAN considerations

Important

Only VSP 4450 Series supports CFM configuration on C-VLANs.

CFM breaks the network into sections, called MEPs, so you can determine exactly where the problem exists.

The MEPs and MIPs configured for SPBM VLANs do not respond to CFM messages sent from C-MAC VLANs because the VLAN and packet encapsulation are different.

To forward customer traffic across the core network backbone, SPBM uses IEEE 802.1ah Provider Backbone Bridging (PBB) MAC-in-MAC encapsulation, which hides the customer MAC (C-MAC) addresses in a backbone MAC (B-MAC) address pair. MAC-in-MAC encapsulation defines a B-MAC destination address (BMAC-DA) and a B-MAC source address (BMAC-SA). In SPBM, each node populates its forwarding database (FDB) with the B-MAC information derived from the IS-IS shortest path tree calculations.

Typically the SPBM Backbone Core Bridges (BCBs) in the SPBM cloud only learn the B-MAC addresses. The Backbone Edge Bridges (BEBs) know the Customer MACs on the appropriate BEBs that terminate

the virtual services networks (VSNs). As such, the nodes within the SPBM cloud have no knowledge of the C-MAC addresses in the VSNs.

Important

To trace a route to a MAC address, the MAC address must be in the VLAN FDB table.

- For C-VLANs, you have to trigger an **l2 ping** to learn the C-MAC address.
- For B-VLANs, you do not have to trigger an **l2 ping** to learn the C-MAC address because IS-IS populates the MAC addresses in the FDB table.

In both cases, linktrace traces the path up to the closest device to that MAC address that supports CFM in the SPBM cloud.

C-VLAN source addresses

CFM uses either the VLAN MAC or the CFM C-MAC for the BMAC-SA for the C-VLANs. The CFM C-MAC is the value of the management base MAC, which ends in `0x64`. The system creates the VLAN MAC after a user adds an IP address to a VLAN.

If a VLAN has a MAC address, the system uses the VLAN MAC as the BMAC-SA by default. If a VLAN does not have a MAC address, the system uses the CFM C-MAC for the BMAC-SA. You may also configure the system to use the CFM C-MAC, even if a VLAN MAC exists.

CFM Configuration Using CLI

This section provides procedures to configure and use Connectivity Fault Management (CFM) using Command Line Interface (CLI). The Shortest Path Bridging MAC (SPBM) network needs a mechanism to debug connectivity issues and to isolate faults. This is performed at Layer 2, not Layer 3. To support troubleshooting of the SPBM cloud, the switch supports a subset of CFM functionality.

Note

When you enable CFM in an SBPM network, as a best practice, enable CFM on the Backbone Edge Bridges (BEB) and on all Backbone Core Bridges (BCB). If you do not enable CFM on a particular node, you cannot obtain CFM debug information from that node.

You can configure CFM using one of two modes: simplified or explicit. Both modes are described in the following sections, but the simplified mode should be used.

Note

If you enable the **cfm spbm enable** command, you cannot assign a MEP/MIP level to an individual SPBM B-VLAN or configure CFM MD maintenance levels individually.

Regardless of whether you have chosen to configure individually or globally, there is one MEP per SPBM B-VLAN and one MIP level per SPBM B-VLAN.

Autogenerated CFM

CFM provides two methods for configuration; autogenerated and explicit. You cannot use both. You must choose one or the other. Use the procedures in this section to configure autogenerated MEPs that eliminate the need to configure a MD, MA, and MEP ID to create a MEP.

- For SPBM B-VLANs, you can use either autogenerated or explicitly configured CFM MEPs.
- For C-VLANs, you can only use autogenerated CFM MEPs.

The CFM show commands that display MD, MA, and MEP information work for both autogenerated and explicitly configured CFM MEPs.

Previous explicit CFM configurations of MDs, MAs and MEPs on SPBM B-VLANs continue to function. However, if you want to enable the autogenerated commands you must first remove the existing MEP and MIP on the SPBM B-VLAN.

The switch only supports one MEP and one MIP, either autogenerated or explicitly configured, on the SPBM B-VLAN. Similarly, the switch only supports one MEP and one MIP on the C-VLAN. This means that if you want to use these autogenerated MEPs, you cannot use your existing CFM configuration. You must first remove the existing MEP or MIP on the SPBM B-VLAN.

For information on configuring autogenerated CFM using the CLI, see:

- [Configuring Autogenerated CFM on SPBM B-VLANs](#) on page 3515
- [Configure Autogenerated CFM on C-VLANs](#) on page 3517

Configuring Autogenerated CFM on SPBM B-VLANs

Use this procedure to configure the autogenerated CFM MEP and MIP level for every SPBM B-VLAN on the chassis. This eliminates the need to explicitly configure an MD, MA, and MEP ID, and to associate the MEP and MIP level to the SPBM B-VLAN.

When you enable this feature, the device creates a global MD (named `spbm`) for all the SPBM Nodal MEPs. This MD has a default maintenance level of 4, which you can change with the `level` attribute. All the MEPs that the device creates use the MEP ID configured under the global context, which has a default value of 1.

The nodal MEPs are automatically associated with the SPBM B-VLANs configured. The MIP level maps to the global level. When you enable the feature, the device automatically associates the MIP level with the SPBM B-VLANs configured. The feature is disabled by default.

Important

CFM supports one MEP or MIP for each SPBM B-VLAN only. This means that if you want to use these autogenerated MEPs, you cannot use your existing CFM configuration. You must first remove the existing MEP or MIP on the SPBM B-VLAN. If you want to continue configuring MEPs manually, skip this procedure.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the maintenance level for every CFM SPBM MEP and MP level on all the SPBM B-VLANs:
`cfm spbm level <0-7>`

You can change this level from the default of 4 either before or after the feature is enabled.

Only configure global CFM at one MD level for each chassis for each VLAN type.
3. Assign a global CFM MEP ID for all CFM SPBM MEPs:
`cfm spbm mepid <1-8191>`
4. Enable the autogenerated CFM for SPBM B-VLANs globally:
`cfm spbm enable`
5. (Optional) Configure the maintenance level for every CFM SPBM MEP and MP level on all the SPBM B-VLANs to the default:
`default cfm spbm level`
6. (Optional) Assign a global CFM MEP ID for all CFM SPBM MEPs to the default:
`default cfm spbm mepid`
7. (Optional) Disable the global CFM MEPs and MIPs:
`no cfm spbm enable`
8. Display the global CFM MEP configuration:
`show cfm spbm`

Example

Configure autogenerated CFM MEPs and MIPs:

```
Switch>enable
Switch#configure terminal
Switch(config)#cfm spbm level 6
Switch(config)#cfm spbm mepid 4
Switch(config)#cfm spbm enable
Switch(config)#show cfm spbm

LEVEL ADMIN      MEPID      MAC
=====
6          enable          4          00:15:e8:b8:a3:df
```

Variable Definitions

The following table defines parameters for the **cfm spbm** command.

Variable	Value
<i>level</i> <0-7>	Specifies the global SPBM CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type.
<i>mepid</i> <1-8191>	Specifies the global MEP ID within the range of 1-8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1.
<i>enable</i>	Enables autogenerated CFM on all SPBM B-VLANs.

Configure Autogenerated CFM on C-VLANs

Use this procedure to configure the autogenerated CFM MEP and MIP level for every C-VLAN on the chassis.

Note

For C-VLANs, you can only use autogenerated CFM MEPs.

Important

CFM supports one MEP or MIP for each C-VLAN. Only autogenerated CFM provides support for configuring MEP and MIPs on C-VLANs. You cannot explicitly configure C-VLANs.

About This Task

When you enable this feature, you create a global MD (named `cmac`) for all the customer MAC (C-MAC) MEPs. This global MD has a default maintenance level of 4, which you can change with the `level` attribute. The autogenerated CFM commands also create an MA for each C-VLAN, a MEP for each C-VLAN, associate the MEP with the corresponding C-VLAN, and a MIP with the C-VLAN.

All the MEPs that the device creates use the MEP ID configured under the global context, which has a default value of 1. The device automatically associates the MEPs with the C-VLANs configured. The MIP level maps to the global level. The device automatically associates the MIP level with the C-VLANs configured when you enable the feature.

The feature is disabled by default.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the maintenance level for every CFM C-MAC MEP and MP level on all the C-VLANs:

```
cfm cmac level <0-7>
```

Only configure global CFM at one MD level for each chassis for each VLAN type.
3. Assign a global CFM MEP ID for all CFM C-MAC MEPs:

```
cfm cmac mepid <1-8191>
```
4. Enable the autogenerated CFM for C-VLANs:

```
cfm cmac enable
```
5. (Optional) Configure the maintenance level for every CFM C-MAC MEPs and MP level on all the C-VLANs to the default:

```
default cfm cmac level
```
6. (Optional) Assign a global CFM MEP ID for all CFM C-MAC MEPs to the default:

```
default cfm cmac mepid
```
7. (Optional) Disable the global CFM MEPs and MIPs:

```
no cfm cmac enable
```
8. Display the global CFM MEP configuration:

```
show cfm cmac
```

Example

Configure autogenerated CFM MEPs and MIP level:

```
Switch>enable
Switch#configure terminal
Switch(config)#cfm cmac level 0
Switch(config)#cfm cmac mepid 4
Switch(config)#cfm cmac enable
Switch(config)#show cfm cmac

LEVEL ADMIN      MEPID      MAC
-----
0          enable      4          00:15:e8:b8:a3:de
```

Variable Definitions

The following table defines parameters for the **cfm cmac** command.

Variable	Value
<i>level</i> <0-7>	Specifies the global C-MAC CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type.
<i>mepid</i> <1-8191>	Specifies the global MEP ID within the range of 1-8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1. Note: The MA takes its name from this value for autogenerated CFM. For example, if you specify 500 as the MEP ID, the MA will also be 500.
<i>enable</i>	Enables autogenerated CFM for all C-MAC VLANs.

Configuring Explicit Mode CFM

In the explicit mode of configuring CFM, you can manually configure an MD, MA, MEP and then associate the MEP to a B-VLAN and assign a MIP level to a B-VLAN.

**Note**

If you use autogenerated CFM, these steps are unnecessary.

Configuring CFM MD

Use this procedure to configure the Connectivity Fault Management (CFM) Maintenance Domain (MD). An MD is the part of a network that is controlled by a single administrator. A single MD can contain several Maintenance Associations (MA).

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create the CFM MD:

```
cfm maintenance-domain WORD<0-22> [index <1-2147483647>] [maintenance-  
level <0-7>] [level <0-7>]
```

3. Display the CFM MD configuration:

```
show cfm maintenance-domain
```
4. Delete the CFM MD:

```
no cfm maintenance-domain WORD<0-22>
```

Example

```
Switch:1> enable

Switch:1# configure terminal

Switch:1(config)# cfm maintenance-domain mdl index 99 maintenance-level 3

Switch:1(config)# show cfm maintenance-domain
```

```

=====
                        Maintenance Domain
=====
Domain Name           Domain Index   Level Domain Type
-----
mdl                   99             3      NODAL
=====
Total number of Maintenance Domain entries: 1.
    
```

```
Switch:1(config)# no cfm maintenance-domain mdl
```

```

Switch:1(config)# show cfm maintenance-domain

=====
                        Maintenance Domain
=====
Domain Name           Domain Index   Level Domain Type
-----
=====
Total number of Maintenance Domain entries: 0.
    
```

Variable Definitions

The following table defines parameters for the **cfm maintenance-domain** command.

Variable	Value
<i>WORD</i> <0-22>	Specifies the maintenance domain name.
<i>index</i> <1-2147483647>	Specifies a maintenance domain entry index.
<i>maintenance-level</i> <0-7>	Specifies the MD maintenance level when creating the MD. The default is 4.
<i>level</i> <0-7>	Modifies the MD maintenance level for an existing MD. The default is 4.

Configuring CFM MA

Use this procedure to configure the CFM Maintenance Association (MA). An MA represents a logical grouping of monitored entities within its domain. It can therefore represent a set of Maintenance Association End Points (MEPs), each configured with the same Maintenance Association ID (MAID) and MD Level, established to verify the integrity of a single service instance.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Create the CFM MA:

```
cfm maintenance-association WORD<0-22> WORD<0-22> [index <1-2147483647>]
```
3. Display the CFM MA configuration:

```
show cfm maintenance-association
```
4. Use the following command, if you want to delete the CFM MA:

```
no cfm maintenance-association WORD<0-22> WORD<0-22>
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)# cfm maintenance-association mdl mal index 98
```

```
Switch:1(config)# show cfm maintenance-association
```

```
=====
Maintenance Association Status
=====
Domain Name      Assn Name      Domain Idx  Assn Idx
-----
mdl              mal            1           98

Total number of Maintenance Association entries: 1.

=====
Maintenance Association config
=====
Domain Name      Assn Name
-----
mdl              mal

Total number of MA entries: 1.
```

Variable Definitions

The following table defines parameters for the **cfm maintenance-association** command.

Variable	Value
<i>WORD<0-22> WORD<0-22></i>	Creates the CFM MA. The first parameter, specifies the MD name. The second parameter, specifies the MA short name.
<i>index <1-2147483647></i>	Specifies a maintenance association entry index.

Configuring CFM MEP

Use this procedure to configure the CFM Maintenance Endpoint (MEP). A MEP represents a managed CFM entity, associated with a specific Domain Service Access Point (DoSAP) of a service instance, which can generate and receive CFM Protocol Data Units (PDU) and track any responses. A MEP is created by MEP ID under the context of an MA.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Create the CFM MEP:

```
cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191> enable [state <enable>]
```
3. Enable an existing CFM MEP:

```
cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191> enable
```
4. Disable an existing CFM MEP:

```
no cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191> enable
```
5. Display the CFM MEP configuration:

```
show cfm maintenance-endpoint
```
6. Delete an existing CFM MEP:

```
no cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191>
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#cfm maintenance-endpoint md1 ma1 1 state enable
```

```
Switch:1(config)#show cfm maintenance-endpoint
```

Total number of MEP entries: 1.
```

Variable Definitions

The following table defines parameters for the **cfm maintenance-endpoint** command.

Variable	Value
<i>WORD</i> <0-22>	The first parameter, specifies the MD name.
<i>WORD</i> <0-22>	The second parameter, specifies the MA short name.
<1-8191>	Specifies the MEP ID.
<i>enable</i>	Enables an existing MEP. Use this parameter with the no option to disable an existing MEP.
<i>state {enable disable}</i>	Enables or disables the MEP when creating the MEP. The default is disabled.

Assigning a MEP/MIP Level to an SPBM B-VLAN

Use this procedure to assign a nodal MEP to an SPBM B-VLAN. The Nodal MEP provides traceability and troubleshooting at the system level for a given B-VLAN. The Nodal B-VLAN MEPs created on the CP and function as if they are connected to the virtual interface of the given B-VLAN. Because of this they are supported for both port and MLT based B-VLANs.

Nodal MPs provide both MEP and MIP functionality for SPBM deployments. Nodal MPs are associated with a B-VLAN and are VLAN encapsulated packets. Each node (chassis) has a given MAC address and communicates with other nodes. The SPBM instance MAC address is used as the MAC address of the Nodal MP.

Before You Begin

- You must configure a CFM MD, MA, and MEP.

Procedure

- Add nodal MEPs to the B-VLAN:

```
vlan nodal-mep <1-4059> WORD<0-22> WORD<0-22> <1-8191>
```
- Display the nodal MEP configuration:

```
show vlan nodal-mep <1-4059>
```
- Remove the nodal MEPs from the B-VLAN:

```
no vlan nodal-mep <1-4059> WORD<0-22> WORD<0-22> <1-8191>
```
- Add nodal MIP level to the B-VLAN:

```
vlan nodal-mip-level <1-4059> WORD<0-15>
```
- Display the nodal MIP level configuration:

```
show vlan nodal-mip-level [<1-4059>]
```
- Remove the nodal MIP level from the B-VLAN:

```
no vlan nodal-mip-level <1-4059> WORD<0-15>
```

Example

```
Switch:1> enable

Switch:1# configure terminal

Switch:1(config)# vlan nodal-mep 100 md1 ma1 2
```

```
Switch:1(config)# show vlan nodal-mep
```

```
=====
                                Vlan Nodal Mep

```

Variable Definitions

The following table defines parameters for the **vlan nodal-mep** command.

Variable	Value
<1-4059>	Specifies the VLAN ID.
WORD<0-22>	The first parameter, specifies the Maintenance Domain name.
WORD<0-22>	The second parameter, specifies the Maintenance Association name.
<1-8191>	Specifies the nodal MEPs to add to the VLAN.

The following table defines parameters for the **vlan nodal-mip-level** command.

Variable	Value
<1-4059>	Adds the nodal MIP level. Specifies the VLAN ID.
WORD<0-15>	Adds the nodal MIP level, which has up to eight levels, ranging from 0 to 7.

Assigning MEP/MIP Levels to SPBM B-VLANs Globally

Note

If you enable the **cfm spbm enable** command, you cannot assign a MEP/MIP level to an individual SPBM B-VLAN or configure CFM MD maintenance levels individually.

About This Task

Enables the global CFM MEP and MIPs for all SPBM B-VLANs.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable simplified CFM configuration for SPBM VLANs:

```
cfm spbm enable
```
3. Enter the CFM SPBM level:

```
cfm spbm level <0-7>
```
4. Enter the CFM SPBM MEPID level:

```
cfm spbm mepid <1-8191>
```

Example

```
Switch:1(config)# cfm spbm level 7
Switch:1(config)# cfm spbm mepid 12
Switch:1(config)# cfm spbm enable
```

Variable Definitions

The following table defines parameters for the **simplified CFM** commands.

Variable	Value
<i>spbm level <0-7></i>	Configures the maintenance level for every CFM SPBM MEP and MIP level on all SPBM B-VLANs. The default is 4.
<i>mepid <1-8191></i>	Assigns a global MEP ID for all CFM SPBM MEPs. The default is 1.
<i>no cfm spbm enable</i>	Disables global configuration of CFM SPBM MEP and MIP levels on all SPBM B-VLANs.
<i>default cfm spbm level</i>	Returns maintenance level to default for all CFM SPBM MEP and MIP level on all SPBM B-VLANs.
<i>default cfm spbm mepid</i>	Returns MEP ID for all CFM SPBM MEPs to default.
<i>show cfm spbm</i>	Displays the global CFM MEP configuration for SPBM B-VLANs.

Trigger a Loopback Test (LBM)

Use this procedure to trigger a loopback test.

The LBM packet is often compared to ping. An MEP transmits the loopback message to an intermediate or endpoint within a domain for the purpose of fault verification. This can be used to check the ability of the network to forward different sized frames.

Note

Product Notice: This procedure does not apply to VSP 8600 Series.

Before You Begin

- You must have a MEP that is associated with a B-VLAN.

Procedure

Trigger the loopback test:

```
loopback WORD<0-22> WORD<0-22> <1-8191> <0x00:0x00:0x00:0x00:0x00:0x00>
[burst-count <1-200>] [data-tlv-size <0-400>] [frame-size <64-1500>]
[interframe-interval <msecs>] [priority <0-7>] [source-mode {nodal|
noVlanMac|smltVirtual}][testfill-pattern <all-zero|all-zero-crc|pseudo-
random-bit-sequence|pseudo-random-bit-sequence-crc>] [time-out <1-10>]
```

Example

```
Switch:1# loopback mdl 4001 13 00:14:0D:A2:B3:DF burst-count 10 priority
3 time-out 5
```

```
Result of LBM from mep: spbm.bvlan1000.8 to MAC address: 00:66:00:66:00:66 :
Sequence number of the first LBM is 150404162
The total number of LBMs sent out is 1
The number of LBRs received is 1
The number of LBRs lost is 0
The percentage of LBMs lost is 0.00%
The RTT Min is 15071 microseconds, Max is 15071 microseconds, Average is 15071.00 microseconds
The Standard Deviation of RTT is 0.00 microseconds
```

Variable Definitions

The following table defines parameters for the **loopback** command.

Variable	Value
<i>WORD<0-22></i>	The first parameter, specifies the MD name.
<i>WORD<0-22></i>	The second parameter, specifies the MA name.
<i><1-8191></i>	Specifies the MEP ID.
<i><0x00:0x00:0x00:0x00:0x00:0x00></i>	Specifies the remote MAC address to reach the MEP/MIP.
<i>burst-count <1-200></i>	Specifies the burst-count.
<i>data-tlv-size <0-400></i>	Specifies the data TLV size.
<i>frame-size <64-1500></i>	Specifies the frame-size. The default is 0.
<i>priority <0-7></i>	Specifies the priority. The default is 7.
<i>source-mode {nodal noVlanMac smltVirtual}]]</i>	Specifies the source mode: <ul style="list-style-type: none"> nodal noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the B-MAC-SA. smltVirtual—Use this value with B-VLANs only. The default is nodal.

Variable	Value
<code>testfill-pattern {all-zero all-zero-crc pseudo-random-bit-sequence pseudo-random-bit-sequence-crc}</code>	<p>Specifies the testfill pattern:</p> <ul style="list-style-type: none"> all-zero — null signal without cyclic redundancy check all-zero-crc — null signal with cyclic redundancy check with 32-bit polynomial pseudo-random-bit-sequence — pseudo-random-bit-sequence without cyclic redundancy check pseudo-random-bit-sequence-crc — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors. The default is 1: all-zero.</p>
<code>time-out <1-10></code>	Specifies the time-out interval in seconds. The default is 3.

Trigger Linktrace (LTM)

Use the following procedure to trigger a linktrace.

The Linktrace Message is often compared to traceroute. An MEP transmits the Linktrace Message packet to a maintenance endpoint with intermediate points responding to indicate the path of the traffic within a domain for the purpose of fault isolation. The packet specifies the target MAC address of an MP, which is the SPBM system ID or the virtual SMLT MAC. MPs on the path to the target address respond with an LTR.

Note

Product Notice: This procedure does not apply to VSP 8600 Series.

Before You Begin

- You must have a MEP that is associated with a VLAN.

Procedure

Trigger the linktrace:

```
linktrace WORD<0-22> WORD<0-22> <1-8191> <0x00:0x00:0x00:0x00:0x00:0x00>
[detail] [priority <0-7>] [source-mode <nodal|noVlanMac|smltVirtual>]
[ttl-value <1-255>]
```

Example

```
Switch:1# linktrace mdl 4001 13 00:bb:00:00:14:00 priority 7
```

```
Please wait for LTM to complete or press any key to abort
```

```
Received LTRs:
```

```
SeqNum: 10575 MD: mdl MA:4001 MepId: 13 Priority: 7
```

```
-----
TTL SRC MAC FWDYES TERMMEP RELAY ACTION
-----
63 00:bb:00:00:10:00 true false Fdb
62 00:bb:00:00:14:00 false true Hit
```

Variable Definitions

The following table defines parameters for the **linktrace** command.

Variable	Value
<i>WORD</i> <0-22>	The first parameter, specifies the MD name.
<i>WORD</i> <0-22>	The second parameter, specifies the MA name.
<1-8191>	Specifies the MEP ID.
<0x00:0x00:0x00:0x00:0x00:0x00>	Specifies the target MAC address to reach the MEP.
<i>detail</i>	Displays linktrace result details.
<i>priority</i> <0-7>	Specifies the priority. The default is 7.
<i>source-mode</i> { <i>nodal</i> <i>noVlanMac</i> <i>smltVirtual</i> }]	Specifies the source mode: <ul style="list-style-type: none"> • 1: nodal • noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the B-MAC-SA. • 2: smltVirtual—Use this value with B-VLANs only. The default is 1: nodal.
<i>tvl-value</i> <1-255>	Specifies the Time-to-Live value. The default is 64.

Trigger a Layer 2 Ping

Use this procedure to trigger a Layer 2 ping, inside an SPBM cloud or network, which acts like native **ping**. This feature enables CFM to debug Layer 2. It can also help you debug IP shortcuts and the record for the shortcuts' ARP.

Before You Begin

- You must have a MEP that is associated with a VLAN.

Procedure

Trigger a Layer 2 ping:

```
12 ping {vlan <1-4059> routernodename WORD<0-255> | vlan <1-4059> mac
<0x00:0x00:0x00:0x00:0x00:0x00>} [burst-count <1-200>] [data-tlv-size
<0-400>] [frame-size <64-1500>] [priority <0-7>] [source-mode <nodal|
smltVirtual>] [testfill-pattern <all-zero|all-zero-crc|pseudo-random-
bit-sequence|pseudo-random-bit-sequence-crc>] [time-out <1-10>]
```

OR

```
12 ping {ip-address WORD<0-255>} [burst-count <1-200>] [data-tlv-size
<0-400>] [frame-size <64-1500>] [priority <0-7>] [source-mode <nodal|
smltVirtual>] [testfill-pattern <all-zero|all-zero-crc|pseudo-random-
bit-sequence|pseudo-random-bit-sequence-crc>] [time-out <1-10>] [vrf
WORD<1-16>]
```

Example

```
Switch:1# l2 ping vlan 2 mac 00.14.0d.bf.a3.df
```

```
Please wait for l2ping to complete or press any key to abort
----00:14:0d:bf:a3:df L2 PING Statistics---- 0(68) bytes of data
1 packets transmitted, 0 packets received, 100.00% packet loss
```

```
Switch:1# l2 ping vlan 2 routernodename MONTIO
```

```
Please wait for l2ping to complete or press any key to abort

----00:14:0d:a2:b3:df L2 PING Statistics---- 0(68) bytes of data
1 packets transmitted, 1 packets received, 0.00% packet loss
round-trip (us) min/max/ave/stdv = 26895/26895/26895.00/ 0.00
```

```
Switch:1# l2 ping ip-address 192.0.2.10
```

```
Please wait for l2ping to complete or press any key to abort

```

Variable Definitions

The following table defines parameters to configure the Layer 2 ping parameters.

Variable	Value
<i>{vlan <1-4059></i> <i>routernodename WORD<0-255> }</i> <i>{vlan <1-4059> mac</i> <i><0x00:0x00:0x00:0x00:0x00:0x00> }</i> <i>{ip-address WORD<0-255> }</i>	Specifies the destination for the Layer 2 ping: <ul style="list-style-type: none"> <i><1-4059></i> – Specifies the VLAN ID. <i>WORD<0-255></i> – Specifies the Router node name. <i><XX:XX:XX:XX:XX:XX></i> – Specifies the MAC address. <i><A.B.C.D></i> – Specifies the IP address.
<i>burst-count <1-200></i>	Specifies the burst count.
<i>data-tlv-size <0-400></i>	Specifies the data TLV size. The default is 0.
<i>frame-size <64-1500>]</i>	Specifies the frame size. The default is 0.
<i>testfill-pattern <all-zero </i> <i>all-zero-crc pseudo-random-</i> <i>bit-sequence pseudo-random-</i> <i>bit-sequence-crc></i>	Specifies the testfill pattern: <ul style="list-style-type: none"> <i>all-zero</i> – null signal without cyclic redundancy check <i>all-zero-crc</i> – null signal with cyclic redundancy check with 32-bit polynomial <i>pseudo-random-bit-sequence</i> – pseudo-random-bit-sequence without cyclic redundancy check <i>pseudo-random-bit-sequence-crc</i> – pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors. The default is all-zero.</p>
<i>priority <0-7></i>	Specifies the priority. The default is 7.

Variable	Value
<code>time-out <1-10></code>	Specifies the interval in seconds. The default is 3.
<code>source-mode{nodal smltVirtual}] </code>	Specifies the source mode: <ul style="list-style-type: none"> • 1: nodal • 2: smltVirtual—Use this value with B-VLANs only. The default is 1: nodal.
<code>vrf WORD<1-16></code>	Specifies the VRF name.

Trigger a Layer 2 Traceroute

Note

This procedure does not apply to XA1400 Series.

Use this procedure to trigger a Layer 2 traceroute, which acts like native **traceroute**. This feature enables CFM to debug Layer 2 in an SPBM cloud or network. It can determine the path used by IS-IS to get from one MEP to another, by showing all the hops between. Therefore, it can show where connectivity is lost. It can also work for IP shortcuts.

Important

To trace a route to a MAC address, the MAC address must be in the VLAN FDB table.

- For B-VLANs, you do not have to trigger an **l2ping** to learn the MAC address because IS-IS populates the MAC addresses in the FDB table.

linktrace traces the path up to the closest device to that MAC address that supports CFM.

Before You Begin

- You must have a MEP that is associated with a VLAN.

Procedure

Trigger a Layer 2 traceroute:

```
12 traceroute {ip-address WORD<0-255>} [ttl <1-255>] [vrf WORD<1-16>]
```

```
12 traceroute {<vlan <1-4059> routernodename WORD<0-255> | <vlan <1-4059> mac <0x00:0x00:0x00:0x00:0x00:0x00>} [priority <0-7>] [source-mode <nodal|smltVirtual>] [ttl <1-255>]
```

Examples

```
Switch:1#12 traceroute vlan 2 routernodename Switch-MONTIO
Please wait for l2traceroute to complete or press any key to abort

12traceroute to Switch-MONTIO (00:14:0d:a2:b3:df), vlan 2
0 Switch-PETER4 (00:15:9b:11:33:df)
1 Switch-MONTIO (00:14:0d:a2:b3:df)

Switch:1#12 traceroute ip-address 192.0.2.10
Please wait for l2trace to complete or press any key to abort

L2 Trace Statistics : IP 192.0.2.10, paths found 1
=====
```

```
Switch-SHAMIM (00:1a:8f:08:53:df), vlan 2
0 Switch-PETER4 (00:15:9b:11:33:df)
1 Switch-MONTIO (00:14:0d:a2:b3:df)
```

Variable Definitions

The following table defines parameters for the **12 traceroute** command.

Variable	Value
<code>{vlan <1-4059></code> <code>routernodename WORD<0-255> }</code> <code>{vlan <1-4059>mac</code> <code><0x00:0x00:0x00:0x00:0x00:0</code> <code>x00> }</code> <code>{ip-address WORD<0-255> }</code>	Specifies the destination for the Layer 2 traceroute: <ul style="list-style-type: none"> • <code><1-4059></code> – Specifies the VLAN ID • <code>WORD<0-255></code> – Specifies the Router Node Name • <code><XX:XX:XX:XX:XX:XX></code> – Specifies the MAC address • <code>WORD<0-255></code> – Specifies the IP address
<code>ttl-value <1-255></code>	Specifies the TTL value. The default is 64.
<code>priority <0-7></code>	Specifies the priority. The default is 7.
<code>source-mode{nodal </code> <code>smltVirtual}} </code>	Specifies the source mode: <ul style="list-style-type: none"> • 1: nodal • 2: smltVirtual—Use this value with B-VLANs only. The default is 1: nodal.
<code>vrf WORD<1-16</code>	Specifies the VRF name.

Trigger a Layer 2 Tracetree

Note

This procedure does not apply to XA1400 Series.

Use this procedure to trigger a Layer 2 tracetree. Layer 2 tracetree allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. The command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

Note

This command is supported on SPBM B-VLANs only, not C-VLANs.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

Procedure

Trigger a Layer 2 tracetree:

```
12 tracetree {<1-4059> <1-16777215> [routernodename WORD<0-255> |
<1-4059> <1-16777215>] [mac <0x00:0x00:0x00:0x00:0x00:0x00>]} [priority
<0-7>] [source-mode <nodal|noVlanMac|smltVirtual>] [ttl-value <1-255>]
```

Example

```
Switch:1#l2 tracetree 500 1
Switch:1# l2 tracetree 500 1

Please wait for l2tracetree to complete or press any key to abort

l2tracetree to 53:55:10:00:00:01, vlan 500 i-sid 1 nickname 5.55.10
hops 64
1   Switch-PETER4          00:15:9b:11:33:df -> Switch-MONTI0          00:14:0d:a2:b3:df
2   Switch-MONTI0          00:14:0d:a2:b3:df -> Switch-LEE2             00:15:e8:b8:a3:df
```

Variable Definitions

The following table defines parameters for the **l2 tracetree** command.

Variable	Value
{ <1-4059><1-16777215> routernodename WORD<0-255> <1-4059><1-16777215> mac <0x00:0x00:0x00:0x00:0x00:0x00>}	<ul style="list-style-type: none"> • <1-4059> – Specifies the VLAN ID. • <1-16777215> – Specifies the I-SID. • WORD<0-255> – Specifies the Router Node Name. • <0x00:0x00:0x00:0x00:0x00:0x00> – Specifies the MAC address.
ttl-value <1-255>	Specifies the TTL value. The default is 64.
priority <0-7>	Specifies the priority value. The default is 7.
source-mode<nodal noVlanMac smltVirtual>	Specifies the source mode. The default is nodal.

Triggering a Layer 2 Tracetree-fan

About This Task

Use this procedure to trigger a Layer 2 tracetree-fan from the nickname server to make sure that all the nodes towards the nickname client support the FAN protocol. Layer 2 tracetree-fan allows a user to trigger an LTM on the internal Fabric Area Network (FAN) I-SID. This command allows the user to trace the FAN tree.

Procedure

Trigger a Layer 2 tracetree-fan:

```
l2 tracetree-fan [mac <0x00:0x00:0x00:0x00:0x00:0x00>] [priority <0-7>]
[routernodename WORD<0-255>] [ttl-value <1-255>]
```

Example

```
Switch:1# l2 tracetree-fan

Switch:1# l2 tracetree-fan

Please wait for l2tracetree to complete or press any key to abort

l2tracetree to b1:ad:aa:41:b0:84, vlan 4051 i-sid 16777001 nickname 0.00.00 hops 64
1   Switch-PETER4          b0:ad:aa:41:b0:84 -> Switch-MONTI0          b0:ad:aa:41:48:84
```

1	Switch-PETER4	b0:ad:aa:41:b0:84 -> Switch-MONTI1	b0:ad:aa:42:88:84
2	Switch-MONTI0	b0:ad:aa:41:48:84 -> Switch-LEE2	b0:ad:aa:43:3c:84

Trigger a Layer 2 Tracemroute

Note

This procedure does not apply to XA1400 Series.

Use this procedure to debug the IP Multicast over Fabric Connect stream path using **12 tracemroute** on the VLAN (Layer 2) or the VRF (Layer 3). This procedure queries the SPBM multicast module to determine the B-VLAN, I-SID and nickname for the S and G streams. The nickname and I-SID are used to create a multicast MAC address.

Note

The VLAN option is only valid for a VLAN that has an I-SID configured and IGMP snooping enabled.

Before You Begin

- On the source and destination nodes, you must configure an autogenerated or an explicit CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Trigger a Layer 2 tracemroute on the VLAN:

```
12 tracemroute source <A.B.C.D> group <A.B.C.D> vlan <1-4059>[priority <0-7>] [ttl-value <1-255>]
```

Note

For the preceding command, if you do not specify a VLAN, **12 tracemroute** uses the global default VRF.

Wait for the I2 tracemroute to complete or press any key to abort.

3. Trigger a Layer 2 tracemroute on the VRF:

```
12 tracemroute source <A.B.C.D> group <A.B.C.D> vrf WORD<1-16> [priority <0-7>] [ttl-value <1-255>]
```

Note

For the preceding command, if you do not specify a VRF, **12 tracemroute** uses the global default VRF.

Wait for the I2 tracemroute to complete or press any key to abort.

Examples

The following is a sample output for a Layer 2 tracemroute on a VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#12 tracemroute source 192.0.2.81 233.252.0.1 vlan 201

Please wait for l2 tracemroute to complete or press any key to abort.

Source 192.0.2.81

Group: 233.252.0.1

VLAN:201

BMAC: 03:00:03:f4:24:01

B-VLAN: 10

I-SID: 16000001

=====
1 PETER4 00:03:00:00:00:00 -> LEE1 00:14:0d:bf:a3:df
2 LEE1 00:14:0d:bf:a3:df -> LEE2 00:15:e8:b8:a3:df
```

The following is a sample output for a Layer 2 tracemroute on a VRF:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#12 tracemroute source 192.0.2.10 group 233.252.0.1 vrf red

Please wait for l2 tracemroute to complete or press any key to abort.

Source 192.0.2.10

Group: 233.252.0.1

VRF: redID 1

BMAC: 03:00:04:f4:24:01

B-VLAN: 20

I-SID: 16000001

```

Variable Definitions

The following table defines parameters for the **12 tracemroute** command.

Variable	Value
<i>source</i> <A.B.C.D>	Specifies the source IP address.
<i>group</i> <A.B.C.D>	Specifies the IP address of the multicast group.
<i>vlan</i> <1-4084>	Specifies the VLAN value.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies the VRF name. If you do not specify a VRF name, then the results are shown for the flow in the Global Router (default) context.
<code>priority <0-7></code>	Specifies the priority value.
<code>ttl <1-255></code>	Specifies the time-to-live (TTL) for the trace packet, which is how many hops the trace packet takes before it is dropped.

Using trace CFM to Diagnose Problems

Use the following procedure to display trace information for CFM.

About This Task

Use trace to observe the status of a software module at a certain time.

For example, if you notice a CPU utilization issue (generally a sustained spike above 90%) perform a trace of the control plane activity.

Use the **trace level 120 <0-4>** command to trace CFM module information, including CLI, instrumentation, show config, and platform dependent code. The CFM module ID is 120.

Use the **trace cfm level <0-4>** command to trace platform independent code and CFM protocol code.

Caution

Risk of traffic loss

Using the trace tool inappropriately can cause primary CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Clear the trace:

```
clear trace
```

3. Begin the trace operation:

```
trace cfm level <0-4>
```

Wait approximately 30 seconds, and then stop trace.

4. Stop tracing:

```
trace shutdown
```

5. View the trace results:

```
show trace cfm
```

6. Begin the trace operation for the CFM module:

```
trace level 120 <0-4>
```

Wait approximately 30 seconds, and then stop trace.

7. View trace results:

```
trace screen enable
```

Important

If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

8. Save the trace file to the Compact Flash card for retrieval.

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt. By default, the system saves the file to the external flash.

9. Search trace results for a specific string value, for example, the word error:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# clear trace
Switch:1(config)# trace cfm level 3
Switch:1(config)# trace shutdown
Switch:1(config)# show trace cfm
=====
                        CFM Tracing Info
=====
Status      : Enabled
Level       : VERBOSE
Switch:1(config)#trace level 120 3
Switch:1(config)# save trace
Switch:1(config)# trace grep error
Switch:1(config)#trace grep 00-1A-4B-8A-FB-6B
```

Variable Definitions

The following table defines parameters for the **trace** command.

Variable	Value
<i>cfm level</i> [<0-4>]	Starts the trace by specifying the level. <ul style="list-style-type: none"> • <0-4> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<i>filter</i>	Configures a filter trace for a file or module.

Variable	Value
<code>flags</code>	Configures trace flags for IS-IS or OSPF.
<code>grep [WORD<0-128>]</code>	Searches trace results for a specific string value, for example, the word error. Performs a comparison of trace messages.
<code>level [<Module_ID>] [<0-4>]</code>	Starts the trace by specifying the module ID and level. <ul style="list-style-type: none"> <code><Module_ID></code> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the show trace modid-list command or CLI command completion Help. <code><0-4></code> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<code>route-map</code>	Enables or disables the trace route-map. The values are on and off.
<code>screen {disable enable}</code>	Enables the display of trace output to the screen.
<code>shutdown</code>	Stops the trace operation.
<code>spbm isis level [<0-4>]</code>	Starts the trace by specifying the level. <ul style="list-style-type: none"> <code><0-4></code> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose. <p>The default is 1, very terse.</p>

The following table defines parameters for the **save trace** command.

Variable	Value
<code>file WORD<1-99></code>	Specifies the file name in one of the following formats: <ul style="list-style-type: none"> <code>a.b.c.d:<file></code> <code>x:x:x:x:x:x:<file></code> <code>/intflash/<file></code> <code>/extflash/<file></code> <code>/usb/<file></code> <code>/mnt/intflash/ <file></code> <code>/mnt/extflash/ <file></code> <p><code>/mnt/intflash</code> is the internal flash of the CPU. <code>/mnt/extflash</code> is the external flash of the CPU.</p>

Using trace SPBM to Diagnose Problems

Use the following procedure to display trace information for SPBM IS-IS. In the case of IS-IS, this procedure also provides information related to the flags set.

About This Task

Use the **trace level 119 <0-4>** command to trace IS-IS module information, including CLI, instrumentation, show config and platform dependent code. The IS-IS module ID is 119.

Use the **trace level 125 <0-4>** command to trace SPBM module information, including CLI, instrumentation, show config and platform dependent code. The SPBM module ID is 125.

Use the **trace spbm isis level** command to trace platform independent code, IS-IS protocol, IS-IS hello, IS-IS adjacency, LSP processing, and IS-IS computation.

Caution Risk of traffic loss

Using the trace tool inappropriately can cause primary CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Clear the trace:

```
clear trace
```

3. Begin the trace operation:

```
trace spbm isis level <0-4>
```

Wait approximately 30 seconds, and then stop trace.

4. Stop tracing:

```
trace shutdown
```

5. Display the trace information for SPBM IS-IS:

```
show trace spbm isis
```

6. Begin the trace operation for the SPBM module:

```
trace level 125 <0-4>
```

Wait approximately 30 seconds, and then stop trace.

7. Begin the trace operation for the IS-IS module:

```
trace level 119 <0-4>
```

Wait approximately 30 seconds, and then stop trace.

8. View trace results:

```
trace screen enable
```

Important

If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

9. Save the trace file to the Compact Flash card for retrieval.

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt. By default, the system saves the file to the external flash.

10. Search trace results for a specific string value, for example, the word error:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# clear trace
Switch:1(config)# trace spbm isis level 3
Switch:1(config)# trace shutdown
Switch:1(config)# show trace spbm isis
=====
                        SPBM ISIS Tracing Info
=====
Status      : Enabled
Level       : VERY_TERSE
Flag Info   :
Switch:1(config)#trace level 125 3
Switch:1(config)#trace level 119 3
Switch:1(config)# save trace
Switch:1(config)# trace grep error
Switch:1(config)#trace grep 00-1A-4B-8A-FB-6B
```

Variable Definitions

The following table defines parameters for the **trace** command.

Variable	Value
<i>cfm level</i> [<0-4>]	Starts the trace by specifying the level. <ul style="list-style-type: none"> <0-4> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<i>filter</i>	Configure a filter trace for a file or module.
<i>flags</i>	Configure trace flags for IS-IS or OSPF.
<i>grep</i> [WORD<0-128>]	Searches trace results for a specific string value, for example, the word error. Performs a comparison of trace messages.

Variable	Value
<code>level [<Module_ID>] [<0-4>]</code>	<p>Starts the trace by specifying the module ID and level.</p> <ul style="list-style-type: none"> • <code><Module_ID></code> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the show trace modid-list command or CLI command completion Help. • <code><0-4></code> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<code>route-map</code>	Enables or disables the trace route-map. The values are on and off.
<code>screen {disable enable}</code>	Enables the display of trace output to the screen.
<code>shutdown</code>	Stops the trace operation.
<code>spbm isis level [<0-4>]</code>	<p>Starts the trace by specifying the level.</p> <ul style="list-style-type: none"> • <code><0-4></code> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose. <p>The default is 1, very terse.</p>

The following table defines parameters for the **save trace** command.

Variable	Value
<code>file WORD<1-99></code>	<p>Specifies the file name in one of the following formats:</p> <ul style="list-style-type: none"> • <code>a.b.c.d:<file></code> • <code>x:x:x:x:x:x:<file></code> • <code>/intflash/<file></code> • <code>/extflash/<file></code> • <code>/usb/<file></code> • <code>/mnt/intflash/ <file></code> • <code>/mnt/extflash/ <file></code> <p><code>/mnt/intflash</code> is the internal flash of the CPU. <code>/mnt/extflash</code> is the external flash of the CPU.</p>

CFM Configuration Using EDM

This section provides procedures to configure Connectivity Fault Management (CFM) using Enterprise Device Manager (EDM).

Note

When you enable CFM in an SPBM network, as a best practice, enable CFM on the Backbone Edge Bridges (BEB) and on all Backbone Core Bridges (BCB). If you do not enable CFM on a particular node, you cannot obtain CFM debug information from that node.

Autogenerated CFM

CFM provides two methods for creating MEPs: autogenerated and explicit. You cannot use both. You must choose one or the other. Use the procedures in this section to configure autogenerated MEPs that eliminate the need to configure an MD, MA, and MEP ID to create a MEP.

- For SPBM B-VLANs, you can use either autogenerated or explicitly configured CFM MEPs.
- For C-VLANs, you can only use autogenerated CFM MEPs.

Previous explicit CFM configurations of MDs, MAs and MEPs on SPBM B-VLANs continue to function. However, if you want to enable the autogenerated commands, you must first remove the existing MEP and MIP on the SPBM B-VLAN. The switch only supports one MEP or MIP on the SPBM B-VLAN, either explicitly configured or autogenerated.

For autogenerated CFM configuration information for EDM, see the following tasks:

- [Configure Autogenerated CFM on SPBM B-VLANs](#) on page 3540
- [Configure Autogenerated CFM on C-VLANs](#) on page 3541

Configure Autogenerated CFM on SPBM B-VLANs

Use this procedure to configure the autogenerated CFM MEP and MIP level for every SPBM B-VLAN on the chassis. This configuration eliminates the need to explicitly configure an MD, MA, and MEP ID and to associate the MEP and MIP level to the SPBM B-VLAN.

To configure autogenerated CFM on C-VLANs, see [Configure Autogenerated CFM on C-VLANs](#) on page 3541.

About This Task

When you enable this feature, the device creates a global MD (named `spbm`) for all the SPBM Nodal MEPs. This MD has a default maintenance level of 4, which you can change with the `level` attribute. All the MEPs that the device creates use the MEP ID configured under the global context, which has a default value of 1. The nodal MEPs are automatically associated with the SPBM B-VLANs configured. The MIP level maps to the global level. When you enable the feature, the device automatically associates the MIP level with the SPBM B-VLANs configured. The feature is disabled by default.

Important

CFM supports one MEP or MIP for each SPBM B-VLAN only. This means that if you want to use these autogenerated MEPs, you cannot use your existing CFM configuration. You must first remove the existing MEP or MIP on the SPBM B-VLAN. If you want to continue configuring MEPs manually, skip this procedure.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **CFM**.
3. Select the **Global** tab.
4. Select **enable** next to **SpbmAdminState**.
5. Select **Apply**.

Global Field Descriptions

Use the data in the following table to configure the global MEP and MIP parameters.

Name	Description
SpbmAdminState	Enables or disables autogenerated CFM for B-VLANs. The default is disable.
SpbmLevel	Specifies the global SPBM CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type.
SpbmMepld	Specifies the global MEP ID within the range of 1 to 8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1.
CmacAdminState	Enables or disables autogenerated CFM for C-VLANs. The default is disable. This field does not apply for all hardware platforms.
CmacLevel	Specifies the global C-MAC CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type. This field does not apply for all hardware platforms.
CmacMepld	Specifies the global MEP ID within the range of 1 to 8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1. This field does not apply for all hardware platforms.
Bmac	Displays the B-MAC address of the node. This field does not apply for all hardware platforms.
Cmac	Displays the C-MAC address of the node. This field does not apply for all hardware platforms.

Configure Autogenerated CFM on C-VLANs

Use this procedure to configure the autogenerated CFM MEP and MIP level for every C-VLAN on the chassis.

To configure autogenerated CFM on SPBM B-VLANs, see [Configure Autogenerated CFM on SPBM B-VLANs](#) on page 3540.

Note

For C-VLANs, you can only use autogenerated CFM MEPs.

Important

CFM supports one MEP or MIP on each C-VLAN. Only autogenerated CFM provides support for configuring MEP and MIPs on C-VLANs. You cannot explicitly configure C-VLANs.

About This Task

When you enable this feature, you create a global MD (named `cmac`) for all the customer MAC (C-MAC) MEPs. This MD has a default maintenance level of 4, which you can change with the `level` attribute. The autogenerated CFM commands also create an MA for each C-VLAN, a MEP for each C-VLAN, and associate the MEP with the corresponding C-VLAN and a MIP with the C-VLAN.

All the MEPs that the device creates use the MEP ID configured under the global context, which has a default value of 1. The device automatically associates the MEPs with the C-VLANs configured. The MIP level maps to the global level. The device automatically associates the MIP level with the C-VLANs configured when you enable the feature.

The feature is disabled by default.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **CFM**.
3. Select the **Global** tab.
4. Select **enable** next to **CmacAdminState**.
5. In the fields provided, specify a maintenance level and a MEP ID.
6. Select **Apply**.

Global Field Descriptions

Use the data in the following table to configure the global MEP and MIP parameters.

Name	Description
SpbmAdminState	Enables or disables autogenerated CFM for B-VLANs. The default is disable.
SpbmLevel	Specifies the global SPBM CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type.
SpbmMepld	Specifies the global MEP ID within the range of 1 to 8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1.
CmacAdminState	Enables or disables autogenerated CFM for C-VLANs. The default is disable. This field does not apply for all hardware platforms.

Name	Description
CmacLevel	Specifies the global C-MAC CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type. This field does not apply for all hardware platforms.
CmacMepld	Specifies the global MEP ID within the range of 1 to 8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1. This field does not apply for all hardware platforms.
Bmac	Displays the B-MAC address of the node. This field does not apply for all hardware platforms.
Cmac	Displays the C-MAC address of the node. This field does not apply for all hardware platforms.

Configuring Explicit CFM

For SPBM B-VLANs, CFM provides two methods for creating MEPs: autogenerated and explicit. You cannot use both. Use the procedures in this section to configure MEPs explicitly.

If you want to create autogenerated CFM MEPs that eliminate the need to configure an MD, MA, and MEP ID, see the procedures in [Autogenerated CFM](#) on page 3540.

For C-VLANs, you can only use the autogenerated method.

Note

The CFM show commands that display MD, MA, and MEP information work for both autogenerated and explicitly-configured CFM MEPs.

Configure CFM MD

Use this procedure to configure a Connectivity Fault Management (CFM) Maintenance Domain (MD). An MD is the part of a network that is controlled by a single administrator. A single MD can contain several Maintenance Associations (MA).

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **MD** tab.
4. Click **Insert**.
5. In the fields provided, specify an index value, name, and level for the MD.
6. Click **Insert**.

MD Field Descriptions

Use the data in the following table to use the **MD** tab.

Name	Description
Index	Specifies a maintenance domain entry index.
Name	Specifies the MD name.
NumOfMa	Indicates the number of MAs that belong to this maintenance domain.
Level	Specifies the MD maintenance level. The default is 4.
NumOfMip	Indicates the number of MIPs that belong to this maintenance domain
Type	Indicates the type of domain.

Configure CFM MA

Use this procedure to configure a CFM Maintenance Association (MA). An MA represents a logical grouping of monitored entities within its Domain. It can therefore represent a set of Maintenance Endpoints (MEPs), each configured with the same Maintenance Association ID (MAID) and MD Level, established to verify the integrity of a single service instance.

Before You Begin

- You must configure a CFM MD.

Procedure

- In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
- Click **CFM**.
- Click the **MD** tab.
- Highlight an existing MD, and then click **MaintenanceAssociation**.
- In the **MA** tab, click **Insert**.
- In the fields provided, specify an index value and name for the MA.
- Click **Insert**.

MA Field Descriptions

Use the data in the following table to use the **MA** tab.

Name	Description
DomainIndex	Specifies the maintenance domain entry index.
AssociationIndex	Specifies a maintenance association entry index.
DomainName	Specifies the MD name.
AssociationName	Specifies the MA name.
NumOfMep	Indicates the number of MEPs that belong to this maintenance association.

Configure CFM MEP

Use this procedure to configure the CFM Maintenance Endpoint (MEP). A MEP represents a managed CFM entity, associated with a specific Domain Service Access Point (DoSAP) of a service instance, which can generate and receive CFM Protocol Data Units (PDU) and track any responses. A MEP is created by MEP ID under the context of an MA.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **MD** tab.
4. Highlight an existing MD, and then click **MaintenanceAssociation**.
5. In the **MA** tab, highlight an existing MA, and then click **MaintenanceEndpoint**.
6. Click **Insert**.
7. In the fields provided, specify the ID and the administrative state of the MEP.
8. Click **Insert**.

MEP Field Descriptions

Use the data in the following table to use the **MEP** tab.

Name	Description
DomainIndex	Specifies the MD index.
AssociationIndex	Specifies the MA index.
Id	Specifies the MEP ID.
DomainName	Specifies the MD name.
AssociationName	Specifies the MA name.
AdminState	Specifies the administrative state of the MEP. The default is disable.
MepType	Specifies the MEP type: <ul style="list-style-type: none"> • trunk • sg • endpt • vlan • port • endptClient • nodal • remotetrunk • remotesg • remoteendpt • remoteVlan • remotePort • remoteEndptClient
ServiceDescription	Specifies the service to which this MEP is assigned.

Configure CFM Nodal MEP

Use this procedure to configure the CFM nodal Maintenance Endpoint (MEP). The Nodal MEP provides traceability and troubleshooting at the system level for a given B-VLAN. The Nodal B-VLAN MEPs created on the CP and function as if they are connected to the virtual interface of the given B-VLAN. Because of this they are supported for both port and MLT based B-VLANs.

Nodal MPs provide both MEP and Maintenance Intermediate Point (MIP) functionality for SPBM deployments. Nodal MPs are associated with a B-VLAN and are VLAN encapsulated packets. Each node (chassis) has a given MAC address and communicates with other nodes. The SPBM instance MAC address is used as the MAC address of the Nodal MP.

Before You Begin

- You must configure a CFM MD, MA, and MEP.

Procedure

- In the navigation pane, expand **Configuration > VLAN**.
- Click **VLANs**.
- Click the **Advanced** tab.
- Select a VLAN with a type of `spbm-bvlan`.
- Click **Nodal**.
- In the **NodalMepList** field, specify the nodal MEPs to add to the VLAN.
- Click **Apply**.

Nodal MEP/MIP Field Descriptions

Use the data in the following table to use the **Nodal MEP/MIP** tab.

Name	Description
NodalMepList	Specifies the nodal MEPs to add to the VLAN, in the format <code><mdName.maName.mepId></code> , for example <code>md10.ma20.30</code> .
NumOfNodalMep	Indicates the number of nodal MEPs assigned to this VLAN.
NodalMipLevelList	Specifies a MIP level list.
NumOfNodalMipLevel	Indicates the number of nodal MIP levels assigned to this VLAN that allows MIP functionality to be enabled on a per level per VLAN basis.

Configure Layer 2 Ping

Use this procedure to configure a Layer 2 ping inside an SPBM cloud or network. This feature enables CFM to debug Layer 2. It can also help you debug IP shortcuts and the record for the shortcuts' ARP.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**.
3. From the **L2Ping** tab, configure the Layer 2 ping properties.
4. To initiate a Layer 2 ping, highlight an entry and click the **Start** button.
5. To update a Layer 2 ping, click the **Refresh** button.
6. To stop the Layer 2 ping, click the **Stop** button.

L2Ping Field Descriptions

Use the data in the following table to use the **L2Ping** tab.

Name	Description
VlanId	Identifies the backbone VLAN.
DestMacAddress	Specifies the target MAC address.
HostName	Specifies the target host name.
DestIsHostName	Indicates whether the host name is (true) or is not (false) used for L2Ping transmission.
Messages	Specifies the number of L2Ping messages to be transmitted. The default is 1.
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2Ping messages. • abort: the service aborted or is about to abort the L2Ping messages. <p>This field is also used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time. The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: the L2Ping Messages will be (or have been) sent. • false: the L2Ping Messages will not be sent. <p>The default is true.</p>
Priority	Specifies a 3-bit value to be used in the VLAN header, if present in the transmitted frame. The default is 7.
TimeoutInt	Specifies the interval to wait for an L2Ping time-out. The default value is 3 seconds.

Name	Description
TestPattern	<p>Specifies the test pattern to use in the L2Ping PDU:</p> <ul style="list-style-type: none"> allZero: null signal without cyclic redundancy check allZeroCrc: null signal with cyclic redundancy check with 32-bit polynomial pseudoRandomBitSequence: pseudo-random-bit-sequence without cyclic redundancy check pseudoRandomBitSequenceCrc: pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors. The default value is allZero.</p>
DataSize	Specifies an arbitrary amount of data to be included in the data TLV, if the data size is selected to be sent. The default is 0.
FrameSize	Specifies the frame size. If the frame size is specified then the data size is internally calculated and the calculated data size is included in the data TLV. The default is 0.
SourceMode	<p>Specifies the source mode of the transmit loopback service:</p> <ul style="list-style-type: none"> nodal noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the B-MAC-SA. smltVirtual — Use the smltVirtual option with B-VLANs only. <p>The default is nodal.</p>
SeqNumber	The transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
Result	Displays the Layer 2 Ping result.

Initiate a Layer 2 Traceroute

Note

This procedure does not apply to XA1400 Series.

Use this procedure to trigger a Layer 2 traceroute. This feature enables CFM to debug Layer 2 in an SPBM cloud or network. It can determine the path used by IS—IS to get from one MEP to another, by showing all the hops between. Therefore, it can show where connectivity is lost. It can also work for IP shortcuts.

If you configure **IsTraceTree** to false then EDM performs Traceroute on the unicast path. If you configure **IsTraceTree** to true then EDM performs TraceTree on the multicast tree.

For more information on configuring tracertree, see [Configure a Layer 2 Tracertree](#) on page 3564.

Important

To trace a route to a MAC address, the MAC address must be in the VLAN FDB table. For B-VLANs, you do not have to trigger an **L2Ping** to learn the MAC address because IS-IS populates the MAC addresses in the FDB table. Linktrace traces the path up to the closest device to that MAC address that supports CFM.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2 Traceroute/TraceTree** tab.
4. To start the traceroute, highlight an entry, and then select **Start**.
5. To update the traceroute, select **Refresh**.
6. To stop the traceroute, select **Stop**.

L2 Traceroute/TraceTree Field Descriptions

Use the data in the following table to use the **L2 Traceroute/TraceTree** tab.

Name	Description
VlanId	Specifies a value that uniquely identifies the Backbone VLAN (B-VLAN).
Priority	Specifies a 3-bit value to be used in the VLAN header, if present in the transmitted frame. The default is 7.
DestMacAddress	Specifies the target MAC address.
HostName	Specifies the target host name.
DestIsHostName	Specifies whether the host name is (true) or is not (false) used for the L2Trace transmission.
Isid	Specifies the Service Instance Identifier (I-SID).
IsTraceTree	Specifies whether the multicast tree or unicast path is traced: <ul style="list-style-type: none"> • If you configure IsTraceTree to false then EDM performs Traceroute on the unicast path. • If you configure IsTraceTree to true then EDM performs TraceTree on the multicast tree.

Name	Description
Status	<p>Indicates the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2Trace messages. • abort: the service aborted or is about to abort the L2Trace messages. <p>This field is also used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time. The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: the L2Trace messages will be (or have been) sent. • false: the L2Trace messages will not be sent. <p>The default is true.</p>
Ttl	<p>Specifies the number of hops remaining to this L2Trace.</p> <p>This value is decremented by 1 by each Bridge that handles the L2Trace. The decremented value is returned in the L2Trace. If 0 on output, the L2Trace is not transmitted to the next hop. The value of the time-to-live (TTL) field in the L2Trace is defined by the originating MEP. The default value is 64.</p>
SourceMode	<p>Specifies the source mode:</p> <ul style="list-style-type: none"> • 1: nodal • noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the B-MAC-SA. • 2: smltVirtual—Use this value with B-VLANs only. <p>The default is 1: nodal.</p>

Name	Description
SeqNumber	Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
Flag	L2Trace result flag that indicates L2Trace status or error code: <ul style="list-style-type: none"> • none (1): No error • internalError (2): L2Trace internal error • invalidMac (3): Invalid MAC address • mepDisabled (4): MEP must be enabled in order to perform L2Trace • noL2TraceResponse (5): No L2Trace response received • l2TraceToOwnMepMac (6): L2Trace to own MEP MAC is not sent • l2TraceComplete (7): L2Trace completed • l2TraceLookupFailure (8): Lookup failure for L2Trace • l2TraceLeafNode (9): On a leaf node in the I-SID tree • l2TraceNotInTree (10): Not in the I-SID tree • l2TraceSmltNotPrimary (11): Requested SMLT source from non-primary node

View Layer 2 Traceroute Results

Note

This procedure does not apply to XA1400 Series.

Use this procedure to view Layer 2 traceroute results. This feature enables CFM to debug Layer 2. It can also help you debug ARP problems by providing the ability to troubleshoot next hop ARP records.

About This Task

You can display Layer 2 tracetable results to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID. For more information, see [View Layer 2 Tracetable Results](#) on page 3566.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2Traceroute/TraceTree** tab.
4. Select **Refresh** to update the results.
5. To view the traceroute results, highlight an entry, and then select **Result**.

L2 Traceroute/Tracetable Result Field Descriptions

Use the data in the following table to use the **L2 Traceroute/Tracetable Result** tab.

Name	Description
VlanId	A value that uniquely identifies the Backbone VLAN (B-VLAN).
SeqNumber	The transaction identifier/sequence number returned by a previous transmit linktrace message command, indicating which L2Trace's response of the L2Trace is going to be returned. The default is 0.
Hop	The number of hops away from L2Trace initiator.
ReceiveOrder	An index to distinguish among multiple L2Trace responses with the same Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the responses.
Ttl	Time-to-Live (TTL) field value for a returned L2Trace response.
SrcMac	MAC address of the MP that responds to the L2Trace request for this L2TraceReply.
HostName	The host name of the replying node.
LastSrcMac	The MAC address of the node that forwarded the L2Trace to the responding node.
LastHostName	The host name of the node that forwarded the L2Trace to the responding node.

Configure Layer 2 IP Ping

Use this procedure to configure Layer 2 IP ping

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.
- If you want to run a Layer 2 IP Ping for a specific VRF, you must use EDM in the specific VRF context first. For more information, see the procedure for selecting and launching a VRF context view in [Select and Launch a VRF Context View](#) on page 3853.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**.
3. Click the **L2 IP Ping** tab.
4. To add a new entry, click **Insert**, specify the destination IP address and optional parameters, and then click **Insert**.
5. To start the Layer 2 IP ping, highlight an entry, and then click **Start**.
6. To update the Layer 2 IP ping, click the **Refresh** button.
7. To stop the Layer 2 IP ping, click **Stop**.

L2 IP Ping Field Descriptions

Use the data in the following table to use the **L2 IP Ping** tab.

Name	Description
IpAddrType	Specifies the address type of destination IP Address (only IPv4 is supported).
IpAddr	Specifies the destination IP Address.
VrfId	Specifies the VRF ID.
VrfName	Specifies the name of the virtual router.
Messages	Specifies the number of L2IpPing messages to be transmitted per MAC/VLAN pair. Range is 1–200. The default is 1.
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2IpPing messages. • abort: the service is aborted or about to abort the L2IpPing messages. <p>This field is also used to avoid concurrency or race condition problems that could occur if two or more management entities try to use the service at the same time. The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: L2IpPing Messages will be or have been sent. • false: L2IpPing Messages will not be sent. <p>The default is true.</p>
TimeoutInt	Specifies the interval to wait for an L2IpPing time-out with a range of 1–10 seconds with a default value of 3 seconds.
TestPattern	<p>Specifies the test pattern to use in the L2IPPing PDU:</p> <ul style="list-style-type: none"> • allZero — null signal without cyclic redundancy check • allZeroCrc — null signal with cyclic redundancy check with 32-bit polynomial • pseudoRandomBitSequence — pseudo-random-bit-sequence without cyclic redundancy check • pseudoRandomBitSequenceCrc — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors. The default value is allZero.</p>

Name	Description
DataSize	Specifies an arbitrary amount of data to be included in the data TLV, if the data size is selected to be sent. The range is 0–400. The default is 0.
PathsFound	Specifies the number of paths found to execute the command. The default is 0.

View Layer 2 IP Ping Results

Use this procedure to view Layer 2 IP ping results.

Note

After you trigger Layer 2 IP Ping, you must click the **Refresh** button to update the results.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**.
3. Click the **L2 IP Ping** tab.
4. To view the Layer 2 IP ping results, highlight an entry, and then click **Result**.

L2 IP Ping Result Field Descriptions

Use the data in the following table to use the **L2 IP Ping Result** tab.

Name	Description
IpAddrType	The address type of the destination IP Address.
IpAddr	Destination IP Address.
SendOrder	Specifies the order that sessions were sent. It is an index to distinguish among multiple L2Ping sessions. This value is assigned sequentially from 1. It correlates to the number of paths found.
Vrfid	Specifies the VRF ID.
VlanId	Specifies the VLAN ID found from the Layer 3 lookup and used for transmission.
DestMacAddress	An indication of the target MAC Address transmitted.
PortNum	Either the value '0', or the port number of the port used for the L2 IP ping.
DestHostName	The host name of the responding node.
Size	The number of bytes of data sent.
PktsTx	Number of Packets transmitted for this VLAN/MAC.
PktsRx	Number of Packets received for this VLAN/MAC.
PercentLossWhole	Percentage of packet loss for this VLAN/MAC.
PercentLossFract	Percentage of packet loss for this VLAN/MAC.

Name	Description
MinRoundTrip	Minimum time for round-trip for this VLAN/MAC in us.
MaxRoundTrip	Maximum time for round-trip for this VLAN/MAC in us.
RttAvgWhole	Average time for round-trip for this VLAN/MAC in us.
RttAvgFract	Fractional portion of average time for round-trip.
Flag	Result flag indicating status or error code: <ul style="list-style-type: none"> • 1 - No error • 2 - Internal error • 3 - Invalid IP • 4 - L2Trace completed • 5 - Lookup failure for IP (no VLAN/MAC entries)

Configure Layer 2 IP Traceroute

Use this procedure to configure Layer 2 IP traceroute.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN
- If you want to run a Layer 2 IP Traceroute for a specific VRF, you must use EDM in the specific VRF context first. For more information, see the procedure for selecting and launching a VRF context view in [Select and Launch a VRF Context View](#) on page 3853.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**
3. Click the **L2 IP Traceroute** tab.
4. To add a new entry, click **Insert**, specify the destination IP address and, optionally, the TTL value, and then click **Insert**.
5. To start the Layer 2 IP traceroute, highlight an entry, and then click the **Start** button.
6. To update the Layer 2 IP traceroute, click the **Refresh** button.
7. To stop the Layer 2 IP traceroute, click the **Stop** button.

L2 IP Traceroute Field Descriptions

Use the data in the following table to use the **L2 IP Traceroute** tab.

Name	Description
IpAddrType	Specifies the address type of destination IP address (only IPv4 is supported).
IPAddr	Specifies the destination IP Address.
Vrflid	Specifies the VRF ID.

Name	Description
VrfName	Specifies the name of the virtual router.
Ttl	Specifies the number of hops remaining to this L2Trace. This value is decremented by 1 by each Bridge that handles the L2Trace. The decremented value is returned in the L2Trace. If 0 on output, the L2Trace is not transmitted to the next hop. The default value is 64
Status	Indicates the status of the transmit loopback service: <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2Trace messages. • abort: the service is aborted or about to abort the L2Trace messages. This field is also used to avoid concurrency or race condition problems that could occur if two or more management entities try to use the service at the same time. The default is ready.
ResultOk	Indicates the result of the operation: <ul style="list-style-type: none"> • true: the Trace Messages will be or have been sent. • false: the Trace Messages will not be sent The default is true.
PathsFound	Specifies the number of paths found to execute the L2trace. The default is 0.

View Layer 2 IP Traceroute Results

Use this procedure to view Layer 2 IP traceroute results.

Note

After you trigger Layer 2 IP traceroute, you must click the **Refresh** button to update the results.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**.
3. Click the **L2 IP Traceroute** tab.
4. To view the Layer 2 IP traceroute results, highlight an entry, and then click **Result**.

L2 IP Traceroute Result Field Descriptions

Use the data in the following table to use the **L2 IP Traceoute Result** tab.

Name	Description
IpAddrType	Specifies the address type of destination IP address.
IpAddr	Specifies the destination IP address.
SendOrder	Denotes the order that sessions are sent. It is an index to distinguish among multiple L2Trace sessions. It correlates to the number of paths found. This value is assigned sequentially from 1.
Hop	Specifies the number of Layer 2 hops away from L2Trace initiator.
ReceiveOrder	Specifies the order that sessions are sent. It is an index to distinguish among multiple L2Trace responses with the same Send Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the responses.
Ttl	Specifies the time-to-live (TTL) field value for a returned L2Trace response.
VrfId	Specifies the VRF ID.
VlanId	Specifies the VLAN found from Layer 3 lookup and used for transmission.
DestMacAddress	Indicates the target MAC address transmitted.
PortNum	Specifies either the value '0', or the port number of the port used for the l2trace.
SeqNumber	Specifies the transaction identifier/sequence number used in linktrace message packet. The default is 0.
SrcMac	Specifies the MAC address of the MP that responded to L2Trace request for this L2traceReply.
HostName	Specifies the host name of the replying node.
LastSrcMac	Specifies the MAC address of the node that forwarded the L2Trace to the responding node.

Name	Description
LastHostName	Specifies the host name of the node that forwarded the L2Trace to the responding node.
Flag	L2Trace result flag indicating status or error code: <ul style="list-style-type: none"> • none (1): No error • internalError (2): L2Trace internal error • invalidMac (3): Invalid MAC address • mepDisabled (4): MEP must be enabled in order to perform L2Trace • noL2TraceResponse (5): No L2Trace response received • l2TraceToOwnMepMac (6): L2Trace to own MEP MAC is not sent • l2TraceComplete (7): L2Trace completed • l2TraceLookupFailure (8): Lookup failure for L2Trace

Trigger a Loopback Test

Use this procedure to trigger a loopback test.

The LBM packet is often compared to ping. An MEP transmits the loopback message to an intermediate or endpoint within a domain for the purpose of fault verification. This can be used to check the ability of the network to forward different sized frames.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **LBM** tab.
4. Configure the loopback test properties as required.
5. Click **Apply**.
6. To trigger the loopback test, double-click in the **Status** field, select **transmit**.
7. Click **Apply**.
8. To update the loopback test, click the **Refresh** button.

LBM Field Descriptions

Use the data in the following table to use the **LBM** tab.

Name	Description
DomainIndex	Specifies the MD index value.
AssociationIndex	Specifies the MA index value.
Index	Specifies the Maintenance Endpoint index value.
DomainName	Specifies the MD name.
AssociationName	Specifies the MA name.
DestMacAddress	Specifies the remote MAC address to reach the MEP/MIP.
Messages	Specifies the number of loopback messages to be transmitted. The default is 1.
VlanPriority	Specifies the priority. The default is 7.
SeqNumber	Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
ResultOk	Indicates the result of the operation: <ul style="list-style-type: none"> • true: The Loopback Messages will be (or have been) sent. • false: The Loopback Messages will not be sent. The default is true.
Status	Indicates the status of the transmit loopback service: <ul style="list-style-type: none"> • ready: The service is available. • transmit: The service is transmitting, or about to transmit, the Loopback messages. • abort: The service is aborted or about to abort the Loopback messages. The default is ready.
Result	Displays the LBM result.
TimeoutInt	Specifies the timeout interval in seconds. The default value is 3 seconds.
InterFrameInt	Specifies the interval between LBM frames with a range of (0..1000) msec and a default value of 500 msec. The value of 0 msec indicates to send the frames as fast as possible. The default is 500.

Name	Description
TestPattern	<p>Specifies the testfill pattern:</p> <ul style="list-style-type: none"> • allZero — null signal without cyclic redundancy check • allZeroCrc — null signal with cyclic redundancy check with 32-bit polynomial • pseudoRandomBitSequence — pseudo-random-bit-sequence without cyclic redundancy check • pseudoRandomBitSequenceCrc — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors. The default value is allZero.</p>
DataSize	<p>Specifies the data type-length-value (TLV) size. The default is 0.</p>
FrameSize	<p>Specifies the frame-size. The default is 0.</p>
Sourcemode	<p>Specifies the source mode of the transmit loopback service:</p> <ul style="list-style-type: none"> • nodal • noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the B-MAC-SA. • smltVirtual — Use the smltVirtual option with B-VLANs only. <p>The default is nodal.</p>

Trigger Linktrace

Use the following procedure to trigger a linktrace. The link trace message is often compared to traceroute. An MEP transmits the Linktrace Message packet to a maintenance endpoint with intermediate points responding to indicate the path of the traffic within a domain for the purpose of fault isolation. The packet specifies the target MAC address of an MP, which is the SPBM system ID or the virtual SMLT MAC. MPs on the path to the target address respond with an LTR.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **LTM** tab.
4. Configure the linktrace test properties as required.
5. Click **Apply**.

6. To trigger the linktrace test, double-click in the Status field, select **transmit**, and then click **Apply**.
OR

Highlight an entry, and then click **Start**.

7. To update the linktrace, click the **Refresh** button.
8. To stop the linktrace, click **Stop**.
9. To view the results of the linktrace, click **Result**.

LTM Field Descriptions

Use the data in the following table to use the **LTM** tab.

Name	Description
DomainIndex	Specifies the MD index value.
AssociationIndex	Specifies the MA index value.
Index	Specifies the MEP index value.
DomainName	Specifies the MD name.
AssociationName	Specifies the MA name.
VlanPriority	Specifies the VLAN priority, a 3-bit value to be used in the VLAN tag, if present in the transmitted frame. The default is 7.
DestMacAddress	Specifies the remote MAC address to reach the MEP.
Ttl	Indicates the number of hops remaining to this LTM. This value is decremented by 1 by each bridge that handles the LTM. The decremented value is returned in the LTR. If the value is 0 on output, the LTM is not transmitted to the next hop. The value of the TTL field in the LTM is specified at the originating MEP. The default value is 64.
SeqNumber	Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
ResultOk	Indicates the result of the operation: <ul style="list-style-type: none"> • true: The Loopback Messages will be (or have been) sent. • false: The Loopback Messages will not be sent. The default is true.
Status	Indicates the status of the transmit loopback service: <ul style="list-style-type: none"> • ready: The service is available. • transmit: The service is transmitting, or about to transmit, the LTM messages. • abort: The service is aborted, or about to abort, the LTM message. The default is ready.

Name	Description
Flag	Displays the LTM result flag indicating LTM status or error code. Each value represents a status or error case: <ul style="list-style-type: none"> • 1 - No error • 2 - LTM internal error • 3 - Unknown Remote Maintenance Endpoint • 4 - Invalid Remote Maintenance Endpoint MAC Address • 5 - Unset Remote Maintenance Endpoint MAC address • 6 - MEP must be enabled in order to perform LTM • 7 - No LTR response received • 8 - Linktrace to own MEP MAC is not sent • 9 - Endpoint must be enabled in order to perform LTM • 10 - Pbt-trunk must be enabled in order to perform LTM • 11 - LTM completed • 12 - LTM leaf node
SourceMode	Specifies the source mode of the transmit loopback service: <ul style="list-style-type: none"> • nodal • noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the B-MAC-SA. • smltVirtual — Use the smltVirtual option with B-VLANs only. The default is nodal.

View Linktrace Results

Use this procedure to view linktrace results.

Note

After you trigger linktrace, you must click the **Refresh** button to update the results.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **LTM** tab.
4. Highlight an entry, and then click **Result**.

Link Trace Replies Field Descriptions

Use the data in the following table to use the **Link Trace Result** tab.

Name	Description
DomainIndex	Indicates the Maintenance Domain Index.
AssociationIndex	Indicates the Maintenance Association Index.
MepId	Indicates the Maintenance EndPoint ID.
SeqNumber	Indicates the transaction identifier/sequence number returned by a previous transmit linktrace message command, indicating which LTM response is going to be returned. The default is 0.
Hop	Indicates the number of hops away from the LTM initiator.
ReceiveOrder	Indicates the index value used to distinguish among multiple LTRs with the same LTR Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the LTRs.
Ttl	Indicates the TTL field value for a returned LTR.
DomainName	Indicates the Maintenance Domain Name.
AssociationName	Indicates the Maintenance Association Name.
Forwarded	Indicates if a LTM was forwarded by the responding MP, as returned in the FwdYes flag of the flags field.
TerminalMep	Displays a boolean value stating whether the forwarded LTM reached a MEP enclosing its MA, as returned in the Terminal MEP flag of the Flags field.
LastEgressIdentifier	Displays an octet field holding the Last Egress Identifier returned in the LTR Egress Identifier TLV of the LTR. The Last Egress Identifier identifies the MEP Linktrace Indicator that originated, or the Linktrace Responder that forwarded, the LTM to which this LTR is the response. This is the same value as the Egress Identifier TLV of that LTM.
NextEgressIdentifier	Displays an octet field holding the Next Egress Identifier returned in the LTR Egress Identifier TLV of the LTR. The Next Egress Identifier Identifies the Linktrace Responder that transmitted this LTR, and can forward the LTM to the next hop. This is the same value as the Egress Identifier TLV of the forwarded LTM, if any. If the FwdYes bit of the Flags field is false, the contents of this field are undefined, and the field is ignored by the receiver.
RelayAction	Indicates the value returned in the RelayAction field.
SrcMac	Displays the MAC address of the MP that responded to the LTM request for this LTR.
IngressAction	Displays the value returned in the IngressAction Field of the LTM. The value ingNoTlv indicates that no Reply Ingress TLV was returned in the LTM.

Name	Description
IngressMac	Displays the MAC address returned in the ingress MAC address field. If the rcCfmLtrReplyIngress object contains the value ingNoTlv(5), then the contents of this field are meaningless.
EgressAction	Displays the value returned in the Egress Action Field of the LTM. The value egrNoTlv(5) indicates that no Reply Egress TLV was returned in the LTM.
EgressMac	Displays the MAC address returned in the egress MAC address field. If the rcCfmLtrReplyEgress object contains the value egrNoTlv(5), then the contents of this field are meaningless.

Configure a Layer 2 Tracetree

Note

This procedure does not apply to XA1400 Series.

Use this procedure to configure a Layer 2 Tracetree. This feature enables CFM to debug Layer 2. Layer 2 Tracetree allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. The command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

About This Task

If you configure **IsTraceTree** to false, then EDM performs Traceroute on the unicast path. If you configure **IsTraceTree** to true, then EDM performs TraceTree on the multicast tree.

Note

This command is supported on SPBM B-VLANs only, not C-VLANs.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. From the **L2 Traceroute/TraceTree** tab, configure the Layer 2 tracetree properties.
4. In the **IsTraceTree** field double-click and select **true** for EDM to perform Tracetree on the multicast tree.

5. Select **Apply**.
6. Select **Refresh** to update the results.

L2Tracetree Field Descriptions

Use the data in the following table to use the **L2Tracetree** tab.

Name	Description
VlanId	Identifies the Backbone VLAN.
Priority	Specifies a 3-bit value to be used in the VLAN header, if present in the transmitted frame. The default is 7.
DestMacAddress	Specifies the target MAC address.
HostName	Specifies the target host name.
DestIsHostName	Indicates whether the host name is (true) or is not (false) used for L2Tracetree transmission.
Isid	Specifies the service instance identifier (I-SID).
IsTraceTree	Specifies whether the multicast tree or unicast path is traced. If you configure IsTraceTree to false then EDM performs Traceroute on the unicast path. If you configure IsTraceTree to true then EDM performs TraceTree on the multicast tree.
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2Tracetree messages. • abort: the service aborted or is about to abort the L2Tracetree messages. <p>This field is also used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time. The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: the L2Tracetree Messages will be (or have been) sent. • false: the L2Tracetree Messages will not be sent <p>The default is true.</p>

Name	Description
Ttl	Specifies the Time-to-Live value. Indicates the number of hops remaining to this L2Tracetree. The tracetree is decremented by one by each bridge that handles the Layer 2 tracetree and the decremented value is returned to the tracetree. If the output is 0, then the L2Tracetree is not transmitted to the next hop. The value of the TTL field in the L2Tracetree is transmitted by the originating MEP is controlled by a managed object. The default is 64.
SourceMode	Specifies the source mode of the transmit loopback service: <ul style="list-style-type: none"> • nodal • noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the B-MAC-SA. • smltVirtual — Use the smltVirtual option with B-VLANs only. The default is nodal.
SeqNumber	The transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
Flag	Specifies the L2Tracetree result flag, which indicates the L2Tracetree status or error code. Each sum represents a status or error: <ul style="list-style-type: none"> • 1 — No error • 2 — L2Tracetree internal error • 3 — Invalid MAC address • 4 — MEP must be enabled in order to perform L2Tracetree • 5 — No L2Tracetree response received • 6 — L2Tracetree to own MEP MAC is not sent • 7 — L2Tracetree completed • 8 — Lookup failure for L2Tracetree • 9 — On a leaf node in the I-SID tree • 10 — Not in the I-SID tree • 11 — Requested SMLT source from nonprimary node

View Layer 2 Tracetree Results

Note

This procedure does not apply to XA1400 Series.

Use this procedure to view Layer 2 Tracetree results. The Layer 2 Tracetree command is a proprietary command that allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID.

This command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2 Traceroute/TraceTree** tab.
4. In the **IsTraceTree** field double-click and select **true** for EDM to perform Tracetree on the multicast tree.
5. Select **Apply**.
6. Select **Refresh** to update the results.
7. To view the tracetree results, highlight an entry, and then select **Result**.

L2 Traceroute/Tracetree Result Field Descriptions

Use the data in the following table to use the **L2 Traceroute/Tracetree Result** tab.

Name	Description
VlanId	A value that uniquely identifies the Backbone VLAN (B-VLAN).
SeqNumber	The transaction identifier/sequence number returned by a previous transmit linktrace message command, that indicates which response of the L2Tracetree is going to be returned. The default is 0.
Hop	The number of hops away from L2Tracetree initiator.
ReceiveOrder	An index to distinguish among multiple L2Tracetree responses with the same Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the responses.
Ttl	Time-to-Live (TTL) field value for a returned L2Tracetree response.
SrcMac	MAC address of the MP that responds to the L2Tracetree request for this L2tractreeReply.
HostName	The host name of the replying node.
LastSrcMac	The MAC address of the node that forwarded the L2Tracetree to the responding node.
LastHostName	The host name of the node that forwarded the L2Tracetree to the responding node.

Configure Layer 2 Trace Multicast Route on a VLAN**Note**

This procedure does not apply to XA1400 Series.

Use this procedure to configure the Layer 2 tracemroute on the VLAN (Layer 2). This procedure queries the SPBM multicast module to determine the B-VLAN, I-SID, and nickname for the S and G streams. The nickname and I-SID are used to create a multicast MAC address.

**Note**

If you want to run a Layer 2 tracemroute on a VRF, make sure you are in the proper VRF context.

Before You Begin

On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > L2Ping/L2Trace Route**.
2. Select the **L2MCAST Traceroute** tab.
3. Select **Insert** to insert the Layer 2 MCAST Traceroute.
4. Enter the **SrclpAddr**.
5. Enter the **GroupIpAddr**.
6. Enter the **ServiceType**. If you want to perform a Layer 2 tracemroute on a VLAN, select **vlan**. If you want to perform a Layer 2 tracemroute on a Layer 3 GRT, select **vrfid**.

**Note**

If you want to perform a Layer 2 tracemroute on a Layer 2 or a Layer 3 VRF, review the following procedure [Configuring Layer 2 tracemroute on a VRF](#).

7. In the **ServiceId** field, enter the VLAN ID.
8. Enter the **Priority**.
9. Enter the **Ttl** value.
10. Select **Insert**.
11. Select **Apply** to save your changes.
12. To start the Layer 2 tracemoute, set the Status to transmit and select **Start**.
13. Update the Layer 2 tracemroute by selecting **Refresh**.
14. To stop the Layer 2 tracemroute, select **Stop**.
15. To see the result, select **Result**.

L2 MCAST Traceroute Field Descriptions

Use the data in the following table to use the **L2 MCAST Traceroute** tab.

Name	Description
SrclpAddrType	Specifies the source IP address type as IPv4.
SrclpAddr	Specifies the source IP address of the flow where the multicast trace tree originates.
GroupIpAddrType	Specifies the group IP address type as IPv4.
GroupIpAddr	Specifies the group IP address.
ServiceType	Specifies where you configure the Layer 2 tracemroute. This is either VLAN or VRF.
ServiceId	Specifies the VLAN ID.
VRFName	Specifies the VRF name.
Priority	Specifies the priority value. The value is between 0 and 7.
Ttl	Specifies the returned trace response. The TTL value is between 1 and 255.
SeqNumber	Specifies the transaction identifier/sequence number of the first message to be sent.
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: Specifies the service is available. • transmit: Specifies the service is transmitting, or about to transmit the trace messages. • abort: Specifies the services is aborted or about to abort the trace messages. <p>The column will also be used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time.</p>
ResultOK	<p>Specifies the result of the operation:</p> <ul style="list-style-type: none"> • true: The trace messages will be or have been sent. • false: The trace messages will not be sent.
Flag	<p>Specifies the result flag indicating that the Layer 2 trace status or error code. Each value represents a status or error case.</p> <ul style="list-style-type: none"> • 1 – No error • 2 – Internal Error • 3 – Mep must be enabled to perform the trace • 4 – No response received • 5 – Trace completed • 6 – On a leaf node in the I-SID tree • 7 – No data I-SID was found for S, G

Configure Layer 2 Tracemroute on a VRF

Note

This procedure does not apply to XA1400 Series.

Use this procedure to configure the Layer 2 tracemroute on the VRF (Layer 3). This procedure queries the SPBM multicast module to determine the B-VLAN, I-SID and nickname for the S and G streams. The nickname and I-SID are used to create a multicast MAC address.

Note

If you want to run a Layer 2 tracemroute on a VRF, make sure you are in the proper VRF context.

To perform a Layer 3 tracemroute on a VLAN, see [Configure Layer 2 Trace Multicast Route on a VLAN](#) on page 3568.

Before You Begin

On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

Procedure

1. In the navigation pane, expand **Configuration > VRF Context View > Set VRF Context View**.
2. Select a VRF, and then select the **Launch VRF Context View** tab.
3. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > L2Ping/L2Trace Route**.
4. Select the **L2MCAST Traceroute** tab.
5. Select **Insert**.
6. Type the **SrcIpAddr**.
7. Type the **GroupIpAddr**.
8. Select the **ServiceType**. If you want to perform a Layer 2 tracemroute on a Layer 2 VRF, select **vlan**. If you want to perform a Layer 2 tracemroute on a Layer 3 VRF, select **vrfid**.
9. In the **ServiceId**, type the VLAN ID.
10. Type the **Priority**.
11. Type the **Ttl** value.
12. Select **Insert**.
13. Select **Apply** to save your changes.
14. To start the Layer 2 tracemroute, configure the Status to transmit, and then select **Start**.
15. To update the Layer 2 tracemroute, select **Refresh**.
16. To stop the Layer 2 tracemroute, select **Stop**.
17. To see the result, select **Result**.

L2 MCAST Traceroute Field Descriptions

Use the data in the following table to use the **L2 MCAST Traceroute** tab.

Name	Description
SrcIpAddrType	Specifies the source IP address type as IPv4.
SrcIpAddr	Specifies the source IP address of the flow where the multicast trace tree originates.
GroupIpAddrType	Specifies the group IP address type as IPv4.

Name	Description
GroupIpAddr	Specifies the group IP address.
ServiceType	Specifies where you configure the Layer 2 tracemroute. This is either VLAN or VRF.
ServiceId	Specifies the VLAN ID.
VRFName	Specifies the VRF name.
Priority	Specifies the priority value. The value is between 0 and 7.
Ttl	Specifies the returned trace response. The TTL value is between 1 and 255.
SeqNumber	Specifies the transaction identifier/sequence number of the first message to be sent.
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> ready: Specifies the service is available. transmit: Specifies the service is transmitting, or about to transmit the trace messages. abort: Specifies the services is aborted or about to abort the trace messages. <p>The column will also be used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time.</p>
ResultOK	<p>Specifies the result of the operation:</p> <ul style="list-style-type: none"> true: The trace messages will be or have been sent. false: The trace messages will not be sent.
Flag	<p>Specifies the result flag indicating that the Layer 2 trace status or error code. Each value represents a status or error case.</p> <ul style="list-style-type: none"> 1 – No error 2 – Internal Error 3 – Mep must be enabled to perform the trace 4 – No response received 5 – Trace completed 6 – On a leaf node in the I-SID tree 7 – No data I-SID was found for S, G

View Layer 2 Trace Multicast Route Results

Note

This procedure does not apply to XA1400 Series.

Use this procedure to view Layer 2 tracemroute results.

Note

If you want to run a Layer 2 tracemroute on a VRF, make sure you are in the proper VRF context.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > L2Ping/L2Trace Route**.
2. Select the **L2 MCAST Traceroute** tab.
3. To view the CFMI2 trace multicast route results, highlight an entry and select **Result**.

L2tracemroute Result Field Descriptions

Use the data in the following table to use the **L2tracemroute Result** tab.

Name	Description
VlanId	Specifies a value that uniquely identifies the C-VLAN.
SeqNumber	Specifies the transaction identifier/sequence number returned by a previous transmit linktrace message command. Indicates which I2 tracemroute response is going to be returned.
Hop	Specifies the number of hops away from the I2 tracemroute initiator.
ReceiveOrder	Specifies an index to distinguish among multiple I2 tracemroute responses with the same transaction identifier field value. This value is assigned sequentially from 1, in the order that the linktrace initiator received the responses.
Ttl	Specifies the TTL value for a returned I2 tracemroute response.
SrcMac	Specifies the MAC address of the MP that responds to the I2 tracemroute request for this I2 tracemrouteReply.
HostName	Specifies the host name of the replying node.
LastSrcMac	Specifies the MAC address of the node that forwarded the I2 tracemroute to the responding node.
LastHostName	Specifies the host name of the node that forwarded the I2 tracemroute to the responding node.

CFM Configuration Example

This section provides a configuration example for Connectivity Fault Management (CFM).

CFM Configuration Example

The following sections show the steps required to configure CFM.

Note

The following commands are not supported on all hardware platforms:

- cfm maintenance-domain
- cfm maintenance-association
- vlan nodal-mip-level

Switch A

```

MAINTENANCE-DOMAIN CONFIGURATION

cfm maintenance-domain "spbm" index 1 maintenance-level 6

MAINTENANCE-ASSOCIATION CONFIGURATION

cfm maintenance-association "spbm" "2" index 1
cfm maintenance-association "spbm" "3" index 2

MAINTENANCE-ENDPOINT CONFIGURATION

cfm maintenance-endpoint "spbm" "2" 1 state enable
cfm maintenance-endpoint "spbm" "3" 1 state enable

VLAN NODAL MEP/MIP CONFIGURATION

vlan nodal-mep 2 spbm 2 1
vlan nodal-mip-level 2 6
vlan nodal-mep 3 spbm 3 1
vlan nodal-mip-level 3 6
    
```

Switch B

```

MAINTENANCE-DOMAIN CONFIGURATION

cfm maintenance-domain spbm index 1 maintenance-level 6

MAINTENANCE-ASSOCIATION CONFIGURATION

cfm maintenance-association "spbm" "2" index 1
cfm maintenance-association "spbm" "3" index 2

MAINTENANCE-ENDPOINT CONFIGURATION

cfm maintenance-endpoint "spbm" "2" 2 state enable
cfm maintenance-endpoint "spbm" "3" 2 state enable

VLAN NODAL MEP/MIP CONFIGURATION

vlan nodal-mep 2 spbm 2 2
vlan nodal-mip-level 2 6
vlan nodal-mep 3 spbm 3 2
vlan nodal-mip-level 3 6
    
```

CFM Sample Output

The following sections show sample CFM output.

L2ping can use the system ID or the router name. The example below shows a case where the VLAN and MAC are given.

show isis adjacencies

```

Switch:1# show isis adjacencies

Software Troubleshooting Tool Configuration

Troubleshooting Tool Fundamentals

This section provides conceptual information about the methods and monitoring tools you can use for troubleshooting problems. This section also contains precautionary notices that you must read for the safe operation of the network.

Troubleshooting Overview

The types of problems that typically occur with networks involve connectivity and performance. This section also contains precautionary notices that you must read for the safe operation of the switch. The switch supports a diverse range of network architectures and protocols, some of which maintain and monitor connectivity and isolate connectivity faults.

In addition, the switch supports a wide range of diagnostic tools that you can use to monitor and analyze traffic, capture and analyze data packets, trace data flows, view statistics, and manage event messages.

Certain protocols and tools are tailored for troubleshooting specific switch network topologies. Other tools are more general in their application and you can use them to diagnose and monitor ingress and egress traffic on the switch.

If connectivity problems occur and the source of the problem is unknown, it is usually best to follow the Open Systems Interconnection (OSI) network architecture layers. Confirm that your physical environment, such as the cable and port connections, operates without failures before moving up to the network and application layers.

To gather information about a problem, consider the following information:

- Consider the OSI model when you troubleshoot. Start at Layer 1 and move upwards. The Address Resolution Protocol (ARP) can cause problems; ARP operates at Layer 2 to resolve MAC addresses to IP addresses (Layer 3).
- Device-specific tools and protocols can help you gather information. This document outlines switch-specific tools.
- You can use client- and server-based tools from Microsoft, Linux, and UNIX. For example, you can use Windows tools like ifconfig, ipconfig, winipcfg, and route print to obtain IP information and routing tables. Servers also maintain route tables.

The following command output shows example output of the route print command.

```

```

- Other network problems can give the impression that a device has a problem. For instance, problems with a Domain Name Service (DNS) server, another switch, firewall, or access point can appear to be routing problems.

Debug Files

The switch stores debug files in the intflash directory.

The debug file is in a zipped format and contains information to help debug the device, including:

- a memory snapshot
- logs
- traces

This best practice is to delete these files to ensure enough space exists in the internal flash. New files do not overwrite old files. You must remove the files; otherwise, the internal flash may not have enough free space for necessary activities, for example, to store a core dump file if the switch fails, or you may not have the space to transfer a new release to the internal flash to upgrade your switch.

The switch stores a maximum of 32 files for each debug file for each slot, depending on the file size of each debug file. The internal flash provides 2 GB of storage. The system displays a message on the console to inform you when less than 700 MB is available.

The **debug-file remove** command can delete the following types of debug files:

- core
- archive
- PMEM
- dmalloc
- flrec
- wd_stats

If you want to delete a specific file, you must use the **remove** command.

SNMP

The switch does not support SNMP for the **show debug-file** or the **debug-file remove** commands.

Digital Diagnostic Monitoring

Use Digital Diagnostic Monitoring (DDM) to monitor laser operating characteristics such as temperature, voltage, current, and power. This feature works during active laser operation without affecting data traffic. Transceivers in various form factors support DDM. Use the CLI command **show pluggable-optical-modules {basic|config|detail|temperature|voltage}** to make use of DDM functionality.

An interface that supports DDM is a Digital Diagnostic Interface (DDI). These devices provide real-time monitoring of individual DDI transceivers on a variety of switches and routers. The DDM software

provides warnings or alarms when the temperature, voltage, laser bias current, transmitter power or receiver power fall outside of vendor-specified thresholds during initialization.

For information about DDM and supported transceivers, see [Extreme Optics](#) website and [Port Performance Management](#) on page 2604.

```
Switch:1#show pluggable-optical-modules config

Flight Recorder

Table 262: Flight Recorder product support

Feature	Product	Release introduced
Flight Recorder for system health monitoring	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50

The Flight Recorder is a high level term for the framework in place on the switch to store both history and current state information for various kernel, system, and application data with minimal overhead to execution. This data can later be accessed on-demand when debugging systems issues to give engineers the best possible troubleshooting information. Functionally, the Flight Recorder consists of two elements; Persistent Memory and Always-on Trace.

The Persistent Memory feature stores information in volatile memory outside of any process. This feature provides information on crashes, errors, and outages that are not the result of a power failure. Persistent Memory data not saved to non-volatile storage before a power failure will be lost. Persistent Memory snapshots are taken when:

- a critical process stops functioning
- a process stops responding
- the hardware watchdog activates
- the user initiates a snapshot in the CLI

The Always-on Trace feature creates an ongoing, circular log of every trace call recently executed regardless of the trace level enabled by the user. The Always-On Trace feature uses circular logging, and therefore stores the most recent traces of the process.

Flight Recorder functionality is provided only through CLI. The following commands are used to make use of this feature:

- **flight-recorder all {slot[-slot][,...]}**

For VSP 8600, the valid slots are 1-8, SF1-SF3, all.

The command creates a flight-recorder snapshot, trace and archive.

- **flight-recorder archive {slot[-slot][,...]}**

For VSP 8600, the valid slots are 1-8, SF1-SF3, all.

This command creates a tarball of flight-recorder files, log files, and configuration files.

- **flight-recorder snapshot {slot[-slot][,...]}.**

For VSP 8600, the valid slots are 1-8, SF1-SF3, all.

This command takes a snapshot of PMEM data.

- **flight-recorder trace {slot[-slot][,...]}**

For VSP 8600, the valid slots are 1-8, SF1-SF3, all.

This command takes snapshot of always-on-trace data.

Port Mirroring

Table 263: Port Mirroring product support

Feature	Product	Release introduced
Ingress mirroring (port and flow-based)	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50

	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50

True egress port-based mirroring that produces an identical copy of an outgoing packet is supported only on the VSP 4450 Series. On all other platforms, the mirrored copy does not reflect changes that occur in the switch to the outgoing packet (for example, packet fields that are updated during IP routing). As a result, the mirrored copy is not identical to the outgoing packet.

Use the port mirroring feature to monitor and analyze network traffic. Port mirroring supports both ingress (incoming traffic) and egress (outgoing traffic) port mirroring. When you enable port mirroring, the system forwards ingress or egress packets normally from the mirrored (source) port, and sends a copy of the packet to the mirroring (destination) port.

Port Mirroring Overview

Port mirroring causes the switch to make a copy of a traffic flow and send the copy to a device for analysis. Use port mirroring in diagnostic sniffing—use the mirror to view the packets in the flow without breaking the physical connection to place a packet sniffer inline. You can also use mirroring for security reasons.

You can use egress mirroring to monitor packets as they leave specified ports. Egress mirroring on the switch is done at the end of the ingress pipeline. Since packet modifications occur in the egress pipeline, some of the changes will not be reflected in the mirrored version of the packet. Changes that occur in the egress pipeline may be reflected in the mirrored packet due to the metadata that is carried with the packet. Metadata notifies the egress pipeline what to change.

Use a network analyzer to observe and analyze packet traffic at the mirroring port. Unlike other methods that analyze packet traffic, the packet traffic is uninterrupted and packets flow normally through the mirrored port.

You can mirror to a port or list of ports or a MultiLink Trunking (MLT) group. The switch supports one-to-many, many-to-one, and many-to-many mirroring configurations.

Ingress and Egress Mirrored Ports

You can use all ports in the system to function as an ingress port for mirroring (mirrored port), an egress port for mirroring (mirrored port), or as a mirroring port (where all the mirrored traffic is redirected). The number of mirroring ports (also called destination ports) that you can configure is limited by the hardware. The hardware limitation is four ports simultaneously (where each mirroring direction counts as one). For example, if two mirroring ports are designated to mirror both ingress and egress traffic then all four mirroring ports are consumed.

The following table describes ingress mirroring functionality. Only one type of mirroring destination is supported at a time. You cannot mirror the same port to multiple classes of destinations, for example, MLT. However, you can mirror to multiple physical destinations.

Important

Mirroring packets from one NNI port to another NNI port is not supported. Mirror to access ports, not NNI ports.

Flow or ACL-based based mirroring is not supported for ingress and egress on VSP 8600 Series.

Table 264: Ingress mirroring functionality

Function	Support information
Ingress port mirroring and ingress flow mirroring	Supported. Maximum of four mirror-to-ports per box.
One port to one port	Supported
One to MLT group [for threat protection system (TPS applications)]	Supported
One to many (multicast group ID/VLAN)	Not supported
One to one (remote mirrored destination)	Not supported
Many to one (multiple mirrored ports to one mirroring port)	Supported
Many to MLT group	Supported
Many to many (VLAN/multicast group ID) (multiple ports with several different destinations)	Not supported
Many to one (relation between Remote Mirror Source [RMS] and Remote Mirror Termination [RMT])	Not supported
VLAN and port combination as a mirroring destination	Not supported
Ingress flow mirroring	Supported
Allow filters to specify a separate destination for each access control entry	Supported

The following table describes egress mirroring functionality.

Table 265: Egress mirroring functionality

Function	Support information
Egress port mirroring	Supported
One port to one port	Supported
One to MLT groups (for TPS applications)	Supported
One to many (multicast group ID/VLAN)	Not supported
Many to one (multiple mirrored ports to one mirroring port)	Supported
Many to MLT group	Supported
Many to many (multicast group ID) (multiple ports with several different destinations)	Supported

Table 265: Egress mirroring functionality (continued)

Function	Support information
Many to one (relation between Remote Mirror Source [RMS] and Remote Mirror Termination [RMT])	Not supported
VLAN and port combination as mirroring destination	Not supported
Egress flow mirroring	Supported
Allow filter to specify a separate destination for each access control entry	Supported

Port Configuration

You can specify a destination multilink trunking (MLT) group, a destination port or set of ports.

There are two port mirroring modes: rx (ingress, that is, inPort) and tx (egress, that is, outPort). In rx mode, when you configure the ACE mirror or ACL global options to mirror packets, use the ACE to configure the mirroring destination port.

Note

XA1400 Series does not support ACL global action to mirror packets.

To modify a port mirroring instance, first disable the instance. Also, to change a port or MLT entry, first remove whichever parameter is attached to the entry, and then add the required entry.

ACLs, ACEs, and Port Mirroring

You can use filters to reduce the amount of mirrored traffic. You can configure the mirroring action globally in an access control list (ACL), or for a specific access control entry (ACE) by using the ACE mirror actions. If you use the global action, mirroring applies to all ACEs that match in an ACL.

To use filters with port mirroring, apply an ACL to the mirrored port in the egress and ingress directions. Traffic patterns that match the ACL or ACE with an action of permit are forwarded to the destination and also to the mirroring port. Traffic patterns that match an ACE with an action of drop (deny) are not forwarded to the destination, but still reach the mirroring port. For example, for an ACL or ACE with a match action of permit, packets are mirrored to the specified mirroring destination on the ACE. If you enable a port or VLAN filter, then that filter is the mirroring filter.

You can specify more than one mirroring destination by using multiple ACEs. Use each ACE to specify a different destination.

You can configure a port-based and a flow-based mirroring filter on the same port. If such a case occurs, then the flow-based mirror takes precedence.

Note

XA1400 Series does not support ACL global action to mirror packets.

For information about how to configure ACLs and ACEs for port mirroring using CLI, see the following sections:

- [Configuring Global Mirroring Actions with an ACL](#) on page 3611
- [Configure ACE Actions to Mirror](#) on page 3611

For information about how to configure ACLs and ACEs for port mirroring using EDM, see the following sections:

- [Configure ACLs for Mirroring](#) on page 3635
- [Configure ACEs for Mirroring](#) on page 3636

Port Mirroring Considerations and Restrictions

Although you can configure the switch to monitor both ingress and egress traffic, some restrictions apply:

- VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series, VSP 8600 Series, and XA1400 Series do not support true egress mirroring because packets are mirrored prior to the completion of packet processing, so egress mirrored packets can differ from the packets egressing the port.

Only VSP 4450 Series supports true egress mirroring.

Note

To mirror the egress traffic for VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series, and VSP 8600 Series platforms, you can use the NEXT-hop device ingress mirroring to capture the egress packets of the switch.

- Mirrored traffic shares ingress queue and fabric bandwidth with normal traffic and therefore can impact normal traffic. Therefore, use these features with this potential consequence in mind and enable them only for troubleshooting, debugging, or for security purposes such as packet sniffing, intrusion detection, or intrusion prevention.
- You can configure as many ingress mirroring flows as you have filters.
- To avoid VLAN members from seeing mirrored traffic, you must remove mirroring (destination) ports from all VLANs.
- The MAC drops an error packet, for example, packets that are too short or too long. Control packets consumed by the MAC (802.3x flow control) are also not mirrored.
- Certain control packets generated by the CP cannot be egress mirrored, such as those in the following list:
 - BPDU
 - EAPoL
 - IP Directed Broadcast
 - LACP
 - LLDP
 - Multicast routed packets
 - NAAP
 - NLB
 - Nodal CFM
 - TDP
 - VLACP
- The system displays ingress multicast packets in egress mirroring.

- On the VSP 7400 Series, if incoming traffic from the same source port is simultaneously ingress mirrored on an incoming port into one I-SID and egress mirrored on another outgoing port into a different I-SID, the mirrored packet carries an I-SID associated with ingress mirroring.
- On the VSP 7400 Series, any incoming traffic that does not contain a VLAN tag is not mirrored into an I-SID if the offset ID is in the range 2 to 1000. It is mirrored to an I-SID only if the offset ID is 1.
- On the XA1400 Series the global mirrored action is not supported.
- On the XA1400 Series you can configure the ACE to perform the mirroring operation. You can use the ACE mirror parameter, to configure a specific mirror to an MLT ID, port, or port list. Filters are not applied on mirrored packets.
- On the XA1400 Series you can configure a port mirror and a flow based ACE mirror action on the same port.
- For VSP 4900 Series or VSP 7400 Series:
 - To use an Extreme Integrated Application Hosting port with a connect type as OVS or SR-IOV for Port Mirroring, associate VLAN 4091 to the virtual machine (VM) vport to send the mirrored packets to the VM.

Port Mirroring Resources

Port mirroring resources are limited to four ports simultaneously (where each mirroring direction counts as one). For example, if two mirroring ports are designated to mirror both ingress and egress traffic then all four mirroring ports are consumed.

Port mirroring shares these four resources with other applications such as port mirroring RSPAN, Fabric Extend, Application Telemetry, IPFIX, and ACL with mirror action. Each one of these applications consumes at least one port mirroring resource. (port mirroring RSPAN consumes two if you configure both Ingress and Egress modes.)

Important

To enable any one of the preceding applications, you must have at least one free mirroring resource. If all four port mirroring resources are already in use, the switch displays a `Resource not available` error message when you try to enable the application.

The VSP 8600 Series uses the four reserved resources for port mirroring and ACLs that have a mirroring action. For the other applications, this restriction does not apply because the VSP 8600 Series uses mirroring resources that do not come out of the four reserved port mirroring resources.

If you receive a `Resource not available` error message, you can use the **`show mirror-resources`** command to view information about mirror resource usage. For more information, see [Displaying Mirror Resource Usage](#) on page 3610.

The **`show mirror-resources`** command is not available on all platforms. Use CLI command completion Help to determine if the command is available on your switch.

General Diagnostic Tools

The switch has diagnostic features available with Enterprise Device Manager (EDM) and Command Line Interface (CLI). You can use these diagnostic tools to help you troubleshoot operational and configuration issues. You can perform such tasks as configuring and displaying log files, viewing and

monitoring port statistics, tracing a route, running loopback and ping tests, and viewing the address resolution table.

Traceroute

Traceroute determines the path a packet takes to reach a destination by returning the sequence of hops (IP addresses) the packet traverses.

According to RFC1393, traceroute operates by: "sending out a packet with a time-to-live (TTL) of 1. The first hop then sends back an ICMP error message indicating that the packet could not be forwarded because the TTL expired. The packet is then resent with a TTL of 2, and the second hop returns the TTL expired. This process continues until the destination is reached. The purpose behind this is to record the source of each ICMP TTL exceeded message to provide a trace of the path the packet took to reach the destination."

Ping

Ping is a simple and useful diagnostic tool to determine reachability. When you use ping, the switch sends an ICMP echo request to a destination IP address. If the destination receives the packet, it responds with an ICMP echo response.

If a ping test is successful, the destination is alive and reachable. Even if a router is reachable, it could have improperly working interfaces or corrupted routing tables.

Trace

Use trace commands to provide detailed data collection about software modules on the switch. The trace toolset can be used to trace multiple modules simultaneously and provides options to specify the verbosity level of the output.

You can enable trace logging through the boot config trace-logging flag.

Caution **Risk of traffic loss**

Using the trace tool inappropriately can cause a CPU lockup conditions, loss of access to the switch, loss of protocols, and service degradation.

Tip

While these occurrences are uncommon, when using the trace level tool, minimize this risk. The following actions are:

- In situations where trace data is required concurrently from multiple modules, consider troubleshooting during a maintenance window if feasible. Consider a maintenance window period if the switch is stable but CPU utilization is high and CPU traces (example trace levels 9 and 11) are required to diagnose the cause.
- Run trace commands from the console port when the CPU utilization is already high. While you can enable or disable tracing when directly connected to the console port.

Activate tracing on one software module at a time.

- Initially activate tracing at lower verbosity settings (that is, 2 rather than 3). Increase to verbosity level 3 or 4 only if required, and after level 2 runs safely.
- Avoid leaving traces active for extended periods of time. For high CPU utilizations, a few seconds (typically less than 5 seconds) is generally sufficient to identify the cause for sustained high CPU utilization.

Fabric RSPAN (Mirror to I-SID)

Table 266: Fabric RSPAN product support

Feature	Product	Release introduced
Fabric RSPAN (Mirror to I-SID)	VSP 4450 Series	VOSS 6.0 Flow-based mirroring into single I-SID only
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 6.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.0
	VSP 8400 Series	VOSS 6.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

Remote mirroring is an important functionality that helps in:

- Intrusion Detection or Intrusion Prevention Systems
- Network Port debugging and packet capture
- Mirror and Monitor traffic to central collector or analyzers
- Mirror and Monitor traffic to distributed collectors or analyzers

With the Fabric RSPAN (Mirror to I-SID) feature, mirrored traffic captured from any switch in the network is sent to a remote switch over an SPB cloud for traffic analysis. With this feature, you can monitor traffic on ports from different switches connected in the network, using just one network analyzer connected to a remote switch which acts as a collector. The source device where the traffic is mirrored to an I-SID, is known as Mirroring BEB (Backbone Edge Bridge), and the remote device where the traffic analyzer is connected for mirrored traffic analysis is known as Monitoring BEB.

The traffic source on the mirroring BEB is supported in the following ways:

- Port based mirroring — Any packet incoming or outgoing through a port is mirrored to a monitoring I-SID configured for that port.
- Flow based mirroring — Any particular packet flow configured in the system using filter based ACLs is mirrored to a monitoring I-SID configured for that flow.

Fabric RSPAN (Mirror to I-SID) Restrictions and Requirements

- Remote mirroring of traffic is not supported on NNI ports, Fabric Extend Layer 2 core ports, and Open Networking Adapter (ONA) devices and ports.
- Mirroring resources will be shared between Fabric RSPAN and regular port mirroring. Fabric RSPAN uses one out of four resources for mirroring if the mode is configured as Rx (Ingress) mirroring. In case of mode Tx (Egress) mirroring, it uses one more entry with same TX-LB port. Hence if mode Rx and Tx are configured for Fabric RSPAN, then only two unique destination ports can be used for regular port mirroring. For example, if you configure Fabric RSPAN on the switch, the regular port mirroring functionality can use only three unique destination ports. And, if all the four unique ports are used by the port mirroring functionality, you cannot configure Fabric RSPAN functionality on that node.
- When the monitor I-SID used for mirroring Fabric RSPAN traffic ingressing to I-SID is used to mirror regular traffic into SPB network, it will remove the customer tag in the mirrored packets. Hence, as a best practice, use different monitor I-SIDs for mirroring regular traffic and Fabric RSPAN traffic.
- Monitoring egress-ports and egress-mlt will not support regular production network traffic.
- The QoS value must be same for all mirror entries having common monitor I-SID, as the BMAC QoS is mapped to a monitor I-SID. QoS value configured for a specific monitor I-SID offset overrides the existing value for all mirroring entries sharing the same monitor I-SID.
- Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.
- Egress flow-based I-SID mirroring is not supported.
- VSP 7400 Series does not support the following combinations for I-SID mirroring:
 - Deny option for Filter ACL with monitor-isid-offset for Inport/Invlan/InVSN
 - Redirect-Next-Hop along with monitor-isid-offset when monitor-isid-offset is greater than 1
 - Remove Tag option along with monitor-isid-offset
- For VSP 4900 Series or VSP 7400 Series:
 - To use an Extreme Integrated Application Hosting port as an analyzer port on a monitoring BEB for Fabric RSPAN (Mirror to I-SID), you must associate outer-tag 4091 to egress port 1/s1 or 1/s2 if the connect type is OVS or SR-IOV. Use the **monitor-by-isid <1-1000> map-to-vid <1-4093>** command to configure VLAN 4091 for Fabric RSPAN.

Software Troubleshooting Tool Configuration Using CLI

Use the tools described in this section to perform troubleshooting procedures using CLI.

Using CLI for Troubleshooting

You can use CLI to provide diagnostic information.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Disable scrolling of the output display:

```
terminal more disable
```

3. View configuration file information:

```
more WORD<1-99>
```

4. Capture the output for the following command after you observe a problem with the device:

```
show running-config [verbose] [module {app-telemetry | boot | cfm |
cli | diag | dvr | eap | endpoint-tracking | energy-saver | fa | fhs |
filter | ike | ip | ipfix | ipsec | ipv6 | iqagent | isis | i-sid |
lACP | license | lldp | lst | macsec | mlt | naap | nls | ntp | ovsdb
| port | qos | radius | restconf | rmon | sflow | security | slamon |
slpp | smtp | spbm | stg | sys | tacacs | virtualservice | vlan | web
| vxlan}]
```

5. Capture the output for the following command after you observe a problem with the device:

```
show tech
```

6. Capture the output for the following commands after you observe a problem with the device:

Note

The **show interfaces gigabitEthernet statistics rmon** command displays information only if you previously configured **rmon stats** or **rmon history**.

- `show interfaces gigabitEthernet statistics <dhcp-relay [vrf WORD<1-16>][vrfids WORD<0-512>] [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show interfaces gigabitEthernet statistics lACP [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show interfaces gigabitEthernet statistics rate-limiting [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show interfaces gigabitEthernet statistics policer [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show interfaces gigabitEthernet statistics rmon [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show interfaces gigabitEthernet statistics verbose [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show interfaces gigabitEthernet statistics vlACP [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`

7. Capture the output for the following command after you observe a problem with the device:

Note

Product Notice: If you run this command on an XA1400 Series switch, most of the values report as zero (0). To see port-level error counters for XA1400 Series, use the `show io nic-counters` command instead.

```
show interfaces gigabitEthernet error [collision|ospf|verbose] [{slot/
port[/sub-port] [-slot/port[/sub-port]] [,...]]]
```

Examples

Due to the length of command output, the following examples are truncated.

Capture the output for the following commands after you observe a problem with the device:

```

Variable Definitions

The following table defines parameters for the **more** command.

Variable	Value
<i>WORD</i> <1-99>	Specifies the file name to view. Provide the filename in one of the following formats: a.b.c.d:<file>, /intflash/<file>.

The following table defines parameters for the **show running-config** command.

Variable	Value
<code>module {app-telemetry boot cfm cli diag dvr eap endpoint-tracking energy-saver fa fhs filter ike ip ipfix ipsec ipv6 iqagent isis i-sid lacp license lldp lst macsec mlt naap nls ntp ovssdb port qos radius restconf rmon sflow security slamon slpp smtp spbm stg sys tacacs virtualservice vlan web vxlan}</code>	Specifies the command group for which you request configuration settings. Note: All configuration modules are not supported on all hardware platforms. For information about feature support, see VOSS Feature Support Matrix .
<code>verbose</code>	Specifies a complete list of all configuration information about the switch.

The following table defines parameters for the **show interfaces gigabitEthernet statistics** command.

Variable	Value
<code>dhcp-relay [vrf WORD<1-16>] [vrfids WORD<0-512> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]</code>	Displays port Dynamic Host Configuration Protocol (DHCP) statistics.
<code>lacp {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Displays Link Aggregation Control Protocol (LACP) statistics.
<code>rate-limiting {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Displays port ingress rate-limiting statistics.
<code>rmon {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [history]</code>	Displays Remote Network Monitoring (RMON) statistics.
<code>verbose</code>	Displays a complete list of all statistics.
<code>vlacp [history] {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Displays port Virtual Link Aggregation Control Protocol (VLACP) statistics. <ul style="list-style-type: none"> • <code>history</code>—Displays the VLACP port counter profile. • <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> <p>Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port.slot/port.slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

The following table defines parameters for the **show interfaces gigabitEthernet error** command.

Variable	Value
<i>collision</i>	Displays port collision error information.
<i>ospf</i>	Displays ports Open Shortest Path First (OSPF) error information.
<i>verbose</i>	Displays all port error information.
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Display NIC Counters

Note

This procedure only applies to XA1400 Series.

Use the following procedure to display the NIC statistics and counters.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display NIC counter statistics:

```
show io nic-counters
```

Example

```
Switch:1# show io nic-counters

===== PORT 1 NIC STATS =====

bash-4.3# ethtool -S eth1 | grep -v queue
NIC statistics:
  rx_packets: 3698179
  tx_packets: 500856
  rx_bytes: 273670137
  tx_bytes: 67740387
  rx_broadcast: 1905912
  tx_broadcast: 117620
  rx_multicast: 1622656
  tx_multicast: 285392
  multicast: 1622656
  collisions: 0

```

Using Software Record Dumps

About This Task

Capture a dump of the software records from ingress traffic to help troubleshoot performance problems. Generally, a verbosity level of 1 suffices.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Dump software record information:
dump ar <1-12> WORD<1-1536> <0-3>

Example

```
Switch:1> enable
```

```
Switch:1# dump ar 1 vlan 1
```

Variable Definitions

The following table defines parameters for the **dump ar** command.

Variable	Value
<1>	Specifies the slot number.
WORD<1-1536>	Specifies a record type in the AR table. Options include vlan, ip_subnet, mac_vlan, mac, arp, ip, ipmc, protocol, all.
<0-3>	Specifies the verbosity from 0-3. Higher numbers specify more verbosity.

Use Trace to Diagnose Problems

Use trace to observe the status of a software module at a given time.

About This Task

For example, if you notice a CPU utilization issue (generally a sustained spike above 90%) perform a trace of the control plane activity.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Clear the trace:

```
clear trace
```
3. Identify the module ID for which you want to use the trace tool:

```
show trace modid-list
```
4. Begin the trace operation:

```
trace level [<Module_ID>] [<0-4>]
```
5. Wait approximately 30 seconds.

The default trace settings for CPU utilization are:

 - High CPU Utilization: 90%
 - High Track Duration: 5 seconds
 - Low CPU Utilization: 75%
 - Low Track Duration: 5 seconds
6. Stop tracing:

```
trace shutdown
```
7. View the trace results:

```
show trace file [tail]
```
8. Search trace results for a specific string value, for example, the word error:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

9. Stop tracing:

```
trace shutdown
```

Example

```
Switch:1> enable
```

Clear the trace:

```
Switch:1# clear trace
```

Identify the module ID for which you want to use the trace tool:

```
Switch:1# show trace modid-list
```

```
0 - COMMON
1 - SNMP
2 - RMON
3 - PORT_MGR
4 - CHAS_MGR
5 - BRIDGE
6 - HWIF
7 - SIM
8 - CPP
9 - NETDRV
10 - VLAN_MGR
11 - CLI
12 - MAIN
12 - P2IP
12 - RCIP
15 - WEBSRV
16 - ACIF
17 - GBIF
18 - WDT
19 - TDP
20 - MAN_DIAG
21 - MAN_TEST
```

```
--More-- (q = quit)
```

Begin the trace operation:

```
Switch:1# trace level 2 3
```

Stop tracing:

```
Switch:1# trace shutdown
```

Save the trace file to the internal flash card for retrieval:

```
Switch:1# save trace
```

Search trace results for a specific string value, for example, the word error:

```
Switch:1# trace grep error
```

Search trace results for a specific string value, for example, MAC address 00-1A-4B-8A-FB-6B:

```
Switch:1# trace grep 00-1A-4B-8A-FB-6B
```

Variable Definitions

The following table defines parameters for the **trace** command.

Variable	Value
<code>grep [WORD<0-128>]</code>	Search trace results for a specific string value, for example, the word error. Performs a comparison of trace messages.
<code>level [<Module_ID>] [<0-4>]</code>	Starts the trace by specifying the module ID and level. <ul style="list-style-type: none"> • <code><Module_ID></code> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the show trace modid-list command or CLI command completion Help. • <code><0-4></code> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<code>shutdown</code>	Stops the trace operation.
<code>screen {disable enable}</code>	Enables the display of trace output to the screen.

The following table defines parameters for the **save trace** command.

Variable	Value
<code>file WORD<1-99></code>	Specifies the file name in one of the following formats: <ul style="list-style-type: none"> • a.b.c.d:<file>

Use Trace to Diagnose IPv6 Problems

Use trace to observe the status of IPv6 at a certain time.

Before You Begin

- Confirm that trace level 99 is set to a value of 1 before you use trace to diagnose IPv6 problems. Trace level 1 is very terse.

Caution Risk of traffic loss

Using the trace tool inappropriately can cause primary CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Activate or deactivate the trace for the IPv6 base:

```
trace ipv6 base <disable|enable> <all|debug|error|icmp|info|ipclient|nbr|pkt|warn> [vrf WORD <1-16>]
```

3. Activate or deactivate the trace for IPv6 forwarding:

```
trace ipv6 forwarding <disable|enable> <all|debug|error|info|pkt|warn>
[vrf WORD <1-16>]
```
4. Activate or deactivate the trace for IPv6 neighbor discovery:

```
trace ipv6 nd <disable|enable> <all|debug|error|info|nbr|pkt|redirect|
warn> [vrf WORD <1-16>]
```
5. Activate or deactivate the trace for IPv6 OSPF:

```
trace ipv6 ospf <disable|enable> <adj|all|config|error|import|info|
lsa|pkt|spf|warn> [vrf WORD <1-16>]
```
6. Activate or deactivate the trace for the IPv6 routing table manager:

```
trace ipv6 rtm <disable|enable> <all|change-list|debug|error|fib|info|
redist|update|warn> [vrf WORD <1-16>]
```
7. Activate or deactivate the trace for IPv6 transport:

```
trace ipv6 transport <disable|enable> <all|common|tcp|udp> [vrf WORD
<1-16>]
```
8. Deactivate the trace to prevent service degradation:

```
trace shutdown

clear trace
```

Examples

```
Switch:1>enable
```

Activate the trace for all the IPv6 base categories on the Management Router:

```
Switch:1#trace ipv6 base enable all vrf MgmtRouter
```

Activate the trace for all the IPv6 forwarding categories:

```
Switch:1#trace ipv6 forwarding enable all
```

Activate the trace for all the IPv6 neighbor discovery categories:

```
Switch:1#trace ipv6 nd enable all
```

Activate the trace for the all IPv6 routing table manager categories:

```
Switch:1#trace ipv6 rtm enable all
```

Activate the trace for all the IPv6 transport categories:

```
Switch:1#trace ipv6 transport enable all
```

Deactivate the trace:

```
Switch:1#trace shutdown
```

```
Switch:1#clear trace
```

```
Removed 5 files.
```

Variable Definitions

The following table defines parameters for the **trace ipv6** command.

Variable	Value
<i>base</i> <disable enable> <all debug error icmp info ipclient nbr pkt warn>	Enables or disables a specific trace category for IPv6 base.
<i>forwarding</i> <disable enable> <all debug error info pkt warn>	Enables or disables a specific trace category for IPv6 forwarding.
<i>nd</i> <disable enable> <all debug error info nbr pkt redirect warn>	Enables or disables a specific trace category for IPv6 neighbor discovery.
<i>ospf</i> <disable enable> <adj all config error import info lsa pkt spf warn>	Enables or disables a specific trace category for IPv6 OSPF.
<i>rtm</i> <disable enable> <all change-list debug error fib info redist update warn>	Enables or disables a specific trace category for IPv6 routing table manager.
<i>transport</i> <disable enable> <all common tcp udp>	Enables or disables a specific trace category for IPv6 transport.
<i>vrf</i> WORD<1-16>	Specifies the VRF name.

View and Delete Debug Files

Use this procedure to view and delete debug files.

Delete debug files to free space in the intflash, which has 2 GB of space. As a best practice, delete these files to ensure enough space exists in intflash. New debug files do not overwrite old debug files. You must remove the file; otherwise, enough free space may not exist in the intflash to store the core dump if the switch fails or enough space may not exist for you to transfer a new release to the intflash of the switch to upgrade your switch.

The **debug-file remove** command can delete the following types of files:

- core
- archive
- PMEM
- dmalloc
- flrec
- wd_stats

If you want to delete a specific file, you must use the **remove** command. For more information, see [VOSS CLI Commands Reference](#).

Procedure

1. To enter User EXEC mode, log on to the switch.

2. View debug files:

```
show debug-file [all][{slot[-slot]}[,...]]
```
3. Delete debug files:

```
debug-file remove [all][{slot[-slot]}[,...]]
```
4. Enter Privileged EXEC mode:

```
enable
```
5. View core files:

```
show core-files {slot[-slot]}[,...]]
```

Example

The following example shows how you view all debug files for all slots, and then remove the debug files for slot 1.

```
Switch>show debug-file

Variable Definitions

The following table defines parameters for the **show core-files** command.

Variable	Value
<code>{slot[-slot][,...]}</code>	Displays the core files for the slot that you select.

The following table defines parameters for the **show debug-file** command.

Variable	Value
<code>all</code>	Displays all types of debug files
<code>{slot[-slot][,...]}</code>	Displays debug files for the slot that you select. If you do not select a slot number, the device displays all types of the archived debug files present in a slot by slot basis. If you select a slot number, the device only displays archived files for the slot you select.

The following table defines parameters for the **debug-file remove** command.

Variable	Value
<code>all</code>	Removes all types of debug files in all slots. If you use the option all with the remove debug-file command, then the device deletes all types of debug files, including the latest debug files.
<code>{slot[-slot][,...]}</code> Note: Exception: only supported on VSP 8600 Series.	Removes debug files for the slot that you select. When you clear archived files, if you do not select a slot number, the device deletes all types of archived debug files except the latest file in each slot. Valid slots are 1-12, SF1-SF6, and all.

Configuring Port Mirroring

Use port mirroring to aid in diagnostic and security operations.

About This Task

Use port mirroring to make a copy of a traffic flow and send that copy to a device for analysis, for example, for diagnostic sniffing. Use the mirror to see the packets in the flow without breaking into the physical connection to place a packet onto the sniffer inline. You can also use port mirroring for security. You can send flows to inspection engines for post processing.

Connect the sniffer (or other traffic analyzer) to the output port you specify in this procedure.

Procedure

1. Enter Global Configuration mode:

```
enable
configure terminal
```

2. Create a port mirroring instance:

```
mirror-by-port <1-479> in-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} {monitor-mlt <1-512>| out-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

3. Create an I-SID mirroring instance:

```
mirror-by-port <1-479> [in-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} monitor-isid-offset <1-1000> [mode <rx|tx|both>] [qos <qos-level>]]
```

4. Configure the mode:

```
mirror-by-port <1-479> mode <both|rx|tx>
```

Note

- When you configure `tx` mode port mirroring on T-UNI and SPBM NNI ports, unknown unicast, broadcast and multicast traffic packets that ingress these ports and the system displays it on the mirror destination port, although they do not egress the mirror source port. This is because `tx` mode port mirroring happens on the mirror source port before the source port squelching logic drops the packets at the egress port.
- The available four mirroring resources are shared between Fabric RSPAN and regular port mirroring, and are allocated based on the mode configured, Ingress (`rx`) or Egress (`tx`). Each configured mode occupies one mirroring resource, but when you configure the mode as `both`, it occupies two mirroring resources (one for Rx and one for Tx).
- Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

5. Enable the mirroring instance:

```
mirror-by-port <1-479> enable
```

6. Modify existing mirroring entries as required:

```
mirror-by-port mirror-port <1-479> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

OR

```
mirror-by-port monitor-mlt <1-479> <1-512>
```

OR

```
mirror-by-port monitor-port <1-479> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

Note

Before you can modify an existing entry, you must disable the entry: `no mirror-by-port <1-479> enable`.

7. Modify QoS value for Fabric RSPAN mirroring session:

```
mirror-by-port <1-479> qos <0-5>
```
8. Verify the configuration:

```
show mirror-by-port
```

Example

Port mirroring configuration:

```
Switch:1> enable
Switch:1# configure terminal
```

Create the port mirroring instance:

```
Switch:1(config)# mirror-by-port 8 in-port 1/15 out-port 1/1
```

The analyzer connects to port 1/1.

Disable the entry:

```
Switch:1(config)# no mirror-by-port 8 enable
```

Mirror both ingress and egress traffic passing through port 1/16:

```
Switch:1(config)# mirror-by-port 8 mode both
```

Enable mirroring for the instance:

```
Switch:1(config)# mirror-by-port 8 enable
```

Fabric RSPAN configuration:

```
Switch:1> enable
Switch:1# configure terminal
```

Create the Fabric RSPAN mirroring instance:

```
Switch:1(config)#mirror-by-port 3 in-port 1/3 monitor-isid-offset 3 mode both qos 3
```

Disable the entry:

```
Switch:1(config)# no mirror-by-port 3 enable
```

Mirror the egress traffic passing through port 1/3:

```
Switch:1(config)# mirror-by-port 3 mode tx
```

Enable Fabric RSPAN for the instance:

```
Switch:1(config)# mirror-by-port 3 enable
```

The sample command output in the following example does not necessarily reflect the preceding examples.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#show mirror-by-port
```

```
=====
                          Diag Mirror-By-Port

=====

```

Variable Definitions

The following table defines parameters for the **mirror-by-port** command.

Variable	Value
<code><1-479></code>	Specifies the entry ID.
<code>enable</code>	Enables or disables a mirroring instance already created in the mirror-by-port table.
<code>in-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} out-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Creates a new mirror-by-port table entry. <ul style="list-style-type: none"> <code>in-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> specifies the mirrored port. <code>monitor-mlt <1-512></code> specifies the mirroring MLT ID from 1-512. <code>out-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> specifies the mirroring port.
<code>mirror-port <1-479> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Modifies the mirrored port. Before you can modify an existing entry, you must disable the entry: <code>no mirror-by-port <1-479> enable</code> .
<code>monitor-ip <1-479> {A.B.C.D} [dscp <0-63>] [ttl <2-255>]</code>	Creates a mirroring instance for Layer 3 mirroring. The destination must be an IP address {A.B.C.D}. The default DSCP is 0 and the default TTL is 255.
<code>monitor-mlt <1-479> <1-512></code>	Modifies the monitoring MLT. <1-512> specifies the mirroring MLT ID. Before you can modify an existing entry, you must disable the entry: <code>no mirror-by-port <1-479> enable</code> .
<code>monitor-port <1-479> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Modifies the monitoring ports. Before you can modify an existing entry, you must disable the entry: <code>no mirror-by-port <1-479> enable</code> .

Variable	Value
<code>monitor-vlan <1-479> <1-4059></code>	Modifies the monitoring VLAN. Before you can modify an existing entry, you must disable the entry: <code>no mirror-by-port <1-479></code> <code>enable</code> . Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<code>mode <both rx tx></code>	Configures the mirroring mode. The default is <code>rx</code> . <ul style="list-style-type: none"> <code>both</code> mirrors both egress and ingress packets. <code>rx</code> mirrors ingress packets. <code>tx</code> mirrors egress packets.
<code>monitor-isid-offset <1-1000></code>	Specifies the offset ID that is mapped to the actual monitor I-SID where packets are mirrored. Monitor I-SID = base monitor I-SID + offset ID. The base monitor I-SID is 16776000.
<code>qos <0-5></code>	Specifies the Quality of Service (QoS) profiles for the system. Monitoring I-SID supports six different QoS levels, each QoS level can be configured individually. Default value is 1.

Displaying Mirror Resource Usage

About This Task

Mirror resources can be consumed by internal processes that are not easily identified, which can lead to unexpected resource shortages. Use the following procedure to display mirror resource usage.

Procedure

- To enter User EXEC mode, log on to the switch.
- Display mirror resource usage:

```
show mirror-resources
```

Example

```
Switch:1#show mirror-resources
<Switch> Mirror Resource Manager stats:
      2 unique mirror destinations allocated, system max is 4
-----
Mirror      | Mirror    | Total | Mirror
Destination | Direction | Refs  | Users
-----
Port 1/2    | Egress   | 1     | MBP ID 1
Port 1/2    | Ingress  | 1     | MBP ID 1
-----
Function execution completed successfully
```

Configuring Global Mirroring Actions with an ACL

Configure the global action to mirror packets that match an access control list (ACL).

Before You Begin

- The ACL exists.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure the global action for an ACL:

```
filter acl set <1-2048> global-action {monitor-dst-mlt <1-512>|
monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Configure the global action for an ACL:

```
Switch:1(config)# filter acl set 200 global-action monitor-dst-mlt 20
```

Variable Definitions

The following table defines parameters for the **filter acl set** command.

Variable	Value
<1-2048>	Specifies an ACL ID from 1-2048.
<i>default-action</i> <deny permit>	Specifies the global action to take for packets that do not match an ACL.
<i>global-action</i> { <i>monitor-dst-mlt</i> PT_MLT<1-512> <i>monitor-dst-ports</i> { <i>slot/port</i> [/ <i>sub-port</i>] [- <i>slot/port</i> [/ <i>sub-port</i>]] [,...]}	Specifies the global action to take for matching ACLs: <ul style="list-style-type: none"> monitor destination MLT—Configures mirroring to a destination MultiLink Trunking (MLT) group. monitor destination ports—Configures mirroring to a destination port or ports.

Configure ACE Actions to Mirror

Important

Product Notice: VSP 8600 Series supports Policy Based Routing (Redirect Next Hop) Per VRF as a demo feature. Do not use this feature in production environments.

Configure actions to use filters for flow-based mirroring.

Before You Begin

- The access control entry (ACE) exists.

About This Task

If you use the mirror action, ensure that you specify the mirroring destination: MLTs or ports.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure actions for an ACE:

```
filter acl ace action <1-2048> <1-2000> {permit|deny} monitor-dst-mlt  
<1-512>
```

OR

```
filter acl ace action <1-2048> <1-2000> {permit|deny} monitor-dst-  
ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

3. Ensure the configuration is correct:

```
show filter acl action [<1-2048>] [<1-2000>]
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# filter acl ace action 901 1 permit monitor-dst-mlt 5
```

Variable Definitions

The following table defines parameters for the **filter acl ace action** command.

Variable	Value
<i>1-2048</i>	Specifies the ACL ID from 1-2048
<i>1-2000</i>	Specifies the ACE ID from 1-2000.
<i>monitor-dst-mlt <1-512></i>	Configures mirroring to a destination MLT group.
<i>monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Configures mirroring to a destination port or ports.
<i>{permit deny}</i>	Configures the action mode for security ACEs. The default value is permit.

Clearing ARP Information for an Interface

Clear the Address Resolution Protocol (ARP) cache as part of ARP problem resolution procedures.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear ARP information:

```
clear ip arp interface gigabitethernet {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

OR

```
clear ip arp interface vlan <1-4059>
```

Example

```
Switch:1> enable
```

```
Switch:1# clear ip arp interface gigabitethernet 1/1
```

Variable Definitions

The following table defines parameters for the **clear ip arp interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Flush Routing, MAC, and ARP Tables for a Port

Flush or clear the routing tables for administrative and troubleshooting purposes. The clear and flush commands perform the same function; they remove the contents of the table.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Flush IP routing tables by port:

```
action flushIp
```

3. Flush the MAC address tables by port:

```
action flushMacFdb
```

Note

Flushing MAC address tables multiple times in a very short period of time can cause undefined errors. Wait at least 10 seconds between MAC flushes on VSP 8600 Series.

4. Flush ARP tables by port:

```
action flushArp
```

5. Flush all tables with one command:

```
action flushAll
```

6. Exit to Global Configuration mode:

```
exit
```

7. Clear a routing table for a port:

```
clear ip route gigabitethernet {slot/port[sub-port]}
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#action flushAll
Switch:1(config-if)#exit
Switch:1(config)#clear ip route gigabitethernet 1/1
```

Variable Definitions

The following table defines parameters for the **clear ip route gigabitethernet** command.

Variable	Value
<i>{slot/port[/sub-port]}</i>	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Flush Routing, MAC, and ARP Tables for a VLAN

Flush or clear the routing tables for administrative and troubleshooting purposes. The clear and flush commands perform the same function; they remove the contents of the table.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Flush IP routing tables by VLAN:

```
vlan action <1-4059> flushIp
```
3. Flush the MAC address tables by VLAN:

```
vlan action <1-4059> flushMacFdb
```

Note

Flushing MAC address tables multiple times in a very short period of time can cause undefined errors. Wait at least 10 seconds between MAC flushes on VSP 8600 Series.

4. Flush ARP tables by VLAN:

```
vlan action <1-4059> flushArp
```
5. Flush all tables with one command:

```
vlan action <1-4059> all
```
6. Clear a routing table for a VLAN:

```
clear ip route vlan <1-4059>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config-if)#vlan action 123 all
Switch:1(config)#clear ip route vlan 123
```

Variable Definitions

The following table defines parameters for the **vlan action** and **clear ip route vlan** commands.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

*Ping an IP Device***About This Task**

Ping a device to test the connection between the switch and another network device. After you ping a device, the switch sends an Internet Control Message Protocol (ICMP) packet to the target device. If the device receives the packet, it sends a ping reply. After the switch receives the reply, a message displays that indicates traffic can reach the specified IP address. If the switch does not receive a reply, the message indicates the address does not respond.

Ping and traceroute can fail for VRF routes if you use large packet sizes for the operation. Do not use packet sizes larger than the following:

- Ping for VRF: 1480 bytes
- Traceroute for VRF: 1444 bytes

**Note**

Exception: large packets for VRF routes are supported on the CLIP Segmented Management Instance.

You can specify a management instance ID to use the correct source for the outgoing ICMP ECHO request packet.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Ping an IP network connection:

```
ping WORD<0-256> [-d] [-I <1-60>] [-s] [-t <1-120>] [count <1-9999>]
[datasize <28-9216|28-51200>] [grt] [interface gigabitEthernet {slot/
port[sub-port]}|mgmtEthernet mgmt | tunnel <1-2000> | vlan <1-4059>]
[scopeid <1-9999>] [source WORD<1-256>] [vrf WORD<1-16>]
```
3. Ping an IP network connection using a Global Routing Table (GRT):

```
ping WORD<0-256> [-d] [-I <1-60>] [-s] [-t <1-120>] [count <1-9999>]
[datasize <28-9216|28-51200>] grt [interface gigabitEthernet {slot/
port[sub-port]}| tunnel <1-2000> | vlan <1-4059>] [source WORD<1-246>]
```
4. Ping a network connection using a Segmented Management Instance:

```
ping WORD<0-256> [-s] [-t <1-120>] [count <1-9999>] [datasize
<28-9216|28-51200>] mgmt [clip | oob | vlan]
```

**Note**

If you do not use the *mgmt* parameter, the **ping** command uses the IP routing stack to initiate the ping request.

If you ping a device using a management CLIP, the ping source IP address is configured as the management CLIP IP address. If you ping a device using a management VLAN, the ping source IP address is configured as the management VLAN IP address.

Examples

Ping an IP device from a GRT VLAN IP interface:

```
Switch:1#ping 192.0.2.16 grt interface vlan 1
192.0.2.16 is alive
```

Ping a device using the management routing table:

```
Switch:1#ping 192.0.2.12 mgmt
```

Ping a device using a management CLIP:

```
Switch:1#ping 192.0.2.12 mgmt clip
```

Ping an IP device using a management VLAN:

```
Switch:1#ping 192.0.2.12 mgmt vlan
```

Variable Definitions

The following table defines parameters for the **ping** command.

Variable	Value
<i>count</i> <1-9999>	Specifies the number of times to ping. The default is 1.
<i>-d</i>	Configures the ping debug mode. This variable detects local software failures (ping related threads creation or write to sending socket) and receiving issues (icmp packet too short or wrong icmp packet type). This parameter does not apply if you use the mgmt [clip oob vlan] parameter.
<i>datasize</i> <28-9216 28-51200>	Specifies the size of ping data sent in bytes. The datasize for IPv4 addresses is 28-9216. The datasize for IPv6 addresses is 28-51200. The default is 64.
<i>grt</i> Note: Exception: not supported on VSP 8600 Series.	Specifies the ping in Global Routing Table context.
<i>-I</i> <1-60>	Specifies the interval between transmissions in seconds.

Variable	Value
<pre>interface gigabitEthernet {slot/ port[sub-port]} mgmtEthernet mgmt tunnel <1-2000> vlan <1-4059></pre>	<p>Specifies the outgoing interface. Additional ping interface parameters:</p> <ul style="list-style-type: none"> gigabitEthernet {slot/port[sub-port]}: gigabitEthernet port mgmtEthernet mgmt: identifies the physical management port <p>Note: mgmtEthernet is only supported on VSP 8600 Series.</p> <ul style="list-style-type: none"> tunnel: tunnel ID as a value from 1 to 2000 vlan: <p>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.</p> <p>This parameter does not apply if you use the mgmt [clip oob vlan] parameter.</p>
<pre>mgmt [clip oob vlan]</pre> <p>Note: Exception: <i>vlan</i> and <i>oob</i> not supported on VSP 8600 Series.</p>	<p>Specifies the Segmented Management Instance as the source for the outgoing ICMP ECHO packet. The packet goes out this specific interface only. If you do not specify the management interface type, the ping command uses the management routing table to determine the best management interface and selects the source IP based on the egress management interface.</p>
<pre>-s</pre>	<p>Configures the continuous ping at the interval rate defined by the <i>[-I]</i> parameter or until you enter a Ctrl + C keystroke.</p>
<pre>scopeid <1-9999></pre>	<p>Specifies the circuit ID for IPv6. This parameter does not apply if you use the mgmt [clip oob vlan] parameter.</p>
<pre>source WORD<1-256></pre>	<p>Specifies the source IP address for the ping command. This parameter does not apply if you use the mgmt [clip oob vlan] parameter.</p>
<pre>-t <1-120></pre>	<p>Specifies the no-answer timeout value in seconds. The default is 5.</p>

Variable	Value
<code>WORD<0-256></code>	Specifies the host name or IPv4 (a.b.c.d) or IPv6 (x:x:x:x:x:x) address.
<code>vrf WORD<1-16></code>	Specifies the virtual router and forwarder (VRF) name. This parameter does not apply if you use the <code>mgmt [clip oob vlan]</code> parameter.

Run a Traceroute Test

Use traceroute to determine the route packets take through a network to a destination.

About This Task

Ping and traceroute can fail for VRF routes if you use large packet sizes for the operation. Do not use packet sizes larger than the following:

- Ping for VRF: 1480 bytes
- Traceroute for VRF: 1444 bytes

Note

Exception: large packet sizes are supported when running ping and traceroute on the Segmented Management Instance.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Run a traceroute test:

```
traceroute WORD<0-256> [<1-1176>] [-m <1-255>] [-p <1-65535>] [-q <1-255>] [-v] [-w <1-255>] [grt [source]] [mgmt [clip | oob | vlan]] [source <WORD 1-256>] [vrf <WORD 1-16>]
```

3. Run a traceroute test using a Segmented Management Instance:

```
traceroute WORD<0-256> [<1-1176>] [-m <1-255>] [-p <1-65535>] [-q <1-255>] [-w <1-255>] [grt [source]] mgmt [<clip | oob | vlan>]
```

Note

If you do not use the `mgmt` parameter, the **traceroute** command uses the IP routing stack to initiate the traceroute request.

Examples

Run a traceroute test with a probe packet size of 200 and a max time to live of 60:

```
Switch:1>enable
Switch:1#traceroute 192.0.2.33 200 -m 60
```

Run a traceroute test for an IPv6 address:

```
Switch:1#traceroute 2001:db8::1
```

Run a traceroute test using the management routing table:

```
Switch:1#traceroute 192.0.2.12 mgmt
```

Run a traceroute test using a management CLIP:

```
Switch:1#traceroute 192.0.2.12 mgmt clip
```

Run a traceroute test using a management VLAN:

```
Switch:1#traceroute 192.0.2.12 mgmt vlan
```

Variable Definitions

The following table defines parameters for the **traceroute** command.

Variable	Value
<code>-m <1-255></code>	Specifies the maximum time-to-live (TTL).
<code>-p <1-65535></code>	Specifies the base UDP port number. The default is 33434. Note: If the traceroute action is directed to an IPv6 host address, Linux increments the UDP port on a per-TTL basis. For an IPv4 host address, Linux increments the UDP port on a per-probe basis. Because the traceroute command sends a default of three probes, three incrementing ports will be sent for an IPv4 host address. If you use the <code>-p</code> parameter with a value greater than 65533, the traceroute command fails for an IPv4 host address because the maximum port number, 65535, is exceeded. If you send a traceroute probe into the device through the Segmented Management Instance or any VOSS routing interface, you must use the default UDP port range of 33434 to 33534. Using other ports will fail.
<code>-q <1-255></code>	Specifies the number of probes per TTL.
<code>-v</code>	Specifies verbose mode (detailed output). This parameter does not apply if you use the <code>mgmt [clip oob vlan]</code> parameter.
<code>-w <1-255></code>	Specifies the wait time for each probe.
<code><1-1176></code>	Specifies the size of the probe packet.
<code>grt</code> Note: Exception: not supported on VSP 8600 Series	Specifies the traceroute command is executed in grt context.

Variable	Value
<code>mgmt [<clip oob vlan>]</code> Note: Exception: <code>oob</code> not supported on VSP 4450 Series , XA1400 Series, or VSP 8600 Series Note: Exception: <code>vlan</code> not supported on VSP 8600 Series	Specifies the Segmented Management Instance as the source for the outgoing packet. The packet goes out this specific interface only. If you do not specify the management interface type, the tracert command uses the management routing table to determine the best management interface and selects the source IP based on the egress management interface.
<code>source <WORD 1-256></code>	Specifies the source IP address. This parameter does not apply if you use the <code>mgmt [clip oob vlan]</code> parameter.
<code>WORD<0-256></code>	Specifies the destination IPv4 or IPv6 address, or hostname.
<code>vrf <WORD 1-16></code>	Specifies the VRF instance by VRF name. This parameter does not apply if you use the <code>mgmt [clip oob vlan]</code> parameter.

Showing SNMP Logs

Show the full SNMP logs. SNMP logs display the alarms and events that have been registered on the device.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Show the logs:

```
show fulltech file WORD<1-99>
```

Variable Definitions

The following table defines parameters for the **show fulltech** command.

Variable	Value
<code>file WORD<1-99></code>	This variable represents the log file to be opened and displayed. It is displayed in the following format: <ul style="list-style-type: none"> • <code>/intflash/<file></code>

Using Trace to Examine IS-IS Control Packets

Use trace as a debug tool to examine the code flow and Intermediate-System-to-Intermediate-System (IS-IS) control packets. When you enable IS-IS trace flags, the system displays only trace information about the set flag.

Before You Begin

- You must know what you want to trace before you enable trace.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Enable the Intermediate-System-to-Intermediate-System trace flags:

```
trace flags isis set { none | tx-hello | rx-hello | tx-pkt | rx-pkt |  
adj | opt | tx-lsack | rx-lsack | tx-lsp | rx-lsp | pkt-err | nbr-  
mismatch | flood | prefix | nbr-change | intf-change | decide | fdb |  
dr | dd-masterslave | auth-fail | config | purge | policy | redist |  
tx-snp | rx-snp | timer | global | perf | ucast-fib | node | mcast-fib  
| isid | ip-shortcut }
```

3. Identify the module ID for which you want to use the trace tool:

```
show trace modid-list
```

4. Clear the trace:

```
clear trace
```

5. Begin the trace operation:

```
trace level [Module_ID] [<0-4>]
```

OR

```
trace spbm isis level [<0-4>]
```

OR

```
trace cfm level [<0-4>]
```

Note

- Module ID 119 represents the IS-IS module.

6. Wait approximately 30 seconds.

The default trace settings for CPU utilization are:

- High CPU Utilization: 90%
- High Track Duration: 5 seconds
- Low CPU Utilization: 75%
- Low Track Duration: 5 seconds

7. Stop tracing:

```
trace shutdown
```

8. View the trace results:

```
trace screen enable
```

Important

If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

9. Save the trace file.

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt.

10. Display trace lines saved to a file:

```
show trace file [tail]
```

11. Search trace results for a specific string value:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

12. Stop tracing:

```
trace shutdown
```

13. Disable the Intermediate-System-to-Intermediate-System trace flags:

```
trace flags isis remove { none | tx-hello | rx-hello | tx-pkt | rx-pkt
| adj | opt | tx-lsack | rx-lsack | tx-lsp | rx-lsp | pkt-err | nbr-
mismatch | flood | spf-intra | spf-inter | spf-extern | prefix | nbr-
change | intf-change | decide | fdb | dr | dd-masterslave | auth-fail
| config | purge | policy | redist | tx-snp | rx-snp | timer | spbm-
decide | global | perf | ucast-fib | node | mcast-fib | isid | ip-
shortcut }
```

Example

```
Switch:1> enable
```

Clear prior trace information:

```
Switch:1# clear trace
```

Enable IS-IS trace flags for received IS-IS hello packets:

```
Switch:1# trace flags isis set rx-hello
```

Enable IS-IS trace flags for transmitted IS-IS hello packets:

```
Switch:1# trace flags isis set tx-hello
```

Configure the module ID to 119 (IS-IS module) and the trace to 4 (very verbose):

```
Switch:1# trace level 119 4
```

Enable the display of trace output to the screen:

```
Switch:1# trace screen enable
Switch:1# Screen tracing is on
```

Disable the display of trace output to the screen:

```
Switch:1# trace screen disable  
Switch:1# Screen tracing is off
```

Variable Definitions

The following table defines parameters for the **trace flags isis** command.

Variable	Value
<pre>remove { none tx-hello rx-hello tx-pkt rx-pkt adj opt tx-lsack rx-lsack tx-lsp rx-lsp pkt-err nbr-mismatch flood prefix nbr-change intf-change decide fdb dr auth-fail config purge policy redistrib tx-snp rx-snp timer global perf ucast-fib node isid ip-shortcut }</pre>	<p>Removes the Intermediate-System-to-Intermediate-System (IS-IS) trace flags for the specified option.</p>
<pre>set { none tx-hello rx-hello tx-pkt rx-pkt adj opt tx-lsack rx-lsack tx-lsp rx-lsp pkt-err nbr-mismatch flood prefix nbr-change intf-change decide fdb dr auth-fail config purge policy redistrib tx-snp rx-snp timer global perf ucast-fib node isid ip-shortcut }</pre>	<p>Enables the Intermediate-System-to-Intermediate-System (IS-IS) trace flags for the specified option.</p> <ul style="list-style-type: none"> • none — none • tx-hello — Transmitted IS-IS hello packet • rx-hello — Received IS-IS hello packet • tx-pkt — Transmitted packet • rx-pkt — Received packet • adj — Adjacencies • opt — IS-IS TLVs • tx-lsack — Transmitted LSP acknowledgement • rx-lsack — Received LSP acknowledgement • tx-lsp — Transmitted Link State Packet • rx-lsp — Received Link State Packet • pkt-err — Packet Error • nbr-mismatch — Neighbor mismatch • flood — Flood • prefix — Prefix • nbr-change — Neighbor change • intf-change — IS-IS circuit (interface) events • decide — Shortest Path First computation • fdb — Filtering Database • dr — Designated Router • auth-fail — Authorization failed • config — Configuration • purge — Link State Packet purge • redistrib — Redistribute • tx-snp — Transmitted Sequence Number PDU (CSNP and PSNP) • rx-snp — Received Sequence Number Packet (CSNP and PSNP) • timer — Timer • perf — SPBM performance

Variable	Value
	<ul style="list-style-type: none"> • ucast-fib — Unicast Forwarding Information Base • node — Node • isid — I-SID • ip-shortcut — IP Shortcut

The following table defines parameters for the **show trace** command.

Variable	Value
<i>auto</i>	Displays the current configuration for the automatic trace function.
<i>file [tail]</i>	Displays the trace results saved to a file.
<i>level</i>	Displays the current trace level for all modules.
<i>modid-list</i>	Specifies the module ID list.

The following table defines parameters for the **trace** command.

Variable	Value
<i>grep [WORD<0-128>]</i>	Specifies the search keyword. You can use a specific MAC address. You can search for errors, using the command, trace grep error .
<i>cfm level [<0-4>]</i>	Starts tracing by CFM. <ul style="list-style-type: none"> • <0-4> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<i>spbm isis level [<0-4>]</i>	Specifies exactly which IS-IS component to display. <ul style="list-style-type: none"> • <0-4> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<i>level [<Module_ID>] [<0-4>]</i>	Starts the trace by specifying the module ID and level. <Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the show trace modid-list command or CLI command completion Help. 0-4 specifies the trace level: <ul style="list-style-type: none"> • 0 — Disabled • 1 — Very terse • 2 — Terse • 3 — Verbose • 4 — Very verbose

Variable	Value
<i>shutdown</i>	Stops the trace operation.
<i>screen {disable enable}</i>	Enables or disables the display of trace output to the screen. Important: Avoid using the screen to view commands if you use trace level 3 (verbose) or trace level 4 (very verbose) due to the volume of information generated and the effect on the system.

The following table defines parameters for the **save trace** command.

Variable	Value
<i>file WORD<1-99></i>	Specifies the file name in one of the following formats: <ul style="list-style-type: none"> a.b.c.d: <file> WORD<1-99> is a string of 1-99 characters. Note: If you do not specify a file name, the file name is systrace.txt.

Viewing the Metric Type of IS-IS Route in TLVs - Detailed

About This Task

Use the following procedure to view the detailed information about metric type of IS-IS routes in TLVs in Link State Packets (LSP).

Procedure

1. Display the detail view of TLV 135:
`show isis lsdb tlv 135 detail`
2. Display the detail view of TLV 184:
`show isis lsdb tlv 184 detail`

Example

Viewing the metric type of IS-IS route in TLV 135

```
Switch:1#show isis lsdb tlv 135 detail

=====
                        ISIS LSDB (DETAIL)
=====

Level-1 LspID: 4072.0000.0000.00-02      SeqNum: 0x00000009      Lifetime: 1110
      Chksum: 0x31ce  PDU Length: 46
      Host_name: evp4k
      Attributes:      IS-Type 1

Viewing the Metric Type of IS-IS Route in TLVs - Summarized

About This Task

Use the following procedure to view the summarized information about metric type of IS-IS routes in TLVs. You can also view the metric type of the prefix.

Procedure

Display the summarized view of TLVs 135 and 184:

```
show isis lsdb ip-unicast
```

Example

Display the summarized view of TLVs.

```

evp4k:1#show isis lsdb ip-unicast

=====
                        ISIS IP-UNICAST-ROUTE SUMMARY

Configuring I-SID Monitoring

Use the following procedure to configure Fabric RSPAN (Mirror to I-SID) on the Backbone Edge Bridge (BEB) connected to the monitor station.

Note

Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

Note

If you change the egress port or egress MLT for a particular session using a separate CLI command, it overwrites the existing egress port list or egress MLT.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a monitor by I-SID entry:

Note

If you use the Extreme Integrated Application Hosting (IAH) port 1/s1 as the analyzer port on the monitoring BEB for remote mirroring, you must associate it to VLAN ID 4091.

```
monitor-by-isid <1-1000> [monitor-isid-offset <1-1000> {egress-mlt <1-512> | egress-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}] [map-to-vid <1-4093>]]
```

3. Configure map to VLAN ID:

```
monitor-by-isid <1-1000> map-to-vid <1-4093>
```

4. Configure egress MLT:

```
monitor-by-isid <1-1000> egress-mlt <1-512>
```

5. Configure egress port:

```
monitor-by-isid <1-1000> egress-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

6. Enable monitoring by I-SID entry:

```
monitor-by-isid <1-1000> enable
```

Note

Disable the entries (egress ports, MLT, and VLAN ID) to modify or remove parameters in the existing configuration.

Example

```
Switch:1> enable
Switch:1# configure terminal
```

```

Switch:1(config)# monitor-by-isid 1 monitor-isid-offset 1 egress-port 1/6
Switch:1(config)# monitor-by-isid 2 monitor-isid-offset 2 egress-port 1/7 map-to-vid 200
Switch:1(config)# monitor-by-isid 3 monitor-isid-offset 3 egress-port 1/7 map-to-vid 201
Switch:1(config)# monitor-by-isid 2 egress-port 1/8
Switch:1(config)# monitor-by-isid 1 monitor-isid-offset 1000 egress-ports 1/1 egress-mlt
16 map-to-vid 1000
Switch:1(config)# monitor-by-isid 7 monitor-isid-offset 7 egress-mlt 2 map-to-vid 203
Switch:1(config)# monitor-by-isid 2 egress-mlt 3

```

Variable Definitions

The following table defines parameters for the **monitor-by-isid** command.

Variable	Value
<code><1-1000></code>	Specifies the monitoring session.
<code>monitor-isid-offset <1-1000></code>	Specifies the offset ID that is mapped to the actual monitor I-SID where packets are mirrored. Monitor I-SID = Base monitor I-SID + Offset ID. The base monitor I-SID is 16776000.
<code>egress-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port to which the analyzers connect.
<code>egress-mlt <1-512></code>	Specifies the MLT to which the analyzers connect.
<code>map-to-vid <1-4093></code>	Maps the mirrored packet to a specified VLAN ID for analysis. This parameter is optional. Note: If you use the Extreme Integrated Application Hosting (IAH) port 1/s1 as the analyzer port on the monitoring BEB for remote mirroring, you must associate it to VLAN ID 4091.

Displaying I-SID Monitoring Diagnostics

Use the following procedure to display the **monitor-by-isid** entries on the monitoring BEB.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enter the following command:

```
show monitor-by-isid WORD<1-1024>
```

Example

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# show monitor-by-isid 3
=====
                    Diag Monitor-By-ISID
=====
ID MONITOR_ISID  ISID_OFFSET  EGRESS_PORTS  EGRESS_MLT  MAP_TO_VLAN  ENABLE
=====

```

```
3 16776000 1 1/4, 1/5 1 999 true
-----
```

Variable Definitions

The following table defines parameters for the **show monitor-by-isid** command.

Variable	Value
<i>WORD<1-1024></i>	Specifies the session ID list ranging from 1 to 1000.

Displaying I-SID Mirroring Statistics

Use the following procedure to display the statistics of the number of packets mirrored into I-SID on the mirroring BEB.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enter the following command:

```
show isid-mirroring stats [monitor-isid-offset WORD<1-1024>]
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# show isid-mirroring stats monitor-isid-offset 1
=====
Mirror Statistics Info
=====
ISID      ISID_OFFSET  PACKETS
-----
16776000      1           100
-----
```

Variable Definitions

The following table defines parameters for the **show isid-mirroring stats** command.

Variable	Value
<i>monitor-isid-offset WORD<1-1024></i>	Specifies the offset ID mapped to monitor the I-SID. The offset ID ranges from 1 to 1000.

Clearing Fabric RSPAN (Mirror to I-SID) Statistics

Use the following procedure to clear Fabric RSPAN (Mirror to I-SID) statistics of packets mirrored into the specified mirroring I-SID or all mirroring I-SIDs on the BEB.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter the following command:

```
clear isid-mirroring stats monitor-isid-offset WORD<1-1024>
```

Note

You must use this command on the Mirroring BEB to clear the statistics of packets mirrored into I-SID.

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Clear all Fabric RSPAN statistics:

```
Switch:1(config)# clear isid-mirroring stats
```

Clear all Fabric RSPAN (Mirror to I-SID) statistics of packets mirrored into the specified mirroring I-SID

```
Switch:1(config)# clear isid-mirroring stats monitor-isid-offset 1
```

Variable Definitions

The following table defines parameters for the **clear isid-mirroring stats** command.

Variable	Value
<i>monitor-isid-offset WORD<1-1024></i>	Specifies the offset ID that is mapped to the actual monitor I-SID where packets are mirrored. Monitor I-SID = base monitor I-SID + offset ID. The range of the <i>monitor-isid-offset</i> is 1 to 1000. The base monitor I-SID is 16776000.

Software Troubleshooting Tool Configuration Using EDM

Use the tools described in this section to perform troubleshooting procedures using Enterprise Device Manager (EDM).

Flush Routing Tables by VLAN

About This Task

For administrative and troubleshooting purposes, sometimes you must flush the routing tables. You can use EDM to flush the routing tables by VLAN or flush them by port. Perform this procedure to flush the IP routing table for a VLAN.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Advanced** tab.

4. In the **Vlan Operation Action** box for the VLAN you want to flush, double-click, and then select a flush option from the list.

In a VLAN context, all entries associated with the VLAN are flushed. You can also flush the Address Resolution Protocol (ARP) entries and IP routes for the VLAN.

5. Click **Apply**.

Flush Routing Tables by Port

About This Task

For administrative and troubleshooting purposes, sometimes you must flush the routing tables. You can use EDM to flush the routing tables by VLAN or flush them by port. Perform this procedure to flush the IP routing table for a port.

Procedure

1. On the Device Physical View, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **General**.
4. Click the Interface tab.
5. In the **Action** section, select **flushAll**.

In a port context, all entries associated with the port are flushed. You can flush the ARP entries and IP routes for a port. After you flush a routing table, it is not automatically repopulated. The repopulation time delay depends on the routing protocols in use.

6. Click **Apply**.

Configure Port Mirroring

Before You Begin

- To change a port mirroring configuration, first disable mirroring.

About This Task

Use port mirroring to aid in diagnostic and security operations.

Use port mirroring to make a copy of a traffic flow and send that copy to a device for analysis, for example, for diagnostic sniffing. Use the mirror to see the packets in the flow without breaking into the physical connection to place a packet onto the sniffer inline. You can also use port mirroring for security. You can send flows to inspection engines for post processing.

Connect the sniffer (or other traffic analyzer) to the output port you specify in this procedure.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **General**.
3. Select the **Port Mirrors** tab.
4. Select **Insert**.
5. To enable port mirroring for the instance, select the **Enable** check box.

6. Configure mirroring as required.

Note

- When you configure `tx` mode port mirroring on T-UNI and SPBM NNI ports, unknown unicast, broadcast and multicast traffic packets that ingress these ports and the system displays on the mirror destination port, although they do not egress the mirror source port. This is because `tx` mode port mirroring happens on the mirror source port before the source port squelching logic drops the packets at the egress port.
- The available four mirroring resources are shared between Fabric RSPAN and regular port mirroring, and are allocated based on the mode configured, Ingress (`rx`) or Egress (`tx`). Each configured mode occupies one mirroring resource, but when you configure the mode as `both`, it occupies two mirroring resources (one for Rx and one for Tx).
- Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

7. Select **Insert**.

Port Mirrors Field Descriptions

Use the data in the following table to use the **Port Mirrors** tab.

Name	Description
Id	Specifies an assigned identifier for the configured port mirroring instance.
MirroredPortList	Specifies a port to be mirrored (the source port).
Enable	Enables or disables this port mirroring instance. The default value is Enable.
Mode	Specifies the traffic direction of the packet being mirrored: <ul style="list-style-type: none"> • <code>tx</code> mirrors egress packets. • <code>rx</code> mirrors ingress packets. • <code>both</code> mirrors both egress and ingress packets. The default is <code>rx</code> .
MirroringPortList	Specifies a destination port (the port to which the mirrored packets are forwarded). Configures the mirroring port.
MirroringMltId	Specifies the destination MultiLink trunking ID.
MonitoringIsidOffset	Used to configure the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored.
MonitoringIsid	Specifies the actual monitor I-SID value to which the packets are mirrored.
MirroringQos	Used to define the Quality of Service (QoS) profiles for the mirrored packet into monitoring I-SID.

Configure ACLs for Mirroring

Configure the access control list (ACL) to mirror packets for an access control entry (ACE) that matches a particular packet.

Before You Begin

- The ACL exists.

About This Task

To modify an ACL parameter, double-click the parameter you wish to change. Change the value, and then click Apply. You cannot change a parameter that the system displays it dimmed; in this case, delete the ACL, and then configure a new one.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Double-click the parameter **MirrorMltId** to configure mirroring to a destination MLT group.
5. Double-click the parameter **MirrorDstPortList** to configure mirroring to a destination port or ports.

ACL Field Descriptions

Use the data in the following table to use the **ACL** tab.

Name	Description
AcId	Specifies a unique identifier for the ACL from 1-2048.
Type	Specifies whether the ACL is VLAN- or port-based. Valid options are <ul style="list-style-type: none"> • inVlan • inPort • outPort <p>Important: The inVlan ACLs drop packets if you add a VLAN after ACE creation.</p>
Name	Specifies a descriptive user-defined name for the ACL.
VlanList	For inVlan type, specifies all VLANs to associate with the ACL.
PortList	For inPort and outPort ACL types, specifies the ports to associate with the ACL.
DefaultAction	Specifies the action taken when no ACEs in the ACL match. Valid options are deny and permit. Deny means the system drops the packets; permit means the system forwards packets. The default is permit.
ControlPktAction	Specifies the action for control packets, if you configure DefaultAction to deny. If DefaultAction is permit, this value is ignored.

Name	Description
State	Enables or disables all of the ACEs in the ACL. The default value is enable.
PktType	Indicates the packet type that this ACL is applicable to. The default is IPv4.
MirrorMltd	Configures mirroring to a destination MLT group.
MirrorDstPortList	Configures mirroring to a destination port or ports.

Configure ACEs for Mirroring

Before You Begin

- The ACL exists.
- The ACE exists.

About This Task

Configure actions to use filters for flow mirroring. Use an ACE to define the mirroring actions the filter performs.

If you use the mirror action, ensure that you specify the mirroring destination: IP address, MLTs, ports, or VLANs.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the ACL for which to modify an ACE.
5. Click **ACE**.
6. Select an ACE, and then click **Action**.
7. Configure one of: **DstPortList**, **DstMltd**, or **DstIp**.
8. Click **Apply**.

Action Field Descriptions

Use the data in the following table to use the **Action** tab.

Note

The table lists the options for both Security ACEs and QoS ACEs. Dependent upon the ACE the system displays different options on the EDM interface.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies a unique identifier and priority for the ACE.
Mode	Indicates the operating mode associated with this ACE. Valid options are deny, permit and none. The default is none.

Name	Description
RemarkDscp	Specifies the new Per-Hop Behavior (PHB) for matching packets: phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, phbcs7. This action is a QoS action. The ACE ID must be in the range of 1001–2000.
RemarkDot1Priority	Specifies the new 802.1 priority bit for matching packets: zero, one, two, three, four, five, six, or seven. This action is a QoS action. The ACE ID must be in the range of 1001–2000. The default is disable.
InternalQoS	This variable is a QoS action. The ACE ID must be in the range of 1001–2000. The default value is 1.
RedirectNextHop	Redirects matching IP traffic to the next hop. The default is 0.0.0.0.
RedirectUnreach	Configures the desired behavior for redirected traffic when the specified next-hop is not reachable. The default value is deny.
Count	Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.
Log	This action logs to the switch. Use this parameter with either a security or QoS ACE. The default is disabled.
DstPortList	Specifies the ports to which to mirror traffic.
DstMtlId	Specifies the Multilink Trunking (MLT) group to which to mirror traffic.
DstIp	Configures mirroring to a destination IP address for flow-based mirroring.
DstIpDscp	Optionally, configures the DSCP value. The default is 256 (disabled).
DstIpTtl	Optionally, configures the time-to-live value. The default TTL is 64.

Run a Ping Test

About This Task

Use ping to determine if an entity is reachable.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Ping Control** tab.
4. Click **Insert**.
5. In the **OwnerIndex** box, type the owner index.

6. In the **TestName** box, type the name of the test.
7. In the **TargetAddress** box, type the host IP address.
8. From the **AdminStatus** options, select **enabled**.
9. In the remainder of the option boxes, type the desired values.
10. Click **Insert**.
11. Select an entry, and then click **Start**.
Let the test run for several seconds.
12. Select an entry, and then click **Stop**.
13. View the Ping results.

Ping Control Field Descriptions

Use the data in the following table to use the **Ping Control** tab.

Name	Description
OwnerIndex	Provides access control by a security administrator using the View-Based Access Control Model (VACM) for tables in which multiple users need to independently create or modify entries. This is a string of up to 32 characters.
TestName	Specifies the name of the ping test.
TargetAddress	Specifies the host address to use at a remote host to perform a ping operation.
DataSize	Specifies the size of the data portion (in octets) to transmit in a ping operation. The default is 16.
TimeOut	Specifies the timeout value, in seconds, for a remote ping operation. The default is 3 seconds.
ProbeCount	Specifies the number of times to perform a ping operation at a remote host. The default is 1.
AdminStatus	Specifies the state of the ping control entry: enabled or disabled. The default is disabled.
DataFill	Determines the data portion of a probe packet.
Frequency	Specifies the number of seconds to wait before repeating a ping test. The default is 0.
MaxRows	Specifies the maximum number of entries allowed in the PingProbeHistory table. The default is 50.

Name	Description
TrapGeneration	Specifies when to generate a notification. The options are: <ul style="list-style-type: none"> • ProbeFailure—Generates a PingProbeFailed notification subject to the value of TrapProbeFailureFilter. The object TrapProbeFailureFilter can specify the number of successive probe failures that are required before a pingProbeFailed notification is generated. • TestFailure—Generates a PingTestFailed notification. The object TrapTestFailureFilter can determine the number of probe failures that signal when a test fails. • TestCompletion—Generates a PingTestCompleted notification. The value of this object defaults to zero, indicating that none of the above options have been selected.
TrapProbeFailureFilter	Specifies the number of successive probe failures that are required before a pingProbeFailed notification is generated. The default is 1.
TrapTestFailureFilter	Determines the number of probe failures that signal when a test fails. The default is 1.
Descr	Describes the remote ping test. The default is 0x00.
SourceAddress	Specifies the IP address (a.b.c.d) as the source address in outgoing probe packets.
ByPassRouteTable	Enables (optionally) the bypassing of the route table. The default is disabled.

View Ping Results

About This Task

View ping results to view performance-related data.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Ping Control** tab.
4. Select a ping test entry.
5. Click **Ping Result**.

Ping Result Field Descriptions

Use the data in the following table to use the **Ping Result** tab.

Name	Description
OwnerIndex	Specifies the ping test owner.
TestName	Specifies the test name.
OperStatus	Indicates the operational status of the test. The default is disabled.
IpTargetAddressType	Specifies the IP address type of the target. The default is unknown.
IpTargetAddress	Specifies the IP address of the target.
MinRtt	Specifies the minimum ping round-trip-time (RTT) received. A value of 0 means that no RTT is received.
MaxRtt	Specifies the maximum ping RTT received. A value of 0 means that no RTT is received.
AverageRtt	Specifies the current average ping RTT.
ProbeResponses	Specifies the number of responses to probes.
SentProbes	Specifies the number of sent probes.
RttSumOfSquares	Specifies the sum of squares of RTT for all probes received.
LastGoodProbe	Specifies the date and time when the last response is received for a probe.

View Ping Probe History

About This Task

View the ping probe history to view the history of ping tests performed by the switch.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Select a ping entry.
4. Click **Ping Probe History**.

Ping Probe History Field Descriptions

Use the data in the following table to use the **Ping Probe History** tab.

Name	Description
OwnerIndex	Specifies the owner index
TestName	Indicates the name given to the test.

Name	Description
Index	Specifies the index number.
Response	Indicates the amount of time, measured in milliseconds, between request (probe) and response, or when the request timed out. Response is reported as 0 when it is not possible to transmit a probe.
Status	Indicates the status of the response; the result of a particular probe done by a remote host.
LastRC	Indicates the last implementation-method-specific reply code (RC) received. If ICMP Echo is used, then a successful probe ends when an ICMP response is received that contains the code ICMP_ECHOREPLY(0).
Time	Indicates the timestamp for this probe result.

Run a Traceroute Test

About This Task

Run a traceroute test to determine the route packets take through a network to a destination.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Trace Route Control** tab.
4. Click **Insert**.
5. Configure the instance as required.
6. Click **Insert**.
7. Select an entry, and then click **Start**.
Let the test run for several seconds.
8. Select an entry, and then click **Stop**.
9. View the traceroute test results.

Trace Route Control Field Descriptions

Use the data in the following table to use the **Trace Route Control** tab.

Name	Description
OwnerIndex	Provides access control by a security administrator using the VACM for tables in which multiple users need to independently create or modify entries.
TestName	Specifies the name of the traceroute test.

Name	Description
TargetAddressType	Specifies the type of host address to use on the traceroute request at the remote host. The default is IPv4.
TargetAddress	Specifies the host address used on the traceroute request at the remote host.
ByPassRouteTable	Enables bypassing of the route table. If you enable this variable, the remote host bypasses the normal routing tables and sends directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. You can use this variable to perform the traceroute operation to a local host through an interface that has no route defined. The default is disabled.
DataSize	Specifies the size of the data portion of a traceroute request in octets. The default is 1.
TimeOut	Specifies the timeout value, in seconds, for a traceroute request. The default is 3.
ProbesPerHop	Specifies the number of times to reissue a traceroute request with the same time-to-live (TTL) value. The default is 3.
Port	<p>Specifies the UDP port to which to send the traceroute request. Specify a port that is not in use at the destination (target) host. The default is the IANA assigned port 33434.</p> <p>Note: If the traceroute action is directed to an IPv6 host address, Linux increments the UDP port on a per-TTL basis. For an IPv4 host address, Linux increments the UDP port on a per-probe basis. Because the traceroute command sends a default of three probes, three incrementing ports will be sent for an IPv4 host address. If you use the -p parameter with a value greater than 65533, the traceroute command fails for an IPv4 host address because the maximum port number, 65535, is exceeded.</p>
MaxTtl	Specifies the maximum time-to-live from 1–255. The default is 30.
DSField	Specifies the value to store in the Differentiated Services (DS) field in the IP packet used to encapsulate the traceroute probe. The default is 0.
SourceAddressType	Specifies the type of the source address to use at a remote host.
SourceAddress	Uses the specified IP address (which must be an IP number, not a hostname) as the source address in outgoing probe packets.
IfIndex	Directs the traceroute probes to be transmitted over the specified interface. The default is 0.
MiscOptions	Enables an application to specify implementation-dependent options.

Name	Description
MaxFailures	Indicates the maximum number of consecutive timeouts allowed before terminating a remote traceroute request. The default is 5.
DontFragment	Enables setting of the do not fragment (DF) flag in the IP header for a probe. The default is disabled.
InitialTtl	Specifies the initial time-to-live (TTL) value to use. The default is 1.
Frequency	Specifies the number of seconds to wait before repeating a traceroute test as defined by the value of the various objects in the corresponding row. The default is 0.
StorageType	Specifies the storage type for this row.
AdminStatus	Specifies the desired state for TraceRouteCtlEntry. The options are enabled or disabled. The default is disabled.
MaxRows	Specifies the maximum number of entries allowed in the TraceRouteProbeHistoryTable. The default is 50.
TrapGeneration	Determines when to generate a notification for this entry. The options are <ul style="list-style-type: none"> • pathChange —Generates a TraceRoutePathChange notification after the current path varies from a previously determined path. • testFailure —Generates a TraceRouteTestFailed notification after the full path to a target cannot be determined. • testCompletion —Generates a TraceRouteTestCompleted notification after the path to a target has been determined.
Descr	Describes the remote traceroute test.
CreateHopsEntries	Stores the current path for a traceroute test in the TraceRouteHopsTable on an individual hop basis when the value of this object is true. The default is false.
Type	Reports or selects the implementation method to use for performing a traceroute operation.

View Traceroute Results

About This Task

View traceroute results to view performance-related data.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Trace Route Control** tab.
4. Select a traceroute entry.

5. Click **Trace Route Result**.

Trace Route Result Field Descriptions

Use the data in the following table to use the **Trace Route Result** tab.

Name	Description
OwnerIndex	Specifies the index of the owner.
TestName	Specifies the name of the test.
OperStatus	Specifies the operational status of the test. The default is disabled.
CurHopCount	Specifies the current count of hops.
CurProbeCount	Specifies the current count of probes.
IpTgtAddressType	Specifies the IP target address type
IpTgtAddr	Specifies the IP target address.
TestAttempts	Specifies the number of test attempts.
TestSuccesses	Specifies the number of successful test attempts.
LastGoodPath	Specifies the date and time when the last response is received for a probe.

View the Traceroute History

About This Task

View the traceroute history to view the history of traceroute tests performed by the switch.

The traceroute probe history contains probe information for the hops in the routing path.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Trace Route Control** tab.
4. Select an entry.
5. Click **Trace Route Probe History**.

Route Probe History Field Descriptions

Use the data in the following table to use the **Trace Route Probe History** tab.

Name	Description
OwnerIndex	Identifies the Trace Route entry to which a probe result belongs.
TestName	Specifies the test name.
Index	Specifies the Index.
HopIndex	Indicates for which hop in a traceroute path the probe results are intended.
ProbeIndex	Specifies the index of a probe for a particular hop in a traceroute path.
HAddrType	Specifies the IP address type of the hop to which this probe belongs.
HAddr	Specifies the IP address of the hop to which this probe belongs.
Response	Specifies the cumulative results at any time.
Status	Specifies the status of the probe.
LastRC	When a new entry is added, the old entry is purged if the total number of entries exceeds the specified maximum number of entries in the Control Table Entry.
Time	Specifies the response time of the probe.

Configure I-SID Monitoring

Use the following procedure to configure Fabric RSPAN on the Backbone Edge Bridge (BEB) connected to the monitor station.

Note

Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

Note

If you change the egress port or egress MLT for a particular session using a CLI command, it overwrites the existing egress port list or egress MLT.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **General**.
3. Click the **Monitor-By-ISID** tab.
4. Click **Insert**.
5. Configure the parameters as required.

6. Click **Insert**.
7. To modify mappings, double-click a parameter to view a list of options.
8. Click **Apply**.

Monitor-By-ISID Field Descriptions

Use the data in the following table to use the **Monitor-By-ISID** tab.

Name	Description
Index	Specifies the entry that contains monitor by I-SID information.
MonitorIsidOffset	Configures the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored.
MonitorIsid	Specifies the actual monitor I-SID value to which packets are mirrored.
EgressPortList	Specifies the egress ports to which traffic analyzers connect.
EgressMltId	Specifies the egress MLT ID to which traffic analyzers connect.
MapToVlanId	Specifies the VLAN ID to map with mirrored traffic on the monitoring node.
Enable	Enables or disables monitoring by I-SID.

View and Clear Fabric RSPAN (Mirror to I-SID) Statistics

Use the following procedure to view or clear statistics of the number of packets mirrored into I-SID on the mirroring BEB.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **General**.
3. Click the **Isid-Mirroring Stats** tab.

Isid-Mirroring Stats Field Descriptions

Use the data in the following table to use the **Isid-Mirroring Stats** tab.

Name	Description
Index	Specifies the entry that contains Fabric RSPAN statistics information.
MonitorIsid	Specifies the actual monitor I-SID value to which the packets are mirrored.
MirroredPackets	Specifies the number of packets mirrored into I-SID on the mirroring BEB.
ClearStats	Clears the Fabric RSPAN statistics.

General Troubleshooting

Hardware Troubleshooting

The following sections provide troubleshooting information for common hardware problems.

Using Trace to Diagnose Hardware Problems

Use trace to observe the status of a hardware module at a given time.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Begin the trace operation:

```
line-card 1 trace level [Module_ID]{<0-4>}
```
3. Search the trace for a specific string value:

```
line-card 1 trace grep {WORD<0-1024>}
```

Example

```
Switch:1>enable
```

Begin the trace operation:

```
Switch:1#line-card 1 trace level 67 1
```

Search the trace for a specific string value:

```
Switch:1#line-card 1 trace grep 00-1A-4B-8A-FB-6B
```

Variable Definitions

The following table defines parameters for the **line-card 1** command.

Variable	Value
<i><Module_ID></i> {<0-4>}	Starts the trace by specifying the module ID and level. <i><Module_ID></i> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the show trace modid-list command or CLI command completion Help. <i><0-4></i> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<i>WORD</i> <0-1024>	Performs a string search in the trace.

Troubleshooting USB Viewing Problems

After you insert a USB device in the USB slot, the Linux system automatically detects and mounts the device. If you cannot view files on the device, perform this procedure.

Note

Not all hardware platforms can use the USB device for additional file storage. Some platforms use the USB as part of the system operation and must never be removed. For more information, see your hardware documentation.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Check the file system:

```
ls /usb/
```

3. Remove a USB device:

- a. Unmount the USB device:

```
usb-stop
```

- b. Wait for the response that indicates it is safe to remove the device.

- c. Physically remove the device.

4. Remove and then reinsert the device.

5. Check the device for errors:

```
dos-chkdisk /usb
```

Run the **dos-chkdisk /usb repair** command, if at the end of the **dos-chkdisk /usb** command output you see:

1) Correct

2) Don't correct

6. If errors are detected, then you can reformat the device:

```
dos-format /usb
```

Caution

If you format the device, you erase all data on the device.

Example

Check the file system:

```
Switch:1>enable
Switch:1#ls /usb/
Listing Directory /usb/:
drwxr-xr-x 4 0 0 4096 Jan 1 1970 ./
drwxrwxr-x

```

If errors are detected, reformat the disk:

```
Switch:1#dos-format /usb
```

Software Troubleshooting

This section contains general troubleshooting information for the switch software.

Failure to Read Failed Configuration File

The device can fail to read and load a saved configuration file after it starts. This situation occurs if you enable the factorydefaults boot configuration flag. Configure the flag to false: `no boot config flags factorydefaults`.

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# no boot config flags factorydefaults
```

No Web Management Interface Access to a Device

If the device and the PC that runs the web browser are in the same network, you can find that even though other applications, for example, Telnet, can access a particular switch, the web management interface cannot. This situation can occur if the web browser has a proxy server that resolves the www path and returns the reachable IP address to the browser. If no route exists from the proxy server to the device, the HTTP query does not reach the device, and does not receive a response.

To prevent this problem, ensure that if the web browser uses a proxy server, you specify a route from the proxy server to the device.

Configuration in EDM is not applied using CLI

In EDM, if you apply configuration that disrupts the connection to the web server, and you do not close the EDM session, you cannot apply the same configuration using CLI. This situation occurs if you, for example, delete the Segmented Management Instance, or the management IP address or the route used to access EDM, and you do not close the EDM session afterwards.

To prevent this issue, you must close the EDM session before you can apply the same configuration using CLI.

Layer 1 Troubleshooting

Use the information in this section to troubleshoot Layer 1 (physical layer) problems.

Troubleshooting Fiber Optic Links

About This Task

You can troubleshoot fiber optic links to ensure that the optical transmitters and receivers operate correctly, and to determine if a receiver is saturated, or does not receive enough power.

To troubleshoot optical links and devices, you can use Digital Diagnostic Monitoring (DDM), as well as published optical specifications.

For more information about transceivers, see [Extreme Optics](#) website.

Important

As a best practice, use transceivers documented in [Extreme Optics](#) website, as they have been through extensive qualification and testing. Extreme Networks is not responsible for issues related to third party transceivers.

Procedure

1. Measure the transmit power.
2. Compare the measured transmit power with the specified launch power.
The values are similar. If the measured power is far below the specified value, a faulty transmitter is a possible cause.
3. Compare the measured transmit power for the near-end optical device to the measured transmit power for the far-end device.
Large differences can mean that the optical devices are mismatched (that is, -SX versus -LX).
4. Measure the receive power at each end of the link.

5. Compare the receive power to the transmit power.
 - For short fiber links, the transmit and received power are similar (after taking into consideration connection losses).
 - For long fiber links, the transmit and received power are similar (after taking into consideration connection losses and fiber attenuation).

Large differences can mean a damaged fiber or dirty or faulty connectors. Large differences can also mean that the link does not use the right type of fiber (single mode or multimode). If the receiver power is measured to be zero, and the link worked previously, it is probable that the far-end transmitter is not operating or the fiber is broken.

6. Compare the measured receive power for the near-end optical device to the measured receive power for the far-end device.

Large differences could mean that the optical devices are mismatched (that is, -SX versus -LX). If optical devices are mismatched, the receiver can be saturated (overdriven).

7. If a receiver is saturated but still operable, install a suitable attenuator.

For long-haul optical devices, the receive power must be significantly less than the transmit power.
8. To help debug the link, loop back the local transmit and receive ports, and use the DDM parameters to help determine the fault.

Reset a QSFP+ or QSFP28 Transceiver

Reset a transceiver to simulate removal and reinsertion of the transceiver, which can be helpful in troubleshooting. For example, if authentication of the transceiver fails but you believe the transceiver is a qualified Extreme Networks part, you can reset the transceiver to begin the authentication process again.

About This Task

Resetting the transceiver stops traffic and triggers log messages similar to the removal and insertion of the transceiver.

Before You Begin

- Before you use the **pluggable-optical-module reset** command, ensure the port is administratively down to avoid link flaps.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Reset the transceiver:

```
pluggable-optical-module reset {slot/port[/sub-port]}
```

Important

Not all hardware platforms support these port types. For more information, see your hardware documentation.

Examples

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#pluggable-optical-module reset 1/41
Switch:1(config)#

Variable Definitions

The following table defines parameters for the **pluggable-optical-module reset** command.

Variable	Value
<code>{slot/port[/sub-port]}</code>	Specifies location of the transceiver to reset. Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Layer 2 and 3 Troubleshooting

Troubleshooting BPDU Guard

The following procedures provide information to troubleshoot issues with Bridge Protocol Data Unit (BPDU) Guard.

No Packets Received on the Port

For BPDU Guard to work on a port, the port must receive BPDU packets. Perform the following procedure to troubleshoot cases when the port does not receive packets.

Procedure

1. Enter Privileged EXEC mode:
enable

2. Show the BPDU Guard status for the port:

```
show spanning-tree bpduguard {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

3. Use the following command to verify that the port receives packets:

```
show interface gigabitEthernet statistics verbose {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

4. Verify that the remote port is sending packets:

```
show spanning-tree {mstp|rstp} port role [{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

```
show spanning-tree {mstp|rstp} port statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

Example

Port 1/8 receives packets. The remote port is disabled and does not send BPDU packets.

The following example shows that BPDU Guard is enabled for port 1/8. The BPDU Guard administrative state for the port is enabled but the timer counter is 0.

```
Switch:1>enable
Switch:1#show spanning-tree bpduguard 1/8

Variable Definitions

Use the data in the following table to use the **show spanning-tree bpduguard** command.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Use the data in the following table to use the **show interface gigabitEthernet statistics verbose** command.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Use the data in the following table to use the **show spanning-tree** command.

Variable	Value
<i>{mstp rstp}</i>	Specifies the spanning tree protocol.
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Troubleshooting IPv6 VRRP

The following sections describe troubleshooting information for IPv6 Virtual Router Redundancy Protocol (VRRP).

VRRP Transitions

When a VRRP transition takes place with the backup taking over as the master, look for the following message in the syslog on the new master, as well as the old master. This message provides information to allow you to determine the cause of the transition.

IPv6 Vrrp State Transition Trap(Port/Vlan=200, Type=masterToInitialize, Cause=shutdownReceived, VrId=20, VrIpAddr=fe80:0:0:0:0:0:0:200, Addr=fe80:0:0:0:224:7fff:fe9d:1a03)

In this message, see the Type and Cause fields.

Note

Although all of the possible causes and types are listed below, the system does not display all of the listed causes and types in the trap/log message.

The following table describes the VRRP transition types.

Table 267: Transition type

Type value	Type definition
1	None
2	Master to backup
3	Backup to master
4	Initialize to master
5	Master to initialize
6	Initialize to backup
7	Backup to initialize
8	Backup to backup master
9	Backup master to backup

The following table describes the VRRP transition causes.

Table 268: Transition cause

Cause value	Cause definition
1	None
2	Higher priority advertisement received
3	Shutdown received
4	VRRP address and physical address match
5	Master down interval
6	Preemption
7	Critical IP goes down
8	User disabling VRRP
9	VRRP status synced from primary
10	IPv6 interface on which VRRP is configured goes down
11	Lower priority advertisement received
12	Advertisement received from higher interface IP address with equal priority

Table 268: Transition cause (continued)

Cause value	Cause definition
13	Advertisement received from lower interface IP address with equal priority
14	User enabled VRRP
15	Transition because of any other cause

Enabling Trace Messages for IPv6 VRRP Troubleshooting

Use this procedure to enable trace messages for IPv6 VRRP.

When VRRP is enabled on two routing switches, the master-backup relationship forms with one router taking the responsibility of routing. If the master-backup relationship is not formed between the VRRP virtual routers, look for the following trace messages to ensure that the master is sending the advertisements correctly and the backup is processing them.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. To troubleshoot IPv6 VRRP, you can enable RCIP6 trace messages with the command:
`trace level 66 3`
3. And to provide additional trace information, you can also enable the following traces:
`trace ipv6 nd enable`
`trace ipv6 base enable all`
`trace ipv6 forwarding enable all`
`trace ipv6 rtm enable all`
`trace ipv6 transport enable all`

4. When VRRP is enabled on two routing switches, the master-backup relationship forms with one router taking the responsibility of routing. If the master-backup relationship is not formed between the VRRP virtual routers, look for the following trace messages to ensure that the master is sending the advertisements correctly and the backup is processing them. On the master router, look for the following RCIP6 trace messages.

- tMainTask RCIP6: rcip6_vrrp.c: 5118: VRF name: GlobalRouter (VRF id 0): ipv6VrrpTic: Am Master for Vrid 200 on IfIndex 2053 Timer 1

If VRRP is enabled on the interface, this timer kicks off every second and shows the state for the VRID.

- [11/18/09 15:08:20:383] tMainTask RCIP6: rcip6_vrrp.c: 5924: ipv6VrrpSendAdvertisement: for Vrid 200 on IfIndex 2053

```
[11/18/09 15:08:20:583] tMainTask RCIP6: rcip6_vrrp.c: 5175: VRF
name: GlobalRouter (VRF id 0): ipv6VrrpTic:
ipv6VrrpSendAdvertisement
```

The preceding trace messages show that the VRRP master is sending the advertisements correctly at the end of advertisement interval for a VRID.

5. On the backup router, look for the following RCIP6 trace messages.

- tMainTask RCIP6: rcip6_vrrp.c: 5236: VRF name: GlobalRouter (VRF id 0): ipv6VrrpTic: Am Backup for Vrid 200 on IfIndex 2052 Timer 1
- tMainTask RCIP6: rcip6_vrrp.c: 4854: ipv6VrrpIn: Vrid 200 on IfIndex 2052
- tMainTask RCIP6: rcip6_vrrp.c: 5545: VRF name: GlobalRouter (VRF id 0): rcIpVrrpProcessAdvt: Am backup for Vrid 200 on IfIndex 2052

The preceding trace messages show that the backup router is receiving the advertisements sent by the master and correctly processing them.

Risks Associated with Enabling Trace Messages

When traces are enabled on VRRP master, VrrpTic messages are logged for every second and any other configured traces keep displaying, so there is no guarantee that the backup will receive the advertisement from the master within 3 seconds, so it can transit to master also. There is also the risk of toggling of VRRP states (from backup to master and back again).

Enable the limited traces based on whichever is required.

VRRP with Higher Priority Running as Backup

The VRRP router with the higher priority can display as the backup for the following reasons

- Hold-down timer is running.
- The configured Critical IP is not reachable or does not exist.

If the critical-IP is configured for VRRP master, and the critical interface goes down or is deleted, the master transitions to the backup state. In this case, the log shows the transition cause as 1 like many other cases.

If the holddown timer is configured for VRRP master, the holddown timer delays the preemption, giving the device, which is becoming the master enough time to construct routing tables.

Procedure

- To determine that the issue is with the critical interface, look for the following trace message.

```
tMainTask RCIP6: rcip6_vrrp.c: 5152: VRF name: GlobalRouter (VRF id
0): ipv6VrrpTic: Becoming backup for Vrid 200 on IfIndex 2052 because
of invalid critical IP
```
- If the holddown Timer is configured for VRRP master, the holddown timer delays the preemption, giving the device, which is becoming the master enough time to construct routing tables.

```
tMainTask RCIP6: rcip6_vrrp.c: Enter in HoldDown processing,Vrid 200
LastRecvd 0 MasterDown 3, Holddown time remaining 970, Holddownstate 2
```

Troubleshooting RSMLT

The following sections provide information for troubleshooting IPv4 Split Multi-Link Trunking (RSMLT).

RSMLT Peers Not Up

If, after a series of reconfigurations, RSMLT peers do not transition to the up state, use the following procedure to troubleshoot the issue. You can observe this issue on dual-stack VLANs after multiple delete and re-adds of IPv4 interfaces.

Procedure

- Display the RSMLT configuration. This command shows whether the peers are up:

```
show ip rsmlt peer
```
- Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
- To recover the peers if they are down, disable and reenble RSMLT on both IST peers:

```
no ip rsmlt

ip rsmlt
```
- If the problem persists, boot from a saved configuration.

Example

Display the RSMLT configuration:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 1
Switch:1(config-if)#show ip rsmlt peer
```

```
=====
Ip Rsmlt Peer Info - GlobalRouter
=====
```

```

-----
Switch:1(config-if)#no ip rsmlt
Switch:1(config-if)#ip rsmlt
    
```

Enabling Trace Messages for RSMLT Troubleshooting

Use the following procedure to obtain additional RSMLT-related information.

Procedure

If the preceding information does not resolve the issue, you can use the following command to obtain additional RSMLT-related information:

```
trace level 173 4
```

Important

Enabling this trace on a loaded system can slow down the CPU, especially if executed through the console. Use Telnet if possible.

Troubleshooting IPv6 Connectivity Loss

If the switch experiences loss of IPv6 connectivity, use the following procedure to troubleshoot the issue.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Through the command line interface, make sure the required routes are in place and the corresponding neighbor entries are resolved (that is, in REACHABLE, PROBE, DELAY or STALE state).

3. INCOMPLETE neighbor state indicates a problem if the corresponding neighbor is used by some of the IPv6 routes. This applies to neighbor entries with link-local addresses.

**Note**

Global addresses are not normally used as next hops. Having a global IPv6 neighbor entry as INCOMPLETE does not usually lead to a connectivity issue.

4. If the corresponding route is not in place then this is a routing issue. If the neighbor is not present or is INCOMPLETE, then further debugging is needed on the network level (that is, the state of other nodes needs to be examined).
5. Disabling and re-enabling IPv6 on the VLAN often recovers connectivity.
6. Display the RSMLT and MLT status:

```
show ip rsmlt
```

```
show mlt
```

Make sure the RSMLT peer MAC is learned and the IST state is `ist`.

Troubleshooting vIST Failure

About This Task

When you use Virtual Inter-Switch Trunk (vIST), all critical network traffic runs on this link. If vIST fails, network protocols such as RIP, VRRP, OSPF, and VLACP go down and eventually cause a network outage.

vIST uses an SPBM tunnel to virtually connect two nodes that can be anywhere in the SPBM cloud. Even if the two vIST nodes are directly connected by an MLT link, the vIST VLAN does not have MLT ports as members. Instead, it is configured to be an SPBM C-VLAN.

**Note**

For more information on vIST and a configuration example, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2356.

The vIST tunnel is up as long as there is SPBM connectivity between the IST peers. If there is a vIST failure, check the following procedure for some possible reasons:

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Verify that the vIST VLAN is configured on the vIST switch:

```
show virtual-ist
```

3. Verify that an I-SID is associated with the vIST VLAN:

```
show isis spbm i-sid discover
```

Important

The I-SID associated with the vIST VLAN should be the same on the vIST peer, and this I-SID should not be used anywhere else in the network.

4. Verify that the vIST peers are on the same subnet.
5. If peer ARP is not resolved, enable **trace level 14** to see if ARP request/response are being sent/received.

6. If vIST is not up, check the **mac fdb table** and verify that the peer MAC is synchronized:

```
show vlan mac-address-entry <1-4059>
```

7. If the vIST peer MAC is learned, check to see if the peer IP address is reachable.

- a. Use **show virtual-ist** to obtain the vIST peer IP address.

- b. Ping the peer IP address.

8. If unable to **ping** the peer IP address, check to see if ARP is resolved.

```
show ip arp vlan <vid>
```

Multicast Troubleshooting

Use the following information to troubleshoot multicast features and multicast routing.

Multicast Feature Troubleshooting

Use the information in this section to troubleshoot multicast feature problems.

Troubleshooting IGMP Layer 2 Querier

The following sections provide troubleshooting information for the IGMP Layer 2 Querier feature.

Querier Not Elected

If a Querier is not elected, use the following procedure to troubleshoot the issue.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. As the IGMP Layer 2 Querier is based on IGMP snoop, check whether IGMP snoop is enabled on the VLAN:

```
show ip igmp interface vlan
```

If IGMP snoop is disabled, the Layer 2 Querier cannot work until IGMP snoop and IGMP Layer 2 Querier are reenabled.

Example

Check whether IGMP snoop is enabled on the VLAN:

```
Switch:1>enable
Switch:1#show ip igmp interface vlan
```

```

Enable Trace Messages for IGMP Layer 2 Querier Troubleshooting

If the preceding information does not address your issue, you can also use the following trace command to view additional information related to Layer 2 querier.

Caution

Using the trace tool inappropriately can cause primary CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation. If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Use the following trace command to begin the trace operation for additional information related to Layer 2 querier:

```
trace level 23 <1-4>
```
3. Stop tracing:

```
trace shutdown
```

4. View the trace results:

```
trace screen enable
```
5. View trace saved to a file:

```
show trace file [tail]
```

Variable Definitions

Use the data in the following table to use the **trace** command.

Variable	Value
<i>level</i> [<Module_ID>] [<1-4>]	Starts the trace by specifying the module ID and level. Module ID 23 represents the IGMP module <Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the show trace modid-list command or CLI command completion Help. <0-4> specifies the trace level: <ul style="list-style-type: none"> • 0 – Disabled • 1 – Very terse • 2 – Terse • 3 – Verbose • 4 – Very verbose
<i>shutdown</i>	Stops the trace operation.
<i>screen {disable enable}</i>	Enables or disables the display of trace output to the screen. Important: Avoid using the screen to view commands if you use trace level 3 (verbose) or trace level 4 (very verbose) due to the volume of information generated and the effect on the system.

Use the data in the following table to use the **show trace** command.

Variable	Value
<i>file [tail]</i>	Displays the trace results saved to a file.
<i>level</i>	Displays the current trace level for all modules.
<i>modid-list</i>	Specifies the module ID list.

Troubleshoot IGMPv3 Backwards Compatibility

If you configure the switch to operate in v2-v3 compatibility mode, the switch supports all IGMPv2 and v3 messages. The switch parses the group address of the messages. If the group address is out of SSM range and it is a v3 message, the switch drops the message. If it is a v2 message, IGMP snoop processes handle the message.

To troubleshoot issues with the IGMPv3 backwards compatibility feature, perform the following procedure.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Verify that the SSM static channel is configured for the v1/v2 joins received. Display the configured SSM static channels:
show ip igmp ssm-map
3. Verify that the SSM group range is configured for the v1/v2 joins received. Display the configured SSM group range:
show ip igmp ssm

Example

Display the configured SSM static channels and display the configured SSM group range:

```
Switch:1#show ip igmp ssm-map
=====
                        Igmp Ssm Channel - GlobalRouter
=====
GROUP                SOURCE                MODE                ACTIVE                STATUS
-----
233.252.0.1          192.0.2.200 dynamic            false                enabled
233.252.0.2          192.0.2.200 dynamic            false                enabled
233.252.0.3          192.0.2.200 dynamic            false                enabled
233.252.0.4          192.0.2.200 dynamic            false                enabled
233.252.0.5          192.0.2.200 dynamic            false                enabled
233.252.0.6          192.0.2.200 dynamic            false                enabled
233.252.0.7          192.0.2.200 dynamic            false                enabled
233.252.0.8          192.0.2.200 dynamic            false                enabled
233.252.0.9          192.0.2.200 dynamic            false                enabled

*Multicast Routing Troubleshooting Using CLI***View IGMP Interface Information**

Perform this procedure to view the IGMP interface table.

About This Task

If an interface does not use an IP address, the system does not display it in the IGMP table. One exception is an IGMP snooping interface, which does not require an interface IP address.

If an interface uses an IP address, but neither IGMP snoop or PIM is enabled, the system displays the interface as inactive in the Status field.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View IGMP interfaces:

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]} |vlan <1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-
512>]
```

Example

View IGMP interfaces:

```
Switch:1#show ip igmp interface
=====
                        IgmP Interface - GlobalRouter
=====
IF          QUERY   OPER      QUERY  WRONG      LASTMEM

1 out of 1 entries displayed
```

Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

Variable	Value
<i>gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. If you do not specify a slot and port, the command output includes all IGMP interfaces.
<i>vlan <1-4059></i>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. If you do not specify a VLAN ID, the command output includes all IGMP interfaces.
<i>vrf WORD <1-16></i>	Optionally, identifies the VRF name. If you do not specify a VRF name, the results display information for the Global Router. If you specify a VRF name, the results display information only for the VRF you specify.
<i>vrfids WORD <0-512></i>	Optionally, identifies the VRF ID. If you do not specify a range of VRF IDs, the results display information for the Global Router. If you specify a VRF ID or range of VRF IDs, the results display information only for the VRF you specify.

View Multicast Group Trace Information for IGMP Snoop

About This Task

Multicast group trace tracks the data flow path of the multicast streams.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display the multicast group trace for an IGMP snoop-enabled interface:
show ip igmp snoop-trace [source {A.B.C.D}] [group {A.B.C.D}]

Example

Display the multicast group trace for an IGMP snoop-enabled interface:

```
Switch:1# show ip igmp snoop-trace
```

```
=====
                               Snoop Trace - GlobalRouter
=====
```

GROUP ADDRESS	SOURCE ADDRESS	IN VLAN	IN PORT	OUT VLAN	OUT PORT	TYPE
233.252.0.1	192.0.2.6	500	1/1	500	1/5	ACCESS
233.252.0.10	192.0.2.7	500	1/1	500	1/10	ACCESS

Variable Definitions

The following table defines parameters for the **show ip igmp snoop-trace** command.

Variable	Value
<i>group {A.B.C.D}</i>	Specifies the group IP address in the format a.b.c.d.
<i>source {A.B.C.D}</i>	Specifies the source IP address in the format a.b.c.d.

View IGMP Group Information

View information about IGMP groups to see the current group operation on the switch.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View IGMP group information:
show ip igmp group group <A.B.C.D> detail [port {slot/port[/sub-port]} [-slot/port[/sub-port]][,...]] [vlan <1-4059>] [vrf WORD <1-16>] [vrfids WORD <0-512>]

show ip igmp group group <A.B.C.D> tracked-members [member-subnet <A.B.C.D./X>] [port {slot/port[/sub-port]} [-slot/port[/sub-port]][,...]] [source-subnet <A.B.C.D./X>] [vlan <1-4059>] [vrf WORD <1-16>] [vrfids WORD <0-512>]

Example

View IGMP group information:

```
Switch:1>enable
Switch:1#show ip igmp group group 232.0.0.0

=====
                          Igmp Group - GlobalRouter
=====

1 out of 271 group Receivers displayed

Total number of unique groups 271
```

Variable Definitions

The following table defines parameters for the **show ip igmp group** command.

Variable	Value
<i>count</i>	Displays the number of entries in the IGMP group.
<i>group</i> <A.B.C.D>	Specifies the address of the IGMP group.
<i>member-subnet</i> {default <A.B.C.D>}]	Specifies the IP address and mask of the IGMP member.
<i>vrf</i> WORD<1-16>	Specifies the VRF name.
<i>vrfids</i> WORD<0-512>	Specifies the VRF ID.

The following table defines parameters for the **show ip igmp group group** command.

Variable	Value
<code>detail [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} vlan <1-4059> vrfWORD <1-16> vrfidsWORD <0-255>]</code>	<p>Use the <i>detail</i> parameter to show IGMPv3-specific data.</p> <p>For data related to a specific interface use the following:</p> <ul style="list-style-type: none"> <code>port{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> – Specifies the port list. <code>vlan <1-4059></code>– Specifies the VLAN. <p>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.</p> <ul style="list-style-type: none"> <code>vrf WORD<1-16></code> <p>– Specifies the VRF name.</p> <ul style="list-style-type: none"> <code>vrfids WORD<0-255></code> – Specifies the VRF ID.
<code>tracked-members</code>	Use the <i>tracked-members</i> parameter to view all the tracked members for a specific group.
<code>vrf WORD<1-16></code>	Specifies the VRF name.
<code>vrfids WORD<0-512></code>	Specifies the VRF ID.

The following table defines parameters for the **show ip igmp group group <A.B.C.D> tracked-members** command.

Variable	Value
<code>member-subnet {default <A.B.C.D>}</code>	Specifies the IP address and mask of the IGMP member.
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port list.
<code>source-subnet <A.B.C.D/X></code>	Specifies the source IP address and the subnet mask.
<code>vlan <1-4059></code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<code>vrf WORD<1-16></code>	Specifies the VRF name.
<code>vrfids WORD<0-512></code>	Specifies the VRF ID.

Determine the Data Stream Learned with IP Multicast over Fabric Connect on the VLAN

Use this procedure to determine the data stream learned when IP Multicast over Fabric Connect is configured on the VLAN.

About This Task

The following section shows sample output for the **show ip mroute route** command.

In this table, every stream uses one (*,G) entry and x (S,G) entries, depending on how many servers forward traffic to the same group.

The 0.0.0.0 mask is always tied to a (*,G) entry.

If you do not specify a VRF name or range of VRF IDs, the results display information for the Global Router. If you do specify a VRF name or range of VRF IDs, the results display information only for the VRFs you specify.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Determine the data stream learned:

```
show ip mroute route [vrf WORD <0-32>] [vrfids <0-255>]
```

Example

Determine the data stream learned:

```
Switch:1>show ip mroute route

=====
                        Mroute Route - GlobalRouter
=====
GROUP                SOURCE                SRCMASK                UPSTREAM_NBR        IF        EXPIR        PROT
-----
233.252.0.1          0.0.0.0                0.0.0.0                0.0.0.0            V3         30          spb-access
233.252.0.1          192.0.2.102           255.255.255.0          0.0.0.0            -          0           spb-network
233.252.0.2          0.0.0.0                0.0.0.0                0.0.0.0            V2         30          pimsm
225.1.1.1            198.51.100.99         255.255.255.0          0.0.0.0            V3         173         spb-pim-gw

Total 4
```

Variable Definitions

The following table defines parameters for the **show ip mroute route** command.

Variable	Value
<code>vrf WORD<0-32></code>	Specifies the VRF name.
<code>vrfids <0-255></code>	Specifies the VRF ID.

Display the SPBM Multicast Database

You can determine the database used by the SPBM multicast module by using the following procedure.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Show the SPBM multicast database:

```
show isis spbm ip-multicast-route [all][detail][group {A.B.C.D}][vlan
<2-4059>][vrf WORD<0-16>][vsn-isis <1-16777215>]
```

Important

When you use this command without parameters or use the detail or group optional parameters without specifying a VLAN ID or VSN I-SID, the command output displays Layer 3 context only. No Layer 2 context is displayed.

Example

Show the SPBM multicast database:

```
Switch(config)#show isis spbm ip-multicast-route

=====
                        SPBM IP-MULTICAST FIB ENTRY INFO
=====
Source           Group           Data ISID   BVLAN Source-BEB
-----
192.2.0.1        233.252.0.246   16000001  101   EVP
-----
Total Number of SPBM IP MULTICAST ROUTE Entries: 1
-----
```

Variable Definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

Variable	Value
<i>all</i>	Displays all IP Multicast over Fabric Connect route information.
<i>detail</i>	Displays detailed IP Multicast over Fabric Connect route information.
<i>group {A.B.C.D}</i> <i>source {A.B.C.D}</i>	Displays information on the group IP address for the IP Multicast over Fabric Connect route. If you select source it will also display the source IP address.
<i>vlan <2-4059></i>	Displays IP Multicast over Fabric Connect route information by VLAN.
<i>vrf WORD<0-16></i>	Displays IP Multicast over Fabric Connect route information by VRF.
<i>vsn-isis <1-16777215></i>	Displays IP Multicast over Fabric Connect route information by I-SID.

Troubleshoot IP Multicast over Fabric Connect for Layer 2 VSNs

If traffic is not moving properly, use the following procedure to determine the issue.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Ensure that all switch nodes in the network operate with the most recent software release to support IP Multicast over Fabric Connect:

```
show software
```

3. If any ERS 8800 nodes exist in the network, ensure you upgrade them to the current release:
`show software`
4. Ensure that you create and enable SPBM infrastructure globally.
 - a. Ensure that SPBM is enabled globally:
`show spbm`
 - b. Ensure that IS-IS is enabled globally:
`show isis`
 - c. Ensure an SPBM instance exists and at least one Backbone VLAN exists (B-VID). Also ensure multicast is enabled:
`show isis spbm`
5. Ensure that you enable the CFM configuration.
 - a. Ensure a CFM maintenance-association exists:
`show cfm maintenance-association`
 - b. Ensure a CFM maintenance-domain exists:
`show cfm maintenance-domain`
 - c. Ensure a maintenance-endpoint exists in the MEP ID column and is enabled in the ADMIN column:
`show cfm maintenance-endpoint`
6. Ensure a Customer VLAN (C-VLAN) exists and ensure you add UNI ports to the C-VLAN.
 - a. Display C-VLAN information:
`show vlan i-sid`
 - b. Display ports for the C-VLAN:
`show vlan members port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`
 - c. Display NNI and UNI receivers:
`show isis spbm ip-multicast-route detail`
7. Ensure that you assign the same I-SID to the C-VLAN on all of the BEBs where you configure the C-VLAN:
`show vlan i-sid`
8. Ensure that you enable IP Multicast over Fabric Connect globally:
`show isis spbm`
9. Ensure the you enable IGMP Snooping on the C-VLAN on all of the Backbone Edge Bridges (BEBs). Ensure the protocol configured on the VLAN added is snoop-spb in the MODE column, which indicates IGMP is enabled on a VLAN with an associated I-SID (IP Multicast over Fabric Connect for a Layer 2 VSN):
`show ip igmp interface`
10. Ensure that you enable IGMP Snooping on access Layer 2 switches to prevent flooding of multicast traffic to non-receiver ports:
`show ip igmp snoop-trace`
`show ip igmp interface`

11. Ensure that the IGMP version used by the multicast hosts and the Layer 2 switches outside the SPBM network is the same as the IGMP version configured on the C-VLAN:

```
show ip igmp interface
```

Troubleshooting IP Multicast over Fabric Connect for Layer 3 VSNs

If traffic is not moving properly, use the following procedure to determine the issue.

Procedure

1. Ensure that all switch nodes in the network operate with the most recent software release to support IP Multicast over Fabric Connect:

```
show software
```

2. If ERS 8800 nodes exist in the network, ensure you upgrade them to the current release:

```
show software
```

3. Ensure that you create and enable SPBM infrastructure globally.

- a. Ensure that SPBM is enabled globally:

```
show spbm
```

- b. Ensure that IS-IS is enabled globally:

```
show isis
```

- c. Ensure an SPBM instance exists with at least one Backbone VLAN (B-VID). Also ensure multicast is enabled:

```
show isis spbm
```

4. Ensure that you enable the CFM configuration.

- a. Ensure a CFM maintenance-association exists:

```
show cfm maintenance-association
```

- b. Ensure a CFM maintenance-domain exists:

```
show cfm maintenance-domain
```

- c. Ensure a maintenance-endpoint exists in the MEP ID column and is enabled in the ADMIN column:

```
show cfm maintenance-endpoint
```

5. Ensure the following on all the Backbone Edge Bridges (BEBs) where the Layer 3 VSN is present.

- a. Ensure that you enable IP multicast globally:

```
show isis spbm
```

- b. Ensure that you create an IPVPN for the VRF:

```
show ip ipvpn [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

- c. Ensure that you assign an I-SID to the VRF:

```
show isis spbm ip-multicast-route all
```

- d. Ensure that you enable the MVPN:

```
show ip vrf mvpn
```

6. On the VLANs that need Layer 3 VSN IP Multicast over Fabric Connect routing, create an IP interface on the VLAN if one does not exist. The address should be on the same subnet as the IGMP hosts connected to the VLAN. Also, ensure that you enable IP Multicast over Fabric Connect.

7. Enter VLAN Interface Configuration mode:

```
enable  
  
configure terminal  
  
interface vlan <1-4059>
```
8. Create an IP interface on the VLAN and enable IP Multicast over Fabric Connect:

```
ip address <A.B.C.D>  
  
ip spb-multicast enable
```
9. Ensure that you enable IGMP Snooping on access Layer 2 switches to prevent flooding of multicast traffic to non-receiver ports:

```
show ip igmp snoop-trace  
  
show ip igmp interface
```
10. Ensure that the IGMP version used by the multicast hosts and the Layer 2 switches outside the SPBM network is the same as the IGMP version configured on the C-VLAN:

```
show ip igmp interface
```

Troubleshooting IP Multicast over Fabric Connect for IP Shortcuts

If traffic is not moving properly, use the following procedure to determine the issue.

Procedure

1. Ensure that all switch nodes in the network operate with the most recent software release to support IP Multicast over Fabric Connect:

```
show software
```
2. Ensure that all ERS 8800 nodes in the network have the current release:

```
show software
```
3. Ensure that you create and enable SPBM infrastructure globally.
 - a. Ensure that SPBM is enabled globally:

```
show spbm
```
 - b. Ensure that IS-IS is enabled globally:

```
show isis
```
 - c. Ensure an SPBM instance exists and at least one Backbone VLAN exists (B-VID). Also ensure multicast is enabled:

```
show isis spbm
```
4. Ensure that you enable the CFM configuration.
 - a. Ensure a CFM maintenance-association exists:

```
show cfm maintenance-association
```
 - b. Ensure a CFM maintenance-domain exists:

```
show cfm maintenance-domain
```
 - c. Ensure a maintenance-endpoint exists in the MEP ID column and is enabled in the ADMIN column:

```
show cfm maintenance-endpoint
```

5. Ensure the following on all BEBs where you want IP Multicast over Fabric Connect. Ensure that you enable IP Multicast over Fabric Connect globally:

```
show isis spbm
```
6. On the VLANs that need Layer 3 VSN IP Multicast over Fabric Connect routing, create an IP interface on the VLAN if one does not exist. The address should be on the same subnet as the IGMP hosts connected to the VLAN. Also, ensure that you enable IP Multicast over Fabric Connect. Create an IP interface on the VLAN and enable IP Multicast over Fabric Connect.
7. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
8. Create an IP interface on the VLAN and enable IP Multicast over Fabric Connect:

```
ip address <A.B.C.D>

ip spb-multicast enable
```
9. Ensure that you enable IGMP Snooping on access Layer 2 switches to prevent flooding of multicast traffic to non-receiver ports:

```
show ip igmp snoop-trace

show ip igmp interface
```
10. Ensure that the IGMP version used by the multicast hosts and the Layer 2 switches outside the SPBM network is the same as the IGMP version configured on the C-VLAN:

```
show ip igmp interface
```

View the Hardware Resource Usage

About This Task

The switch can query the number of ingress and egress IP multicast streams traversing the switch. After you configure the thresholds for ingress and egress records, if the record-usage goes beyond the threshold, the device notifies you by way of a trap on the console, logged message, or both.

If you do not configure the thresholds, the switch displays only the ingress and egress records currently in use.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the hardware resource usage:

```
show ip mroute hw-resource-usage
```

Example

Show the hardware resource usage:

```
Switch:1>show ip mroute hw-resource-usage
=====
                          Multicast Hardware Resource Usage
=====
```

EGRESS	INGRESS	EGRESS	INGRESS	LOG MSG	SEND TRAP	SEND TRAP
REC IN-USE	REC IN-USE	THRESHOLD	THRESHOLD	ONLY	ONLY	AND LOG

0	0	0	0	false	false	false

Using PIM Debugging Commands

Use Protocol Independent Multicast (PIM) traces to aid in PIM troubleshooting.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Start debug trace message output:

```
debug ip pim pimdbgtrace
```
3. Stop debug trace message output:

```
no debug ip pim pimdbgtrace
```

```
default debug ip pim pimdbgtrace
```
4. Configure the system to display trace messages forwarded by the device:

```
debug ip pim send-dbg-trace
```
5. Stop the system from displaying trace messages forwarded by the device:

```
no debug ip pim send-dbg-trace
```

```
default debug ip pim send-dbg-trace
```
6. Configure the system to display trace messages received by the device:

```
debug ip pim rcv-dbg-trace
```
7. Stop the system from displaying trace messages received by the device:

```
no debug ip pim rcv-dbg-trace
```

```
default debug ip pim rcv-dbg-trace
```
8. Configure the system to display hello messages forwarded or received by the device:

```
debug ip pim hello
```
9. Stop the system from displaying hello messages forwarded or received by the device:

```
no debug ip pim hello
```

```
default debug ip pim hello
```
10. Configure the system to display and log debug trace messages:

```
debug ip pim pimdbglog
```
11. Stop the system from displaying and logging debug trace messages:

```
no debug ip pim pimdbglog
```

```
default debug ip pim pimdbglog
```
12. Configure the system to display register messages forwarded or received by the device:

```
debug ip pim register
```

13. Stop the system from displaying register messages forwarded or received by the device:

```
no debug ip pim register
```

```
default debug ip pim register
```

14. Configure the system to display debug trace messages after an enabled message type, for example, hello or register, is received from a specific sender IP address:

```
debug ip pim source {A.B.C.D}
```

Variable Definitions

The following table defines parameters for the **debug ip pim** command.

Variable	Value
<i>assert</i>	Displays the assert debug traces. The default is false (disabled).
<i>bstrap</i>	Displays bootstrap debug traces. The default is false (disabled).
<i>group {A.B.C.D}</i>	Displays debug traces from a specific group IP address. The default is 0.0.0.0 (disabled).
<i>hello</i>	Displays hello debug traces. The default is false (disabled).
<i>joinprune</i>	Displays join and prune debug traces. The default is false (disabled).
<i>pimdbglog</i>	Logs debug traces. The default is false (disabled).
<i>pimdbgtrace</i>	Displays PIM debug traces. The default is false (disabled).
<i>rcv-dbg-trace</i>	Displays trace messages received by the switch. The default is false (disabled).
<i>register</i>	If enabled, the system displays register debug traces. The default is false (disabled).
<i>regstop</i>	Displays register stop debug traces. The default is false (disabled).
<i>rp-adv</i>	Displays RP advertisement debug traces. The default is false (disabled).
<i>send-dbg-trace</i>	Displays trace messages forwarded by the switch. The default is false (disabled).
<i>source {A.B.C.D}</i>	Displays debug traces from a specific source IP address. The default is 0.0.0.0 (disabled).

Determine the Protocol Configured on the Added VLAN

Use this procedure to determine the protocol configured on the added VLAN.

The protocol configured on the added VLAN can be one of the following values:

- snoop
- snoop-spb
- route-spb
- pim

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Determine the protocol configured on the added VLAN:

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]] [vlan <1-4059>] [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

The protocol displays under the Mode column of the command output.

Example

Determine the protocol configured on the added VLAN:

```
Switch:1#show ip igmp interface

=====
                        Icmp Interface - GlobalRouter
=====
IF      QUERY      OPER      QUERY  WRONG      LASTMEM
INTVL  STATUS  VERS.  VERS  QUERIER  MAXRSPT  QUERY  JOINS  ROBUST  QUERY  MODE  L2ISID
-----
V100   125     activ  2     2    0.0.0.0   100   0     0     2     10   snoop-spb 1100

1 out of 1 entries displayed
```

Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

Variable	Value
<i>gigabitethernet</i> {slot/port[/sub-port]} [-slot/port[/sub-port]][,...]	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>vlan</i> <1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<i>vrf</i> WORD<1-16>	Specifies the VRF instance by the VRF name.
<i>vrfids</i> WORD<0-512>	Specifies the VRF ID for which to display statistics.

Multicast routing troubleshooting using EDM

Use the information in this section to help you troubleshoot multicast routing problems using Enterprise Device Manager (EDM).

View IGMP Interface Information

Use the Interface tab to view the IGMP interface table. You can use this procedure to determine the protocol configured on the added VLAN.

The protocol configured on the added VLAN can be one of the following values:

- snoop
- pim

About This Task

If an interface does not use an IP address, the system does not display it in the IGMP table. If an interface uses an IP address, but neither IGMP snoop or PIM is enabled, the system displays the interface as inactive in the Status field.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IGMP**.
3. Select the **Interface** tab.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
IfIndex	Shows the interface where IGMP is enabled.
QueryInterval	Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The default is 125.
Status	Shows the IGMP row status. If an interface uses an IP address and PIM-SM is enabled, the status is active. Otherwise, it is notInService.
Version	Configures the version of IGMP (1, 2, or 3) that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.
OperVersion	Shows the version of IGMP that currently runs on this interface.
Querier	Shows the address of the IGMP querier on the IP subnet to which this interface attaches.
QueryMaxResponseTime	Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds). Important: You must configure this value lower than the QueryInterval.

Name	Description
WrongVersionQueries	Shows the number of queries received with an IGMP version that does not match the interface. You must configure all routers on a LAN to run the same version of IGMP. If the interface receives queries with the wrong version, this value indicates a version mismatch.
Joins	Shows the number of times this interface added a group membership, which is the same as the number of times an entry for this interface is added to the cache table. This number gives an indication of the amount of IGMP activity over time.
Robustness	Tunes for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect a network to lose query packets, increase the robustness value. The default value of 2 means that the switch drops one query for each query interval without the querier aging out.
LastMembQueryIntvl	Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of second. As a best practice, configure this parameter to values greater than 3. If you do not need a fast leave process, you can configure values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.)
OtherQuerierPresent Timeout	Shows the length of time that must pass before a multicast router determines that no other querier exists. If the local router is the querier, the value is 0.
FlushAction	Configures the flush action to one of the following: <ul style="list-style-type: none"> • none • flushGrpMem • flushMrouter • flushSender
RouterAlertEnable	Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option. Important: To maximize network performance, configure this parameter according to the version of IGMP currently in use. <ul style="list-style-type: none"> • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable
SsmSnoopEnable	Enables SSM snoop.
SnoopQuerierEnable	Enables IGMP Layer 2 Querier.

Name	Description
SnoopQuerierAddr	Specifies the pseudo address of the IGMP snoop querier.
ExplicitHostTrackingEnable	Enables or disables IGMPv3 to track hosts for each channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.
McastMode	Indicates the protocol configured on the VLAN. <ul style="list-style-type: none"> snoop — Indicates IGMP snooping is enabled on a VLAN. snoop-spb — Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN). pim — Indicates PIM is enabled. routed-spb — Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts.
ExtnUpnpFilterEnable	Enables Universal Plug and Play (uPnP) Filtering to filter multicast packets destined for a specific range. The default is disabled.
ExtnUpnpFilterAddress	Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32.
ExtnUpnpFilterAddressMask	Indicates the IGMP uPnP Filtering IP subnet to which this interface is attached.
SnoopOrigin	Specifies the origin of IGMP Snooping configuration on the port. The supported values are: <ul style="list-style-type: none"> config - Set by the user. radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.

Determine the Data Stream Learned when IP Multicast over Fabric Connect is Configured on the VLAN

Use the following procedure to determine the data stream learned when IP multicast is configured on the VLAN.

Procedure

1. In the navigation pane, expand **Configuration > IP > Multicast**.
2. Click the **Routes** tab.

Multicast Field Descriptions

Use the information in the following table to help you use the **Multicast** tab.

Field	Description
Group	Indicates the IP multicast group for which this entry specifies a next hop on an outgoing interface.
Source	Indicates the network address that, when combined with the corresponding value of ipMRouteNextHopSourceMask, identifies the sources for which this entry specifies a next hop on an outgoing interface.

Field	Description
SourceMask	Indicates the network mask, when combined with the corresponding value of ipMRouteNextHopSource, identifies the sources for which this entry specifies a next hop on an outgoing interface.
UpstreamNeighbor	Indicates the address of the upstream neighbor from which IP datagrams from these sources to this multicast address are received, or 0.0.0.0 if the upstream neighbor is known.
Interface	Indicates the value of ifIndex for the interface on which IP datagrams sent by these sources to this multicast address are received. A value of 0 indicates that datagrams are not subject to an incoming interface check, but can be accepted on multiple interfaces (for example, in CBT).
ExpiryTime	Indicates the minimum amount of time remaining before this entry ages out. The value 0 indicates that the entry is not subject to aging.
Protocol	Indicates the outgoing mechanism through which the switch learns this route. For IP Multicast over Fabric Connect, this value is spb-access or spb-network. Spb-access indicates the datastream learned was from the UNI ports. Spb-network indicates that the datastream learned was from the SPBM cloud.

Show the SPBM Multicast Database

Determine the database used by the SPBM multicast module.

Procedure

1. In the navigation pane, expand **Configuration > ISIS > SPBM**.
2. Click the **IpMcastRoutes** tab.

IpMcastRoutes field descriptions

Use the data in the following table to use the **IpMcastRoutes** tab.

Name	Description
Vsnlsid	Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.
Group	Specifies the group IP address for the IP Multicast over Fabric Connect route.
Source	Specifies the IP address where the IP Multicast over Fabric Connect route originated.
NickName	Specifies the nick name used to filter criteria.
SourceBeb	Specifies the source BEB for the IP multicast route.
VlanID	Specifies the ID for the C-VLAN.
VrfName	Specifies the VRF name.

Name	Description
Datalsid	Specifies the data I-SID for the IP Multicast over Fabric Connect route. A a BEB receives IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID.
Type	Specifies the type for the IP Multicast over Fabric Connect route.
Bvlan	Specifies the B-VLAN for the IP Multicast over Fabric Connect route.
NniInterfaces	Specifies the NNI ports for the IP multicast route. SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports that face a customer VLAN are user-to-network interface (UNI) ports.

Troubleshooting Fabric Attach

The following sections help you troubleshoot problems with Fabric Attach (FA) using either the Command Line Interface (CLI) or the Enterprise Device Manager (EDM).

Troubleshooting workflow

Troubleshoot FA in the following sequence:

- **Verify FA configuration:**

As a first step, for proper operation, verify that FA is enabled properly at both the global and interface levels. Use the procedures in this section to verify FA configuration.

- **Verify LLDP port-level transmission and reception:**

LLDP operates at the interface level. Enabling FA at the port level automatically enables LLDP transmission and reception at the port level. Similarly, enabling FA at the MLT level automatically enables LLDP transmission and reception for all ports in that MLT. Use the procedures in this section to verify LLDP interface (port or MLT) statistics.

- **Verify FA discovery, I-SID-to-VLAN mapping assignments and Switched UNI I-SID creation:**

After you verify LLDP transmission, verify that FA element discovery completed successfully. After a successful FA discovery, FA clients can send I-SID-to-VLAN mapping assignments to the FA Server on an FA-enabled port or MLT. The FA server accepts or rejects these mapping assignments. A prerequisite to successful mapping assignments is that IS-IS and SPBM are properly configured on the FA server. Successful FA mappings result in the creation of ELAN I-SIDs with end-points of type Switched UNI on the FA Server switch.

Troubleshoot Fabric Attach using CLI

View Fabric Attach Configuration

To operate properly, Fabric Attach (FA) must be configured properly at both the global and interface level on the switch. Use this procedure to verify FA configuration.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. To verify that FA is enabled globally, enter one of the following commands:
 - `show fa`
 - `show fa agent`
3. To view all FA interfaces (ports and MLTs), enter:

```
show fa interface
```
4. To view FA interface configuration on ports, use one of the following commands:
 - To view FA configuration on all ports, enter:

```
show fa interface port
```
 - To view FA configuration on a specific port, enter:

```
show fa interface port [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```
5. To view FA interface configuration on MLTs, use one of the following commands:
 - To view FA configuration on all MLTs, enter:

```
show fa interface mlt
```
 - To view FA configuration on a specific MLT, enter:

```
show fa interface mlt [<1-512>]
```
 - To view FA interface configuration based on the authentication status, enter:

```
show fa interface [enabled-auth] [disabled-auth]
```

Example

Verify that FA is configured globally.

```
Switch:1>show fa

=====
                          Fabric Attach Configuration
=====
                          FA Service : enabled
                          FA Element Type : server
                          FA Assignment Timeout : 240
                          FA Discovery Timeout : 240
                          FA Provision Mode : spbm
```

Verify FA configuration at the interface (port or MLT) level, on all interfaces.

In the following example output, note that:

- FA is enabled on interfaces 2/10, 4/11 and M1t2.
- Both FA and message authentication are disabled on port 4/6.
- Both FA and message authentication are enabled on port 4/11.

```
Switch:1#show fa interface

Troubleshoot Fabric Attach using EDM

Graph LLDP Reception Statistics

Use this procedure to graphically view the LLDP reception statistics.

About This Task

LLDP operates at the port interface level. Enabling FA on a port automatically enables LLDP transmission and reception on that port. It also enables traffic tagging and disables spanning tree on that port.

Enabling FA on an MLT enables LLDP transmission and reception on all ports in that MLT.

Note

When a port is removed from an MLT, LLDP transmission on that port stops and spanning tree is enabled. Any I-SID-to-VLAN mappings on that port are removed, if not already learned on any other port in the MLT. This also causes the Switched UNI I-SID to be deleted from the MLT. However, if the mappings are learned on another port on the MLT, the Switched UNI I-SID continues to exist for that MLT.

For ports in an LACP MLT, when FA is enabled, tagging is enabled on all ports in the LACP MLT. The consistency check for FA is based on key membership. If all ports with the same key do not support FA, FA is not successfully enabled on those ports.

Note

If a slot is removed from the switch chassis, the statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > 802_1ab.LLDP**.
2. Click the **RX Stats** tab.
3. To view the reception statistics graphically for a port:
 - a. Select a row, and click **Graph**.
The system displays the **RX Stats-Graph,<port-number>** tab.
 - b. Select one of the parameters, and click the appropriate icon in the upper-left corner of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
4. To clear the existing counters, and fix a reference point in time to restart the counters, click **Clear Counters**.
5. To export the statistical data to a file, click **Export**.
6. To configure a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

RX Stats Field Descriptions

Use the data in the following table to use the **RX Stats** tab.

Name	Description
FramesDiscardedTotal	Specifies the number of LLDP frames received on the port, but discarded, for any reason. This counter provides an indication of possible LLDP header formatting problems in the sending system, or LLDP PDU validation problems in the receiving system.
FramesErrors	Specifies the number of invalid LLDP frames received on the port.
FramesTotal	Specifies the total number of LLDP frames received on the port.
TLVsDiscardedTotal	Specifies the number of LLDP TLVs discarded on the port, for any reason.
TLVsUnrecognizedTotal	Specifies the number of LLDP TLVs on the port, that are unrecognized on that port. An unrecognized TLV is referred to as the TLV whose type value is in the range of reserved TLV types (000 1001-111 1110). An unrecognized TLV could be, for example, a basic management TLV from a later LLDP version.

Graph LLDP Transmission Statistics

Use this procedure to view the LLDP transmission (TX) statistics. You can also view the statistics graphically.

About This Task

LLDP operates at the port interface level. Enabling FA on a port automatically enables LLDP transmission and reception on that port. It also enables traffic tagging and disables spanning tree on that port.

Enabling FA on an MLT enables LLDP transmission and reception on all ports in that MLT.

Note

When a port is removed from an MLT, LLDP transmission on that port stops and spanning tree is enabled. Any I-SID-to-VLAN mappings on that port are removed, if not already learned on any other port in the MLT. This also causes the Switched UNI I-SID to be deleted from the MLT. However, if the mappings are learned on another port on the MLT, the Switched UNI I-SID continues to exist for that MLT.

For ports in an LACP MLT, when FA is enabled, tagging is enabled on all ports in the LACP MLT. The consistency check for FA is based on key membership. If all ports with the same key do not support FA, FA is not successfully enabled on those ports.

Note

If a slot is removed from the switch chassis, the statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > 802_1ab.LLDP**.
2. Click the **TX Stats** tab.
The system displays the transmission statistics.
3. To view the transmission statistics graphically for a port:
 - a. Select a row, and click **Graph**.
The system displays the **TX Stats-Graph,<port-number>** tab.
 - b. To view the graph, select one of the parameters, and click the appropriate icon on the upper-left corner of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
4. To clear the existing counters, and fix a reference point in time to restart the counters, click **Clear Counters**.
5. To export the statistical data to a file, click **Export**.
6. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

TX Stats Field Descriptions

Use the data in the following table to use the **TX Stats** tab.

Name	Description
FramesTotal	Specifies the total number of LLDP frames transmitted.

Troubleshooting FA Server Rejection of I-SID-to-VLAN Assignments Using Trace

Consider an FA solution where the FA Server receives I-SID-to-VLAN assignment requests from a proxy device and some of these assignment requests are rejected by the FA Server. Use this procedure to help you troubleshoot the cause of the rejection.

Note

When the FA Server rejects an I-SID-to-VLAN assignment request, the error message in the log file lists a generic reason for the failure, such as `rejected due to application error (status 9)`. To troubleshoot further, you must use trace.

This procedure also demonstrates how you can configure trace for enhanced troubleshooting.

Procedure

Begin troubleshooting on the FA Server

1. Enter Privileged EXEC mode:

```
enable
```

2. Verify that router IS-IS is enabled. This is required for proper FA operation.

```
show isis
```

Note

I-SID-to-VLAN assignments are always rejected if router IS-IS is disabled.

3. Verify that FA is enabled on the interface on which I-SID-to-VLAN assignments are expected.

```
show fa interface [disabled-auth] [enabled-auth] [mlt <1-512>] [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]]
```

4. Verify the discovery and authentication status of the proxy device, on the interface.

```
show fa elements [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]]
```

5. Determine the I-SID-to-VLAN assignments received on the interface and which ones are rejected.

```
show fa assignment [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]]
```

6. View the log file to determine the cause of the assignment rejection.

```
show log file module fa
```

Note

When the FA Server rejects an I-SID-to-VLAN assignment request, only a generic reason for the rejection is logged.

Enhanced troubleshooting using trace

7. Configure trace:

- a. Enable keyword search in the trace output:

```
trace grep WORD<0-128>
```

- b. Set the trace level for FA:

```
trace level <Module_ID>
```

Note

- <Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the **show trace modid-list** command or CLI command completion Help.
- FA uses the trace level 221.

- c. Turn on trace:

```
trace screen [enable] |[disable]
```

Example:

The following example simulates a configuration error on the FA Server as a result of which the FA Server rejects I-SID-to-VLAN assignments from the proxy device. When the FA Server rejects an I-SID-to-VLAN assignment, the error message listed in the log file is a generic reason for the rejection, as demonstrated in this example. To troubleshoot further, set up trace.

On the FA Server, assume that the interface MLT 1 consists of ports 1/5 and 1/6. Assume that a proxy device sends I-SID-to-VLAN assignment mapping requests with I-SID 9005 and CVID 400, on this interface.

Simulate a configuration error on the FA Server:

Configure a management I-SID with a C-VID value that is different from that of the C-VID in the I-SID-to-VLAN assignment request from the proxy. So, for example, configure a management I-SID with C-VID 999, which is different from the C-VID advertised by the proxy, which is 400. This causes rejection of I-SID-to-VLAN assignment requests on the interface.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface mlt 1
Switch:1(config-mlt)#no fa enable
Switch:1(config-mlt)#fa management i-sid 9005 c-vid 999
Switch:1(config-mlt)#fa enable
Switch:1(config-mlt)#exit
Switch:1(config)#exit
```

At this stage, the FA Server rejects I-SID-to-VLAN assignments as shown below.

```
Switch:1#show fa assignment

Troubleshooting FAN Transit

Use the following section to troubleshoot Fabric Area Network (FAN) Transit information on a switch.

View FAN Transit information - Detailed

About This Task

Use this procedure to verify detailed FAN Transit information of a switch acting as a transit node in a FAN. Transit nodes are not members of the FAN and only forward FAN traffic.

This procedure also includes verification on the FAN member nodes.

Procedure

Verification on FAN member nodes:

1. Verify that the node is a FAN member:

```
show isis
```
2. Verify that the node signals FAN membership on TLV 147:

```
show isis lsdB local tlv 147 detail
```
3. Verify that the node creates FAN multicast FIB entries for itself and the other member nodes:

```
show isis spbm multicast-fib
```
4. Verify that the transit node is a part of the FAN tree:

```
l2 tracetree-fan
```
5. Verify that the transit node is in the SPB path between the FAN member nodes:

```
show isis spbm unicast-tree <2-4059>
```

Verification on the transit node:

6. Verify that the transit node is not a member of the FAN and does not signal FAN membership on TLV 147:

```
show isis

show isis lsdB local tlv 147 detail
```
7. Verify that the transit node creates FAN multicast FIB entries for the FAN member nodes:

```
show isis spbm multicast-fib
```

Example

Use the following example to verify FAN Transit information on a transit node between two end-point SPB nodes, BEB-A and BEB-B.

Verification on BEB-A:

Note

You can execute the following commands on either BEB-A or BEB-B. The following example displays the sample outputs for BEB-A.

Verify that BEB-A is a member of the FAN. The `FAN Member` attribute displays as `Yes`.

```

BEB-A:1#show isis

Upper Layer Troubleshooting

Troubleshooting SNMP

About This Task

Troubleshoot Simple Network Management Protocol (SNMP) if the network management station (NMS) does not receive traps.

Verify the management configurations for the management station. Also verify the management station setup. If the management station can reach a device but not receive traps, verify the trap configurations (that is, the trap destination address and the traps to be sent).

If you enable enhanced secure mode, the switch does not support the default SNMPv1 and default SNMPv2 community strings, and default SNMPv3 user name. The individual in the administrator access level role can configure a non-default value for the community strings, and the switch can continue to support SNMPv1 and SNMPv2. The individual in the administrator access level role can also configure a non-default value for the SNMPv3 user name and the switch can continue to support SNMPv3. If you disable enhanced secure mode, the SNMPv1 and SNMPv2 support for community strings remains the same, and the default SNMPv3 user name remains the same. Enhanced secure mode is disabled by default.

Procedure

1. From the NMS, ping the IP address for the switch. If you can ping successfully, the IP address is valid and you may have a problem with the SNMP setup.
If you cannot ping the switch, you have a problem with either the path or the IP address.
2. Telnet to the switch.
If you can Telnet, the switch IP address is correct.
3. If Telnet does not work, connect to the console port using a serial line connection and ensure that the IP address configuration is correct.
4. If the management station is on a separate subnet, make sure that the gateway address and subnet mask are correct.
5. Using a management application, perform an SNMP Get request and an SNMP Set request (that is, try to poll the device or change a configuration using management software).
6. If you cannot reach the device using SNMP, access the console port, and then ensure that the SNMP community strings and traps are correct.
7. Use sniffer traces to verify that the switch receives the poll.
8. Use sniffer traces to verify that the NMS receives the response.
9. Verify that the data in the response is the data that was requested.

SNMP Trap not Received

Perform the following procedure to troubleshoot issues in which an SNMP trap is not received.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Show the BPDU Guard status for the port:

```
show spanning-tree bpduguard {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
3. Configure the correct SNMP target information:

```
snmp-server host WORD<1-256> [port <1-65535>] v3 {noAuthNoPriv|
authNoPriv|authPriv WORD<1-32> [inform [timeout <1-2147483647>]
[retries <0-255>]] [filter WORD<1-32>]}
```

Example

In the following example, BPDU guard is enabled on port 1/8, BPDU packets are received, port 1/8 is disabled, and the TimerCount is incrementing, but no SNMP trap is ever received.

```
Switch:1>enable
Switch:1#show spanning-tree bpduguard 1/8

=====
                        Bpdu Guard
=====
Port          PORT      PORT      TIMER  BPDUGUARD  BPDUGUARD
NUM          MLTID  ADMIN_STATE  OPER_STATE  TIMEOUT  COUNT  ADMIN_STATE  ORIGIN
-----
1/8          Down    Down        120      0      Disabled  CONFIG
```

Variable Definitions

The following table defines parameters for the **show spanning-tree** command.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

The following table defines parameters for the **snmp-server host** command.

Variable	Value
<i>filter WORD<1-32></i>	Specifies a filter profile name.
<i>host WORD<1-256></i>	Specifies the IPv4 or IPv6 host address

Variable	Value
<i>inform</i> [<i>timeout</i> <1-2147483647>]	Specifies the notify type. The optional timeout parameter configures the timeout value, which specifies the time to wait for a reply before resending the inform message. Time is specified in centiseconds
<i>noAuthNoPriv</i> <i>authNoPriv</i> <i>authPriv</i> <i>WORD</i> <1-32>	Specifies the security level.
<i>port</i> <1-65535>	Specifies the port number that will be set as the destination port at the UDP level in the trap packet.
<i>retries</i> <0-255>	Specifies the number of packets to be sent if no reply is received.
{ <i>slot/port</i> [/ <i>sub-port</i>] [- <i>slot/port</i> [/ <i>sub-port</i>]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Troubleshooting DHCP

About This Task

Perform this procedure to troubleshoot the following Dynamic Host Configuration Protocol (DHCP) scenarios:

- The client cannot obtain a DHCP address when in the same subnet.
- The client cannot obtain a DHCP address when in a different subnet.

When the DHCP server and client are on the different subnets or VLANs, you must configure the device as a DHCP relay agent. The device must forward DHCP requests to the DHCP server. You must perform extra troubleshooting steps to troubleshoot the DHCP relay agent.

Procedure

1. Check the physical connectivity between the DHCP client and server.
2. Verify network connectivity by configuring a static IP address on a client workstation.
If the workstation still cannot reach the network, the problem is not DHCP. Start troubleshooting network connectivity.
3. Attempt to obtain an IP address from the DHCP server by manually forcing the client to send a DHCP request.
If the client obtains an IP address after the PC startup is complete, the issue is not the DHCP server.
4. Obtain an IP address on the same subnet or VLAN as the DHCP server.
If the issue persists, the problem may be with the DHCP server. If DHCP is working on the same subnet or VLAN as the DHCP server, the DHCP issue can be with the DHCP relay agent.
5. Confirm the DHCP relay agent configuration is correct.
6. Obtain sniffer traces where the traffic ingresses and egresses the switch and also on the client side of the network.
7. Check the logs on the switch for errors such as size exceeded or incorrect packet format.

*Troubleshooting DHCP Relay***Before You Begin**

- Configure the server to reply to the client subnet. Check the server configuration file to verify the configuration.
- Configure a route on the server for the client subnet to create a path on which to send replies.

About This Task

Perform this procedure to troubleshoot the DHCP relay agent.

Procedure

1. Verify that the interfaces that link the client and server are up, and that the ports are in the forwarding state.
 - a. To verify client availability, you can configure a temporary static IP address on the client, and then use the `ping` command.

```
ping WORD<0-256>
```

- b. To verify the port is in the forwarding state, use the following command for the slot and port number:

```
show spanning-tree [rstp|mstp] port role [{slot/port[/sub-port]}[-slot/port[/sub-port]][, ...]]
```

**Note**

Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

If STP detects loops in the configuration, it blocks ports to avoid flooding in the network. In this situation, the port is not in the forwarding state.

2. Ensure that DHCP is enabled on the client interface and that a valid forwarding path exists and is enabled. Ensure the server is reachable.
3. View the statistics counters for the relay.
4. If request or reply counters do not increase, use a sniffer tool to ensure that the client sends the packets, and that the interface module receives the packets.

You can configure mirroring for the ingress port to verify if the packets reach the module.

- a. If the client sends the packets, check that the packets reach the CPP and search the trace results for the ingress port:

```
trace level 9 3
```

```
trace grep WORD<0-128>
```

- b. If the packets reach the CPP, check that they reach the DHCP protocol; check for errors or packet drop messages:

```
trace level 170 3
```

```
trace grep WORD<0-128>
```

- If Option 82 is enabled, check the statistic counters for dropped packets, and perform a trace for the DHCP protocol:

```
trace level 170 3
```

Example

```
Switch:1# ping 192.0.2.31
```

```
Switch:1:#show spanning-tree mstp port role

Variable Definitions

Use the data in the following table to use the troubleshooting commands in this procedure.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>WORD<0-128></i>	Specifies the text string to use as the search criterion.
<i>WORD<0-256></i>	Specifies the IP address.

Troubleshooting Client Connection to the DHCP Server

About This Task

Perform this procedure if the client cannot reach the DHCP server.

Procedure

1. Check that the DHCP relay agent in the network switch is correctly configured.
2. Check that the DHCP server configuration is correct.
3. Check for routing issues.
The routing in the network may not be configured so that DHCP request and reply packets are propagated. You can use ping and traceroute.
4. Check that the DHCP pools are correctly configured.
5. If the client cannot reach the server because the link is down, enable auto-negotiation on the link.

Troubleshooting IPv6 DHCP Relay

The following sections provide troubleshooting information for IPv6 DHCP Relay.

IPv6 DHCP Relay Switch Side Troubleshooting

With DHCP Relay, the switch only participates in forwarding the requests and replies to and from the client and the DHCP server. The switch always acts as the relay agent, on which you configure the forward path to the server.

To troubleshoot DHCP Relay issues on the switch, use the following procedure.

Procedure

1. Verify that the DHCP server is reachable using ping. If ping is working and the DHCP server is reachable, DHCP should work.
2. Verify that the relay agents and the forward path configured are reachable. Ping the server and the gateway to the server.
3. Check that the relay agent configurations are correct. Also verify that DHCP is enabled on the switch:

```
show ipv6 dhcp-relay interface {gigabitEthernet {slot/port[/sub-port]}  
[-slot/port[/sub-port]][, ...]}|vlan <1-4059>
```
4. Verify that IPv6 forwarding is enabled globally:

```
show ipv6 global
```
5. Verify that the IPv6 based VLAN where the DHCP relay agent is configured is enabled:

```
show ipv6 interface vlan <1-4059>
```
6. In a scenario with VRRP and SMLT, configure VRRP IP as the DHCP relay agent.
7. When using the VRRP VRID as the relay agent, make sure the VRRP configurations are proper.
8. To verify that relay forward and relay receive are working, enable trace for DHCP with IPv6, and grep trace for relay:

```
trace level 66 3  
  
trace grep relay  
  
trace screen enable
```
9. Display the count of DHCP Relay requests and replies to verify the system received requests and replies:

```
show ipv6 dhcp-relay counters
```

IPv6 DHCP Relay Server Side Troubleshooting

Use the following procedure to troubleshoot IPv6 DHCP Relay on the server side.

Procedure

1. Enable the services on the server side, and then create an IP pool.
The IP pool must contain the range of addresses that you want to assign to the clients.
Configure the IP pool with the same network subnet as that of the relay agent.
2. When the configuration is complete, initiate a DHCP request from a client.
3. Check the log file available on the server to verify the reason for packet drop.
4. Capture the packets on the server side using Ethereal.
5. From the server side, use ping to verify that the relay agent address is reachable.
Ensure that a route to the relay is configured.
6. For more configuration aspects, see the Microsoft webpage for troubleshooting and configuration issues.

Note

You can receive some log messages that indicate the system cannot forward packets. However, certain situations are not DHCP failures.

Example 1: if you receive the message `0x00108796 (relayMsgSend): cannot find route entry for destination` on the console, you must ping the server. If the server is not reachable, the system cannot forward the packet. This is not a DHCP issue.

Example 2: if you receive the message `0x00108705` this indicates a problem at the transmission level. Check the server reachability and ensure that MAC learning is correct before you pursue DHCP issues.

IPv6 DHCP Relay Client Side Troubleshooting

You can collect a client console dump, which can be used to analyze why the received packet cannot be processed and the allocated address cannot be used by the client.

In addition, restarting the client can also fix the issue in some cases.

Make sure the client supports IPv6 requests.

Connect the server directly to the client. If the IP is assigned, then the problem is with the relay.

Enabling Trace Messages for IPv6 DHCP Relay

Use this procedure to enable trace for IPv6 DHCP Relay and enable IPv6 forwarding trace.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. To troubleshoot IPv6 DHCP Relay, you can enable `rcip6` trace messages using the following command:
`trace level 66 3`

3. You can also enable IPv6 forwarding trace using the following command:

```
trace ipv6 forwarding enable <all|debug|error|info|pkt|warn>
```

Example

Enable rcip6 trace messages and enable IPv6 forwarding trace:

```
Switch:1>enable
Switch:1#trace level 66 3
Switch:1#trace ipv6 forwarding
```

Troubleshooting TACACS+

The switch supports the Terminal Access Controller Access Control System plus (TACACS+) client. TACACS+ is a remote authentication protocol that provides centralized validation of users who attempt to gain access to a router or network access server (NAS). The TACACS+ feature is disabled by default.

The switch implementation of TACACS+ does not support:

- Earlier versions of TACACS
- Point-to-Point Protocol (PPP) authentication and accounting
- IPv6 addresses

See the following sections to troubleshoot TACACS+.

Unable to Log On Using Telnet

If you cannot log on using Telnet or rlogin, perform the following steps.

Note

Rlogin is only supported on the VSP 8600 Series.

Procedure

1. Check whether the TACACS+ server is available or unreachable.
2. On the TACACS+ server, check whether you configured the privilege level correctly. On successful authorization, the TACACS+ server returns an access level to the switch for the current user, which determines the user access privileges. The switch supports access levels 1 to 6 and access level 15.

The following table maps user accounts to TACACS+ privilege level.

Switch access level	TACACS+ privilege level	Description
NONE	0	If the TACACS+ server returns an access level of 0, the user is denied access. You cannot log into the device if you have an access level of 0.
READ ONLY	1	Permits you to view only configuration and status information.

Switch access level	TACACS+ privilege level	Description
LAYER 1 READ WRITE	2	Permits you to view most of the switch configuration and status information and change physical port settings.
LAYER 2 READ WRITE	3	Permits you to view and change configuration and status information for Layer 2 (bridging and switching) functions.
LAYER 3 READ WRITE	4	Permits you to view and change configuration and status information for Layer 2 and Layer 3 (routing) functions.
READ WRITE	5	Permits you to view and change configuration and status information across the switch. This level does not allow you to change security and password settings.
READ WRITE ALL	6	Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings.
NONE	7 to 14	If the TACACS+ server returns an access level of 7 to 14, the user is denied access. You cannot log into the device if you have an access level of 7 to 14.
READ WRITE ALL	15	Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings. Note: Access level 15 is internally mapped to access level 6, which ensures consistency with other vendor implementations. The switch does not differentiate between an access level of 6 and an access level of 15.

After you enable TACACS+ authorization, the current privilege-level to command mapping on the switch is no longer relevant because the TACACS+ server has complete responsibility for command

authorization. TACACS+ authorization provides access to the system based on username, not based on privilege level.

Note

If you want to switch to a privilege level 'X' using **tacacs switch level <1-15>** command, you must create a user "\$enabX\$" on the TACACS+ server. X is the privilege level that you want to change.

3. On the TACACS+ server, check whether you configured the password and user name correctly.
4. On the TACACS+ server, check whether you configured the switch IP address in the trust list.
5. Check whether you configured the encryption key, connection mode (single connection or per-session connection), and TCP port number the same on the TACACS+ server and switch.
6. If you can log on to the switch, check whether the TACACS+ server configured on the platform has the correct IP address:
`show tacacs`
7. Use the output from the **show tacacs** command to verify whether you configured the single connection option on the platform, and whether the TACACS+ server supports the single connection.

Example

Check whether the TACACS+ server configured on the platform has the correct IP address:

```
Switch:1>enable
Switch:1(config)#show tacacs

Global Status:

    global enable : false

    authentication enabled for : cli

    accounting enabled for : none

    authorization : disabled

    User privilege levels set for command authorization : None

Server:

    create :

Prio  Status  Key      Port  IP address  Timeout  Single  Source  SourceEnabled
-----
Primary NotConn ***** 3    192.0.2.254 30    true  5.5.5.5  true
Backup  NotConn ***** 47   198.51.100.1 10   false 0.0.0.0  false
```

Unable to Log On Using SSH

If you cannot log on using Secure Shell (SSH), perform the following steps.

Procedure

1. Verify that the network, the switch, and the TACACS+ server is reachable.
2. Verify whether you configured the SSH client correctly.
3. Verify whether you enabled and configured the SSH function correctly on the switch:
`show ssh global`

Example

Verify whether you enabled and configured SSH function correctly on the switch:

```
Switch:1>enable
Switch:1#show ssh global

Total Active Sessions : 0
  version              : v2only
  port                 : 22
  max-sessions         : 4
  timeout              : 60
  action rsa-keygen    : rsa-keysize 2048
  action dsa-keygen    : dsa-keysize 2048
  rsa-auth             : true
  dsa-auth             : true
  pass-auth            : false
  enable               : true
```

Job Aid

The following table describes the fields in the output for the **show ssh global** command.

Parameter	Description
Total active sessions	Specifies the number of active SSH sessions underway.
version	Specifies if SSH is version 1 or version 2. The default is v2. As a best practice, configure the version to v2 only.
port	Specifies the SSH connection port. The default is 22. You cannot configure the following TCP ports as SSH connection ports: 0 to 1024 (except port 22), 1100, 4095, 5000, 5111, 6000, or 999.
max-sessions	Specifies the maximum number of SSH sessions allowed. The default is 4.
timeout	Specifies the SSH connection authentication timeout in seconds. The default is 60 seconds.
action rsa-keygen	Specifies the SSH RSA key size.
action dsa-keygen	Specifies the SSH DSA key size.
rsa-auth	Specifies if RSA authentication is enabled or disabled. The default is enabled.
dsa-auth	Specifies if DSA authentication is enabled or disabled. The default is enabled.
pass-auth	Specifies if password authentication is enabled or disabled. The default is enabled.
enable	Specifies if SSH secure mode is enabled. False is disabled. Secure is enabled.

Unable to Log On by any Means

If you cannot log on by any means, perform the following steps.

Note

Rlogin is only supported on VSP 8600 Series.

Procedure

1. Check whether the TACACS+ server runs properly and try to restart the TACACS+ server.

2. Check whether you enabled both TACACS+ and RADIUS on the switch.

```
show radius
```

```
show tacacs
```

If TACACS+ fails, RADIUS can take over the authentication, authorization, and accounting (AAA) process.

3. Check whether you configured the TACACS+ server to unencrypted mode, as the switch always sends encrypted TACACS+ messages.
4. Check whether you configured the switch properly. In particular, check the IP address and key.
5. Check whether you configured the encryption key, connection mode (single connection or per-session connection), and TCP port number the same on the TACACS+ server and switch.
6. If the server connects directly, check whether the administrative and operation status of the port is up:

```
show interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. If the server is connected in a network, check whether the switch has a route configured to the server network:

```
show ip route
```

8. If the server is connected in a network, check whether the switch has a route configured to the server network:

```
show ip route and show ipv6 route
```

9. For the Out-of-Band (OOB) or VLAN Segmented Management Instance, check whether the switch has a route configured to the server network:

```
show mgmt ip route, show mgmt ipv6 route, and show mgmt ip route static
```

10. For Segmented Management Instance troubleshooting, check the management network statistics:

```
show mgmt ip arp, show khi mgmt statistics, show mgmt ip ip-statistics, and show mgmt ip icmp-statistics
```

Examples

Check if you enabled both TACACS+ and RADIUS on the switch:

```
Switch:1>enable
Switch:1(config)#show tacacs

Global Status:

  global enable : false

  authentication enabled for : cli

  accounting enabled for : none

  authorization : disabled

  User privilege levels set for command authorization : None

Server:

  create :
```

```

Prio   Status  Key      Port  IP address  Timeout Single Source SourceEnabled
Primary NotConn ***** 3     192.0.2.254 30    true 5.5.5.5 true
Backup NotConn ***** 47    198.51.100.1 10   false 0.0.0.0 false
    
```

```

Switch:1>show radius
      acct-attribute-value : 193
      acct-enable         : false
      acct-include-cli-commands : false
      access-priority-attribute : 192
      auth-info-attr-value : 91
      command-access-attribute : 194
      cli-commands-attribute : 195
      cli-cmd-count       : 40
      cli-profile-enable  : false
      enable              : false
      igap-passwd-attrib : standard
      igap-timeout-log-fsize : 512
      maxserver           : 10
      mcast-addr-attr-value : 90
      supported-vendor-ids : 1584, 562, 1916
      secure-flag        : false
    
```

Check if the administrative and operation status of the port is up:

```

Switch:1#show interface gigabitethernet 1/2

=====

Administrator Unable to Obtain Accounting Information from the TACACS+ Server

If the administrator is unable to obtain accounting information from the TACACS+ server, perform the following steps.

Procedure

1. Check whether you enabled accounting on the switch:
`show tacacs`
2. Check whether you enabled accounting on the TACACS+ server.

Example

Check whether accounting is enabled on the switch:

```

Switch:1>enable
Switch:1(config)#show tacacs

Global Status:

  global enable : false

  authentication enabled for : cli

  accounting enabled for : none
    
```

```

authorization : disabled

User privilege levels set for command authorization : None

Server:

                create :

Prio  Status  Key      Port  IP address  Timeout Single Source SourceEnabled

```

Trap Server Cannot Receive Trap Packets from the Switch

If the trap server cannot receive trap packets from the switch, perform the following steps.

Procedure

1. Check whether you configured the trap server correctly on the switch:
`show snmp-server host`
2. Check whether a firewall exists between the switch and the trap server.

Example

Check whether you configured the trap server correctly on the switch:

```

Switch:1>enable
Switch:1#show snmp-server host

Troubleshooting TACACS+ Problems

Use the **trace level** command to check traps and log files to see any TACACS+ failure. If TACACS+ experiences failure conditions, the TACACS+ module sends SNMP traps to notify the user. The TACACS+ module also logs the failure information into the system log file.

About This Task

Caution

Using the trace tool inappropriately can cause primary CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation. If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Configure the trace level for the TACACS+ module:

```
trace level 109 <1-4>
```

The TACACS+ module ID is 109.
3. Stop trace:

```
trace shutdown
```
4. View the trace results on screen:

```
trace screen enable
```
5. View trace saved to a file:

```
show trace file [tail]
```

6. Save the trace file to the Compact Flash card for retrieval:

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt. By default, the system saves the file to the external flash.

7. Save the trace file for retrieval:

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt.

Variable Definitions

The following table defines parameters for the **trace** command.

Variable	Value
<i>level</i> [<Module_ID>] [<1-4>]	Starts the trace by specifying the module ID and level. Module ID 23 represents the IGMP module <Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the show trace modid-list command or CLI command completion Help. <0-4> specifies the trace level: <ul style="list-style-type: none"> • 0 – Disabled • 1 – Very terse • 2 – Terse • 3 – Verbose • 4 – Very verbose
<i>shutdown</i>	Stops the trace operation.
<i>screen {disable enable}</i>	Enables or disables the display of trace output to the screen. Important: As a best practice, avoid using the screen to view commands if you use trace level 3 (verbose) or trace level 4 (very verbose) due to the volume of information generated and the effect on the system.

The following table defines parameters for the **show trace** command.

Variable	Value
<i>file [tail]</i>	Displays the trace results saved to a file.
<i>level</i>	Displays the current trace level for all modules.
<i>modid-list</i>	Specifies the module ID list.

Using BGP Debugging Commands

Use global and peer debug commands to display specific debug messages for the global and peer Border Gateway Protocol (BGP) configuration, including the BGP neighbors.

You can use these commands to troubleshoot the BGP configuration.

Procedure

1. Enter BGP Router Configuration mode:
enable

configure terminal

router bgp
2. Show specific debug messages for the global BGP configuration:
global-debug mask *WORD*<1-100>
3. Display specific debug messages for the global BGP neighbors:
neighbor-debug-all mask *WORD*<1-100>
4. Display specific debug messages for BGP peers or peer groups:
neighbor <nbr_ipaddr|peer-group-name> neighbor-debug-mask *WORD*<1-100>
5. Display debug messages on the console:
debug-screen <on|off>

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# router bgp
```

Display the global debug messages for error and packet:

```
Switch:1(router-bgp)#global-debug mask error,packet
```

End (disable) the display of global debug messages:

```
Switch:1(router-bgp)#global-debug mask none
```

Display specific debug messages for the global BGP neighbors:

```
Switch:1(router-bgp)#neighbor-debug-all mask packet,event
```

Display specific debug messages for BGP peers or peer groups:

```
Switch:1(router-bgp)#neighbor 192.0.2.10 neighbor-debug-mask event,trace
```

Display debug messages on the console:

```
Switch:1(router-bgp)#debug-screen on
```

Variable Definitions

The following table defines parameters for the **global-debug mask** and **neighbor-debug-all mask** commands.

Variable	Value
<i>WORD</i> <1-100>	Specifies one or more mask choices that you enter, separated by commas with no space between choices. For example: [<mask>,<mask>,<mask>...]. Options include: none, all, error, packet, event, trace, warning, state, init, filter, update.

The following table defines parameters for the **neighbor** command.

Variable	Value
< <i>nbr_ipaddr</i> <i>peer-group-name</i> >	Specifies the IP address or the group name of the peer.
<i>WORD</i> <1-100>	Specifies one or more mask choices that you enter, separated by commas with no space between choices. For example: [<mask>,<mask>,<mask>...]. Options include: none, all, error, packet, event, trace, warning, state, init, filter, update.

Job Aid

Use debug command values to control debug messages for global BGP message types, and for message types associated with a specified BGP peer or peer group. The following table identifies mask categories and messages.

Table 269: Mask categories and messages

Mask category	Message
none	None disables the display of all debug messages.
all	All configures the device to show all categories of debug messages.
error	Error configures the device to show error debug messages.
packet	Packet configures the device to show packet debug messages.
event	Event configures the device to show event debug messages.
warning	Warning configures the device to show warning debug messages.
init	Init configures the device to show initialization debug messages.
filter	Filter configures the device to show filter-related debug messages.
update	Update configures the device to show update-related debug messages.

Traps Reference

The switch generates alarms, traps, and logs. This section provides information about traps.

Note

The OID values of the rclsisTrap (OID 1.3.6.1.4.1.2272.1.63.9) table are populated only when the Duplicate ISIS Sys-id & Nickname condition is present. This MIB table captures this specific condition only. Use other tables such as rclsisAdjTable (OID 1.3.6.1.4.1.2272.1.63.10) or isisSAdjTable (OID 1.3.6.1.3.37.1.6.1) to gather IS-IS information.

Proprietary Traps

The following tables describe proprietary traps for the switch. All of the following traps have a status of current.

Table 270: 1.3.6.1.4.1.45.4.8.0.xx series

OID	Notification type	Objects	Description
1.3.6.1.4.1.45.4.8.0.1	slaMonitorAgentExceptionDetected	slaMonitorAgentExceptionDetected	The SLA Monitor (SLA Mon) agent process has terminated unexpectedly. You must reenale SLA Monitor to restart the SLA Monitor agent.

Table 271: 1.3.6.1.4.1.45.5.17.0.xx series

OID	Notification type	Objects	Description
1.3.6.1.4.1.45.5.17.0.1	bsDhcpSnoopingBindingTableFull	bsDhcpSnoopingNotificationClientMACAddr	A bsDhcpSnoopingBindingTableFull notification is generated when you try adding a new DHCP binding entry, and the binding table is full. The value of bsDhcpSnoopingNotificationClientMACAddr gives the MAC address that cannot be added to the binding table. This notification also indicates that additional untrusted DHCP packets will not be added to the binding table, and will be dropped.
1.3.6.1.4.1.45.5.17.0.2	bsDhcpSnoopingTrap	<ul style="list-style-type: none"> bsDhcpSnoopingNotificationSourcePort bsDhcpSnoopingNotificationMsgType bsDhcpSnoopingNotificationSourceMACAddr bsDhcpSnoopingNotificationClientMACAddr bsDhcpSnoopingIfTrusted 	A bsDhcpSnoopingTrap notification is generated when a DHCP packet is dropped.
1.3.6.1.4.1.45.5.17.0.4	bsDhcpSnoopingStaticEntryMACConflict	bsDhcpSnoopingNotificationSourceMACAddr bsDhcpSnoopingIfIndex	A bsDhcpSnoopingStaticEntryMACConflict notification is generated when a DHCP packet is dropped, because a static entry with the same MAC address was found in the binding table.

Table 272: 1.3.6.1.4.1.45.5.18.0.xx series

OID	Notification type	Objects	Description
1.3.6.1.4.1.45.5.18.0.1	bsaiArpPacketDroppedOnUntrustedPort	<ul style="list-style-type: none"> bsArpInspectionIfTrusted bsArpInspectionNotificationSourceMACAddr 	A bsaiArpPacketDroppedOnUntrustedPort trap signifies that an ARP packet is dropped on an untrusted port, due to an invalid IP or MAC address binding. The port is identified by the instance of bsArpInspectionIfTrusted generated by the trap.

Table 273: 1.3.6.1.4.1.45.5.20.0.xx series

OID	Notification type	Objects	Description
1.3.6.1.4.1.45.5.20.0.2	bsSourceGuardCannotEnablePort	bsSourceGuardConfigMode	A bsSourceGuardCannotEnablePort trap signifies that there are insufficient resources to enable IP Source Guard checking on a port because of internal state changes within the system such as system initialization. The port is identified by the instance of bsSourceGuardConfigMode generated by the trap.
1.3.6.1.4.1.45.5.20.0.1	bsSourceGuardReachedMaxIpEntries	bsSourceGuardConfigMode	A bsSourceGuardReachedMaxIpEntries trap signifies that the maximum number of IP address entries on a port has been reached. The port is identified by the instance of bssourceGuardConfigMode generated by the trap.

Table 274: 1.3.6.1.4.1.45.5.34.0.xx series

OID	Notification type	Objects	Description
1.3.6.1.4.1.45.5.34.0.1	bsnesGloballyEnabled	—	A bsnesGloballyEnabled trap signifies that the Energy Saver feature was enabled globally.
1.3.6.1.4.1.45.5.34.0.2	bsnesGloballyDisabled	—	A bsnesGloballyDisabled trap signifies that the Energy Saver feature was disabled globally.
1.3.6.1.4.1.45.5.34.0.3	bsnesManuallyActivated	—	A bsnesManuallyActivated trap signifies that the Energy Saver was activated manually.
1.3.6.1.4.1.45.5.34.0.4	bsnesManuallyDeactivated	—	A bsnesManuallyDeactivated trap signifies that the Energy Saver feature was deactivated manually.
1.3.6.1.4.1.45.5.34.0.5	bsnesScheduleNotApplied	—	A bsnesScheduleNotApplied trap signifies that a schedule was not applied because SNTP is not synchronized.
1.3.6.1.4.1.45.5.34.0.6	bsnesScheduleApplied	—	A bsnesScheduleApplied trap signifies that SNTP is synchronized and the schedule is being applied.
1.3.6.1.4.1.45.5.34.0.7	bsnesActivated	—	A bsnesActivated trap signifies that the Energy Saver feature was activated by the schedule.
1.3.6.1.4.1.45.5.34.0.8	bsnesDeactivated	—	A bsnesDeactivated trap signifies that the Energy Saver feature was deactivated by the schedule.

Table 275: 1.3.6.1.4.1.45.5.43.0.xx series

OID	Notification type	Objects	Description
1.3.6.1.4.1.45.5.43.0.1	bsLstInterfaceStatusChanged	<ul style="list-style-type: none"> ifIndex bsLstInterfaceStatus bsLstGroupIndex 	A bsLstInterfaceStatusChanged trap signifies that a physical or logical interface changed status in a Link-state tracking (LST) tracking group.
1.3.6.1.4.1.45.5.43.0.2	bsLstInterfaceOperState Changed	<ul style="list-style-type: none"> ifIndex bsLstInterfaceStatus bsLstGroupIndex 	A bsLstInterfaceOperState Changed trap signifies that the operational status of an LST group changed due to an interface status change. For example, when the last interface in an LST group is down, the operational status of the LST group changes to down.

Table 276: 1.3.6.1.4.1.2272.1.4.10.1.1.xxx series

OID	Notification type	Objects	Description
1.3.6.1.4.1.2272.1.4.1.0.1.1.114	rcPortShutdownReason	<ul style="list-style-type: none"> rcPortVLacpTotalFlapCount rcPortVLacpFirstFlapTimeStamp rcPortVLacpLastFlapTimeStamp 	An rcPortShutdownReason trap signifies that the specific VLACP link port status is down as VLACP flaps are detected on that port.

Table 277: 1.3.6.1.4.1.2272.1.21.0.xx series

OID	Notification type	Objects	Description
1.3.6.1.4.1.2272.1.21.0.3	rcnErrorNotification	rcErrorLevel rcErrorCode rcErrorText	An rcnErrorNotification trap signifies that the SNMPv2 entity, acting in an agent role, has detected an error condition.
1.3.6.1.4.1.2272.1.21.0.4	rcnStpNewRoot	rcStgId	An rcnStpNewRoot trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the Spanning Tree Protocol declared the device to be the new root of the spanning tree.
1.3.6.1.4.1.2272.1.21.0.5	rcnStpTopologyChange	rcStgId rcPortIndex	An rcnStpTopologyChange trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the Spanning Tree Protocol has gone due to a topology change event.

Table 277: 1.3.6.1.4.1.2272.1.21.0.xx series (continued)

OID	Notification type	Objects	Description
1.3.6.1.4.1.2272.1.21.0.6	rcnChasPowerSupplyDown	<ul style="list-style-type: none"> rcChasPowerSupplyId rcChasPowerSupplyOperStatus 	An rcnChasPowerSupplyDown trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the rcChasPowerSupplyOperStatus object for one of its power supply units is about to transition into the down state.
1.3.6.1.4.1.2272.1.21.0.7	rcnChasFanDown	<ul style="list-style-type: none"> rcChasFanId rcChasFanOperStatus 	An rcnChasFanDown trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the rcChasFanOperStatus object for one of its power supply units is about to transition into the down state.
1.3.6.1.4.1.2272.1.21.0.8	rcnLinkOscillation	rcPortIndex	An rcnLinkOscillation trap signifies that the SNMPv2 entity, acting in an agent role, has detected an excessive number of link state transitions on the specified port.
1.3.6.1.4.1.2272.1.21.0.9	rcnMacViolation	<ul style="list-style-type: none"> rcErrorText rcPortIndex 	An rcnMacViolation trap signifies that the SNMPv2 entity, acting in an agent role, has received a PDU with an invalid source MAC address.
1.3.6.1.4.1.2272.1.21.0.13	rcn2kTemperature	rc2kChassisTemperature	An rcn2kTemperature trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the chassis is overheating.
1.3.6.1.4.1.2272.1.21.0.14	rcnChasPowerSupplyUp	<ul style="list-style-type: none"> rcChasPowerSupplyId rcChasPowerSupplyOperStatus 	An rcnChasPowerSupplyUp trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the rcChasPowerSupplyOperStatus object for one of its power supply units is about to transition into the up state.
1.3.6.1.4.1.2272.1.21.0.16	rcnStpTCN	<ul style="list-style-type: none"> rcStgId rcPortIndex rcStgBridgeAddresses 	An rcnStpTCN trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the Spanning Tree Protocol has gone due to a topology change event.
1.3.6.1.4.1.2272.1.21.0.17	rcnSmltLstLinkUp	—	An rcnSmltLstLinkUp trap signifies that the split MLT link is from down to up.
1.3.6.1.4.1.2272.1.21.0.18	rcnSmltLstLinkDown	rcnSmltLstLinkDown	An rcnSmltLstLinkDown trap signifies that the split MLT link is from up to down.
1.3.6.1.4.1.2272.1.21.0.19	rcnSmltLinkUp	rcMltSmltId	An rcnSmltLinkUp trap signifies that the split SMLT link is up.
1.3.6.1.4.1.2272.1.21.0.20	rcnSmltLinkDown	rcMltSmltId	An rcnSmltLinkDown trap signifies that the split SMLT link is down.

Table 277: 1.3.6.1.4.1.2272.1.21.0.xx series (continued)

OID	Notification type	Objects	Description
1.3.6.1.4.1.2272.1.21.0.21	rcnChasFanUp	<ul style="list-style-type: none"> rcChasFanId rcChasFanOperStatus 	An rcnChasFanUp trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the rcChasFanOperStatus object for one of its power supply units is about to transition into the up state.
1.3.6.1.4.1.2272.1.21.0.22	rcnPasswordChange	<ul style="list-style-type: none"> rcCliPasswordChange rcCliPassChangeResult 	An rcnPasswordChange trap signifies that the SNMPv2 entity, acting in an agent role, has detected that one of the CLI passwords is changed.
1.3.6.1.4.1.2272.1.21.0.23	rcnEmError	<ul style="list-style-type: none"> rc2kCardIndex rcChasEmModeError 	An rcnEmError trap signifies that the SNMPv2 entity, acting in an agent role, has detected an Em error.
1.3.6.1.4.1.2272.1.21.0.26	rcnSmartCpldTimerFired	rc2kCardIndex	An rcnSmartCpldTimerFired trap signifies that the CP ID timer fired.
1.3.6.1.4.1.2272.1.21.0.27	rcnCardCpldNotUpDate	rc2kCardIndex	An rcnCardCpldNotUpDate trap signifies that the CP ID is not up-to-date.
1.3.6.1.4.1.2272.1.21.0.28	rcnIgapLogFileFull	—	An rcnIgapLogFileFull trap signifies that the IGAP accounting time-out Log File has reached the maximum.
1.3.6.1.4.1.2272.1.21.0.30	rcnSshServerEnabled	rcSshGlobalPort	An rcnSshServerEnabled trap signifies that the SSH server is enabled.
1.3.6.1.4.1.2272.1.21.0.31	rcnSshServerDisabled	rcSshGlobalPort	An rcnSshServerDisabled trap signifies that the SSH server is disabled.
1.3.6.1.4.1.2272.1.21.0.37	rcnSaveConfigAction	rcSysActionL1	An rcnSaveConfigAction trap indicates that the switch run time or boot configuration is being saved.
1.3.6.1.4.1.2272.1.21.0.38	rcnLoopDetectOnPort	<ul style="list-style-type: none"> rcVlanId rcPortIndex 	An rcnLoopDetectOnPort trap indicates that a loop has been detected on a port. The VLAN on that port will be disabled.
	Note: This trap does not apply to all platforms.		
1.3.6.1.4.1.2272.1.21.0.41	rcnAggLinkUp	rcMlId	An rcnAggLinkUp trap is generated when the operational state of the aggregator changes from down to up.
1.3.6.1.4.1.2272.1.21.0.42	rcnAggLinkDown	rcMlId	An rcnAggLinkDown trap is generated when the operational state of the aggregator changes from up to down.
1.3.6.1.4.1.2272.1.21.0.59	rcnFdbProtectViolation	<ul style="list-style-type: none"> rcVlanId rcPortIndex 	The rcnFdbProtectViolation trap signifies that the port has violated the user-configured limit for total number of fdb-entries learned on that port.

Table 277: 1.3.6.1.4.1.2272.1.21.0.xx series (continued)

OID	Notification type	Objects	Description
1.3.6.1.4.1.2272.1.21.0.60	rcnLogMsgControl	<ul style="list-style-type: none"> rcSysMsgLogFrequency rcSysMsgLogText 	An rcnLogMsgControl trap signifies whether the number of times of repetition of the particular Log message has exceeded the particular frequency or count.
1.3.6.1.4.1.2272.1.21.0.61	rcnSaveConfigFile	<ul style="list-style-type: none"> rcSysActionL1 rcSysConfigFileName 	An rcnSaveConfig trap signifies that either the runtime config or the boot config has been saved on the switch.
1.3.6.1.4.1.2272.1.21.0.62	rcnDNSRequestResponse	<ul style="list-style-type: none"> rcSysDnsServerListIpAddr rcSysDnsRequestType 	An rcnDnsRequestResponse trap signifies that the switch sent a query to the DNS server or that it received a successful response from the DNS Server.
1.3.6.1.4.1.2272.1.21.0.63	rcnDuplicateIpAddress	<ul style="list-style-type: none"> ipNetToMediaNetAddress ipNetToMediaPhysAddress 	An rcnDuplicateIpAddress trap signifies that a duplicate IP address is detected on the subnet.
1.3.6.1.4.1.2272.1.21.0.64	rcnLoopDetectPortDown	<ul style="list-style-type: none"> rcPortIndex ifAdminStatus ifOperStatus 	An rcnLoopDetectPortDown trap signifies that a loop has been detected on a port and the port is going to shut down.
1.3.6.1.4.1.2272.1.21.0.67	rcnLoopDetectMacDiscard	<ul style="list-style-type: none"> rcPortIndex rcSysMacFlapLimitTime rcSysMacFlapLimitCount 	An rcnLoopDetectMacDiscard trap signifies that a loop has been detected on a port and the MAC address will be discarded on all ports in that VLAN.
1.3.6.1.4.1.2272.1.21.0.68	rcnAutoRecoverPort	rcPortIndex	An rcnAutoRecoverPort trap signifies that autorecovery has reenabled a port that was previously disabled by link flap.
1.3.6.1.4.1.2272.1.21.0.69	rcnAutoRecoverLoopDetectedPort	rcVlanNewLoopDetectedAction	An rcnAutoRecoverPort trap signifies that autorecovery has cleared the loop detect action that was taken on a port.
1.3.6.1.4.1.2272.1.21.0.74	rcnTacacsAuthFailure	rcTacacsGlobalLastUserName	An rcnTacacsAuthFailure trap signifies that TACACS+ authentication failed for a user.
1.3.6.1.4.1.2272.1.21.0.75	rcnTacacsNoServers	—	An rcnTacacsNoServers trap signifies that you are unable to use any TACACS+ servers for authentication.
1.3.6.1.4.1.2272.1.21.0.76	rcnTacacsRxUnsupportedFrame	<ul style="list-style-type: none"> rcTacacsGlobalLastAddressType rcTacacsGlobalLastAddress 	An rcnTacacsRxUnsupportedFrame trap signifies that an unsupported frame was received from the TACACS+ server.

Table 277: 1.3.6.1.4.1.2272.1.21.0.xx series (continued)

OID	Notification type	Objects	Description
1.3.6.1.4.1.2272.1.21.0.77	rcnTacacsExceededMaxLogins	—	An rcnTacacsExceededMaxLogins trap signifies that there was an attempt to exceed the maximum number of allowed TACACS+ logins.
1.3.6.1.4.1.2272.1.21.0.78	rcnTacacsClientFailure	—	An rcnTacacsClientFailure trap signifies that the TACACS+ Client application is down.
1.3.6.1.4.1.2272.1.21.0.80	rcnVlaccPortDown	rcPortIndex	An rcnVlaccPortDown trap signifies that VLACP is down on the port specified.
1.3.6.1.4.1.2272.1.21.0.81	rcnVlaccPortUp	rcPortIndex	An rcnVlaccPortUp trap signifies that VLACP is up on the port specified.
1.3.6.1.4.1.2272.1.21.0.83	rcnEapMacIntrusion	<ul style="list-style-type: none"> • rcSysIpAddr • rcRadiusPaePortNumber • rcRadiusEapLastAuthMac • rcRadiusEapLastRejMac 	An rcnEapMacIntrusion trap signifies that an EAP MAC intrusion has occurred on this port.
1.3.6.1.4.1.2272.1.21.0.110	rcnMaxRouteWarnClear	rcVrfName	An rcnMaxRouteWarnClear trap signifies that the number of routes in the routing table of the virtual router has dropped below the warning threshold.
1.3.6.1.4.1.2272.1.21.0.111	rcnMaxRouteWarnSet	rcVrfName	An rcnMaxRouteWarnSet trap signifies that the routing table for the virtual router is reaching its maximum size. Take action to prevent this.
1.3.6.1.4.1.2272.1.21.0.112	rcnMaxRouteDropClear	rcVrfName	An rcnMaxRouteDropClear trap signifies that the routing table for the virtual router is no longer dropping new routes as it is below the maximum size.
1.3.6.1.4.1.2272.1.21.0.113	rcnMaxRouteDropSet	rcVrfName	An rcnMaxRouteDropSet trap signifies that the routing table for the virtual router has reached the maximum size, and is now dropping all new nonstatic routes.
1.3.6.1.4.1.2272.1.21.0.117	rcnMstpNewCistRoot	rcStgBridgeAddress	An rcnMstpNewCistRoot trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the Multiple Spanning Tree Protocol has declared the device to be the new root of the common internal spanning tree.

Table 277: 1.3.6.1.4.1.2272.1.21.0.xx series (continued)

OID	Notification type	Objects	Description
1.3.6.1.4.1.2272.1.21.0.118	rcnMstpNewMstiRoot	<ul style="list-style-type: none"> rcStgBridgeAddresses rcStgld 	An rcnMstpNewMstiRoot trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the Multiple Spanning Tree Protocol has declared the device to be the new root of the spanning tree instance.
1.3.6.1.4.1.2272.1.21.0.119	rcnMstpNewCistRegionalRoot	rcStgBridgeAddress	An rcnMstpNewCistRegionalRoot trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the Multiple Spanning Tree Protocol has declared the device to be the new regional root of the common internal spanning tree.
1.3.6.1.4.1.2272.1.21.0.120	rcnRstpNewRoot	rcStgBridgeAddress	An rcnRstpNewRoot trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the Rapid Spanning Tree Protocol has declared the device to be the new root of the spanning tree.
1.3.6.1.4.1.2272.1.21.0.124	rcnRsmltEdgePeerModified	rcVlanId	An rcnRsmltEdgePeerModified trap signifies that the RSMLT peer address is different from that of the stored address. You must save the configuration if EdgeSupport has to use this information on the next restart.

Standard Traps

The following table describes standard traps that the switch can generate.

Table 279: Standard traps

OID	Notification type	Objects	Description
1.3.6.1.2.1.16.0.1	risingAlarm	alarmIndex alarmVariable alarmSampleType alarmValue alarmRisingThreshold	The SNMP trap that is generated after an alarm entry crosses the rising threshold and generates an event that is configured to send SNMP traps. TRAP TYPE ENTERPRISE rmon
1.3.6.1.2.1.16.0.2	fallingAlarm	alarmIndex alarmVariable alarmSampleType alarmValue alarmFallingThreshold	The SNMP trap that is generated after an alarm entry crosses the falling threshold and generates an event that is configured to send SNMP traps. TRAP TYPE ENTERPRISE rmon
1.3.6.1.2.1.46.1.3.0.3	vrrpTrapStateTransition	ifIndex vrrpTrapStateTransitionType vrrpTrapStateTransitionCause vrrpOperVrld vrrpOperIpAddr ipAdEntAddr	A vrrpTrapStateTransition trap signifies a state transition has occurred on a particular Virtual Router Redundancy Protocol (VRRP) interface. Implementation of this trap is optional. vrrpOperIpAddr contains the IP address of the VRRP interface while ipAdEntAddr contains the IP address assigned to the physical interface.
1.3.6.1.2.1.68.0.1	vrrpTrapNewMaster	vrrpOperMasterIpAddr	The newMaster trap indicates that the sending agent has transitioned to Master state.
1.3.6.1.2.1.68.0.2	vrrpTrapAuthFailure	vrrpTrapPacketSrc vrrpTrapAuthErrorType	A vrrpAuthFailure trap signifies that a packet has been received from a router whose authentication key or authentication type conflicts with the authentication key or authentication type of this router.
1.3.6.1.2.1.80.0.1	pingProbeFailed	pingCtlTargetAddressType pingCtlTargetAddress pingResultsOperStatus pingResultsIpTargetAddressType pingResultsIpTargetAddress pingResultsMinRtt pingResultsMaxRtt pingResultsAverageRtt pingResultsProbeResponse pingResultsSentProbes pingResultsRttSumOfSquares pingResultsLastGoodProbe	This trap is generated after a probe failure is detected when the corresponding pingCtlTrapGeneration object is configured to probeFailure(0) subject to the value of pingCtlTrapProbeFailureFilter. The object pingCtlTrapProbeFailureFilter can specify the number of successive probe failures required before this notification can be generated.

Table 279: Standard traps (continued)

OID	Notification type	Objects	Description
1.3.6.1.2.1.80.0.2	pingTestFailed	pingCtlTargetAddressType pingCtlTargetAddress pingResultsOperStatus pingResultsIpTargetAddressType pingResultsIpTargetAddress pingResultsMinRtt pingResultsMaxRtt pingResultsAverageRtt pingResultsProbeResponses pingResultsSentProbes pingResultsRttSumOfSquares pingResultsLastGoodProbe	This trap is generated after a ping test fails when the corresponding pingCtlTrapGeneration object is configured to testFailure(1). In this instance pingCtlTrapTestFailureFilter specifies the number of probes in a test required to fail to consider the test as failed.
1.3.6.1.2.1.80.0.3	pingTestCompleted	pingCtlTargetAddressType pingCtlTargetAddress pingResultsOperStatus pingResultsIpTargetAddressType pingResultsIpTargetAddress pingResultsMinRtt pingResultsMaxRtt pingResultsAverageRtt pingResultsProbeResponses pingResultsSentProbes pingResultsRttSumOfSquares pingResultsLastGoodProbe	This trap is generated at the completion of a ping test when the corresponding pingCtlTrapGeneration object is configured to testCompletion(4).
1.3.6.1.2.1.81.0.1	traceRoutePathChange	traceRouteCtlTargetAddressType traceRouteCtlTargetAddress traceRouteResultsIpTgtAddrType traceRouteResultsIpTgtAddr	This trap is generated after the path to a target changes.

Table 279: Standard traps (continued)

OID	Notification type	Objects	Description
1.3.6.1.2.1.81.0.2	traceRouteTestFailed	traceRouteCtlTargetAddressType traceRouteCtlTargetAddress traceRouteResultsIpTargetAddrType traceRouteResultsIpTargetAddr	This trap is generated is traceroute cannot determine the path to a target (traceRouteNotifications 2).
1.3.6.1.2.1.81.0.3	traceRouteTestCompleted	traceRouteCtlTargetAddressType traceRouteCtlTargetAddress traceRouteResultsIpTargetAddrType traceRouteResultsIpTargetAddr	This trap is generated after the path to a target is determined.
1.3.6.1.6.3.1.1.5.1	coldStart	—	A coldStart trap signifies that the SNMPv2 entity, acting in an agent role, is reinitializing and that its configuration may have been altered.
1.3.6.1.6.3.1.1.5.2	warmStart	—	A warmStart trap signifies that the SNMPv2 entity, acting in an agent role, is reinitializing such that its configuration is unaltered.
1.3.6.1.6.3.1.1.5.3	linkDown	—	A linkDown trap signifies that the sending protocol entity recognizes a failure in one of the communication links represented in the agent configuration. TRAP-TYPE ENTERPRISE snmp
1.3.6.1.6.3.1.1.5.4	linkUp	—	A linkUp trap signifies that the sending protocol entity recognizes that one of the communication links represented in the agent configuration has come up. TRAP-TYPE ENTERPRISE snmp
1.3.6.1.6.3.1.1.5.5	authenticationFailure	—	—

Virtual Link Aggregation Control Protocol

Use Virtual Link Aggregation Control Protocol (VLACP) as an extension to LACP for end-to-end failure detection. VLACP is not a link aggregation protocol, it is a mechanism to periodically check the end-to-end health of a point-to-point connection. VLACP uses the Hello mechanism of LACP to periodically send Hello packets to ensure end-to-end communication. After Hello packets are not received, VLACP transitions to a failure state, which indicates a service provider failure and that the port is disabled.

The VLACP only works for port-to-port communications where there is a guarantee for a logical port-to-port match through the service provider. VLACP does not work for port-to-multiport communications where there is no guarantee for a point-to-point match through the service provider. You can configure VLACP on a port.

You can also use VLACP with MLT to complement its capabilities and provide quick failure detection.

VLACP trap messages are sent to the management stations if the VLACP state changes. If the failure is local, the only traps that are generated are port linkdown or port linkup.

The Ethernet cannot detect end-to-end failures. Functions such as remote fault indication or far-end fault indication extend the Ethernet to detect remote link failures. A major limitation of these functions is that they terminate at the next Ethernet hop. They cannot determine failures on an end-to-end basis.

For example, in [Figure 260](#), after the Enterprise networks connect the aggregated Ethernet trunk groups through a service provider network connection (for example, through a VPN), far-end failures cannot be signaled with Ethernet-based functions that operate end-to-end through the service provider network. The multilink trunk (between Enterprise switches S1 and S2) extends through the Service Provider (SP) network.

The following illustration shows an MLT running with VLACP. VLACP can operate end-to-end, but you can also use it as a point-to-point link.

Figure 260: Problem description (1 of 2)

In the following illustration, if the Layer 2 link on S1 (S1/L2) fails, the link-down failure is not propagated over the SP network to S2 and S2 continues to send traffic over the failed S2/L2 link.

Figure 261: Problem description (2 of 2)

Use VLACP to detect far-end failures, which causes MLT to failover if end-to-end connectivity is not guaranteed for links in an aggregation group. VLACP prevents the failure scenario.

The switch software uses the following VLACP timers:

- fast periodic timer—100 to 20 000 ms; default 200 ms
- slow periodic timer—10 000 to 30 000 ms; default 30 000 ms

VLACP considerations

Use the information in this section to understand the considerations while configuring VLACP into your network.

- If a VLACP-enabled port does not receive a VLACP Data Unit (VLACPDU), it must enter the disabled state. There are occasions where a VLACP-enabled port does not receive a VLACPDU but remains in the forwarding state. To avoid this situation, ensure that the VLACP configuration at the port level is consistent. You must either enable or disable both sides of the point-to-point connection.
- If VLACP is enabled on a MACsec Key Agreement-enabled link, it takes approximately 30 seconds for the VLACP session to begin.

You can configure VLACP on each port. The port can be either an individual port or an MLT member. VLACPDUs can be sent periodically on each port where VLACP is enabled to exchange VLACPDUs from an end-to-end perspective. If VLACPDUs are not received on a particular link, that link is taken down after the expiry timeout occurs (timeout scale x periodic time).

VLACP Flap Detect and Damping

When there is instability or packet loss in a connection, the Virtual Link Aggregation Control Protocol (VLACP) state of the port flaps, causing services such as IP multicast to stop and start rapidly. This behavior causes system-wide instability, including high CPU utilization. In such cases, VLACP Flap Detect and Damping provides link flap detection capability, by configuring a specific time interval and frequency to count the number of VLACP flaps. After the system detects excessive VLACP flaps, it disables the specific VLACP port until the root cause is resolved.

For example, VLACP Flap Detect and Damping detects 3 VLACP flaps within 60 seconds, by default. After the system detects the first VLACP flap, the flap timer starts to count the number of VLACP flaps occurring within 60 seconds. If the flap count reaches 3 before the timer ends, the system disables the specific VLACP port, and generates a Simple Network Management Protocol (SNMP) trap. For more information about SNMP traps, see [Logs and Traps Fundamentals](#) on page 2261.

If you view the port state information, the port displays as operationally down and the reason provided is VLACP_FLAP. The following example shows a port that is disabled because of VLACP flapping; only the relevant sections of the show command output is included.

```
Switch:1#show interface gigabitethernet 1/1
=====
                        Port Interface
=====
```

PORT NUM	INDEX	DESCRIPTION	LINK TRAP	PORT LOCK	MTU	PHYSICAL ADDRESS	STATUS ADMIN	OPERATE
1/1	192	1000BaseTX	true	false	1950	e4:5d:52:3c:64:00	up	down

Port State				
PORT NUM	ADMINSTATUS	PORTSTATE	REASON	DATE
1/1	up	down	VLACP_FLAP	09/19/19 02:22:58

**Note**

VLACP Flap Detect and Damping does not support auto-recovery of VLACP ports; you must reenble the ports manually.

VLACP Flap Detect and Damping Considerations

Use the following information when configuring VLACP Flap Detect and Damping.

- Do not enable VLACP Flap Detect and Damping on Link Aggregation Control Protocol (LACP) enabled ports.

**Note**

Link flap detection takes priority if you enable both VLACP Flap Detect and Damping and link flap detection on the same port.

VLACP Configuration using CLI

Configure Virtual LACP (VLACP) to implement link status control protocol at the port level. VLACP detects end-to-end failures in the switch. Virtual LACP cannot interoperate with Link Aggregation Control Protocol (LACP).

Configure VLACP on a port

Configure VLACP on a port to ensure there is end-to-end reachability. VLACP uses the Hello mechanism of LACP to periodically send Hello packets to ensure there is an end-to-end approach. After Hello packets are not received, VLACP transitions to a failure state and disables the port.

**Important**

Changes made at the global level override and reset all port level settings.

About This Task

Use the following information to prevent flooding VLACP packets across a defaulted switch:

- Use the default MAC address, 01:80:c2:00:11:00, for end-to-end connections that traverse an intermediate network.
- Use the reserved multicast MAC address 01-80-c2-00-00-0f for directly-connected, peer-to-peer links.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure optional parameters for the port. If you do not configure these parameters, the system uses the default values.

- a. Configure the protocol identification for the port:

```
vlacp ethertype <1536-65535 | 0x600-0xffff> [funcmac-addr  
0x00:0x00:0x00:0x00:0x00:0x00]
```

- b. Configure the fast or slow periodic times:

```
vlacp fast-periodic-time <100-20000> | slow-periodic-time  
<10000-30000>
```

You can configure both parameters in the same command entry.

- c. Configure the timeout parameters:

```
vlacp timeout <long|short> timeout-scale <2-10>
```

You can configure both parameters in the same command entry.

3. Enable VLACP on a port:

```
vlacp enable
```

Example

Configure VLACP on port 1/1:

```
Switch:1# configure terminal
```

```
Switch:1# interface GigabitEthernet 1/2
```

```
Switch:1# vlacp fast-periodic-time 400 timeout short
```

```
Switch:1# vlacp enable
```

Variable Definitions

Use the data in the following table to help you use the **vlacp** command.

Variable	Value
<i>enable</i>	Enables VLACP for this port. The default is disabled.
<i>ethertype</i> <1536-65535 0x600-0xffff>	Configures the VLACP protocol identification for this port. Enter the type in decimal or hexadecimal format. The default is 0x8103.
<i>fast-periodic-time</i> <100-20000>	Configures the fast periodic time (in milliseconds) for this port. The default is 200.
<i>funcmac-addr</i> <0x00:0x00:0x00:0x00:0x00:0x00>	Configures the multicast MAC address used for the VLACPDU. Specify a MAC address in the format 0x00:0x00:0x00:0x00:0x00:0x00. The default is 01:80:c2:00:11:00.
<i>slow-periodic-time</i> <10000-30000>	Configures the slow periodic time (in milliseconds) for a specific port type. The default is 30,000.
<i>timeout</i> { <i>long</i> <i>short</i> }	Configures the port to use the long or short timeout: <ul style="list-style-type: none"> <i>long</i> sets the port to use the timeout-scale value multiplied by the slow periodic time. <i>short</i> sets the port to use the timeout-scale value multiplied by the fast periodic time. <p>For example, if you specify a short timeout, set the timeout-scale value to 3, and the fast periodic time to 400 ms, the timer expires within 1000 to 1200 ms. The default is long.</p>
<i>timeout-scale</i> <2-10>	Configures a timeout scale for this port used to calculate the timeout. The default value is 3.

View the VLACP Port Configuration

View the VLACP port configuration to show the port VLACP configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the VLACP port configuration for all interfaces:

```
show vlacp interface gigabitethernet [vid <1-4059>] [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```

Example

```
Switch:1>show vlacp interface gigabitethernet

```

Variable definitions

Use the data in the following table to use the **show vlacp interface gigabitethernet** command.

Variable	Value
<code>vid <1-4059></code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. The VLAN ID is in one of the following formats: A single VLAN ID (vlan-id), a range of VLAN IDs [(vlan-id)-(vlan-id)] or a series of VLAN IDs (vlan-id, vlan-id, vlan-id).
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies a port or list of ports to show only the VLACP information for those ports. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Displaying VLACP Statistics for Specific Ports

Display VLACP statistics for specific ports to manage network performance.

Note

Slot and port information can differ depending on hardware platform.

About This Task

You can enable sequence numbers for each VLACPDU to assist in monitoring performance. The switch counts mismatched PDU sequence numbers to determine packet loss information. By default, sequence numbers are enabled.

You can use the show commands from Privileged EXEC mode but must enter Global Configuration mode to enable or disable the sequence numbers.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Confirm sequence numbers are enabled:

```
show vlacp
```

3. (Optional) Enable sequence numbers for VLACPDUs:
`vlACP sequence-num`
4. View VLACP statistics:
`show interfaces gigabitEthernet statistics vlACP [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`
5. (Optional) View VLACP statistics history:
`show interfaces gigabitEthernet statistics vlACP history [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`
6. (Optional) Clear VLACP statistics:
`clear vlACP stats [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
7. (Optional) Disable sequence numbers for VLACPDUs:
`no vlACP sequence-num`

Example

Determine if sequence numbers are enabled, and then view port statistics. Port numbering may differ depending on your product and configuration.

```
Switch:1(config)#show vlACP
=====
                        VlACP Global Information
=====
                SystemId: 32:11:9f:20:00:00
                  VlACP: enable
          VlACP Sequence Number: enable

Switch:1(config)#show interfaces gigabitEthernet statistics vlACP
=====
                        Port Stats VlACP
=====
PORT      TX      RX      SEQNUM
NUM      VLACPDU  VLACPDU  MISMATCH
-----
8/1       106058   105554   0
12/11     15       12       0
12/23     0        0        0
```

Variable Definitions

Use the data in the following table to use the commands in this procedure.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Enabling or disabling VLACP globally

Use VLACP as an extension to LACP for end-to-end failure detection. Enable or disable VLACP globally to reset the port level configuration. The default is disabled.

About This Task

**Important**

Changes you make at the global level override and reset all port level settings.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable VLACP globally:

```
vlacp enable
```

3. Disable VLACP globally:

```
no vlacp enable
```

Example

Enable VLACP globally:

```
Switch:1(config)# vlacp enable
```

Configure VLACP Flap Detect and Damping on a Port

About This Task

Perform the following procedure to control link state changes on VLACP ports. By default, VLACP Flap Detect and Damping is disabled on all VLACP ports.

**Important**

Do not enable VLACP Flap Detect and Damping on Link Aggregation Control Protocol (LACP) enabled ports.

Before You Begin

- To configure VLACP Flap Detect and Damping on sub-ports, enable channelization. For more information about channelization, see [Channelization](#) on page 531.
- As a best practice, to modify an existing VLACP Flap Detect and Damping configuration, first disable VLACP on the interface.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable VLACP Flap Detect and Damping on the specified port:

```
vlACP flap-detect enable
```

3. Configure the time interval (in seconds) to record VLACP flaps:

```
vlACP flap-interval <10-600>
```

4. Configure the VLACP flap frequency:

```
vlACP flap-frequency <3-30>
```

5. View VLACP Flap Detect and Damping configuration on the specific port:

```
show vlACP interface gigabitEthernet {slot/port[/sub-port] [-slot/
port[/sub-port]][,...]}
```

Example

Configure VLACP Flap Detect and Damping on port 1/3:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/3
Switch:1(config-if)#vlACP flap-detect enable
Switch:1(config-if)#vlACP flap-interval 120
Switch:1(config-if)#vlACP flap-frequency 6
Switch:1(config-if)#show vlACP interface gigabitEthernet 1/3
```

```

=====
```

Variable Definitions

Use data in the following table to use the **vlacp** command.

Variable	Value
<i>flap-detect enable</i>	Enables VLACP Flap Detect and Damping on the specified port. By default, VLACP Flap Detect and Damping is disabled on all ports.
<i>flap-interval</i> <10-600>	Configures VLACP Flap Detect and Damping time interval in seconds. The default value is 60 seconds.
<i>flap-frequency</i> <3-30>	Configures the VLACP Flap count permitted during the configured time interval. The default value is 3.

Clear VLACP Flap Detect and Damping Statistics for a Port

Perform the following procedure to clear the VLACP Flap Detect and Damping statistics for a specific VLACP port or all VLACP ports on the switch.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Clear VLACP Flap Detect and Damping statistics:
clear vlacp flap-stats port [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]

Example

```
Switch:1>enable
Switch:1#clear vlacp flap-stats port 2/11
```

Variable Definitions

Use data in the following table to use the **clear vlacp flap-stats** command.

Variable	Value
<i>port</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

VLACP Configuration using EDM

Configure Virtual LACP (VLACP) to implement link status control protocol at the port level. VLACP cannot interoperate with Link Aggregation Control Protocol (LACP).

Enabling VLACP globally

Enable VLACP globally to detect for end-to-end failure. VLACP uses the Hello mechanism of LACP to periodically send Hello packets to ensure there is an end-to-end approach. After Hello packets are not received, the VLACP transitions to a failure state and the port is disabled.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **MLT/LACP**.
3. Click the **VLACP Global** tab.
4. Select the **VlACPEnable** check box.
5. Click **Apply**.

VLACP Global field descriptions

Use the data in the following table to use the **VLACP Global** tab.

Name	Description
VlACPEnable	Enables VLACP globally. The default is disabled.

Configure VLACP on a Port

Perform the following procedure to enable VLACP on a port. VLACP periodically checks the end-to-end condition of a point-to-point connection. You can also configure VLACP Flap Detect and Damping to control link state changes on VLACP ports. By default, VLACP Flap Detect and Damping is disabled on all VLACP ports.

**Important**

Changes made at the global level override and reset all port level settings.

Before You Begin

- To configure VLACP Flap Detect and Damping on sub-ports, enable channelization.
- As a best practice, to modify an existing VLACP or VLACP Flap Detect and Damping configuration, first disable VLACP on the interface.

About This Task

Use the following information to prevent flooding VLACP packets across a defaulted switch:

- Use the default MAC address, 01:80:c2:00:11:00, for end-to-end connections that traverse an intermediate network.
- Use the reserved multicast MAC address 01-80-c2-00-00-0f for directly-connected, peer-to-peer links.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **VLACP** tab.
5. Configure the parameters, as required.
6. Select **Apply**.

VLACP Field Descriptions

Use data in the following table to use the **VLACP** tab.

Name	Description
AdminEnable	Enables VLACP for the port. The default is disabled.
OperEnable	Specifies the VLACP operational status for the port. The default is false.
FastPeriodicTimer	Specifies the number of milliseconds between periodic transmissions using short timeouts. Use the same value for all LACP-enabled ports. The default value is 200.
SlowPeriodicTimer	Specifies the number of milliseconds between periodic transmissions using long timeouts. Use the same value for all LACP-enabled ports. The default value is 30000.
Timeout	Specifies the timeout control value. Specify long or short timeout. The default value is long.
TimeoutScale	Assigns the value used to calculate timeout from the periodic time for all VLACP-enabled ports. $\text{Timeout} = \text{PeriodicTime} \times \text{TimeoutScale}$. The default value is 3.
EtherType	Specifies the VLACP identification. The ID is in hexadecimal format. The default value is 0x8103.
EtherMacAddress	Specifies the multicast MAC address exclusively used for VLACPDUs. The default is 01:80:c2:00:11:00.
PortState	Specifies the VLACP port state.
FlapDetectEnable	Enables VLACP Flap Detect and Damping on the port. By default, VLACP Flap Detect and Damping is disabled on all ports.
FlapFrequency	Specifies the number of VLACP flaps detected on the port. The port is shut down if the recorded flaps are within the configured time interval. The default value is 3.
FlapInterval	Specifies the time interval (in seconds) during which the VLACP flaps on the port are monitored. The default value is 60 seconds.
TotalFlapCount	Shows the total number of VLACP flaps detected on the port since you enabled VLACP Flap Detect and Damping or cleared the counters and timers.
FirstFlapTimeStamp	Shows the timestamp of the first VLACP flap detected on the port since you enabled VLACP Flap Detect and Damping or cleared the counters and timers.

Name	Description
LastFlapTimeStamp	Shows the timestamp of the latest VLACP flap detected on the port since you enabled VLACP Flap Detect and Damping or cleared the counters and timers.
FlapClearStats	Clears all VLACP Flap Detect and Damping counters and timers.

Configuring VLACP on an Extreme Integrated Application Hosting Port

Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series.

About This Task

Perform this procedure to enable Virtual Link Aggregation Control Protocol (VLACP) on an Extreme Integrated Application Hosting (IAH) port. VLACP periodically checks the end-to-end health of a point-to-point connection.

Procedure

1. In the navigation tree, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **VLACP** tab.
4. Select **AdminEnable**.
5. Configure the other parameters as required.
6. Select **Apply**.

VLACP Field Descriptions

Use data in the following table to configure the **VLACP** tab.

Name	Description
AdminEnable	Enables VLACP on the Extreme Integrated Application Hosting (IAH) port. The default is disabled.
OperEnable	Specifies the VLACP operational status for the IAH port. The default is false.
FastPeriodicTimer	Specifies the number of milliseconds between periodic transmissions using short timeouts. Set the same value for all LACP enabled IAH ports. The default value is 200.
SlowPeriodicTimer	Specifies the number of milliseconds between periodic transmissions using long timeouts. Set the same value for all LACP enabled IAH ports. The default value is 30000.
Timeout	Specifies the timeout control value. The default value is long.

Name	Description
TimeoutScale	Specifies the value used to calculate timeout duration from the periodic time for all VLACP enabled IAHP ports. Timeout = PeriodicTime x TimeoutScale. The default value is 3.
EtherType	Specifies the VLACP protocol identification. The ID is in hexadecimal format. The default value is 0x8103.
EtherMacAddress	Specifies the multicast MAC address exclusively used for VLACPDUs.
PortState	Specifies the VLACP port state.

VLAN Configuration

[VLAN Fundamentals](#) on page 3749

[VLAN Configuration Using CLI](#) on page 3770

[VLAN Configuration using EDM](#) on page 3802

A VLAN is a switched network that is logically segmented by functions, project teams, or applications without regard to the physical location of users. By using a VLAN, you can divide the Local Area Network into smaller groups without interfering with the physical network.

The following topics provide necessary concepts and procedures to configure VLANs.

VLAN Fundamentals

The practical applications of a VLAN include the following:

- You can create VLANs, or workgroups, for common interest groups.
- You can create VLANs, or workgroups, for specific types of network traffic.
- You can add, move, or delete members from these workgroups without making physical changes to the network.

By dividing the network into separate VLANs, you can create separate broadcast domains. This arrangement conserves bandwidth, especially in networks supporting broadcast and multicast applications that flood the network with traffic. A VLAN workgroup can include members from a number of dispersed physical segments on the network, improving traffic flow between them.

The switch performs the Layer 2 switching functions necessary to transmit information within VLANs, as well as the Layer 3 routing functions necessary for VLANs to communicate with one another. You can define a VLAN for a single switch or spanning multiple switches. A port can be a member of multiple VLANs. A VLAN is associated with a spanning tree group.

A VLAN packet is classified before it is forwarded. If the packet matches a classification rule, the port membership is checked. If the port is not an allowed member (potential, static, or active), the system drops the packet.

Port-based VLANs

A port-based VLAN is a VLAN in which you explicitly configure the ports to be in the VLAN. When you create a port-based VLAN on a device, you assign a VLAN identification number (VLAN ID) and specify the ports that belong to the VLAN. These port members are always active port members. The VLAN ID is used to coordinate VLANs across multiple switches. Any type of frame can be classified to a port-based VLAN.

The example in the following figure shows two port-based VLANs: one for the marketing department, and one for the sales department. Ports are assigned to each port-based VLAN. A change in the sales area can move the sales representative at port 1/1 to the marketing department without moving cables. With a port-based VLAN, you only need to indicate in the Command Line Interface (CLI) that port 1/1 in the sales VLAN now is a member of the marketing VLAN.

Figure 262: Port-based VLAN

Private VLANs

Table 281: E-Tree and Private VLANs product support

Feature	Product	Release introduced
E-Tree and private VLANs	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 4.1
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

Table 281: E-Tree and Private VLANs product support (continued)

Feature	Product	Release introduced
Routing on Private VLANs	VSP 4450 Series	Not Supported
	VSP 4900 Series	VOSS 8.5
	VSP 7200 Series	VOSS 8.5
	VSP 7400 Series	VOSS 8.5
	VSP 8200 Series	VOSS 8.5
	VSP 8400 Series	VOSS 8.5
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

Private VLANs provide isolation between ports within a Layer-2 service.

The primary and secondary VLAN make the private VLAN. Standard VLAN configuration takes place on the primary VLAN. The secondary VLAN is used to label traffic ingressing isolated ports.

Ports in the private VLAN are configured as isolated, promiscuous, or trunk. The default value is None.

Port Types

Note

Layer 2 and Layer 3 services based on port types also apply in any routing scenario between two private VLANs or E-trees.

Table 282: Layer 2 services based on port types

Port type	Description
Promiscuous (tagged or untagged ports)	Promiscuous ports communicate with all other ports within the private VLAN. Uses the primary VLAN.
Isolated (tagged or untagged ports)	Isolated ports communicate with the promiscuous ports, but not with any other isolated port. Uses the secondary VLAN.
Trunk (tagged ports)	Trunk ports carry traffic between other port members within the private VLANs. Accepts either primary or secondary VLAN.

Table 283: Layer 3 services based on port types

Port type	Description
Promiscuous (tagged or untagged ports)	Promiscuous ports communicate with all other ports of any Layer 3 VLAN.
Isolated (tagged or untagged ports)	Isolated ports communicate with any promiscuous or regular VLAN ports but not with other isolated ports.
Trunk (tagged ports)	Trunk ports carry traffic between other port members within the private VLANs.

Trunk ports must have VLAN encapsulation enabled. A port can be a single port or can belong to an MLT.

The following figure shows a basic private VLAN topology with private VLAN configured on five switches. All ports connecting to other switches are trunk type ports and all other ports are either promiscuous or isolated ports. On the secondary VLAN, spokes can communicate with hubs, and hubs can communicate with all spokes in the same private VLAN using the primary VLAN, however, spokes cannot communicate with other spokes.

Figure 263: Private VLAN Topology

E-Tree

The E-Tree allows private VLANs to traverse the Shortest Path Bridging MAC (SPBM) network.

For more information about E-Tree and SPBM configuration, see [E-Tree and Private VLAN topology](#) on page 921.

Routing on Private VLANs

You can route traffic out of a private VLAN (PVLAN) by applying an IP address to a PVLAN. IP routing is supported on private VLANs for edge switches. With PVLAN packet routing, two hosts located in different private VLANs can communicate over the network.

Packets can be routed over the network between the following:

- regular VLAN and a private VLAN
- different private VLANs
- different I-SIDs (E-tree)

The number of private VLANs that you configure with an IP address influences the IPv4 Egress ACE count. For information about scaling information, see [VOSS Release Notes](#). Limits are not enforced; either number of private VLANs or number of private VLAN trunk ports can go beyond the recommended values. As a best practice, use the **show io resources filter** command to monitor allocated resources.

Note

You cannot enable IP Multicast on a private VLAN interface. **ip spb-multicast enable** and **ip pim enable** commands are not available on a private VLAN.

Private VLAN Configuration Rules

The following are private VLAN rules for the switch:

- Use private VLANs for Layer 2 and Layer 3 services.
- You cannot configure IP Source Guard (IPSG) on ports that are members of private VLANs.
- Do not use the *untag-port default vlan* parameter on private VLAN interfaces that are operating as trunk ports, because it impacts the private VLAN functionality.

Policy-based VLANs

Received frames are classified into a policy-based VLAN based on certain fields of the frame that matches the associated VLAN policy.

Port membership types

In a policy-based VLAN, a port can be designated as a potential member, a static member, or one not allowed to be a member of the VLAN.

If a port is designated as a potential member of the VLAN, and the incoming traffic matches the policy, the system dynamically adds the port to the active port list of the VLAN, making the port an active member of the VLAN. After the system adds a port to the active list, it can remove the port from the active list due to time-out. Potential member ports that join the VLAN are removed (timed out) from the active port list of the VLAN after the timeout (aging time) period expires.

All members of the Spanning Tree Group associated with a protocol-based VLAN are automatically considered potential members of the VLAN. In addition, all tagged ports (trunk ports) become static ports. If you do not want all the tagged ports to be static members of a protocol-based VLAN, put the port in the disallowed list.

Static port members are always members of the VLAN. Static port members are not aged out due to inactivity and they are not removed from the active list. If a server or router connects to a port, designate that port as a static member of a VLAN. If a server connects to a port that is only a potential member and the server sends very little traffic, a client fails to reach the server if the server port is timed out of the VLAN. As a best practice, make these ports static members of the VLAN.

A disallowed port can never become a member of the VLAN until you add it as a port-member. After you remove a port from the VLAN, the system adds the port to the disallowed list.

On any single spanning-tree instance, an access (untagged) port can belong to one port-based VLAN and many policy-based VLANs. A trunk (tagged) port can belong to many port-based and policy-based VLANs.

The following table describes port membership types for policy-based VLANs.

Table 284: Port membership types for policy-based VLANs

Membership type	Description
Potential	Potential members of a VLAN become active members upon receiving data matching the policy defined for the VLAN (a packet tagged with that VLAN, or an untagged packet matching the policy).
Static (always a member)	Static members are always active members of the VLAN after you configure them as belonging to that VLAN.
Not allowed to join (never a member)	Ports of this type cannot join the VLAN.

The following table lists supported policy-based VLANs.

Table 285: Supported policy-based VLAN types

VLAN type	Support
Protocol-based	supported

Protocol-based VLANs

Protocol-based VLANs are an effective way to segment your network into broadcast domains according to the network protocols in use.

A port member of a port-based VLAN can belong to multiple protocol-based VLANs. Port tagging is not required for a port to be a member of multiple protocol-based VLANs.

The switch supports IPv6 protocol-based VLAN only.

SPBM B-VLAN

Each SPBM network instance is associated with at least one backbone VLAN (B-VLAN) in the core SPBM network.

This VLAN is used for both control plane traffic and dataplane traffic.

Note

Always configure two B-VLANs in the core to allow load distribution over both B-VLANs.

SPBM alters the behavior of the VLAN. When a B-VLAN is associated with an SPBM network the following VLAN attributes and behaviors are modified for the B-VLAN:

- Flooding is disabled
- Broadcasting is disabled
- Source MAC address learning is disabled
- Unknown MAC discard is enabled

Ports cannot be added to a B-VLAN manually, IS-IS takes care of adding ports to the B-VLAN.

Essentially the B-MAC addresses are programmed into the B-VLAN Forwarding Information Bases (FIBs) by IS-IS instead of the traditional VLANs flooding and learning approach.

Modification of the VLAN behavior is necessary to ensure proper control over the SPBM traffic.

VLAN tagging and port types

The switch supports the IEEE 802.1Q specification for tagging frames and coordinating VLANs across multiple switches.

Figure 264 shows how an additional four octet (tag) header is inserted in a frame after the source address and before the frame type. The tag contains the VLAN ID associated with the frame.

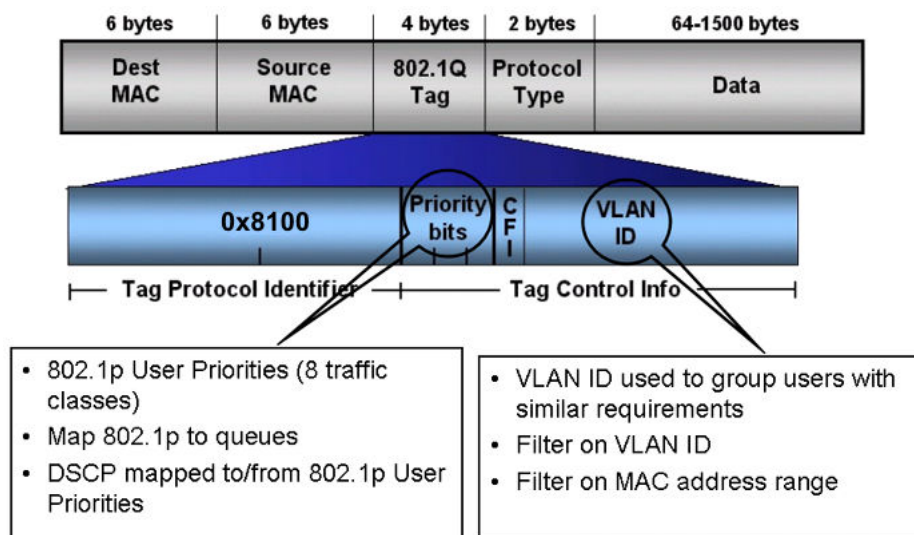

Figure 264: VLAN tag insertion

802.1Q tagged ports

Tagging a frame adds four octets to a frame, possibly making it bigger than the traditional maximum frame size. If a device does not support IEEE 802.1Q tagging, it can have problems interpreting tagged frames that it receives.

Whether tagged frames are sent depends on what you configure at the port level. Tagging is configured as true or false for the port, and is applied to all VLANs on that port.

A port with tagging enabled applies the VLAN ID tag to all packets sent on the port. Tagged ports are typically used to multiplex traffic belonging to multiple VLANs to other IEEE 802.1Q-compliant devices.

If you disable tagging on a port, it does not send tagged frames. A nontagged port connects a switch to devices that do not support IEEE 802.1Q tagging. If a tagged frame is forwarded to a port with tagging configured to false, the switch removes the tag from the frame before sending it to the port.

Treatment of tagged and untagged frames

The switch associates a frame with a VLAN based on the data content of the frame and the configuration of the receiving port. The treatment of the frame depends on whether the frame is tagged or untagged.

If a tagged frame is received on a port, if the port is a static or potential member of the VLAN ID specified in the tag, the switch directs it to that VLAN. If the port is not a member of the VLAN that is identified by the tag in the packet, the switch discards the packet. If a port is untagged, you can configure it to discard tagged frames received on the port. In this case the tagged frame is discarded.

For untagged frames, VLAN membership is implied from the content of the frame itself. You can configure a tagged port to accept or discard untagged frames received on the port.

The default VLAN of a port is the VLAN to which untagged frames are classified if they do not match the criteria of any policy-based VLAN of which the port is a member. The default VLAN of the port can be any port-based VLAN a port belongs to, or the unassigned VLAN (1). Frames classified to the unassigned VLAN are discarded.

The frame is forwarded based on the VLAN on which the frame is received, and on the forwarding options available for that VLAN. The switch tries to associate untagged frames with a VLAN in the following order:

- Does the frame belong to a protocol-based VLAN?
- What is the default VLAN for the receiving port?
- Is the default VLAN for the port not the unassigned VLAN?

If the frame meets none of these criteria, it is discarded.

Untagging default VLAN on a tagged port feature

This feature provides the ability to connect two devices such as an IP phone and a PC to a single port of the switch. Most IP phones ship with an embedded three port switch, and traffic coming from the phone is generally tagged (VLAN ID configured statically or remotely). However, the traffic originating from a PC is usually untagged traffic and must be separated from the IP phone traffic. This separation ensures that broadcast traffic from the PC does not impact voice quality.

After an IP phone is attached to an untagged port, it can fail to register with a remote Internet Telephony Gateway (or equivalent device) dependent on the netmask of the destination IP address (Call Server subnet).

For more information about the Network with IP phone and PC, see the following figure.

Figure 265: Network with IP phone and PC

IP phones and PCs coexist on the same port due to the use of an embedded IP Phone Layer 2 switch. In this scenario if you configure the port as untagged, the egress traffic on this port is untagged and no separation exists between the traffic to the IP phone and the PC. To avoid this condition, the port that connects to the IP phone must be tagged. If the port is tagged, the traffic for the PC is tagged with the default VLAN ID for the port. This configuration creates a problem because the PC does not expect tagged packets. Untag the default VLAN on a tagged port (in this example, port 1/1 that connects to the IP phone) to ensure that the traffic to the PC is sent untagged.

VLAN router interfaces

When you configure routing on a VLAN, you assign an IP address to the VLAN, which acts as a virtual router interface address for the VLAN. This IP address is not associated with a physical port. You can reach the VLAN IP address through any of the VLAN port members. Frames are routed to another VLAN IP address within the device. A port can belong to multiple VLANs; some, all, or none can perform routing.

IP routing and VLANs

The switch supports IP routing on the following types of VLANs:

- Port-based VLANs
- IP protocol-based VLANs

VLAN implementation

This section describes how to implement VLANs and describes default VLANs, the unassigned (NULL) VLAN, and brouter ports. This section also summarizes the defaults and rules regarding VLAN creation on the switch.

- [Default VLAN](#) on page 3758
- [NULL VLAN](#) on page 3758
- [Brouter ports](#) on page 3758

Default VLAN

Devices are factory-configured so that all ports are in a port-based VLAN called the default VLAN. Because all ports are in the default VLAN, the device behaves like a Layer 2 device. The VLAN ID of this default VLAN is always 1, and it is always a port-based VLAN. You cannot delete the default VLAN.

NULL VLAN

Internally, the switch creates a special port-based VLAN called NULL VLAN or unassigned VLAN. This is a place holder VLAN for ports that are not members of any port-based VLAN. When a port is removed from all port-based VLANs, it is added to the NULL VLAN as a port member. Ports can belong to policy-based VLANs as well as to the NULL VLAN. If a frame does not meet the policy criteria and no underlying port-based VLAN exists, the port belongs to the NULL VLAN and the frame is dropped.

Because it is an internal construct, the NULL VLAN cannot be deleted.

Brouter ports

A brouter port is actually a one-port VLAN with an IP interface. The difference between a brouter port and a standard IP protocol-based VLAN configured to perform routing is that the routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic and still route IP traffic. Because a brouter port is a single-port VLAN, it uses one VLAN ID. Each brouter port decreases the number of available VLANs by one.

VLAN configuration rules

The following are VLAN rules for the switch:

- The switch supports configurable VLANs in the range of 1 to 4059. VLAN 0 is invalid. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs on the switch range from 2 to 4094 but, by default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
- A tagged port can belong to multiple VLANs in multiple Spanning Tree Groups.
- Under the default configuration, the default Spanning Tree Group is number 1 if the chassis configuration permits multiple STGs.
- An untagged port can belong to only one port-based VLAN.
- You can configure only one protocol-based VLAN for a given protocol.
- The VLAN membership of a frame is determined by the following order of precedence, if applicable:
 1. IEEE 802.1Q tagged VLAN ID
 2. protocol-based VLAN

3. port-based VLAN default VLAN of the receiving port
- You cannot configure a VLAN name that uses all numbers, for example, 222.

VLAN Feature Support

The following table summarizes supported features.

For the latest scalability information, see [VOSS Release Notes](#).

Table 286: VLAN support

Feature	Description
Number of VLANs	4059
Port-based VLANs	Supported
Policy-based VLANs <ul style="list-style-type: none"> • Protocol-based • SPBM-based 	Supported
IEEE 802.1Q tagging	Supported
IP routing and VLANs	Supported
Special VLANs <ul style="list-style-type: none"> • Default VLAN • Null VLAN • Brouter ports • Private VLAN 	Supported

Network Load Balancing

	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	Not Supported

Microsoft Network Load Balancing (NLB) is a clustering technology available with the Microsoft Windows 2000, Microsoft Windows 2003, Microsoft Windows 2008, and Microsoft Windows 2012 Server family of operating systems. You can use NLB to share the workload among multiple clustering servers. NLB uses a distributed algorithm to load balance TCP/IP network traffic across a number of hosts, enhancing the scalability and availability of the following mission critical, IP-based services:

- web
- VPN
- Streaming media
- Firewalls

NLB also provides high availability by detecting host failures and automatically redistributing traffic to remaining operational hosts.

NLB Considerations and Restrictions

Although the switch interoperates with NLB clusters that operate in Unicast mode and Multicast mode, the following restrictions apply:

- True egress mirroring is not supported on all VOSS hardware platforms. Because packets are mirrored prior to the completion of packet processing, egress mirrored packets can differ from the packets egressing the port. Therefore, NLB Unicast traffic and NLB Multicast traffic destined to the NLB Virtual Mac Address are not mirrored correctly.

Note

To mirror the egress traffic of VOSS hardware platforms, you can use the NEXT-hop device ingress mirroring to capture the egress packets of the switch.

Of the VOSS hardware platforms, only VSP 4450 Series supports true egress mirroring.

- Inter-VRF routing is not supported between an NLB client and an NLB cluster VLAN in Unicast mode or Multicast mode.
- You must configure NLB to use the same mode as the NLB Server.
- Static ARP entries are not supported for NLB Unicast or NLB Multicast.

- For interoperability with NLB, the switch provides configuration options at the VLAN level.
- ARP entries for NLB server IP addresses do not age out when there is still client traffic coming to the NLB servers, even after the NLB servers are no longer reachable.

NLB Clustering in Unicast Mode

When the cluster is running in NLB unicast mode, all servers in the cluster share a common virtual MAC address, which is 02-bf-x-x-x-x (where x-x-x-x is the cluster IP address in hexadecimal form). All traffic destined to this MAC address is sent to all the servers in the cluster. The virtual MAC address is specified in the Sender MAC Address field of the Address Resolution Protocol (ARP) reply from the cluster to the switch. ARP responses from the switch are sent to the virtual MAC address (rather than to the hardware MAC address).

You can configure the switch for NLB unicast mode support. After you enable the NLB unicast option, the switch floods traffic destined to the cluster IP address to all ports on the VLAN. Unicast mode supports connectivity to a secondary virtual IP address. For information about software scaling capabilities in unicast mode, see [VOSS Release Notes](#).

NLB Clustering in Multicast Mode

When the cluster is running in NLB multicast mode, a multicast virtual MAC address with the format 03-bf-x-x-x-x (where x-x-x-x is the cluster IP address in hexadecimal form) is bound to all cluster hosts but the real MAC address of the network adapter is retained. The multicast MAC address is used for client-to-cluster traffic, and the real MAC address of the adapter is used for network traffic specific to the host server.

You can configure the switch for NLB multicast mode support. When you enable NLB multicast mode on a VLAN, the routed traffic destined to the NLB cluster is flooded by default on all ports of the VLAN. All VLANs support multiple cluster IPs by default. You can connect up to 200 NLB clusters to a single VLAN. For information about software scaling capabilities, see [VOSS Release Notes](#).

Note

Shortest Path Bridging MAC (SPBM) supports NLB Unicast and Multicast modes. For more information on SPBM, see [Fabric Basics and Layer 2 Services](#) on page 914.

Supported NLB Topologies

The switch supports Network Load Balancing (NLB) in the following topologies.

Supported NLB topology-example 1

The switch supports NLB when the NLB Cluster connections use a different physical port on the switch than the NLB clients.

The following figure illustrates this configuration where the NLB Server and the NLB Client workstations connect to different aggregation switches, which connect to the switch using different VLANs and different ports.

Figure 266: Supported NLB topology-example 1

Supported NLB topology-example 2

The switch also supports the following topology where the NLB Server and the NLB Client workstations connect to the same aggregation switch and then connect to the switch using the same port.

Note

The switch supports Layer 3 routing between an NLB-enabled VLAN and another VLAN on the same port.

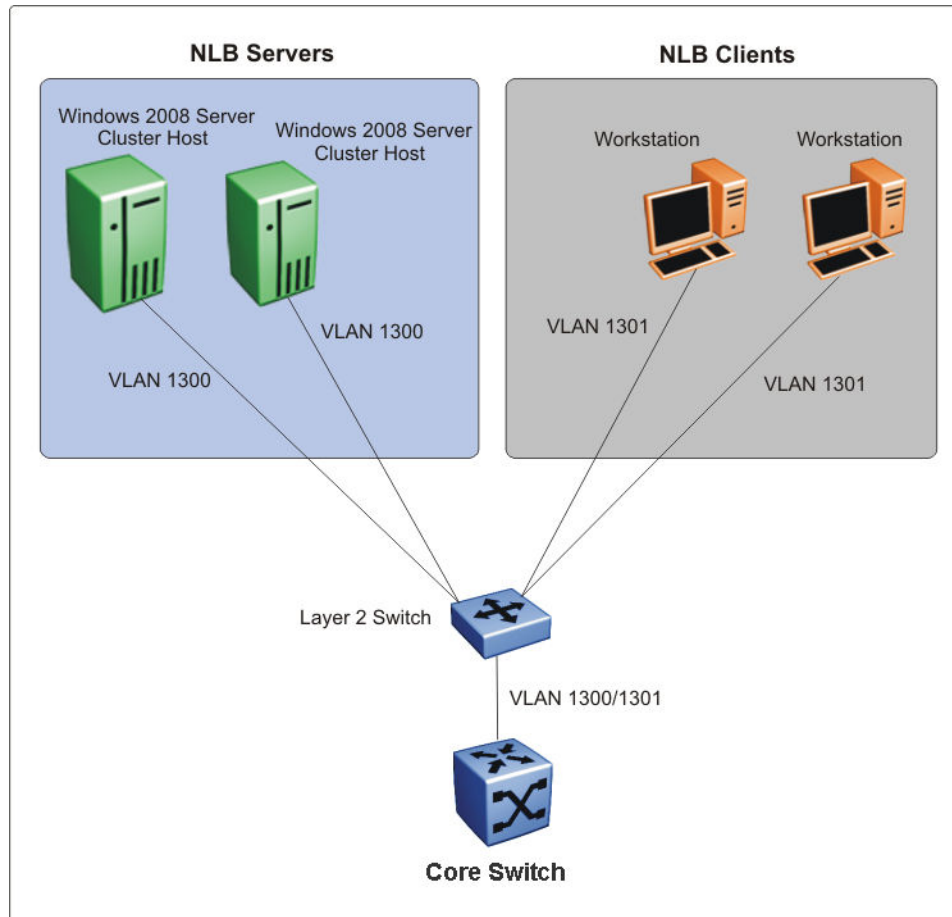

Figure 267: Supported NLB topology—example 2

Other supported NLB topologies

The switch supports NLB in the following other topologies:

- NLB cluster hosts and clients are connected to Layer 2 Ethernet switches that are SMLT connected to the SMLT cluster.
- NLB cluster hosts are directly connected and distributed between the switches and the clients are connected to Layer 2 Ethernet switch that is SMLT connected to the SMLT cluster.
- NLB cluster hosts and clients are directly connected and distributed between the switches in the SMLT cluster.
- NLB cluster hosts and clients are connected to Layer 2 Ethernet switches that are SMLT connected to the SMLT cluster core.

Note

For more information on the above topologies, see *Technical Configuration Guide for Microsoft Network Load Balancing*.

NLB and Directed Broadcast Resource Limits

NLB and Directed Broadcast consume resources from the same pool of 200 resources. When you configure either NLB or Directed Broadcast, the switch uses one resource. If you configure both NLB and Directed Broadcast, the switch uses two resources.

To avoid a situation where there is a lack of resources, adhere to the following limits:

- The number of NLB cluster IP interfaces multiplied by the number of configured clusters must be equal to, or less than, 200. The number of NLB cluster IP interfaces is the key, not the number of VLANs. You can configure 1 VLAN with up to 200 NLB cluster IP interfaces or configure up to 200 VLANs with 1 NLB cluster IP interface per VLAN.

For example: 1 NLB cluster IP interface x 200 clusters = 200 or 2 NLB cluster IP interfaces x 100 clusters = 200

- If you configure VLANs with Directed Broadcast only, you can scale up to 200 VLANs.
- If you configure VLANs with both **NLB** and **Directed Broadcast**, you can only scale up to 100 VLANs assuming there is only 1 NLB cluster IP interface per VLAN.

For information on Directed Broadcast, see [Denial-of-Service Attack Prevention](#) on page 2996.

VLAN MAC-layer Filtering Database and MAC Security

Table 288: FDB Protected by Port product support

Feature	Product	Release introduced
FDB protected by port (MAC security limit-learning)	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.3
	VSP 7200 Series	Not Supported
	VSP 7400 Series	Not Supported
	VSP 8200 Series	Not Supported
	VSP 8400 Series	Not Supported
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

To perform MAC-layer bridging, the device must know the destination MAC-layer address of each device on each attached network to forward packets to the appropriate destination. The system stores MAC-layer addresses in the bridge forwarding database (FDB) table, and can forward packet traffic based on the destination MAC-layer address information.

MAC security

Use MAC security to control traffic from specific number of MAC addresses. You can also limit the number of allowed MAC addresses. You can enable this feature at the port level.

Port-level security applies to traffic for all VLANs received on that port.

Port-level MAC security provides limit-learning option:

- **limit-learning:** This option protects the FDB from traffic from too many MAC addresses, which fill the FDB table.

This option limits the number of MAC addresses a port learns. You can specify a maximum number of addresses. After the number of addresses reaches the maximum, learning stops. The port disables packet forwarding and drops packets from new source MAC address. MAC address learning resumes after enough existing addresses age out and there is room to learn new MAC addresses.

Note

If you configure a limit on a port that has already learned more than the new limit, packet forwarding for those additional MAC addresses continues to work until the port flaps, you flush the MAC address, or the MAC address disappears.

Restrictions

The following list identifies restrictions to MAC security limit-learning:

- This feature is not supported on:
 - MLT ports members
 - NNI ports
 - Transparent Port UNI or Switched UNI
- The switch supports MAC learning only in the VLAN domain; it is not supported in the I-SID domain.
- The port MAC limit does not count static MAC addresses.
- The switch supports the maximum number of MAC addresses a port can learn for non-SPBM configurations.

Prevention of IP Spoofing within a VLAN

VLAN IP as the default gateway

You can prevent VLAN logical IP spoofing by blocking the external use of the device IP address. A configurable option is provided, for each port, which detects a duplicate IP address (that is, an address that is the same as the device VLAN IP address) and blocks all packets with a source or destination address equal to that address.

If an ARP packet is received that has the same source IP address as the logical VLAN IP address of the receiving port, all traffic coming to that port (with this MAC address as source/destination address) is discarded by the hardware. After detecting a duplicate IP address, the device sends a gratuitous ARP packet to inform devices on the VLAN about the correct MAC address for that IP address. You can specify a time on a configurable global timer after which the MAC discard record is deleted, and the device resumes accepting packets from that MAC address.

VRRP IP as the default gateway

Similarly, you can prevent VRRP IP spoofing by blocking the external use of the virtual IP address. A configurable option is provided, for each port, which detects a duplicate IP address (that is, an address that is the same as the device virtual IP address) and blocks all packets with a source or destination address equal to that address.

If an ARP packet is received that has the same source IP address as the virtual IP address of the receiving port, all traffic coming to that port (with this MAC address as source/destination address) is discarded by the hardware. After detecting a duplicate IP address, the device sends a gratuitous ARP packet to inform devices on the VRRP subnet about the correct virtual router MAC address for that IP address. You can specify a time on a configurable global timer after which the MAC discard record is deleted, and the device resumes accepting packets from that MAC address.

Packet spoofing

You can stop spoofed IP packets by configuring the switch to forward only IP packets that contain the correct source IP address of your network. By denying all invalid source IP addresses, you minimize the chance that your network is the source of a spoofed DoS attack.

A spoofed packet is one that comes from the Internet into your network with a source address equal to one of the subnet addresses on your network. The source address belongs to one of the address blocks or subnets on your network. To provide spoofing protection, you can use a filter that examines the source address of all outside packets. If that address belongs to an internal network or a firewall, the packet is dropped.

To prevent DoS attack packets that come from your network with valid source addresses, you need to know the IP network blocks in use. You can create a generic filter that:

- Permits valid source addresses
- Denies all other source addresses

To do so, configure an ingress filter that drops all traffic based on the source address that belongs to your network.

If you do not know the address space completely, it is important that you at least deny private (see RFC1918) and reserved source IP addresses. The following table lists the source addresses to filter.

Table 289: Source addresses to filter

Address	Description
0.0.0.0/8	Historical broadcast. High Secure mode blocks addresses 0.0.0.0/8 and 255.255.255.255/16. If you enable this mode, you do not need to filter these addresses.
10.0.0.0/8	RFC1918 private network
127.0.0.0/8	Loopback
169.254.0.0/16	Link-local networks
172.16.0.0/12	RFC1918 private network
192.0.2.0/24	TEST-NET
192.168.0.0/16	RFC1918 private network
224.0.0.0/4	Class D multicast
240.0.0.0/5	Class E reserved
248.0.0.0/5	Unallocated
255.255.255.255/32	Broadcast1

You can also enable the spoof-detect feature on a port.

VLAN loop prevention

Table 290: Simple Loop Prevention Protocol product support

Feature	Product	Release introduced
Simple Loop Prevention Protocol (SLPP)	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50

Loop prevention

Under certain conditions, such as incorrect configurations or cabling, loops can form. This is true mainly for layer 2 bridged domains, such as VLANs.

Simple Loop Prevention Protocol (SLPP) provides active protection against Layer 2 network loops on a per-VLAN basis. SLPP uses a lightweight hello packet mechanism to detect network loops. Sending hello packets on a per VLAN basis allows SLPP to detect VLAN based network loops for untagged as well as tagged IEEE 802.1Q VLAN link configurations. After SLPP detects a loop, the port is shutdown.

Note

If SLPP is used in a vIST environment, it must be enabled on both the vIST peers. Because, when an SLPP packet of a vIST peer is looped through UNI ports to the other device, that device will shut down its UNI port due to receiving SLPP packets from its peer. A device's own SLPP packets will go over a vIST connection but will not be forwarded by its vIST peer back onto its UNI ports.

Configure the SLPP functionality with the following criteria:

- **SLPP TX Process** – You decide on which VLANs a switch can send SLPP hello packets. The packets are then replicated out all ports which are members of the SLPP-enabled VLAN. As a best practice, enable SLPP on all VLANs.
- **SLPP RX Process** – You decide on which ports the switch can act when receiving an SLPP packet that is sent by the same switch or by its SMLT peer. You must enable this process only on Access SMLT ports. You can enable this process only when the design permits on SMLT CORE ports in the case of a square/full mesh core design.
- **SLPP Action** – The action operationally disables the ports receiving the SLPP packet. You can also tune the network failure behavior. You can choose how many SLPP packets a port needs to receives before a switch takes an action. You need to stagger these values to avoid edge switch isolation – see the best practices at the end of this section.

Loops can be introduced into the network in many ways. One way is through the loss of an MLT/link aggregation configuration caused by user error or malfunctioning equipment. This scenario does not always introduce a broadcast storm, but because all MAC addresses are learned through the looping ports, does significantly impact Layer 2 MAC learning. Spanning Tree cannot in all cases detect such a configuration issue, whereas SLPP reacts and disables the malfunctioning links and limits network impact to a minimum.

The desire is to prevent a loop from causing network problems, while also attempting not to isolate totally the edge where the loop was detected. Total edge closet isolation is the last resort to protect the rest of the network from the loop. With this in mind, some administrators adopt the concept of an SLPP primary switch and SLPP secondary switch. These are strictly design terms and are not configuration parameters. The Rx thresholds are staggered between the primary and secondary switch. Therefore, the primary switch disables an uplink immediately upon a loop occurring. If this resolves the loop issue, then the edge closet still has connectivity back through the SLPP secondary switch. If the loop is not resolved, then the SLPP secondary switch disables the uplink and isolates the closet to protect the rest of the network from the loop.

As the number of VLANs running SLPP scale off of a specific uplink port, the Rx-threshold value may need to be increased to prevent complete isolation of the offending edge. The primary goal of SLPP is to protect the core at all costs. In certain loop conditions, what can occur is the secondary switch also detects the loop and SLPP Rx-threshold of the secondary switch is reached before the primary can stop the loop by taking its port down. Therefore, both switches eventually take their ports down and the edge is isolated. The larger the number of VLANs associated with the port, the more likely this can occur, especially for loop conditions that affect all VLANs.

The loop detection functionality of the device must not be used under normal operating conditions. Only use it if directed by the technical support personnel.

You cannot configure the EtherType for SLPP. The switch uses an EtherType of 0x8102 .

Spanning Tree and Protection against Isolated VLANs

Virtual Local Area Network (VLAN) isolation disrupts packet forwarding. The following figure illustrates the problem. Two VLANs (V1 and V2) connect four devices, and both VLANs are in the same spanning tree group. V2 includes three of the four devices, whereas V1 includes all four devices. After a spanning tree protocol detects a loop, it blocks the link with the highest link cost. In this case, the 100 Mbps link is blocked, which isolates a device in V2. To avoid this problem, either configure V2 on all four devices or use MSTP with a different Multiple Spanning Tree Instance (MSTI) for each VLAN.

Figure 268: VLAN isolation

IGMP Layer 2 Querier

In a Layer 2 multicast network, you can enable Layer 2 querier on one of the switches in the VLAN. IGMP Layer 2 querier provides the IGMP querier function so that the switch can provide the recurring queries that maintain IGMP groups when you do not use multicast routing for multicast traffic.

IGMP Layer 2 Querier Overview

In a multicast network, if you only need to use Layer 2 switching for the multicast traffic, you do not need multicast routing. However, you must have an IGMP querier on the network for multicast traffic to flow from sources to receivers. A multicast router provides the IGMP querier function. You can also use the IGMP Layer 2 Querier feature to provide a querier on a Layer 2 network without a multicast router.

The Layer 2 querier function originates queries for multicast receivers, and processes the responses accordingly. On the connected Layer 2 VLANs, IGMP snoop continues to provide services as normal. IGMP snoop responds to queries and identifies receivers for the multicast traffic.

You must enable Layer 2 querier and configure an IP address for the querier before it can originate IGMP query messages. If a multicast router exists on the network, the switch automatically disables the Layer 2 querier.

In a Layer 2 multicast network, enable Layer 2 querier on only one of the switches in the VLAN. A Layer 2 multicast domain supports only one Layer 2 querier. No querier election exists.

IGMP Snooping

IGMP Snooping enables Layer 2 switches in the network to examine IGMP control protocol packets exchanged between downstream hosts and upstream routers.

When Layer 2 switches examine the IGMP control protocol packets, they:

IGMP Layer 2 Querier and IGMP Interaction

IGMP Layer 2 Querier uses IGMP to learn which groups have members on each of the attached physical networks, and it maintains a list of multicast group memberships for each attached network and a timer for each membership. In this case, multicast group memberships means the presence of at least one member of a multicast group on a given attached network, not a list of all of the members.

IGMP Layer 2 Querier can assume one of two roles for each of the attached networks:

- Querier
- Non-Querier

After you enable IGMP Layer 2 Querier, the system assumes it is a multicast router, so it sends the General Query, Group Specific/Group, and Source Specific Query when Leave/BLOCK messages are received. IGMP queries are required to maintain an IGMP group.

For more information about how to configure IGMP Layer 2 Querier, see [IP Multicast](#) on page 1456.

Switched UNI Layer 3

Create a platform VLAN using the command **vlan create <vlan-id> type port-mstprsp <msti-instance>**. Enable Layer 3 services on the platform VLAN and is associated with the Switched UNI (S-UNI) Service Instance Identifier (I-SID). All S-UNI ports are added to the platform VLAN.

You must associate the S-UNI I-SID to the platform VLAN. After you associate the platform VLAN with the I-SID, it becomes a CVLAN.

The switch performs MAC and ARP learning on the platform VLAN.

Note

You cannot add S-UNI ports or MLT to the S-UNI platform VLANs directly. Add the ports to the I-SID and assign the I-SID to the platform VLAN.

You can associate only port based VLAN with S-UNI I-SID.

VLAN Configuration Using CLI

Create a VLAN

Create a VLAN by port, protocol, or SPBM. Optionally, you can choose to assign the VLAN a name and color.

Assign an IP address to the VLAN. You can also assign a MAC-offset value that allows you to manually change the default MAC address.

About This Task

If you configure the SLA Mon agent address under an IP interface or VLAN, you must remove the SLA Mon address before you can remove the IP address or VLAN.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Create a VLAN by specifying one of the following VLAN types:
 - a. Create a VLAN by port:

```
vlan create <2-4059> [name WORD<0-64>] type port-mstprstp <0-63>
[color <0-32>]
```
 - b. Create a VLAN using a user-defined protocol and specify the frame encapsulation header type:

```
vlan create <2-4059> [name WORD<0-64>] type protocol-mstprstp <0-63>
ipv6 [color <0-32>]
```
 - c. Create an SPBM B-VLAN:

```
vlan create <2-4059> [name WORD<0-64>] type spbm-bvlan [color <0-
32>]
```
3. (Optional) Associate a CVLAN I-SID to the platform VLAN.

```
vlan i-sid <1-4059> <1-16777215> [force]
```
4. Log on to the VLAN Interface Configuration mode for the VLAN ID:

```
interface VLAN <1-4059>
```
5. Assign an IP address to a VLAN:

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} [dvr-one-ip]
```
6. (Optional) Specify the MAC-offset value:

```
ip address <A.B.C.D/X>|<A.B.C.D> <A.B.C.D> dvr-one-ip <MAC-offset>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan create 2 type port-mstprstp 0 color 4
Switch:1(config)#vlan i-sid 2 100
Switch:1(config)#interface vlan 2
Switch:1(config-if)#ip address 192.0.2.0/24 dvr-one-ip
```

Variable Definitions

The following table defines parameters for the **vlan create** command.

Variable	Value
<2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
<i>name WORD</i> <0-64>	Specifies the VLAN name. The name attribute is optional.
<i>type port-mstprstp</i> <0-63> [<i>color</i> <0-32>]	Creates a VLAN by port: <ul style="list-style-type: none"> • <0-63> is the STP instance ID from 0 to 63. • <i>color</i> <0-32> is the color of the VLAN in the range of 0 to 32. <p>Note: MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.</p>
<i>type pvlan-mstprstp</i> <0-63> [<i>color</i> <0-32>]	Creates a private VLAN by port: <ul style="list-style-type: none"> • <0-63> is the STP instance ID from 0 to 63. • <i>color</i> <0-32> is the color of the VLAN in the range of 0 to 32.
<i>type protocol-mstprstp</i> <0-63> ipv6	Creates a VLAN by protocol: <ul style="list-style-type: none"> • <0-63> is the STP instance ID. • <i>color</i> <0-32> is the color of the VLAN in the range of 0 to 32.
<i>type spbm-bvlan</i>	Creates a SPBM B-VLAN.

The following table defines parameters for the **ip address** command.

Variable	Value
<A.B.C.D/X> <A.B.C.D> <A.B.C.D>	Specifies the IP address and subnet mask in the format A.B.C.D/X or A.B.C.D A.B.C.D.
<i>dvr-one-ip</i>	Specifies that the IP address will be used as the DvR gateway IP address and will be used by all other DvR Controllers for the DvR VLAN subnet.
<MAC-offset>	Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help.

The following table defines parameters for the **vlan i-sid** command.

Variable	Value
<code><1-4059></code>	Specifies the VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<code><0-16777215></code>	Specifies the service instance identifier (I-SID). You cannot use I-SID 0x00ffffff. The system reserves this I-SID to advertise the virtual BMAC in an SMLT dual-homing environment. This value is the same for the primary and secondary VLANs.
<code>force</code>	Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.

Create a Private VLAN

About This Task

You can create a private VLAN and set the port type. The primary and secondary VLAN IDs are associated with the same MTSI, the secondary VLAN inherits the primary VLAN configuration. You cannot create another VLAN with the same VLAN ID as the secondary VLAN. The secondary VLAN cannot be any other type of VLAN other than a secondary VLAN.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Create a private VLAN:

```
vlan create <2-4059> type pvlan-mstprstp secondary <2-4059>
```
3. Specify a name for the VLAN:

```
vlan create <2-4059> name
```
4. Enter GigabitEthernet Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

5. Set the port type:

```
private-vlan <isolated|promiscuous|trunk>
```

**Note**

If the port is a member of an MLT, the port inherits the private VLAN port type of the MLT.

6. Exit to Global Configuration mode:

```
exit
```

7. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

8. Add ports to the primary VLAN:

```
vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# vlan create 2 type pvlan-mstprstp 6 secondary 5
```

```
Switch:1(config)# interface gigabitethernet 1/36
```

```
Switch:1(config-if)# private-vlan isolated
```

```
Switch:1(config-if)# exit
```

```
Switch:1(config)# interface vlan 2
```

```
Switch:1(config-if)# vlan members add 2 1/36
```

Variable Definitions

Use the data in the following table to use the **vlan create** command.

Variable	Value
<code><2-4059></code>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
<code>name WORD<0-64></code>	Specifies the VLAN name. The name attribute is optional.
<code>type pvlan-mstprstp <0-63></code>	Creates a private VLAN by port. The variable <code><0-63></code> is the STP instance ID from 0 to 63. Note: MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.
<code>secondary<2-4059></code>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.

Use the data in the following table to use the `private vlan port type` command.

Variable	Value
<code><isolated promiscuous trunk></code>	Specifies the port type. If not specified, the port type defaults to None. <ul style="list-style-type: none"> Isolated: An Isolated port can belong only to one private VLAN Promiscuous: A Promiscuous port can belong to many private VLANs Trunk: A Trunk port can belong to many private VLANs, is tagged, and can also belong to non-private VLANs
<code>no private-vlan</code>	Port defaults to type None.
<code>default private-vlan</code>	Port defaults to type None.

Note

If there are other non-private VLANs using the defined port, the following message is displayed: All non private VLANs using this interface will be removed once this port becomes a member of a private VLAN. Ports with private-vlan type of isolated or promiscuous may only contain private VLANs. Do you wish to continue (y/n) ?

Use the data in the following table to use the `interface vlan` and `vlan members add` commands.

Variable	Value
<code><1-4059></code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Assign an IP Address to a VLAN

Assign an IP address to a VLAN so that it supports routing operations.

Before You Begin

- You must create the VLAN.
- Activate IP forwarding globally.

About This Task

If an IP interface is configured without specifying the VRF instance, it maps to VRF 0 by default.

Use the `vrf` parameter to associate the VLAN with a VRF instance.

Important

The VRRP virtual IP address cannot be same as the local IP address of the port or VLAN on which VRRP is enabled.

Procedure

- Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
- Assign an IP address to a VLAN:

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} [dvr-one-ip] [name WORD
<0-64>]
```
- (Optional) If required, associate the VLAN with a VRF:

```
vrf WORD<1-16>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 2
Switch:1(config-if)#ip address 192.0.2.5 255.255.255.0 dvr-one-ip name Boston
```

Variable Definitions

The following table defines parameters for the **ip address** command.

Variable	Value
<code><A.B.C.D/X> <A.B.C.D> <A.B.C.D></code>	Specifies the IP address and subnet mask in the format A.B.C.D/X or A.B.C.D A.B.C.D.
<code>dvr-one-ip</code>	Specifies that the IP address will be used as the DvR gateway IP address and will be used by all other DvR Controllers for the DvR VLAN subnet.
<code>name WORD <0-64></code>	Specifies the name associated with the IP address on a VLAN. This parameter does not apply to all hardware platforms.

The following table defines parameters for the **vrf** command.

Variable	Value
<code>WORD<0-16></code>	Specifies the VRF of the VLAN.

Performing a general VLAN action

Perform a general VLAN action to initiate a specific function on a VLAN, such as clearing learned MAC addresses or ARP entries from the forwarding database by performing this procedure.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Perform a general VLAN action:

```
vlan action <1-4059> {none|flushMacFdb|flushArp|flushIp|flushDynMemb|
triggerRipUpdate|all}
```

Example

Perform a general VLAN action:

```
Switch(config)# vlan action 1 none
```

```
Switch(config)# vlan action 1 flushMacFdb
```

```
Switch(config)# vlan action 1 flushIp
```

```
Switch(config)# vlan action 1 flushDynMemb
```

Variable Definitions

Use the data in the following table to use the **vlan action** command.

Variable	Value
<i>none</i>	Configures action to none. This action performs no updates.
<i>flushMacFdb</i>	Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN.
<i>flushArp</i>	Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN.
<i>flushIp</i>	Configures action to flushIp. This action removes the learned IP addresses from the forwarding table for the selected VLAN.
<i>flushDynMemb</i>	Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN, and removes MAC addresses learned on those ports for this VLAN.
<i>flushDynMemb</i>	Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN, and removes MAC addresses learned on those ports for this VLAN.
<i>triggerRipUpdate</i>	Configures action to triggerRipUpdate.
<i>all</i>	Configures action to all and performs all preceding actions.

Configuring static MAC addresses for a VLAN

Configure the static MAC address parameters.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a static MAC address of a VLAN:

```
vlan mac-address-static <1-4059> <0x00:0x00:0x00:0x00:0x00:0x00>
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

Example

Configure a static MAC address of a VLAN:

```
Switch(config)# vlan mac-address-static 1 0x00:0x00:0x00:0x00:0x00:0x01
1/1
```

Variable Definitions

Use the data in the following table to use the `vlan mac-address-static` command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<0x00:0x00:0x00:0x00:0x00:0x00>	Indicates the MAC address.
{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Limit MAC Address Learning

Configure the MAC security feature to control traffic from specific number of MAC addresses. The total number of MAC addresses that you can configure are fixed. The switch help text shows the maximum MAC addresses a port can learn in non-SPBM configurations. In an SPBM configuration, the maximum value is reduced by half.

About This Task

This feature limits the number of forwarding database (FDB) entries learned on a particular port to a user-specified value. After the number of learned forwarding database entries reaches the maximum limit, MAC learning stops on that port.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]} or interface mlt <1-512>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Protect the FDB from hits by too many MAC addresses:

```
mac-security [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]] limit-learning enable [max-addr <max-addr>]
```

Example

Protect the FDB from hits by too many MAC addresses:

```
Switch:1(config)#interface gigabitethernet 1/1
Switch:1(config-if)#mac-security limit-learning enable
Switch:1(config-if)#mac-security limit-learning max-addr 5000
```

Variable Definitions

Use the data in the following table to use the **mac-security limit-learning** command.

Variable	Value
<i>enable</i>	Limits the MAC learning for the port. After the number of addresses reaches the maximum, the port disables packet forwarding and drops packets. If you enable <i>limit-learning</i> , the FDB entry for each port is limited to the number you specify in <i>max-addr</i> s.
<i>max-addr</i> s < <i>max-addr</i> s>	Specifies the maximum number of MAC addresses to learn. After the number of addresses reaches the maximum, the port disables packet forwarding and drops packets. The default is 1024. Depending on the hardware platform, the parameter range can vary. Use the CLI Help to see the available range for the switch.
<i>port</i> { <i>slot/</i> <i>port</i> [/ <i>sub-</i> <i>port</i>] <i>[-slot/</i> <i>port</i> [/ <i>sub-</i> <i>port</i>]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. Use this parameter to apply the change to multiple ports without changing CLI modes.

Configuring the forwarding database timeout globally

Use the following procedure to configure the aging time globally for the forwarding database.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enter the following command:

```
mac-address-table aging-time <10-1000000>
```

Variable Definitions

Use the data in the following table to use the **mac-address-table** command.

Variable	Value
<i>aging-time</i>	Specifies the timeout period for dynamically learned mac addresses on the vlan. The default value is 300.
< <i>10-1000000</i> >	Specifies the range for the aging time.

Adding or removing ports in a VLAN

Add or remove the ports in a VLAN to configure the ports in the VLAN.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Add ports in a VLAN:

```
vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} [{portmember|static|notallowed}]
```

3. Remove ports in a VLAN:

```
vlan members remove <1-4059> {slot/port[/sub-port] [-slot/port[/sub-  
port]][,...]} [{portmember|static|notallowed}]
```

Example

Add ports in a VLAN:

```
Switch(config-if)# vlan members add 1 1/2 static
```

Remove ports in a VLAN:

```
Switch(config-if)# vlan members remove 1 1/2 notallowed
```

Variable Definitions

Use the data in the following table to use the **vlan members add** and **vlan members remove** commands.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
portmember	Configures the port type as port member.

Adding or removing source MAC addresses for a VLAN

Add or remove a VLAN source MAC addresses to configure the source MAC address for a source MAC-based VLAN.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Add a VLAN source MAC address:

```
vlan srcmac <1-4059> <0x00:0x00:0x00:0x00:0x00:0x00>
```
3. Remove a VLAN source MAC address:

```
no vlan srcmac <1-4059> <0x00:0x00:0x00:0x00:0x00:0x00>
```

Example

Add a VLAN source MAC address:

```
Switch(config)# vlan create 10 type srcmac-mstprstp 0

Switch(config)# vlan srcmac 10 0x00:0x00:0x00:0x00:0x00:0x11
```

Configure NLB support

Use Microsoft Network Load Balancing (NLB) to share the workload among multiple clustering servers. For information about software scaling capabilities, see [VOSS Release Notes](#).

Before You Begin

- For all modes, configure an IP address on the VLAN enabled with NLB.
- To switch between Unicast NLB and Multicast NLB, you must first disable the NLB support.

About This Task

Use the following procedure to configure NLB support on an IP interface to enable or disable NLB support.

The default value is NLB support disabled.

Note

SPBM supports Network Load Balancing (NLB) Unicast and Multicast modes.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Enable NLB support on an interface:

```
nlb-mode unicast
```

Or,

```
nlb-mode multicast
```

To switch from one nlb-mode to another, you must first disable the NLB support, and then enter the new nlb-mode.

3. (Optional) Disable NLB support on an interface:

```
no nlb-mode
```

Example

Configure unicast mode for VLAN 2, and then switch to multicast mode.

```
Switch:1(config)#interface vlan 2
Switch:1(config-if)#nlb-mode unicast
Switch:1(config-if)#no nlb-mode
Switch:1(config-if)#nlb-mode multicast
```

Configuring a tagged port to discard untagged frames

Configure a tagged port to discard all untagged packets so that the frame is not classified into the default VLAN for the port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a tagged port to discard untagged frames:

```
untagged-frames-discard [port {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]}
```

3. Discard a tagged frame on an untagged port:

```
tagged-frames-discard [port {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]}] enable
```

4. Untag the default VLAN on a tagged port:

```
untag-port-default-vlan [port {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]}] enable
```

Example

Configure a tagged port to discard untagged frames:

```
Switch(config-if)#untagged-frames-discard port 1/1
```

Discard a tagged frame on an untagged port:

```
Switch(config-if)#tagged-frames-discard port 1/1 enable
```

Untag the default VLAN on a tagged port:

```
Switch(config-if)#untag-port-default-vlan port 1/2 enable
```

Variable Definitions

Use the data in the following table to use optional parameters with the **untagged-frames-discard** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring SLPP

Enable the Simple Loop Prevention Protocol (SLPP) globally and for a VLAN to detect a loop and automatically stop it. The VLAN configuration controls the boundary of SLPP-PDU transmission.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable SLPP:

```
slpp enable
```
3. Configure the transmission interval:

```
slpp tx-interval <500-5000>
```
4. Add a VLAN to the transmission list:

```
slpp vid <1-4059>
```

Example

Enable SLPP:

```
Switch(config)# slpp enable
```

Configure the transmission interval to 5000 milliseconds:

```
Switch(config)# slpp tx-interval 5000
```

Add a VLAN, with the VLAN ID 2, to the transmission list:

```
Switch(config)# slpp vid 1
```

Variable Definitions

Use the data in the following table to use the **slpp** command.

Variable	Value
<i>enable</i>	Enables or disables the SLPP operation. You must enable the SLPP operation to enable the SLPP packet transmit and receive process. If you disable the SLPP operation, the system sends no SLPP packets and discards received SLPP packets. To set this option to the default value, use the default operator with the command. The default is disabled.
<i>500-5000</i>	Configures the SLPP packet transmit interval, expressed in milliseconds in a range from 500-5000. The default value is 500. To set this option to the default value, use the default operator with the command.
<i><1-4059></i>	Adds a VLAN, by VLAN ID, to a SLPP transmission list. Use the no operator to remove this configuration.

Job aid

The following table provides SLPP values.

Table 291: SLPP values

Enable SLPP	Setting
Access SMLT	Yes
Core SMLT	No
Primary switch	
Packet Rx threshold	5
Transmission interval	500 milliseconds (ms) (default)
Secondary switch	
Packet Rx threshold	50
Transmission interval	500 ms (default)

Configuring SLPP packet-rx on a port

Enable SLPP by port to detect a loop and automatically stop it.

Important

To provide protection against broadcast and multicast storms, as a best practice, enable Rate Limiting for broadcast traffic and multicast traffic.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure SLPP on a port:

```
slpp port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} packet-
rx [packet-rx-threshold <1-500>]
```

Example

```
Switch(config-if)# slpp port 1/1 packet-rx-threshold 5
```

Variable Definitions

Use the data in the following table to use the **slpp port** command.

Variable	Value
<1-500>	<p>Specifies the SLPP reception threshold on the ports, expressed as an integer. The packet reception threshold specifies how many SLPP packets the port receives before it is administratively disabled. To set this option to the default value, use the default operator with the command. The default value is 1.</p> <p>Note: As a best practice, configure the rx-threshold above 50 slpp packets only on lightly loaded switches. If you configure the rx-threshold to a value greater than 50 on a heavily loaded switch and a loop occurs, the system can experience high CPU utilization.</p>
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	<p>Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

Job aid

The following table provides the SLPP values.

Table 292: SLPP values

Enable SLPP	Setting
Access SMLT	Yes
Core SMLT	No
Primary switch	
Packet Rx threshold	5
Transmission interval	500 milliseconds (ms) (default)
Secondary switch	
Packet Rx threshold	50
Transmission interval	500 ms (default)

Configuring SLPP packet-tx on a VLAN

Enable SLPP by VLAN to detect a loop and automatically stop it. This configuration controls the boundary of SLPP-PDU transmission.

Important

To provide protection against broadcast and multicast storms, as a best practice, enable Rate Limiting for broadcast traffic and multicast traffic.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable SLPP:

```
slpp enable
```

3. Configure the transmission interval:

```
slpp tx-interval <500-5000>
```

4. Add a VLAN to the transmission list:

```
slpp vid <1-4059>
```

Example

Log on to the VLAN Interface Configuration mode:

```
Switch(config)# interface vlan 2
```

Enable SLPP:

```
Switch(config-if)# slpp enable
```

Configure the transmission interval to 500 milliseconds:

```
Switch(config-if)# slpp tx-interval 500
```

Add a VLAN, with the VLAN ID of 2, to the transmission list:

```
Switch(config-if)# slpp vid 2
```

Variable Definitions

Use the data in the following table to use the **slpp** command.

Variable	Value
<i>enable</i>	Activates or disables the SLPP operation. You must enable the SLPP operation to enable the SLPP packet transmit and receive process. If you disable the SLPP operation, the system sends no SLPP packets and discards received SLPP packets. To set this option to the default value, use the default operator with the command. The default is disabled.
<i>500-5000</i>	Configures the SLPP packet transmit interval, expressed in milliseconds in a range from 500-5000. The default value is 500. To set this option to the default value, use the default operator with the command.
<i><1-4059></i>	Adds a VLAN, by VLAN ID, to a SLPP transmission list. Use the no operator to remove this configuration.

Viewing SLPP information

Use SLPP information to view loop information.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View SLPP information:
show slpp

Example

```
Switch# show slpp
```

```

=====
                                SLPP Info
=====
      operation : enabled
      tx-interval : 500
      vlan : 2
=====

```

Viewing SLPP information for a port

Show SLPP information for a port so that you can view the loop information for a port.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View SLPP information for a port:
show slpp interface GigabitEthernet [{slot/port[/sub-port]}[-slot/port[/sub-port]}[,...]]
3. Clear SLPP packet RX counters:
clear slpp stats port [{slot/port[/sub-port]}[-slot/port[/sub-port]}[,...]]

Example

```
Switch# show slpp interface GigabitEthernet 1/7
```

```

=====
                                Port Interface
=====
PORT      PKT-RX      PKT-RX      INCOMING      SLPP PDU
NUM       COUNT      THRESHOLD   VLAN ID       ORIGINATOR
-----
1/7       enabled    5
-----
PORT      PKT-RX      TIME LEFT
NUM       COUNT      TO CLEAR RX COUNT
-----
1/7       29         21600
-----

```

Variable Definitions

Use the data in the following table to use the **show slpp interface GigabitEthernet** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring spoof detection

Configure spoof detection to prevent IP spoofing.

For more information about this feature, see [Prevention of IP Spoofing within a VLAN](#) on page 3765.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable or disable spoof detection:

```
spoof-detect [port {slot/port[-slot/port]}] [enable]
```

```
no spoof-detect [port {slot/port[-slot/port]}] [enable]
```

3. Enable or disable auto-recovery on a port:

```
auto-recover-port [port {slot/port[-slot/port]}] [enable]
```

```
no auto-recover-port [port {slot/port[-slot/port]}] [enable]
```

Example

Enable spoof detection:

```
Switch(config-if)# spoof-detect port 1/1 enable
```

Enable autorecovery on a port:

```
Switch(config-if)# auto-recover-port port 1/1 enable
```

Viewing VLAN information

View the VLAN information to display the basic configuration for all VLANs or a specified VLAN.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View VLAN information:

```
show vlan basic <1-4059>
```
3. View advanced parameters:

```
show vlan advance <1-4059>
```

Example

View VLAN information for VLAN 2:

```
Switch:1> show vlan basic 2
```

```
=====
                                Vlan Basic
=====
```

VLAN ID	NAME	TYPE	INST ID	PROTOCOLID	SUBNETADDR	SUBNETMASK	VRFLD
2	VLAN-2	byPort	0	none	N/A	N/A	0

View VLAN information:

```
Switch:1> show vlan basic
```

```
=====
                                Vlan Basic
=====
```

VLAN ID	NAME	TYPE	INST ID	PROTOCOLID	SUBNETADDR	SUBNETMASK	VRFLD
1	Default	byPort	0	none	N/A	N/A	0

ID        NAME  INDEX TIME  ADDRESS  DEFINEPID ENCAP  DSAP/SSAP
-----
2         Default 2050  0       00:24:7f:9f:6a:03  0x0000

```

Variable Definitions

Use the data in the following table to use optional parameters with the **show vlan basic** and **show vlan advance** commands.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

View Private VLAN Information

You can view the private VLAN information to display the primary and secondary VLANs and I-SIDs, and also view the private VLAN port types.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. View private VLAN information:

```
show vlan private-vlan <1-4059>
```
3. View private VLAN port information:

```
show interfaces gigabitethernet private-vlan
```

Example

View VLAN information for private VLAN :

```
Switch:1(config)# show vlan private-vlan
```

```
=====
                        PRIVATE VLAN
=====
```

Primary VLAN	Primary ISID	Secondary VLAN	Secondary ISID
3	75	5	75
10	22	15	22

```
-----
All 2 out of 2 Total Num of Private Vlans displayed
```

View port information for private VLAN:

```
Switch:1(config)#show interfaces gigabitethernet private-vlan
```

```
=====
                        Port Private Vlans
=====
```

PORT NUM	TAGGING	ORIGIN	PVLAN	PVLAN TYPE	VID TYPE	VID
2/2	enable	CONFIG	enable	promiscuous	-	-

```
-----
All 1 out of 1 Total Num displayed
```

Viewing router port information

View the router port information to display the router port VLAN information for all VLANs on the device or for the specified VLAN.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View router port information:

```
show vlan router-port
```

Example

View router port information:

```
Switch:1> show vlan router-port
```

```
=====
```

Vlan Id	Port	VrfId
2202	1/11	0

```
=====
All 1 out of 1 Total Num of Vlan Router Port Entries displayed
```

Viewing VLAN port member status

View the VLAN port member status to display the port member status for all VLANs on the device or for the specified VLAN.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View VLAN port member status:

```
show vlan members [<1-4059>][null-vlan][port {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]
```

Example

View VLAN port member status:

```
Switch:1> show vlan members port 1/2
```

Vlan Port				
VLAN ID	PORT MEMBER	ACTIVE MEMBER	STATIC MEMBER	NOT_ALLOW MEMBER
2	1/2,1/5-1/8,1/11, 1/14,1/26,1/38	1/2,1/5-1/8,1/11, 1/14,1/26,1/38		
3	1/2,1/5-1/8,1/14, 1/26,1/38	1/2,1/5-1/8,1/14, 1/26,1/38		
4	1/1-1/2,1/5-1/8, 1/13-1/14,1/25- 1/26,1/37-1/38	1/1-1/2,1/5-1/8, 1/13-1/14,1/25- 1/26,1/37-1/38		
100	1/2,1/14,1/23- 1/24,1/26-1/28, 1/38	1/2,1/14,1/23- 1/24,1/26-1/28, 1/38		
300	1/2,1/5-1/8,1/14, 1/26,1/38	1/2,1/5-1/8,1/14, 1/26,1/38		

Variable definitions

Use the data in the following table to use optional parameters with the **show vlan members** command.

Variable	Value
<code>null-vlan</code>	Displays port members of the NULL VLAN. This is a place holder VLAN for ports that are not members of any port-based VLAN. When a port is removed from all port-based VLANs, it is added to the NULL VLAN as a port member. The NULL VLAN is an internal construct and cannot be deleted.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. If you do not specify a port, the command shows information for all the ports.
<code><1-4059></code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. Note: Entering a VLAN ID is optional. If you enter a VLAN ID the command shows information for the specified VLAN or port. Without the VLAN ID the command shows information for all the configured VLANs.

Viewing VLAN source MAC addresses

View the VLAN source MAC addresses to display the source MAC address for a source MAC-based VLAN on the device or for the specified VLAN.

Procedure

View VLAN source MAC addresses:

```
show vlan src-mac [<1-4059>]
```

Example

View VLAN source MAC addresses:

```
Switch(config)# show vlan src-mac
```

```
=====
                        Vlan Srcmac
=====
VLAN_ID   MAC_ADDRESS
-----
10        00:00:00:00:00:11

All 1 out of 1 Total Num of Vlan Srcmac Entries displayed
```

Viewing VLAN forwarding database information

Use this procedure to display the MAC addresses that are learned or statically configured for a VLAN. In order to learn you have to be connected to another switch or host and receive some traffic.

Note

The VSP 4450 Series does not display a log message when MAC learning maximum limit is reached.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View VLAN forwarding database information:

```
show vlan mac-address-entry [<1-4059>]
```

Example

View VLAN forwarding database information:

```
Switch:1> show vlan mac-address-entry
```

```
=====
                        Vlan Fdb
=====
VLAN      MAC              SMLT
ID  STATUS  ADDRESS          INTERFACE  REMOTE  TUNNEL
-----
1    learned  f8:15:47:e1:80:0c  Port-1/2  false  -
2    learned  32:20:d3:81:00:77  Port-1/9  false  -
4    learned  b4:a9:5a:2b:78:31  Port-2/1  false  -

3 out of 3 entries in all fdb(s) displayed.
```

View where entries are learned. The TUNNEL column indicates where in the SPBM network an entry is learned.

```
Switch:1> show vlan mac-address-entry spbm-tunnel-as-mac
```

```
=====
                        Vlan Fdb
=====
VLAN      MAC              SMLT
ID  STATUS  ADDRESS          INTERFACE  REMOTE  TUNNEL
-----
1    learned  f8:15:47:e1:80:0c  Port-1/2  false  -
2    learned  32:20:d3:81:00:77  Port-1/9  false  -
```

```

4    learned    b4:a9:5a:2b:78:31  Port-2/1    false    -
3 out of 3 entries in all fdb(s) displayed.

```

Variable Definitions

Use the data in the following table to use optional parameters with the **show vlan mac-address-entry** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
mac <0x00:0x00:0x00:0x00:0x00:0x00>	Specifies the MAC address.
port {slot/port[-slot/port][,...]}	Specifies the port or port list.
spbm-tunnel-as-mac	Displays where entries are learned. The TUNNEL column indicates where in the SPBM network an entry is learned.

Viewing manual edit MAC addresses

Use the procedure to view the list of manual edit MAC addresses and the associated ports configured as allow-mac for MAC security.

Procedure

View manual edit MAC addresses:

```
show vlan manual-edit-mac
```

Example

View manual edit MAC addresses:

```
Switch(config)# show vlan manual-edit-mac
```

```

=====
                        Manual Edit Mac
=====
MAC ADDRESS           PORTS
-----
00:00:00:00:00:55    1/3
00:00:00:00:00:66    1/3

All 2 out of 2 Total Num of Manual Edit Mac Entries displayed

```

View Port-Level MAC Security

Note

This procedure only applies to VSP 4450 Series, and VSP 4900 Series.

View port-level MAC security to review the configuration.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View port-level MAC security for limit-learning:
show interfaces gigabitethernet limit-fdb-learning [{slot/port[-slot/port]}[,...]]

Example

View port-level MAC security for limit-learning:

```
Switch:1# show interfaces gigabitethernet limit-fdb-learning 1/4-1/5
```

```
=====
                        Port limit-fdb-learning
=====
```

2	unicast	disable			
22	multicast	multicast	1/19-1/21	2	3

```
Total Entries: 2
=====
```

Enable DvR on a Layer 2 VSN (VLAN)

Before You Begin

- Ensure that the VLAN on which to enable DvR exists and is associated with an I-SID.

About This Task

On a Controller, DvR must be manually enabled at the Layer 2 VSN (VLAN) level.

Use this procedure to configure a gateway IPv4 address for a Layer 2 VSN (VLAN) subnet and then enable DvR on it. This address is pushed, along with other Layer 3 configuration information, from the Controllers to the Leaf nodes within the domain, so that the Leaf nodes can create a gateway IP service for each DvR-enabled Layer 2 VSN.

Note

Optionally, you can now use a single IP address in the subnet for every Controller by configuring the DvR VLAN IP to be the same as the DvR GW IP.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
2. Configure a gateway IPv4 address for the VLAN.

```
dvr gw-ipv4 {A.B.C.D}
```

Important

Ensure that you configure the same gateway IPv4 address on all Controllers in the domain that belong to a Layer 2 VSN (VLAN).

3. Enable DvR.

```
dvr enable
```

By default, DvR is disabled.

Example

Enable DvR on the Global Router VLAN.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#vlan create 200 type port-mstprstp 0
Switch:1(config-if)#vlan i-sid 200 20200
Switch:1(config-if)#interface vlan 200
Switch:1(config-if)#dvr gw-ipv4 192.0.2.1
Switch:1(config-if)#dvr enable
Switch:1(config-if)#ip address 192.0.2.2 255.255.0.0
```

Enable DvR on a VLAN associated to a VRF:

```
Switch:1>en
Switch:1#conf t
```

```

Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#vlan create 400 type port-mstprstp 0
Switch:1(config-if)#vlan i-sid 400 20200
Switch:1(config-if)#interface vlan 400
Switch:1(config-if)#vrf vrf500
Switch:1(config-if)#dvr gw-ipv4 198.51.100.1
Switch:1(config-if)#dvr enable
Switch:1(config-if)#ip address 198.51.100.2 255.255.0.0

```

Variable definitions

Use the data in the following table to use the **dvr gw-ipv4** command.

Variable	Value
{A.B.C.D}	Specifies the gateway IPv4 address for the VLAN.

Configure a Single IP Address for All DvR Controllers on a VLAN Subnet

Before You Begin

- Ensure that the VLAN on which to enable DvR exists and is associated with an I-SID.

About This Task

On a Controller, DvR must be manually enabled at the Layer 2 VSN (VLAN) level.

Use this procedure to configure a single IP address to be used for both the DvR GW IP and the VLAN IP in the DvR VLAN. This IP address represents the DvR GW IP address used by all DvR Controllers for the same DvR VLAN. When you configure a DvR VLAN in this way, the Controllers no longer have a unique VLAN IP address.

Note

Optionally, you can use two different IP address for the DvR VLAN and the DvR GW IP.

Procedure

- Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
- Configure a single IP address for both the DvR GW IP and the VLAN IP in the DvR VLAN.

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} dvr-one-ip
```
- Enable DvR.

```
dvr enable
```

By default, DvR is disabled.

Example

Enable DvR.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#vlan create 200 type port-mstprstp 0
Switch:1(config-if)#vlan i-sid 200 20200
Switch:1(config-if)#interface vlan 200
Switch:1(config-if)#ip address 192.0.2.1 255.255.0.0 dvr-one-ip
Switch:1(config-if)#dvr enable
```

Variable Definitions

The following table defines parameters for the **ip address** command.

Variable	Value
<A.B.C.D/X> <A.B.C.D> <A.B.C.D>	Specifies the IP address and subnet mask in the format A.B.C.D/X or A.B.C.D A.B.C.D.
<i>dvr-one-ip</i>	Specifies the IP address used for the DvR gateway IP address and the VLAN IP in the DvR VLAN.

VLAN Configuration using EDM

This section describes how to configure and manage Virtual Local Area Networks (VLAN) using Enterprise Device Manager (EDM).

Configure a VLAN on a Port

Configure a VLAN on a port.

Procedure

1. In the Device Physical View tab, select a port or multiple ports.
2. In the Navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **VLAN** tab.
5. To perform tagging, select **PerformTagging**.
6. To discard tagged frames, select **DiscardTaggedFrames**.
7. To discard untagged frames, select **DiscardUntaggedFrames**.
8. To use the Untag Default VLAN feature, select **UntagDefaultVlan**.

Important

Enable tagging on the port before you configure UntagDefaultVlans.

9. Enter a default VLAN ID.
10. To enable spoof detect, select **SpoofDetect**.
11. In the Classification area, select the types of VLAN to enable.
12. In the **Classification** area, select the Private VLAN port type.
See [Creating a Private VLAN](#) on page 3807 for more information.

13. Select **Apply**.

14. Select **Close**.

VLAN field descriptions

Use the data in the following table to use the **VLAN** tab.

Name	Description
PerformTagging	If checked, this port is a tagged (Trunk) Port. It can belong to multiple port-based VLANs and a VLAN tag is inserted in every frame it transmits. If it is not checked, the port is an untagged (Access) port. The default is disabled.
VlanIdList	Identifies which VLANs this port is assigned.
DiscardTaggedFrames	If selected, and the port is untagged (an access port), tagged frames received on the port are discarded by the forwarding process. If clear, tagged frames are processed normally. The default is disabled.
DiscardUntaggedFrames	If selected and the port is tagged (a trunk port), untagged frames received on the port are discarded by the forwarding process. If clear, untagged frames are processed normally. The default is disabled.
UntagDefaultVLAN	If selected, even if the port is tagged (a trunk port), frames forwarded to the default VLAN for the port are not tagged. The default is disabled.
UntaggedVlanIds	Identifies which VLANs this port is associated with as untagged.
DefaultVlanId	Specifies the VLAN ID assigned to untagged frames received on this trunk port that match no policy-based VLAN to which the port belongs.
SpoofDetect	Enables or disables spoof detection on the specified port.
Protocol	Enables protocol-based VLAN on the port. This feature is always enabled.
PrivateVlanPortType	Specifies the port type. If not specified, the port type defaults to None. <ul style="list-style-type: none"> Isolated: Only private VLANs are permitted on isolated ports. Promiscuous: Only private VLANs are permitted on promiscuous ports. Trunk: The port is tagged.
Origin Note: Exception: not supported on VSP 8600 Series and XA1400 Series.	Specifies the origin of VLAN configuration on the port, either manually configured through CLI or EDM, or dynamically configured through Auto-sense.

Configure the VLAN Feature on an Extreme Integrated Application Hosting Port

Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series.

About This Task

Perform this procedure to configure the VLAN feature on an Extreme Integrated Application Hosting (IAH) port.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **VLAN** tab.
4. Select **PerformTagging**, to enable tagging.
5. Select **DiscardTaggedFrames**, to discard tagged frames.
6. Select **DiscardUntaggedFrames**, to discard untagged frames.
7. Select **UntagDefaultVlan**, to enable the Untag Default VLAN feature.

Important

You must enable tagging on the IAH port before you enable the Untagging Default VLANs feature.

8. In the **DefaultVlanId** field, enter a default VLAN ID.
9. Select **SpoofDetect**, to enable spoof detection.
10. In the **PrivateVlanPortType** field, select a type.
11. Select **Apply**.

VLAN Field Descriptions

Use data in the following table to use the **VLAN** tab.

Name	Description
PerformTagging	Enables tagging (trunking) on the Extreme Integrated Application Hosting (IAH) port. It can belong to multiple port-based VLANs and a VLAN tag is inserted in every frame it transmits. If it is not checked, the IAH port is an untagged (Access) IAH port. The default value is different for each IAH port.
VlanIdList	Shows the VLAN ID to which the IAH port is assigned to.
DiscardTaggedFrames	Enables the functionality to discard tagged frames received on the IAH port by the forwarding process, for untagged (access) IAH port. The default is disabled.

Name	Description
DiscardUntaggedFrames	Enables the functionality to discard untagged frames received on the IAH port by the forwarding process, for tagged (trunk) IAH port. The default is disabled.
UntagDefaultVLAN	Enables the functionality to untag the frames forwarded to the default VLAN, even if the IAH port is tagged (trunk port). The default is disabled.
UntaggedVlanIds	Shows the untagged VLAN IDs associated with the IAH port.
DefaultVlanId	Specifies the VLAN ID assigned to untagged frames received on the IAH port that match no policy-based VLAN to which the IAH port belongs.
SpoofDetect	Enables spoof detection on the specified IAH port.
PrivateVlanPortType	Specifies the following: <ul style="list-style-type: none"> • trunk: tagged IAH port. • isolated: Only private VLANs are permitted on isolated IAH ports. • promiscuous: Only private VLANs are permitted on promiscuous IAH ports. • none: default value.

Viewing existing VLANs

Display existing VLANs to view all defined VLANs, their configurations, and the current status.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. View the configured VLANs in the **Basic** tab.
4. View the configured private VLANs in the **Private VLAN** tab.

Create a Port-Based VLAN

Create a port-based VLAN to add a new VLAN. To create a different type of VLAN, see one of the following procedures:

- [Creating a protocol-based VLAN](#) on page 3812
- [Creating a SPBM B-VLAN](#) on page 3813

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Select **VLANs**.
3. In the **Basic** tab, click **Insert**.
4. In the **Id** box, enter an unused VLAN ID, or use the ID provided.

5. In the **Name** box, type the VLAN name, or use the name provided.
6. In the **Color Identifier** box, click the down arrow and choose a color from the list, or use the color provided.
7. In the **MstpInstance** box, click the down arrow and choose an msti instance from the list.
8. In the **Type** box, select **byPort**.
9. In the **PortMembers** box, click the **(...)** button.
10. Click on the ports to add as member ports.

The ports that are selected are recessed, while the nonselected ports are not recessed. Port numbers that are dimmed cannot be selected as VLAN port members.

11. Click **OK**.
12. Click **Insert**.

Basic Field Descriptions

Use the data in the following table to use the **Basic** tab.

Name	Description
Id	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
Name	Specifies the name of the VLAN.
IfIndex	Specifies the logical interface index assigned to the VLAN.
Color Identifier	Specifies a proprietary color scheme to associate a color with the VLAN. Color does not affect how frames are forwarded.
Type	Specifies the type of VLAN: <ul style="list-style-type: none"> • byPort • byProtocolId • spbm-bvlan • private
MstpInstance	Identifies the MSTP instance.
VrfId	Indicates the Virtual Router to which the VLAN belongs.
VrfName	Indicates the name of the Virtual Router to which the VLAN belongs.
PortMembers	Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.
ActiveMembers	Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.

Name	Description
StaticMembers	Specifies the slot/port of each static member of a policy-based VLAN. The system displays the sub-port only for channelized ports.
NotAllowToJoin	Specifies the slot/ports that are never allowed to become a member of the policy-based VLAN. The system displays the sub-port only for channelized ports.
Protocolld	Specifies the network protocol for protocol-based VLANs. This value is taken from the Assigned Numbers of remote function call (RFC). If the VLAN type is port-based, none is displayed in the Basic tab Protocolld field.
AgingTime	Specifies the timeout period, in seconds, to age out dynamic members of this VLAN. This field only applies to policy-based VLANs. The default is 600.

Note

If you or another user changes the name of an existing VLAN using the VLAN **Basic** tab (or using CLI), the system does not display the new name initially in EDM. To display the updated name, perform one of the following actions:

- Refresh your browser to reload EDM.
- Log out of EDM and log in again to restart EDM.
- Click **Refresh** in the VLAN **Basic** tab toolbar. If the system displays the old VLAN name in other tabs, click **Refresh** on those tabs as well.

Creating a Private VLAN

Before You Begin

- To create a private VLAN, you must set the VLAN type to private and set the private VLAN port type.
- The ports you add to a private VLAN must have a port type of isolated, promiscuous, or trunk.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. In the **Basic** tab, click **Insert**.
4. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
5. In the **Name** box, type the VLAN name, or use the name provided.
6. In the **Color Identifier** box, click the down arrow and choose a color from the list, or use the color provided.
7. In the **MstpInstance** box, click the down arrow and choose an msti instance from the list.
8. In the **Type** box, select **private**.
9. In the **PortMembers** box, click the **(...)** button.

10. Click on the ports to add as member ports.

The ports that are selected are recessed, while the non-selected ports are not recessed. Port numbers that are dimmed cannot be selected as VLAN port members.

11. Click **OK**.
12. In the **Secondary Vlan** box, enter an unused VLAN ID.
13. Click **Insert**.
14. Collapse the **VLANS** tab.

The VLAN is added to the **Basic** tab.

To set the port type for the private VLAN:

15. In the navigation pane, expand the following folders: **Configuration > VLAN**.
16. Click **VLANS**.
17. In the Classification area, select the **PrivateVlanPortType**.
18. Click **Apply**.
19. Click **Close**.

Basic Field Descriptions

Use the data in the following table to use the **Basic** tab.

Name	Description
Id	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
Name	Specifies the name of the VLAN.
IfIndex	Specifies the logical interface index assigned to the VLAN.
Color Identifier	Specifies a proprietary color scheme to associate a color with the VLAN. Color does not affect how frames are forwarded.
Type	Specifies the type of VLAN: <ul style="list-style-type: none"> • byPort • byProtocolId • spbm-bvlan • private
MstpInstance	Identifies the MSTP instance.
VrfId	Indicates the Virtual Router to which the VLAN belongs.
VrfName	Indicates the name of the Virtual Router to which the VLAN belongs.

Name	Description
PortMembers	Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.
ActiveMembers	Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.
StaticMembers	Specifies the slot/port of each static member of a policy-based VLAN. The system displays the sub-port only for channelized ports.
NotAllowToJoin	Specifies the slot/ports that are never allowed to become a member of the policy-based VLAN. The system displays the sub-port only for channelized ports.
ProtocolId	Specifies the network protocol for protocol-based VLANs. This value is taken from the Assigned Numbers of remote function call (RFC). If the VLAN type is port-based, none is displayed in the Basic tab ProtocolId field.
AgingTime	Specifies the timeout period, in seconds, to age out dynamic members of this VLAN. This field only applies to policy-based VLANs. The default is 600.

Note

If you or another user changes the name of an existing VLAN using the VLAN **Basic** tab (or using CLI), the system does not display the new name initially in EDM. To display the updated name, perform one of the following actions:

- Refresh your browser to reload EDM.
- Log out of EDM and log in again to restart EDM.
- Click **Refresh** in the VLAN **Basic** tab toolbar. If the system displays the old VLAN name in other tabs, click **Refresh** on those tabs as well.

VLAN Field Descriptions

Use the data in the following table to use the **VLAN** tab.

Name	Description
PrivateVlanPortType	Specifies the port type. If not specified, the port type defaults to None. <ul style="list-style-type: none"> • Isolated: An Isolated port can belong only to one private VLAN • Promiscuous: A Promiscuous port can belong to many private VLANs. • Trunk: A Trunk port can belong to many private VLANs, is tagged, and can also belong to non-private VLANs.

Viewing Private VLAN information

You can view the private VLAN information to display the primary and secondary VLANs and I-SIDs, and also view the private VLAN port types.

Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **VLANs**.
3. Click **Private VLAN**.

Private VLAN field descriptions

Use the data in the following table to use the **Private VLAN** tab.

Name	Description
Primary Vlan	Shows the VLAN ID for the primary VLAN.
Secondary Vlan	Shows the VLAN ID for the secondary VLAN.
Primary / Secondary I-sid	Shows the I-SID for the VLAN.

Configure an IP address for a VLAN

Assign an IP address to a VLAN to enable routing on the VLAN.

About This Task

If you configure the SLA Mon agent address under an IP interface or VLAN, you must remove the SLA Mon address before you can remove the IP address or VLAN.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. In the **Basic** tab, select the VLAN for which you are configuring an IP address.
4. Select **IP**.
5. Select **Insert**.
6. Configure the required parameters.
7. Select **Insert**.

IP Address field descriptions

Use the data in the following table to use the **IP Address** tab.

Name	Description
Interface	Shows the interface to which this entry applies.
Ip Address	Specifies the IP address to associate with the VLAN.

Name	Description
Net Mask	Specifies the subnet mask associated with the IP address of this entry. The value of the mask is an IP address with all the network bits configured to 1 and all the hosts bits configured to 0.
BcastAddrFormat	Shows the IP broadcast address format on this interface.
ReasmMaxSize	Shows the size of the largest IP datagram which this entity can reassemble from incoming IP fragmented datagrams received on this interface.
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spb-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
BrouterPort	Indicates whether this entry corresponds to a brouter port, as oppose to a routable VLAN.
MacOffset	Specifies the MAC offset value. Routable VLANS are assigned MAC addresses arbitrarily or by offset. Their MAC addresses are: <ul style="list-style-type: none"> • 24 bits: Vendor ID • 12 bits: Chassis ID • 12 bits: 0xA00-0xFFFF If you enter the MAC offset, the lowest 12 bits are 0xA00 plus the offset. If not, they are arbitrary.
VrfId	Associates the VLAN or brouter port with a VRF. VRF ID 0 is reserved for the administrative VRF.

Changing VLAN port membership

Modify VLAN port members to control access to the VLAN.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.
3. Double-click the **PortMembers** number for the VLAN for which you want to modify port membership.
4. Click the port members you wish to add or remove.
5. Click **Ok**.
6. Click **Apply**.

The VLAN port membership is changed.

Creating a protocol-based VLAN

Use a protocol-based VLAN so that the VLAN only carries certain traffic types.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. In the **Basic** tab, click **Insert**.
4. In the **Id** box, type the unique VLAN ID or use the ID provided.
5. In the **Name** box, type the VLAN name or use the name provided.
6. In the **Color Identifier** box, select the color or use the color provided.
This color is used to visually distinguish the VLANs in a network.
7. In the **MstpInstance** box, click the down arrow and choose an MSTI instance from the list.
8. In the **Type** box, select **byProtocolId**.
This activates additional fields needed to configure protocol-based VLANs.
9. To specify the VLAN port membership, click the button **(...)** for one of the following fields:

Port Members

OR

StaticMembers

OR

NotAllowToJoin

10. Click each port button to choose the desired membership color.
Yellow: Potential members—dynamic (potential members are treated as always members)
OR
Green: Always members—static
OR
Red: Never members—not allowed to join

Important

In a protocol-based VLAN, a potential member becomes an active member of the VLAN after a frame of the specified protocol is received.

11. Click **Insert**.

Configure Source MAC Addresses for a Source MAC-Based VLAN

Create a source MAC address for an existing source MAC VLAN.

Before You Begin

- Configure the VLAN.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Select **VLANs**.
3. In the **Basic** tab, select a source MAC address-based VLAN.
4. Select **Mac**.
5. To manually insert a MAC address, select **Insert**, and then enter it in the form nn:nn:nn:nn:nn:nn.
OR
6. To add a MAC address from a file, select **File, Add From File**.
7. Use the selection box to browse for the file location.
8. To save a MAC address to a file, select it, select **File, Save to File**, and then use the selection box to browse for a save location.
9. To delete a MAC address, select it, and then select **Delete Members On Device**.
10. Select **Yes**.
11. Select **Close**.

VLAN MAC field descriptions

Use the data in the following table to use the **VLAN MAC** tab.

Name	Description
MacAddr	Specifies the MAC addresses associated with this VLAN.

Creating a SPBM B-VLAN

Create a Shortest Path Bridging MAC (SPBM) Backbone VLAN (B-VLAN). Each SPBM network instance is associated with at least one backbone VLAN (B-VLAN) in the core SPBM network. This VLAN is used for both control plane traffic and dataplane traffic.

**Note**

As a best practice, configure two B-VLANs in an SPBM dual-homing environment.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. In the **Basic** tab, click **Insert**.
4. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
5. In the **Name** box, type the VLAN name, or use the name provided.
6. In the **Color Identifier** box, click the down arrow and choose a color from the list, or use the color provided.
7. In the **Type** box, select **spbm-bvlan**.
8. Click **Insert**.
9. Collapse the **VLANs** tab.
The VLAN is added to the **Basic** tab.

Configure Advanced VLAN Features

Use advanced VLAN features to configure the VLAN name, aging time, VLAN operation action, and QoS level. The VLAN Operation Action parameter can be useful for troubleshooting.

You can also configure a DvR Gateway IPv4 address on a VLAN, and enable DvR on it.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Advanced** tab.
4. Configure the parameters as required by double-clicking fields to make changes.
You cannot make changes to fields that are dim.
5. Select **Apply**.

Advanced Field Descriptions

Use the data in the following table to use the **Advanced** tab.

Name	Description
Id	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
Name	Specifies the name of the VLAN.
IfIndex	Specifies the logical interface index assigned to the VLAN.
Type	Specifies the type of VLAN: <ul style="list-style-type: none"> • byPort • byProtocolId • spbm-bvlan • private
Isid	Specifies the I-SID number assigned to a customer VLAN (C-VLAN). The range is 0 – 16777215. The default value is 0, which indicates that no I-SID is assigned.
Isid Name	Specifies the name of the I-SID.
Note: This field does not apply to all hardware platforms.	

Name	Description
ProtocolId	Specifies the network protocol for protocol-based VLANs. If the VLAN type is not protocol-based, None is displayed in the Basic tab ProtocolId field.
AgingTime	Specifies the timeout period for dynamic VLAN membership. A potential VLAN port is made ACTIVE after it receives a packet that matches the VLAN; if no such packet is received for AgingTime seconds, the port is no longer active. The default is 600.
MacAddress	Specifies the MAC address assigned to the virtual router interface for this VLAN. This field is relevant only after the VLAN is configured for routing. This MAC address is used as the Source MAC in routed frames and ARP replies.
Vlan Operation Action	<p>Performs an operation on the VLAN. The values are:</p> <ul style="list-style-type: none"> • none • flushMacFdb: Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN. • flushArp: Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN. • flushIp: Configures action to flushIp. This action removes the learned IP addresses from the forwarding table for the selected VLAN. • flushDynMemb: Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN and removes MAC addresses learned on those ports. • all: Configures action to all. This action performs all the supported actions; it does not perform the Snoop-related actions. <p>The default is none.</p>
Result	Specifies the result code after you perform an action.
NlbMode	Enables or disables Microsoft Network Load Balancing (NLB) operations on the VLAN. The default is disabled.
SpbMulticast	Enables or disables Multicast over Fabric Connect. The default is disabled.
SpbPimGatewayMulticast	Enables or disables SPB-PIM Gateway Multicast on a VLAN. The default is disabled.
RmonEnable	Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.

Name	Description
Ipv6FhsSnoopDhcpEnable	Enables or disables IPv6 dhcp snooping on a VLAN. The default is disabled.
Ipv6FhsNDInspectionEnable	Enables or disables neighbor discovery (ND) inspection on a VLAN. The default is disabled.
DvrEnable	Enables or disables DvR on a VLAN that is configured on the DvR Controller. The default is disabled. Note: You must enable DvR on every VLAN that is configured on a DvR Controller.
DvrGwIpv4Addr	Specifies the DvR gateway IPv4 address for a VLAN. Important: Ensure that you configure the same gateway IPv4 address on all Controllers in the DvR domain that belong to a VLAN.
DvrGwIpv4Onelp	Enables or disables the DvR One IP for a VLAN. The default is disabled (false).

Configure NLB Support

Use Microsoft Network Load Balancing (NLB) to share the workload among multiple clustering servers. For more information about software scaling capabilities, see [VOSS Release Notes](#).

Before You Begin

Ensure that the VLAN exists and has an associated IP address.

About This Task

Use the following procedure to configure NLB support on an IP interface to enable or disable NLB support. The default value is NLB support disabled.

Note

- SPBM supports Network Load Balancing (NLB) Unicast and Multicast modes.
- Static multicast ARP entries are not supported for NLB Unicast or NLB Multicast.
- Multicast MAC flooding is not supported for NLB.
- ARP entries for NLB server IP addresses do not age out when there is still client traffic coming to the NLB servers, even after the NLB servers are no longer reachable.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Select **VLANs**.

3. Select the **Advanced** tab.
4. In the row for the VLAN, double-click the value in the **NlbMode** column.
5. Select the appropriate value.
6. Select **Apply**.

Configuring a port to accept tagged or untagged frames

Configure a port to accept tagged or untagged frames.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **VLAN** tab.
5. To configure tagging on the port, select the **PerformTagging** check box.

This setting applies to all VLANs associated with the port.

Note

If the check box is selected, tagging is enabled. All frames sent from this port are tagged. If the check box is cleared, tagging is disabled. The port does not send tagged frames. The switch removes the tag before sending the frame out of the port.

6. To discard tagged frames on a port for which tagging is disabled, select **DiscardTaggedFrames**.
7. To discard untagged frames on a port for which tagging is enabled, select **DiscardUntaggedFrames**.
8. To designate a default VLAN to associate with a packet that does not match a policy-based VLAN, enter a VLAN ID in the **DefaultVLANId** box or use the default VLAN 1.
9. Click **Apply**.
10. Click **Close**.

Configuring untagging default VLAN on a tagged port

Configure an untagged default VLAN on a tagged port to separate untagged packets originating from a PC from the tagged packets originating from an IP phone.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **VLAN** tab.
5. Select **UntagDefaultVlan**.
6. In the **DefaultVlanId**, enter a default VLAN ID.
7. Click **Apply**.
8. Click **Close**.

Configuring SLPP globally

Enable the Simple Loop Prevention Protocol (SLPP) to detect a loop and automatically stop it.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **SLPP**.
3. Click the **Global** tab.
4. Select **GlobalEnable**.
5. In the **TransmissionInterval** box, type a value for the time interval for loop detection.
6. Click **Apply**.

Global field descriptions

Use the data in the following table to use the **Global** tab.

Name	Description
GlobalEnable	Activates or disables SLPP globally. The default is disabled.
TransmissionInterval	Configures the interval for which loop detection occurs. The interval is expressed in milliseconds in a range from 500–5000. The default value is 500.

Job aid

The following table provides the SLPP values.

Table 293: SLPP values

Enable SLPP	Setting
Access SMLT	Yes
Core SMLT	No
Primary switch	
Packet Rx threshold	5
Transmission interval	500 milliseconds (ms) (default)
Secondary switch	
Packet Rx threshold	50
Transmission interval	500 ms (default)

Configuring the SLPP by VLAN

Activate SLPP on a VLAN to enable forwarding of the SLPP packet over the VLAN. This configuration controls the boundary of SLPP-PDU transmission.

Before You Begin

- Enable SLPP globally before you configure it on a VLAN.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **SLPP**.
3. Click the **VLANS** tab.
4. Click **Insert**.
5. Click the **VlanId** ellipses (...).
6. Select the desired VLAN ID.
7. Click **Ok**.
8. Select **SlppEnable**.
9. Click **Insert**.

Insert VLANs Field Descriptions

Use the data in the following table to use the **Insert VLANs** dialog box.

Name	Description
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
SlppEnable	Activates SLPP on the selected VLAN. The SLPP packet transmission and reception process is active only if you enable the SLPP operation. If you disable the SLPP operation, the following occurs: <ul style="list-style-type: none"> • the system sends no SLPP packets • the system discards received SLPP packets The default is enabled.

Configuring the SLPP by port

Use SLPP on a port to avoid traffic loops on the port.

**Note**

To provide protection against broadcast and multicast storms, as a best practice, enable Rate Limiting for broadcast traffic and multicast traffic.

Before You Begin

- Enable SLPP globally before you configure it on a port.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.

2. Click **SLPP**.
3. Click the **Ports** tab.
4. Double-click the **PktRxThreshold** box for the desired port to edit the threshold value for packet reception.
5. Double-click the **SlppEnable** box for the desired port.
6. Select **true** to enable SLPP.
7. Click **Apply**.

Ports field descriptions

Use the data in the following table to use the **Ports** tab.

Name	Description
IfIndex	Specifies the interface index number for a port.
PktRxThreshold	Specifies the threshold for packet reception. Configure the SLPP packet receive threshold to a value (1- 500) that represents the number of received SLPP-PDUs to shut down the port. This variable is a port-level parameter, therefore if the port is tagged, SLPP-PDUs from the various VLANs increment this single threshold counter. The default is 1.
SlppEnable	Activates SLPP on the selected interface. The default is disabled.
IncomingVlanId	Shows the VLAN ID of the classified packet on a port disabled by SLPP.
SrcNodeType	Specifies the source node type of the received SLPP packet.
PktRxCount	Shows the total number of SLPP packets the port received.
TimeToClrPktRxCount	Specifies the timer to clear the SLPP receive counter. After you enable SLPP and the port receives SLPP PDUs, the timer starts. After the timer exceeds the configured value, the system resets the count to zero. The default is 21,600 seconds.
RemainingTimeToClrPktRxCount	Shows the time remaining before the SLPP receive counter is reset to zero.

Job aid

The following table provides the SLPP values.

Table 294: SLPP values

Enable SLPP	Setting
Access SMLT	Yes
Core SMLT	No

Table 294: SLPP values (continued)

Enable SLPP	Setting
Primary switch	
Packet Rx threshold	5
Transmission interval	500 milliseconds (ms) (default)
Secondary switch	
Packet Rx threshold	50
Transmission interval	500 ms (default)

Configuring the forwarding database timeout globally

Configure the forwarding database global timeout to age out dynamically learned forwarding information.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**
2. Click **VLANS**.
3. Click the **FdbAging** tab.
4. Type an interval, in seconds, for aging out dynamically learned forwarding information, or keep the default.
5. Click **Apply**.

FDB Aging field descriptions

Use the data in the following table to use the **FDB Aging** tab.

Name	Description
FdbAging	Specifies the timeout period for dynamically learned mac addresses on the vlan. The default value is 300.

Viewing VLAN forwarding database information

Perform this procedure to view forwarding database entries for all VLANs on the device.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.
3. In the VLANS tab, click the **Forwarding** tab.

Forwarding Field Descriptions

Use the data in the following table to use the **Forwarding** tab.

Name	Description
Vlanid	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
Address	Specifies a unicast MAC address for which the VLAN has forwarding or filtering information.
Status	Specifies the status of the VLAN. The values are: <ul style="list-style-type: none"> • other • invalid • learned • self • mgmt
Port	Specifies either a value of zero (0) or the port number of the port on which a frame having the specified MAC address was seen. A value of cpp indicates a self-assigned MAC address.
BMac	Shows the backbone MAC address if the entry is learned from a Shortest Path Bridging MAC (SPBM) network.
Cvid	Specifies the customer VID.

Viewing the Forwarding Database for a Specific VLAN

Use the forwarding database for VLANs to determine how the system forwards a received frame.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**
2. Click **VLANs**.
3. Select a VLAN.
4. Click **Bridge**.
5. Click the **Forwarding** tab and the VLAN forwarding database information is displayed.

Forwarding Field Descriptions

Use the data in the following table to use the **Forwarding** tab.

Name	Description
Vlanid	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
Address	Specifies a unicast MAC address for which the bridge has forwarding or filtering information.
Status	Specifies the status. Values include the following: <ul style="list-style-type: none"> self—one of the bridge addresses learned—a learned entry that is being used mgmt—a static entry
Port	Specifies either a value of zero (0) or the port number of the port on which a frame having the specified MAC address was seen. A value of cpp indicates a self-assigned MAC address.
Cvid	Identifies the customer VID for this interface.

Clearing learned MAC addresses by VLAN

Use the clear learned MAC addresses feature to flush the bridge forwarding database.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Advanced** tab.
4. Double-click in the **VLAN Operation Action** field.
5. Choose **FlushMacFdb** from the list.
6. Click **Apply**.

Clearing learned MAC addresses for all VLANs by port

Use the following procedure to clear all the forwarding database (FDB) for VLANs associated with this port.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.

4. In the Interface tab **Action** box, select **FlushMacFdb**.
5. Click **Apply**.
All learned MAC addresses are cleared from the forwarding database (FDB) for VLANs associated with this port.
6. Click **Close**.

Configuring static forwarding

Configure static forwarding to specify the group of ports that are allowed to forward frames.

Important

Entries are valid for unicast and for group/broadcast addresses.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Click **Bridge**.
6. In the Bridge, VLAN tab, click the **Static** tab.
7. Click **Insert**.
8. In the **MacAddress** box, enter a forwarding destination MAC address.
9. In the **Port** box, click the ellipsis button (...).
10. Select the port on which the frame is received.
11. Click **Ok**.
12. Click **Insert**.

Static field descriptions

Use the data in the following table to use the **Static** tab.

Name	Description
MacAddress	Specifies the destination MAC address in a frame to which the forwarding information for this entry applies. This object can take the value of a unicast address.
Port	Specifies the port number of the port on which the frame is received.

Name	Description
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
Status	Specifies the status of the VLAN.

Configure Limit Learning

Limit MAC address learning to limit the number of forwarding database (FDB) entries learned on a particular port to a user-specified value. After the number of learned forwarding database entries reaches the maximum limit, MAC learning stops at that port.

Procedure

1. On the Device Physical View tab, select one or more ports.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Select **General**.
4. Select the **Limit-Learning** tab.
5. Configure the parameters as required.
6. Select **Apply**.

Limit Learning field descriptions

Use the data in the following table to use the **Limit-Learning** tab.

Name	Description
PortNum	Shows the slot and port number to configure.
MaxMacCount	Configures the number of entries in the MAC table for the port that causes learning to stop. The default is 1024.
CurrentMacCount	Shows the number of entries currently in the MAC table for the port.
Enable	Enables or disables limit learning for the port. The default is disable.
MacLearning	Shows if MAC learning is enabled or disabled for the port.

VRF Lite provides secure customer data isolation.

VRF Lite Fundamentals

The switch supports what is termed as VRF Lite. Lite conveys the fact that the switch does not use Multiprotocol Label Switching (MPLS) for VRF; VRF Lite is a device virtualization feature, not a network-wide virtualization feature.

Use VRF Lite to offer networking capabilities and traffic isolation to customers that operate over the same node (router). Each virtual router emulates the behavior of a dedicated hardware router; the

network treats each virtual router as a separate physical router. In effect, you can perform the functions of many routers using a single platform that runs VRF Lite. The result is a substantial reduction in the cost associated with providing routing and traffic isolation for multiple clients.

With multicast virtualization for IPv4, the switch can function as multiple virtual multicast routers.

The following figure shows one platform acting as multiple virtual routers, each serving a different customer network.

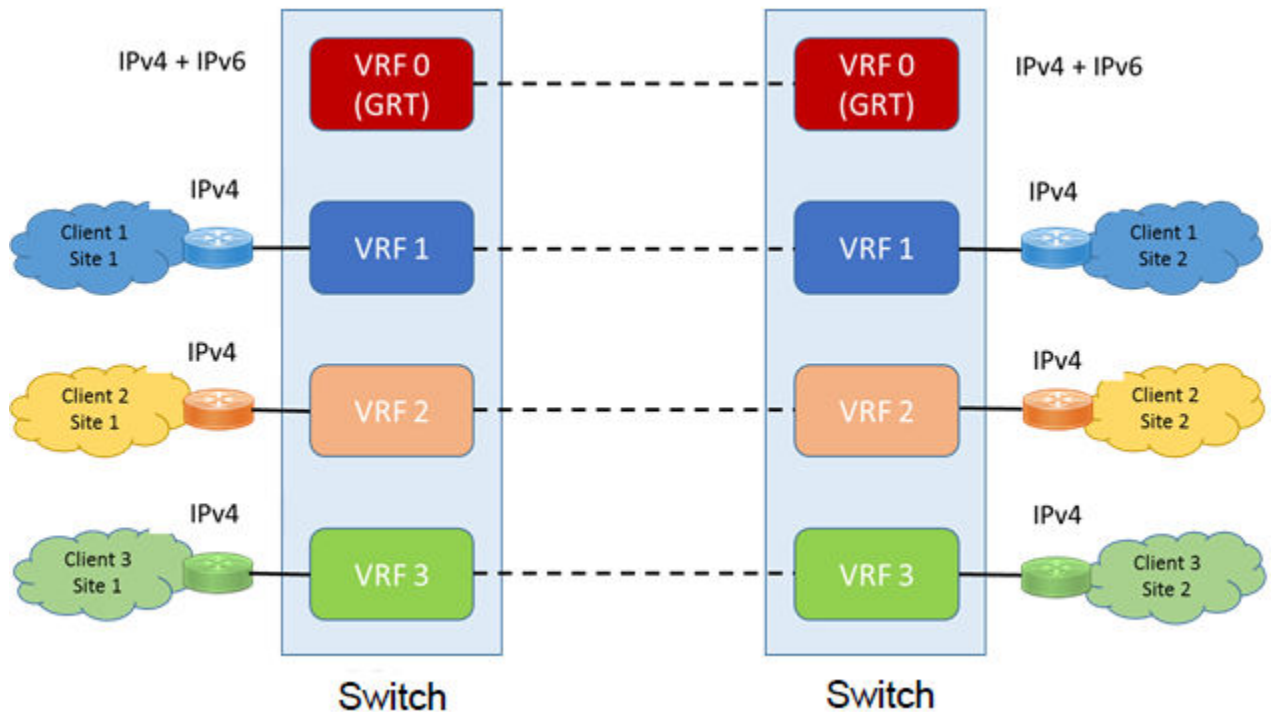

Figure 269: Multiple virtual routers in one system

A switch can support many virtual routers. Each virtual router instance is called a VRF instance. A VRF represents a single instance of a virtual router. Each instance maintains its own routing table. The term Multiple Virtual Router (MVR) is sometimes used to represent a router that contains many VRF instances.

The IPv6 Virtualization functionality adds IPv6 support on VRFs and Layer 3 VSNs. Each VRF instance has its own IPv6 interfaces, IPv6 address space, IPv6 routing table, and IPv6 global parameters. For more information on Layer 3 VSN, see [Layer 3 VSN Configuration](#) on page 1409.

The Global Router, VRF 0, is the first instance of the router. When the system starts, it creates VRF 0 by default. VRF 0 provides all non-virtual and traditional routing services. You cannot delete this instance. You can create and configure other VRF instances, if required.

VRF 0 is the only VRF that you can log into through CLI. CLI requires you to specify the VRF when you enter commands.

You can associate one VRF instance with many IPv4 or IPv6 interfaces. These interfaces are unique for each VRF instance. An interface is an entity with an IPv4 or IPv6 address that has the following characteristics:

- A unique association with a VLAN.
- A unique association with a brouter, if not associated with a VLAN
- A unique association with a circuit

A VLAN can only be associated with a single VRF instance.

Note

- You cannot associate a VLAN or port and a VRF instance if the VLAN or port has an IPv4 or IPv6 address. You must first associate the port and VRF instance and then you can configure the IPv4 or IPv6 address.
- Use the **boot config flag vrf-scaling** command, on supported switches, to increase the total number of supported VRFs. For more information on route scaling, see [VOSS Release Notes](#).

VRF Lite Capability and Functionality

VRF Lite supports virtualization of the following IPv4 and IPv6 protocols and features.

- IPv4 protocols or features:
 - ARP
 - BGP
 - Circuitless IP
 - DHCP
 - IGMP
 - RIP
 - Route policies
 - Route preferences
 - Router Discovery
 - Static routes
 - User Datagram Protocol (UDP)
 - VLAN
 - VRRP
- IPv6 protocols or features:
 - BGP
 - IPv6 Interfaces and IPv6 Static Routes
 - ECMP and Alternative Route
 - OSPF
 - Route redistribution for static and direct routes
 - VRRPv3
 - DHCP Relay
 - IPv6 Reverse Path Forwarding

- ICMP Ping & Traceroute
- ISIS Accept Policies

The switch uses VRF Lite to perform the following actions:

- Partition traffic and data and represent an independent router in the network
- Provide virtual routers that are transparent to end-users
- Support addresses that are not restricted to the assigned address space provided by host Internet Service Providers (ISP)
- Support overlapping IP address spaces in separate VRF instances

Note

If you enable multicast route redistribution between two VRFs, the switch does not support IP addresses that overlap within the two VRFs. The device does not generate an error if addresses overlap. You must avoid this situation.

VRF Lite interoperates with RFC 4364, Layer 3 VPNs. Split MultiLink Trunking (SMLT) and Routed SMLT (RSMLT) are also supported for VRF instances.

Although customer data separation into Layer 3 virtual routing domains is usually a requirement, sometimes customers must access a common network infrastructure. For example, they want to access the Internet, data storage, Voice over IP (VoIP)-public switched telephone network (PSTN), or call signaling services. To interconnect VRF instances, you can use an external firewall that supports virtualization, or use inter-VRF forwarding for specific services. With the inter-VRF solution, you can use routing policies and static routes to inject IP subnets from one VRF instance to another, and you can use filters to restrict access to certain protocols. The following figure depicts inter-VRF forwarding by the switch.

Figure 270: Inter-VRF forwarding

For more information about the latest VRF Lite scalability, see [VOSS Release Notes](#).

For configuration information about multicast virtualization, see [IP Multicast](#) on page 1456.

VRF Lite and inter-VRF route redistribution

The switch supports three route redistribution functions:

- Intra-VRF inter-protocol route redistribution (redistribution within the same VRF instance), for example, redistribute RIP to OSPF.
- Inter-VRF inter-protocol redistribution (redistribution between two VRF instances), for example, redistribute RIP in VRF 2 to OSPF in VRF 4.
- Inter-VRF static routes (for example, a static route in a given VRF instance) configured as a typical static route but with the added parameter of a next-hop-vrf (the next-hop IP address is found in the next-hop-vrf instance).

With inter-VRF route redistribution, a user in one VRF instance can access route data in other VRF instances. You can redistribute routes within a VRF instance or between VRF instances; for example, one VRF instance can redistribute routes to all other VRF instances. You can redistribute Local, static, OSPF, RIP, and BGP routes and both dynamic (OSPF, BGP, and RIP) and static route redistribution is supported.

More than one routing protocol can be present in each VRF instance. Route redistribution can occur either between different protocol types, or between the same protocol types on different VRF instances.

An interface uses redistribution to announce routes that are learned by other protocols (OSPF or BGP, for example). Control route redistribution by using route policies. When you associate routing policies with route redistribution, the policy is checked before the target protocol is updated. Across VRF instances, the policy is checked at the source VRF instance, so only qualified routes are added to the routing table.

You can use static route commands to inject one specific route (including a default route) from one VRF instance to another. The route is added to the target VRF instance, while the next hop is resolved by the next-hop VRF instance.

Static routes are used to direct packets from a given source using a next-hop IP address. The next-hop-vrf option in a static route permits this path to proceed from one VRF to another. Overlapping IP addresses are supported within VRFs, thus it is possible for two VRFs to have identical IP addresses.

The following list describes interVRF route redistribution:

- Redistributed routes are added to the target VRF instance, and their next hop remains in the source VRF instance.
- If either the source or destination VRF instance is deleted, the redistribution configuration is automatically deleted.
- Redistributed routes are not further redistributed to another VRF instance.
- Route redistribution is unidirectional. You must configure route redistribution for the reverse direction if you require it. You can configure different route policies for each direction.
- After you configure interVRF route redistribution between two VRF instances, you must avoid using overlapping IP addresses between these two VRF instances.

Avoid overlapping addresses; the device does not generate an error if addresses overlap.

- Intra-VRF routes take precedence over inter-VRF routes.
- You can physically connect two VRF instances to distribute route across VRF instances (in this case, you do not need to configure route redistribution).

Route Redistribution Operation

To perform redistribution, the device maintains a route change list. The change list contains all the best routes that are either added to or deleted from the forwarding table. When a best route is added to or deleted from the forwarding table, the change list is updated to reflect the change and notify registered protocols. The registered protocols pick up the change from the change list when it becomes available.

An example scenario of interVRF redistribution follows. To redistribute OSPF routes in VRF 1 to RIP in VRF 0:

- Create, enable, and apply a RIP redistribution instance. The source protocol is OSPF and the VRF source is VRF 1.
- When an OSPF route is added in VRF 1, the Routing Table Manager (RTM) in VRF 1 puts the new route into the change list.
- The device notifies RIP in VRF 0, because RIP is registered with the RTM of VRF 1 for OSPF route changes.
- To send OSPF routes from VRF 1 through the RIP interface in VRF 0, the interface uses a route policy with match VRF criterion of VRF 1.

The switch also supports inter-domain multicast routing. For more information, see [IP Multicast](#) on page 1456.

Port parameters and VRF Lite management

You can configure each VRF instance as a separate router, this means that you can configure different routing protocols and associated parameters for each instance. You can associate non0 VRF instances with ports.

The port parameters that you can edit for a VRF instance depend on whether the port belongs to only one, or more than one, VRF instance. For example, if a port belongs to only one VRF, you can edit the port parameters of the VRF. If a port belongs to more than one VRF instance, you cannot edit the port parameters of that port unless you are accessing the port through the Global Router with read-write-all access. If you do not have read-write-all access, you can only edit the GlobalRouter port parameters. If a port belongs to a single non0 VRF, the port parameters can be changed by this VRF. If a port belongs to multiple VRF instances, only a user with read-write-all access who is accessing the port through the Global Router can change this port configuration.

Management VRF

The following sections detail Management VRF features.

Management Port

The management port is a 10/100/1000 Mb/s Ethernet port that you can use for an out-of-band management connection to the switch.

**Note**

Not all hardware platforms provide a dedicated, physical management interface. For more information, see your hardware documentation.

Management Router VRF

**Note**

MgmtRouter is only supported on VSP 8600 Series.

The switch has a separate VRF called Management Router (MgmtRouter) reserved for the management port and the Virtual Management IP address. The configured IP subnet has to be globally unique because the management protocols, for example, SNMP, Telnet, and FTP, can go through in-band or out-of-band ports. The VRF ID for the Management Router is 512.

The switch never switches or routes transit packets between the Management Router VRF port and the Global Router VRF, or between the Management Router VRF and other VRF ports.

The switch honors the VRF of the ingress packet; however, in no circumstance does the switch allow routing between the Management VRF and Global Router VRF. The switch does not support the configuration if you have an out-of-band management network with access to the same networks present in the GRT routing table.

**Note**

IPv6 is not supported on MgmtRouter.

Non Virtualized Client Management Applications

**Note**

This section only applies to VSP 8600 Series.

Ensure that you do not define a default route in the Management Router VRF. A route used for non-virtualized client management applications, such as Telnet, Secure Shell (SSH), and FTP, originating from the switch, will always match a default route defined in the Management Router VRF.

If you want out-of-band management, as a best practice, define a specific static route in the Management Router VRF to the IP subnet where your management application resides.

When you specify a static route in the Management Router VRF, it enables the client management applications originating from the switch to perform out-of-band management without affecting in-band management. This enables in-band management applications to operate in the Global Router VRF.

Non-virtualized client management applications originating from the switch, such as Telnet, SSH, and FTP, follow the behavior listed below:

1. Look at the Management Router VRF route table.

2. If no route is found, the applications will proceed to look in the Global Router VRF table.

Non-virtualized client management applications include:

- DNS
- FTP client with the copy command
- NTP
- rlogin

Note

Rlogin is only supported on VSP 8600 Series.

- RADIUS authentication and accounting
- SSH
- SNMP clients in the form of traps
- SYSLOG
- TACACS+
- Telnet
- TFTP client

For management applications that originate outside the switch, the initial incoming packets establish a VRF context that limits the return path to the same VRF context.

Virtualized Management Applications

Virtualized management applications, such as ping and traceroute, operate using the specified VRF context. To operate ping or traceroute you must specify the desired VRF context. If not specified, ping defaults to the Global Router VRF. For example, if you want to ping a device through the out-of-band management port you must select the Management Router VRF. For example, if you want to ping a device through the out-of-band management port you must select the Management Router VRF.

Note

Ipv6 is not supported on MgmtRouter.

```
Switch:1(config)#ping 192.0.2.1 vrf MgmtRouter
192.0.2.1 is alive
```

Ping test for IPv6:

```
Switch:1(config)#ping 2001:db8::1 vrf vrfRED
2001:db8::1 is alive
```

Traceroute test for IPv4:

```
Switch:1#traceroute 192.0.2.1 vrf MgmtRouter
```

Traceroute test for IPv6:

```
Switch:1#traceroute 2001:db8::1 vrf vrfRED
```

VRF Lite Configuration Rules

You must select the VRF for global IPv4 or IPv6 options before entering commands; not all Global Router parameters are configurable on other VRF instances.

Layer 1 and Layer 2 information (including VLAN information) is global and is not maintained for each VRF instance. However, you can associate a set of VLANs with a VRF instance.

A VLAN cannot belong to more than one VRF instance at a time. When you create a VLAN, more than one physical port can belong to it. You can associate a VRF instance with more than one IPv4 or IPv6 interface (a physical Ethernet port or a VLAN).

Perform physical port assignment at the VLAN and brouter port level. A VRF instance inherits all the ports assigned to its VLANs and brouter ports. You cannot directly assign a physical port to a VRF instance, but it is implicitly assigned when you associate the VRF with VLANs or brouter ports.

For IPv4, after you configure interVRF route redistribution between two VRF instances, avoid overlapping IP addresses between these two VRF instances.

When you configure VRF Lite, remember the following rules:

- You can connect two VRFs from the same system with an external cable.
- An IPv4 or IPv6 routable VLAN can become a member of a VRF.
- An IPv4 or IPv6 interface can belong to only one VRF.
- A VRF can exist even if no interfaces are assigned to it.
- Routing policies apply to VRFs on an individual basis.
- Multiple VRFs on the same node can function in different autonomous systems.

Following rules apply to IPv4 interfaces specifically:

- If you configure an IPv4 interface without specifying the VRF instance, it is mapped to VRF 0 by default.
- VRF Lite supports SMLT and RSMLT.
- VRF Lite supports RIP in and out policies.
- VRF Lite supports OSPF in and out (accept and redistribute) policies.
- Before you delete a VRF instance, disable OSPF. Deleting a VRF instance deletes the OSPF instance if OSPF is disabled.
- When you create a VRF instance, an OSPF instance is not automatically created. To activate OSPF on a VRF instance, first create an OSPF instance, and then enable OSPF.
- You can configure a VRF so it can have IP interfaces with OSPF, RIP, static routes, and policies simultaneously.
- Every IPv4 interface is a member of VRF 0 unless explicitly defined to belong to another VRF.

VRF Lite configuration using the CLI

Use Virtual Router and Forwarding (VRF) Lite to provide many virtual routers using one switch.

This section shows you how to configure a VRF instance and how to associate ports and VLANs with VRF instances.

The following task flow shows you the sequence of procedures you perform to configure VRF Lite.

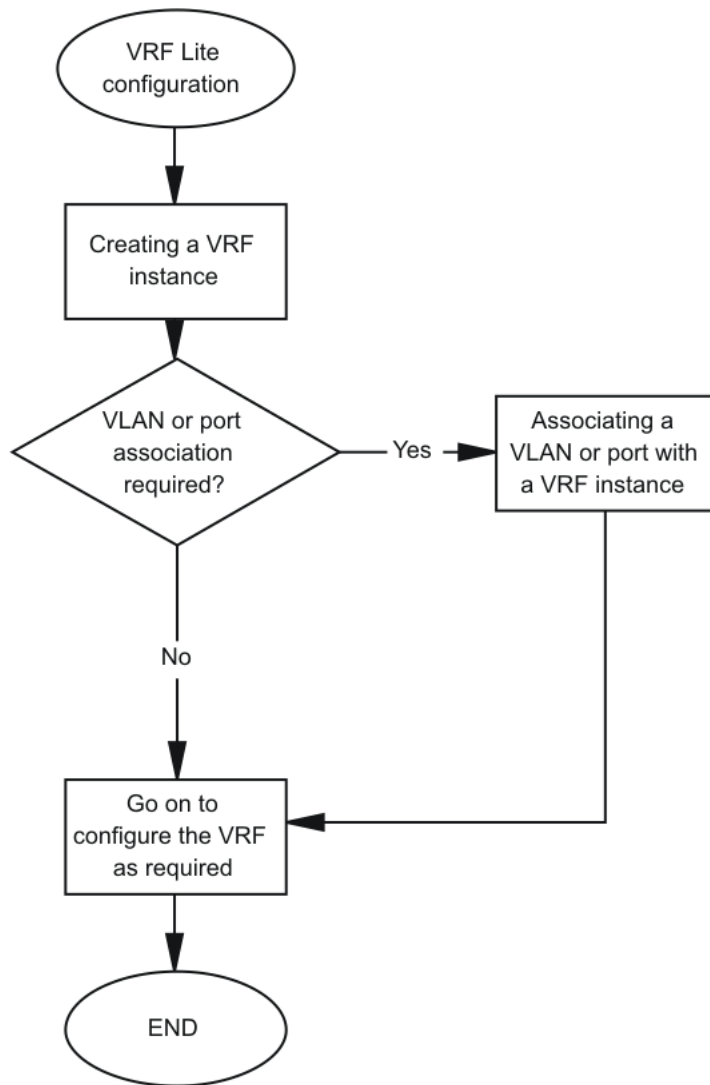

Figure 271: VRF Lite configuration procedures

Create a VRF Instance

About This Task

Create a VRF instance to provide a virtual routing interface for a user.

For more information on route scaling, see [VOSS Release Notes](#).

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Create a VRF instance and specify a VRF name:
`ip vrf WORD<1-16>`

3. Configure the maximum number of routes:

- For IPv4:

```
ip vrf WORD<1-16> max-routes <max-routes>
```

- For IPv6:

```
ip vrf WORD<1-16> ipv6-max-routes <max-routes>
```

4. Enable max-routes traps:

- For IPv4:

```
ip vrf WORD<1-16> max-routes-trap enable
```

- For IPv6:

```
ip vrf WORD<1-16> ipv6-max-routes-trap enable
```

Note

The maximum number of IPv6 routes for the Global Router are fixed and cannot be changed.

5. Enter VRF Router Configuration mode:

```
router vrf WORD<1-16>
```

6. Configure the IP routing protocol triggers for the VRF:

Use one of the following commands on your switch:

- `ip bgp`

`ip bgp` creates both ipv4 and ipv6 instances.

- `ip ospf`

Use `ipv6 ospf` to create an OSPFv3 instance.

- `ip rip`

RIPng is not virtualized, hence the IPv6 configuration does not apply here.

Note

You cannot configure BGP, OSPF, or RIP on a VRF instance unless you first configure the routing protocol trigger.

7. Ensure that the instance is configured correctly:

```
show ip vrf [WORD<1-16>]
```

Examples

Create a VRF instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip vrf vrfRED
```

Configure the maximum number of IPv4 routes and enable max-routes traps.

```
Switch:1(config)#ip vrf vrfRED max-routes 12000
Switch:1(config)#ip vrf vrfRED max-routes-trap enable
```

Enter Router Configuration mode and configure the routing protocol triggers for the VRF:

```
Switch:1(config)#router vrf vrfRED
Switch:1(router-vrf)#ip bgp
Switch:1(router-vrf)#ip ospf
Switch:1(router-vrf)#ip rip
```

To Configure OSPFv3 instance for the VRF:

```
Switch:1(config)#router vrf vrfRED
Switch:1(router-vrf)#ipv6 ospf
```

Exit to Global configuration mode:

```
Switch:1(router-vrf)#exit
```

Configure the maximum number of IPv6 routes and enable IPv6 max-routes traps.

```
Switch:1(config)#ip vrf vrfRED ipv6-max-routes 7700
Switch:1(config)#ip vrf vrfRED ipv6-max-routes-trap enable
```

Ensure that the instance is configured correctly:

```
Switch:1#show ip vrf vrfRED
=====

```

Variable Definitions

The following table defines parameters for the **ip vrf** command.

Variable	Value
Depending on your hardware platform: <i>max-routes</i> <max-routes>	Specifies the maximum number of IPv4 routes for the VRF. Depending on the hardware platform, the parameter range and default value can vary. Use the CLI Help to see the available range for the switch. For route scaling information, see VOSS Release Notes .
<i>ipv6-max-routes</i> <max-routes>	Specifies the maximum number of IPv6 routes for the VRF. Depending on the hardware platform, the parameter range and default value can vary. Use the CLI Help to see the available range for the switch. For route scaling information, see VOSS Release Notes .
<i>max-routes-trap enable</i>	Enables SNMP traps after the maximum number of IPv4 routes are reached.

Variable	Value
<code>ipv6-max-routes-trap enable</code>	Enables SNMP trap generation based on the configured number of maximum IPv6 routes. The default is enabled.
<code>name WORD<0-16></code>	Renames the VRF instance.
<code>vrf-trap</code>	Enables the device to send VRF-related traps.

The following table defines parameters for the **show ip vrf** command.

Variable	Value
<code>max-routes [vrfs WORD<0-512>] [WORD <1-16>]</code>	Displays the maximum number of routes for the specified VRFs. <ul style="list-style-type: none"> <code>vrfs WORD<0-512></code> specifies a list of VRFs by VRF IDs. <code>WORD<1-16></code> specifies a VRF by name.
<code>vrfs WORD<0-512></code>	Specifies a list of VRFs by VRF IDs.
<code>WORD<1-16></code>	Specifies a VRF by name.

Associating a VLAN or port with a VRF instance

You can assign a VRF instance to a port or VLAN. You cannot associate a VLAN or port and a VRF instance if the VLAN or port has an IP address. You can configure the IP address after you associate the port and VRF instance.

Before You Begin

- Ensure the VRF is already configured.

Procedure

- Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Associate the port or VLAN with a VRF instance:

```
vrf WORD<1-16>
```

Example

```
Switch:1> enable
Switch:1# configure terminal
```

Create a VRF named Two:

```
Switch:1(config-if)# ip vrf Two
```

Create a VLAN of type byport:

```
Switch:1(config-if)# vlan create 33 name vlan-30 type port-mstprstp 0
```

Enter VLAN Interface Configuration mode:

```
Switch:1(config-if)# interface vlan 33
```

Assign the VLAN to VRF Two:

```
Switch:1(config-if)# vrf Two
```

Give the VLAN an IP address:

```
Switch:1(config-if)# ip address 192.0.2.1 255.255.255.0
```

Enter VRF configuration mode:

```
Switch:1(config-if)# router vrf Two
```

Variable Definitions

Use the data in the following table to use the **vrf** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies the VRF instance by name.

Create an IP VPN Instance on a VRF

Create an IP VPN instance to advertise IP routes from one VRF to another across a Shortest Path Bridging MAC (SPBM) network.

Before You Begin

- The VRF must exist.

Procedure

- Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

- Create an IP VPN instance on the VRF:

```
ipvpn
```

- Assign a service instance identifier (I-SID) to the IP VPN:

```
i-sid <0-16777215>
```

- Enable IP VPN on the VRF:

```
ipvpn enable
```

By default, a new IP VPN instance is disabled.

- Display all IP VPNs:

```
show ip ipvpn [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

From Global Configuration mode, log on to Router VRF Configuration mode:

```
Switch:1(config)# router vrf red
```

Create the IP VPN instance:

```
Switch:1(router-vrf)# ipvpn
```

Enable IP VPN:

```
Switch:1(router-vrf)# i-sid 100
```

Enable IP VPN:

```
Switch:1(router-vrf)#ipvpn enable
```

```

=====
                        IPv4  IPVPN
=====
VRF Name          VRF ID   IPv4  IPVPN   IPv6  IPVPN   I-SID   I-SID Name
-----
red                1         enabled  disabled  100   ISID-1
-----
1 out of 1 Total active IPv4 L3 VSN displayed, including 0 active IPv6 L3 VSN.

```

Variable definitions

Use the data in the following table to use the **show ip ipvpn** command.

Variable	Value
<i>vrf</i> WORD<1-16>	Specifies the VRF name.
<i>vrfids</i> WORD<0-512>	Specifies the VRF ID.

Use the data in the following table to use the **i-sid** command.

Variable	Value
<i>i-sid</i> <0-16777215>	Assigns an I-SID to the VRF to configure. Use the no or default option to remove the I-SID to VRF allocation for this VRF.

Create an IPv6 VPN Instance**Before You Begin**

The VRF must exist.

About This Task

Create an IPv6 VPN instance to advertise IPv6 routes from a VRF to Shortest Path Bridging MAC (SPBM) network. For more information about Layer 3 Virtual Services Networks (VSNs) and SPBM, see [Layer 3 VSN Configuration](#) on page 1409.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```
2. Create an IPv6 VPN instance:

```
ipv6 ipvpn
```
3. Assign a service instance identifier (I-SID) to the IPv6 VPN:

```
i-sid <0-16777215>
```
4. Enable IPv6 VPN:

```
ipv6 ipvpn enable
```
5. Display all IPv6 VPNs:

```
show ipv6 ipvpn [vrf WORD<1-16> | vrfids WORD<0-512>]
```

Example

Create and enable IPv6 VPN instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrfred
Switch:1(router-vrf)#ipv6 ipvpn
Switch:1(router-vrf)#i-sid 100
Switch:1(router-vrf)#ipv6 ipvpn enable
Switch:1(router-vrf)#show ipv6 ipvpn
=====
                                IPv6 IPVPN
=====
VRF Name          VRF ID  IPv6 IPVPN  IPv4 IPVPN  I-SID      I-SID Name
-----
vrfred            2       enabled    disabled    5555      ISID-5555
-----
1 out of 1 Total IPv6 L3 VSN, 1 active IPv6 and 0 active IPv4 displayed.
```

Variable definitions

Use the data in the following table to configure the **ipv6 ipvpn** command.

Variable	Value
<i>enable</i>	Enables IPv6 IPVPN. The default is disabled.

Use the data in the following table to configure the **i-sid** command.

Variable	Value
<0-16777215>	Assigns an I-SID to the VRF being configured.

Use the data in the following table to configure the **show ipv6 ipvpn** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies the VRF name.
<code>vrfids WORD<0-512></code>	Specifies the VRF ID.

Configure the Maximum Number of VRFs

Perform this procedure to change the maximum number of VRFs and Layer 3 VSNs that the switch supports. Increasing the number of VRFs or Layer 3 VSNs can be useful in a WAN scenario or other large network.

The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [VOSS Release Notes](#).

About This Task

Important

If you enable this boot config flag, and the switch operates in SPBM mode (default configuration), the switch reduces the number of configurable VLANs. In such a configuration, the switch reserves VLANs 3500 to 3998 for internal use. You cannot use these VLANs as either platform VLANs or B-VLANs. You can still use the reserved VLAN range for customer VLANs (C-VLAN) on Flex UNI and B-VLANs on FE-VID.

Enabling the boot config flag to use more than 24 VRFs on VSP 8600 Series requires a license.

Before You Begin

- If the switch operates in SPBM mode, before you enable the boot config flag, perform the following actions:
 - Check in-VLAN filters. If a filter references a VLAN in the 3500 to 3998 range, you must delete the filter or the filter configuration fails when you restart the switch.
 - Delete VLANs in the 3500 to 3998 range.
- Before you disable the boot config flag on VSP 8600 Series, delete additional VRFs if more than 24 exist.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Increase the maximum number of VRFs and Layer 3 VSNs:

```
boot config flag vrf-scaling
```

OR
3. Verify the configuration:

```
show boot config flags
```

4. Save the configuration:

```
save config
```

5. Restart the switch for the change to take effect:

```
reset
```

Examples

Enable the boot config flag to increase the maximum number of VRFs and Layer 3 VSNs. In the following example, the switch operates in SPBM mode and reserves the VLAN ID range of 3500 to 3999. If the switch does not operate in SPBM mode, the system does not display the VLAN warning message when you enable VRF scaling.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flag vrf-scaling
Warning: Vlan 3500 to 3999 will be reserved for internal use.

Warning: Please save the configuration and reboot the switch
for this configuration to take effect.
```

Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags ha-cpu true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags linerate-directed-broadcast false
flags logging true
flags nni-mstp false
flags reboot true
flags rlogind false
flags savetostandby true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
flags vxlan-gw-full-interworking-mode false
```

The following example shows the message that the system displays if you try to enable the boot config flag and configured VLANs use IDs between 3500 and 3999.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flag vrf-scaling

Error: Delete all configured platform vlans between 3500 and 3999 to enable vrf-scaling.
```

Enabling IPv6 trap notifications

About This Task

Perform this procedure to enable SNMP traps when maximum number of IPv6 routes are reached.

Note

Different hardware platforms support different parameter ranges. Use the CLI Help to see the available range.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable max-routes trap:

```
ip vrf WORD<1-16> ipv6-max-routes-trap enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip vrf vrfRED ipv6-max-routes-trap enable
```

Variable definitions

Use the data in the following table to use the **ipv6-max-routes-trap** command.

Variable	Value
<i>enable</i>	Enables SNMP trap generation based on the configured number of maximum IPv6 routes. The default is enabled.

Displaying IPv6 max-routes information

About This Task

Perform this procedure to display the maximum IPv6 routes configured.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display max-routes information:

```
show ip vrf ipv6-max-routes [vrfids WORD<0-512> | WORD<1-16>]
```

Example

```
Switch:1#show ip vrf ipv6-max-routes

VRF Lite configuration using Enterprise Device Manager

Use VRF Lite to provide many virtual routers using a single switch.

Configuring a VRF instance

About This Task

Configure a VRF instance to provide a virtual routing interface for a user.

Note

The maximum routes of IPv4 and IPv6 for Global Router (GRT) are non-configurable and fixed at the system limits.

Maximum route traps are not generated on GRT. For non-default VRFs, the permitted maximum routes can be lower than system limits and traps generate when the limit is exceeded.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VRF**.
2. Click **VRF**.
3. Click the **VRF** tab.
4. Click **Insert**.
5. Specify the VRF ID.
6. Name the VRF instance.
7. Configure VRF Lite-related traps.
8. Configure the other parameters as required.
9. Click **Insert**.

VRF field descriptions

Use the data in the following table to help you use the **VRF** tab.

Name	Description
Id	Specifies the ID number of the VRF instance. VRF ID 0 is reserved for the GlobalRouter.
Name	Names the VRF instance.
ContextName	Identifies the VRF. The SNMPv2 Community String or SNMPv3 contextName denotes the VRF context and is used to logically separate the MIB port management.
TrapEnable	Enables the VRF to send VRF Lite-related traps (VrfUp and VrfDown). The default is enabled.
MaxRoutes	Configures the maximum number of routes allowed for the VRF, which varies depending on the hardware. For scaling information, see VOSS Release Notes . The default value varies for the GlobalRouter and non-default VRFs, depending on your hardware platform.
RpTrigger	Specifies the Routing Protocol (RP) triggers for the VRF. The triggers are used to initiate or shutdown routing protocols on a VRF. You can act upon multiple RPs simultaneously. You can also use this option to bring individual RPs up in steps.
MaxRoutesTrapEnable	Enables the generation of the VRF Max Routes Exceeded traps. The default is enabled.
Ipv6MaxRoutes	Configures the maximum number of IPv6 routes allowed for the VRF, which varies depending on the hardware. For scaling information, see VOSS Release Notes . The default value varies for the GlobalRouter and non-default VRFs, depending on your hardware platform.
Ipv6MaxRoutesTrapEnable	Enables SNMP trap generation after the maximum number of IPv6 routes are reached. The default is enabled.
Active	Displays if the VRF is active (true).

Associating a port to a VRF instance

About This Task

Associate a port to a Virtual Router Forwarding (VRF) instance so that the port becomes a member of the VRF instance.

You can assign a VRF instance to a port after you configure the VRF. The system assigns ports to the GlobalRouter, VRF 0, by default.

Procedure

1. In the **Device Physical** View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **General**.

4. Click the **VRF** tab.
5. To the right of the **BrouterVrflid** box, click the ellipsis (...) button.
6. In the **BrouterVrflid** dialog box, select the required VRF.
7. Click **OK**.
8. Click **Apply**.

VRF field descriptions

Use the data in the following table to use the **VRF** tab.

Name	Description
Vrflids	Shows the VRF ID.
VrfNames	Shows the VRF name.
VrfCount	Shows the number of VRFs to which the port is associated.
BrouterVrflid	Specifies the VRF ID for a brouter port.
BrouterVrfName	Shows the VRF name for a brouter port.

Associating an Extreme Integrated Application Hosting Port to a VRF Instance

About This Task

Perform this procedure to associate an Extreme Integrated Application Hosting (IAH) port to a Virtual Router Forwarding (VRF) instance.

Note

You can associate a VRF instance to an IAH port after you configure the VRF. By default, the IAH ports are associated to the GlobalRouter.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **VRF** tab.
4. (Optional) In the **VrfNames** field, select the **ShowAll** button to view the VRF instances the IAH Port is associated with.
5. In the **BrouterVrflid** field, select the ellipsis (...) button, and select the required VRF instance(s).
6. Select **Ok**.
7. Select **Apply**.

VRF Field Descriptions

Use data in the following table to use the **VRF** tab.

Name	Description
VrfIds	Shows the VRF ID.
VrfNames	Shows the VRF name.
VrfCount	Shows the number of VRFs to which the Extreme Integrated Application Hosting (IAH) port is associated with.
BrouterVrfId	Specifies the VRF ID for a brouter port.
BrouterVrfName	Shows the VRF name for a brouter port.

Configuring interVRF route redistribution policies

Configure interVRF route redistribution so that a VRF interface can announce routes that other protocols learn, for example, OSPF, RIP, or BGP. Use a route policy to control the redistribution of routes.

Before You Begin

- Ensure VRF instances exist.
- Configure route policies, if required.
- Change the VRF instance as required.

About This Task

Procedure

1. In the navigation tree, expand **Configuration > IP**.
2. Select **Policy**.
3. Select the **Route Redistribution** tab.
4. Select **Insert**.
5. Select the ellipsis (...) button near the **DstVrfId** box to select the source and destination VRF IDs.
6. Select the ellipsis (...) button near the **SrcVrfId** box to select the source and destination VRF IDs.
7. In the **Protocol** option box, select the protocol.
8. In the **RouteSource** option box, select the route source.
9. Select **Enable**.
10. Choose the route policy to apply to the redistributed routes.
11. Configure other parameters as required.
12. Select **Insert**.
13. Select the **Applying Policy** tab.
14. Select **RedistributeApply**.
15. Select **Apply**.

Route Redistribution field descriptions

Use the data in the following table to use the **Route Redistribution** tab.

Name	Description
DstVrflid	Specifies the destination VRF ID to use in the redistribution.
Protocol	Specifies the protocols for which you want to receive external routing information.
SrcVrflid	Specifies the source VRF ID to use in the redistribution.
RouteSource	Indicates if the protocol receives notification about the routes this source learns. The route source is equivalent to the owner in the routing table.
Enable	Enables or disables route redistribution. The default is disabled.
RoutePolicy	Specifies the route policies to apply to the redistributed routes from the source VRF. Use the route policy to determine whether the system advertises a specific route to the specified protocol.
Metric	Specifies the metric announced in advertisements. The default is 0.
MetricType	Specifies the metric type (applies to OSPF and BGP only). Specifies a type 1 or a type 2 metric. For metric type 1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type 2, the cost of the external routes is equal to the external cost alone. The default is type2.
Subnets	Indicates that all the subnets must be advertised individually. The values are allow(1), and suppress(2). The default value is allow. This variable applies to OSPF only.

Viewing router port and VRF associations

About This Task

You can view each port and associated VRFs. You can also change the VRFs associated with the port if the port has no IP address.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VRF**.
2. Click **VRF**.
3. Click the **VRF-Ports** tab.
4. To display the VRF names associated with a port, click a cell in one of the table rows and, on the toolbar, click the **ShowVRFNames** button.
5. To change the VRF, double-click the **BrouterVrflid** field for the port.

**Tip**

You can associate a port with more than one VRF.

6. Choose the required VRFs, and then click **Ok**.
7. Click **Apply**.

VRF-Ports field descriptions

Use the data in the following table to use the **VRF-Ports** tab.

Name	Description
Index	Specifies the slot and port.
Type	Specifies the port type.
VrflDs	Identifies the set of VRF IDs to which this port belongs.
VrfCount	Shows the number of VRF instances associated with this port.
BrouterVrflD	Shows the VRF ID for this brouter port.
BrouterVrfName	Shows the VRF name for this brouter port.
Show VrfNames	You can use this toolbar button to identify the set of VRF names to which a port belongs.

Use the data in the following table to use the **Show VrfNames** button.

Name	Description
Index	Specifies the slot and port.
VrfNames	Shows the VRF name for this brouter port.

Viewing global VRF status information

About This Task

View global VRF status information to determine the number of VRFs that are configured and active.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VRF**.
2. Click **VRF**.
3. Click the **Global Status** tab.

Global Status field descriptions

Use the data in the following table to use the **Global Status** tab.

Name	Description
ConfigNextAvailableVrflD	Specifies the number of the next available Virtual Router ID (index).
ConfiguredVRFs	Specifies the number of VRFs configured on this network element.
ActiveVRFs	Specifies the number of VRFs that are active on the network element. These are VRFs for which the OperStatus is up.

Viewing VRF instance statistics and status information

About This Task

View VRF instance status information to determine the operational status of each VRF, as well as other operational parameters.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VRF** .
2. Click **VRF**.
3. Click the **VRF Stats** tab.

VRF Stats field descriptions

Use the data in the following table to use the **VRF Stats** tab.

Name	Description
Id	Specifies the ID number of the VRF instance.
StatRouteEntries	Specifies the total number of routes for this VRF.
StatFIBEntries	Specifies the total number of Forwarding Information Base (FIB) entries for this VRF.
StatUpTime	Specifies the time in (in hundredths of a second) since this VRF entry has been operational.
OperStatus	Shows the operational status of the Virtual Router.
RouterAddressType	Specifies the router address type of this VRF.
Router Address	Specifies the router address of this VRF, derived from one of the interfaces. If a loopback interface is present, you can use the loopback interface address.

Viewing Statistics for a VRF

About This Task

View VRF statistics to ensure the instance is performing as expected.

Procedure

1. In the navigation pane, expand the **Configuration > VRF** folders.
2. Click **VRF**.
3. Click the **VRF** tab.
4. Select a VRF.
5. Click the **Stats** button.

Stats Field Descriptions

Use the data in the following table to use the **Stats** tab.

Name	Description
StatRouteEntries	Specifies the number of routes for this VRF.
StatFIBEntries	Specifies the number of Forwarding Information Base (FIB) entries for this VRF.

Select and Launch a VRF Context View

Use this procedure to open a VRF context view when you use EDM. GlobalRouter is the default view at log in. If you launch a VRF context view, EDM displays the VRF navigation in a new tab.

About This Task**Important**

If you log out from the GRT view, the system generates a warning: all tabs close and your session terminates. If you close a VRF view tab, you close only that view.

**Note**

The Set VRF Context view function is not available to users in a service provider deployment where only a tenant VRF view is assigned.

You can configure both Global Router (GRT) and Virtual Routing and Forwarding (VRF) instances when you launch a VRF context view. You can open five tabs for each EDM session.

Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Select **Set VRF Context View**.
3. Select the **VRF** tab.
4. Select a context to view.
5. Select **Launch VRF Context view**.

A new browser tab opens containing the selected VRF view

VRF field descriptions

Use the descriptions in the following table to use the **VRF** tab.

Name	Description
Id	Shows the unique VRF ID.
Name	Shows the name of the virtual router.
ContextName	Shows the SNMPv3 context name that denotes the VRF context and logically separates the MIB port management.

Create an IP VPN Instance on a VRF

Create an IP VPN instance to advertise IP routes from one VRF to another across a Shortest Path Bridging MAC (SPBM) network.

Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- The VRF must exist.

Procedure

- In the navigation tree, expand **Configuration > IP**.
- Select **IP-VPN**.
- Select the **VPN** tab.
- Select **Insert**.
- Select **[...]**, and then select a VRF from the list.
- Select **OK**.
- Select **Insert**.
By default, the new IP VPN instance is disabled.
- In the **Isid Number** column, double-click the **0** value, and then enter the service instance identifier (I-SID) to assign to the IP-VPN.
- In the **Enable** column, double-click the **disable** value.
- Select the arrow to view a list of choices, and then choose **enable**.
- Select **Apply**.

VPN Field Descriptions

Use the data in the following table to use the **VPN** tab.

Name	Description
Vrfid	Specifies the ID of the VRF to configure.
Enable	Enables or disables the IP VPN instance on the VRF. The default is disabled.
Isid Number	Specifies the I-SID to associate with the VPN. By default, no I-SID is assigned.
Isid Name Note: This field does not apply to all hardware platforms.	Specifies the name of the I-SID associated with the VPN.

Create an IPv6 VPN Instance on a VRF

Create an IPv6 VPN instance to advertise IPv6 routes from a VRF to Shortest Path Bridging MAC (SPBM) network.

Before You Begin

- You must configure the required SPBM IS-IS infrastructure.

- The VRF must exist.

Procedure

1. In the navigation tree, expand **Configuration > IPv6**.
2. Select **IPv6-VPN**.
3. Select the **VPN** tab.
4. Select **Insert**.
5. Select **[...]**, and then select a VRF from the list.
6. Select **OK**.
7. Select **Insert**.
8. In the **IsidNumber** column, double-click the **0** value, and then enter the service instance identifier (I-SID) to assign to the IPv6-VPN.
9. In the **Enable** column, double-click the value and select **true** or **false** from the drop-down list.
10. Select **Apply**.

VPN Field Descriptions

Use the data in the following table to use the **VPN** tab.

Name	Description
VrfId	Specifies the ID of the VRF to configure.
Enable	Enables or disables the IPv6 VPN instance on the VRF. The default is disabled.
IsidNumber	Specifies the I-SID to associate with the IPv6 VPN. By default, no I-SID is assigned.
IsidName Note: This field is not supported on all hardware platforms.	Specifies the name of the I-SID.

Configure the Maximum Number of VRFs

Perform this procedure to change the maximum number of VRFs and Layer 3 VSNs that the switch supports. By default, the switch supports 24 VRFs and Layer 3 VSNs. Increasing the number of VRFs or Layer 3 VSNs can be useful in a WAN scenario or other large network.

The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [VOSS Release Notes](#).

About This Task

Important

If you enable this boot config flag, and the switch operates in SPBM mode (default configuration), the switch reduces the number of configurable VLANs. In such a configuration, the switch reserves VLANs 3500 to 3998 for internal use. You cannot use these VLANs as either platform VLANs or B-VLANs. You can still use the reserved VLAN range for customer VLANs (C-VLAN) on Flex UNI and B-VLANs on FE-VID.

Enabling the boot config flag to use more than 24 VRFs requires a Premier or Premier + MACsec license.

Before You Begin

- If the switch operates in SPBM mode, before you enable this boot config flag, perform the following actions:
 - Check in-VLAN filters. If a filter references a VLAN in the 3500 to 3998 range, you must delete the filter or the filter configuration fails when you restart the switch.
 - Delete VLANs in the 3500 to 3998 range.
- Before you disable this boot config flag, delete additional VRFs if more than 24 exist.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **Boot Config** tab.
4. Perform one of the following actions:
 - a. To enable VRF scaling, select the **EnablevrfScaling** check box.
 - b. To disable VRF scaling, clear the **EnablevrfScaling** check box.

Note

This field does not apply to all hardware platforms.

5. Select **Apply**.
6. Restart the switch for the change to take effect.

VRRP Fundamentals

Because end stations often use a static default gateway IP address, a loss of the default gateway router causes a loss of connectivity to the remote networks.

The Virtual Router Redundancy Protocol (VRRP) (RFC 2338) eliminates the single point of failure that can occur when the single static default gateway router for an end station is lost. VRRP introduces a virtual IP address (transparent to users) shared between two or more routers that connect the common

subnet to the enterprise network. With the virtual IP address as the default gateway on end hosts, VRRP provides dynamic default gateway redundancy in the event of failover.

The VRRP router that controls the IP addresses associated with a virtual router is the primary router and it forwards packets to these IP addresses. The election process provides a dynamic transition of forwarding responsibility if the primary router becomes unavailable.

Note

The VRRP virtual IP address cannot be same as the local IP address of the port or VLAN on which VRRP is enabled.

In the following figure, the first three hosts install a default route to the R1 (virtual router 1) IP address and the other three hosts install a default route to the R2 (virtual router 2) IP address.

This configuration not only shares the load of the outgoing traffic, but it also provides full redundancy. If either router fails, the other router assumes responsibility for both addresses.

Figure 272: Virtual Router Redundancy Protocol configuration

For information about the number of supported VRRP interfaces, see the scaling information in [VOSS Release Notes](#).

The following terms are specific to VRRP:

VRRP router

a router running the VRRP protocol

Virtual router

an abstract object acting as the default router for one or more hosts, consisting of a virtual router ID and a set of addresses

Primary IP address

an IP address selected from the real addresses and used as the source address of packets sent from the router interface (The virtual primary router sends VRRP advertisements using this IP address as the source.)

Virtual primary router

the router that assumes responsibility to forward packets sent to the IP address associated with the virtual router and answer ARP requests for these IP addresses

Virtual router backup

the virtual router that becomes the primary router if the current primary router fails

When a VRRP router is initialized it sends a VRRP advertisement. The VRRP router also broadcasts a gratuitous ARP request that contains the virtual router MAC address for each IP address associated with the virtual router. The VRRP router then transitions to the controlling state.

In the controlling state, the VRRP router functions as the forwarding router for the IP addresses associated with the virtual router. The VRRP router responds to ARP requests for these IP addresses, forwards packets with a destination MAC address equal to the virtual router MAC address, and accepts only packets addressed to IP addresses associated with the virtual router, the router transitions to the backup state to ensure that all Layer 2 switches in the downstream path relearn the new origin of the VRRP MAC addresses.

In the backup state, a VRRP router monitors the availability and state of the primary router. The backup router does not respond to ARP requests and must discard packets with a MAC address equal to the virtual router MAC address. The backup router does not accept packets addressed to IP addresses associated with the virtual router. If a shutdown occurs, the backup router transitions back to the initialize state. If the primary router goes down, the backup router sends the VRRP advertisement and ARP request described in the preceding paragraph and transitions to the controlling state.

If an advertisement timer becomes active, the router sends an advertisement. If an advertisement is received with a 0 priority, the router sends an advertisement. The router transitions to the backup state in the following situations:

- If the priority is greater than the local priority
- If the priority is the same as the local priority and the primary IP address of the sender is greater than the local primary IP address

Otherwise, the router discards the advertisement. If a shutdown occurs, the primary router sends a VRRP advertisement with a priority of 0 and transitions to the initialize state.

Critical IP Address

Within a VRRP VLAN, one link can go down while the remaining links in the VLAN remain operational. Because the VRRP VLAN continues to function, a virtual router associated with that VLAN does not register a master router failure.

As a result, if the local router IP interface connecting the virtual router to the external network fails, this does not automatically trigger a master router failover.

**Note**

In this context, local implies an address from the same VRF as the IP interface where VRRP is being configured.

The critical IP address resolves this issue. If the critical IP address fails, it triggers a failover of the master router.

You can specify the local router IP interface uplink from the VRRP router to the network as the critical IP address. This ensures that, if the local uplink interface fails, VRRP initiates a master router failover to one of the backup routers.

In VRRP, the local network uplink interface on router 1 is shown as the critical IP address for router 1. As well, the same network uplink is shown as the critical IP address for router 2. Router 2 also requires a critical IP address for cases in which it assumes the role of the master router.

With the support of VRRP and the critical IP interface linked to VRRP, you can build reliable small core networks that provide support for converged applications, such as voice and multimedia.

**Note**

A Brouter port with a VLACP Critical IP address in a VRRP is supported.

VRRP and SMLT

The standard implementation of VRRP supports only one active master device for each IP subnet. All other VRRP interfaces in a network are in backup mode.

A deficiency occurs when VRRP-enabled switches use Split MultiLink Trunking (SMLT). If VRRP switches are aggregated into two Split MultiLink Trunk switches, the end host traffic is load-shared on all uplinks to the aggregation switches (based on the Multilink Trunk traffic distribution algorithm).

However, VRRP usually has only one active routing interface enabled. All other VRRP routers are in backup mode. Therefore, all traffic that reaches the backup VRRP router is forwarded over the vIST towards the master VRRP router. In this case, the vIST does not have enough bandwidth to carry all the aggregated traffic.

To resolve this issue, assign the backup router as the backup master router. The backup master router can actively load-share the routing traffic with a master router.

When the backup master router is enabled, the incoming host traffic is forwarded over the SMLT links as usual. When the backup master router is configured along with the critical IP interface and the critical IP interface goes down, the VRRP router transitions to be the backup router with the backup master state down. In this state, the VRRP router does not forward traffic.

VRRP Fast Hello Timers

You can configure the advertisement time interval (in seconds) between sending advertisement messages. This interval permits fast network convergence with standardized VRRP failover. However,

losing connections to servers for more than a second can result in missing critical failures. Customer network uptime in many cases requires faster network convergence, which means network problems must be detected within hundreds of milliseconds. Fast Advertisement Enable and Fast Advertisement Interval meet these requirements

Fast Advertisement Enable acts like a toggle device for the Advertisement Interval and the Fast Advertisement Interval. When Fast Advertisement Enable is enabled, the Fast Advertisement Interval is used instead of the Advertisement Interval.

The Fast Advertisement Interval is similar to the Advertisement Interval parameter except for the unit of measure and the range. The Fast Advertisement Interval is expressed in milliseconds and the range is from 200 to 1000 milliseconds. This unit of measure must be in multiples of 200 milliseconds, otherwise the system displays an error.

When you enable the fast advertisement interval, VRRP can communicate with other switch ports and networking products that have the same configuration.

Handling of IPv4 Layer 2 Unicast Packets at VRRP Backup Master

For VSP 8600 Series 6.2 and VOSS 7.1 releases and later, the handling of IPv4 Layer 2 unicast packets (for example, ARP Request/Reply) with the destination MAC as VRRP MAC has been modified on Backup-Master. These packets are now handled by VRRP Master only.

The Backup-Master forwards all IPv4 Layer 2 unicast packets to the Master and the Master VRRP sends an ARP reply only.

Processing of IP unicast packets (for example, ICMP packets to VRRP IP) or IPv4 routed packets (with destination MAC as VRRP MAC) on VRRP Backup-Master stays the same. For example, the VRRP Backup-Master replies to ICMP requests and routes Layer 3 routed packets to the destination and does not forward these packets to the Master when they arrive at the Backup-Master.

To reflect the above changes, the VRRP MAC entry on the Backup-Master now points to the Master instead of itself, and the ARP entry for VRRP IP on the backup-master points to local.

VRRP Guidelines

VRRP Guidelines

VRRP provides another layer of resiliency to your network design by providing default gateway redundancy for end users. If a VRRP-enabled router that connects to the default gateway fails, failover to the VRRP backup router ensures no interruption for end users who attempt to route from their local subnet.

Only the VRRP Master router forwards traffic for a given subnet. The backup VRRP router does not route traffic destined for the default gateway.

To enable both VRRP switches to route traffic, the switch software has an extension to VRRP, the BackupMaster, that creates an active-active environment for routing. If you enable BackupMaster on the backup router, the backup router no longer switches traffic to the VRRP Master. Instead the

BackupMaster routes all traffic received on the BackupMaster IP interface according to the switch routing table.

Figure 273: VRRP with BackupMaster

Stagger VRRP instances on a network or subnet basis. The following figure shows the VRRP Masters and BackupMasters for two subnets. For more information about how to configure VRRP using the Command Line Interface (CLI) and Enterprise Device Manager (EDM), see [VRRP Configuration Using the CLI](#) on page 3871 and [VRRP configuration using EDM](#) on page 3896.

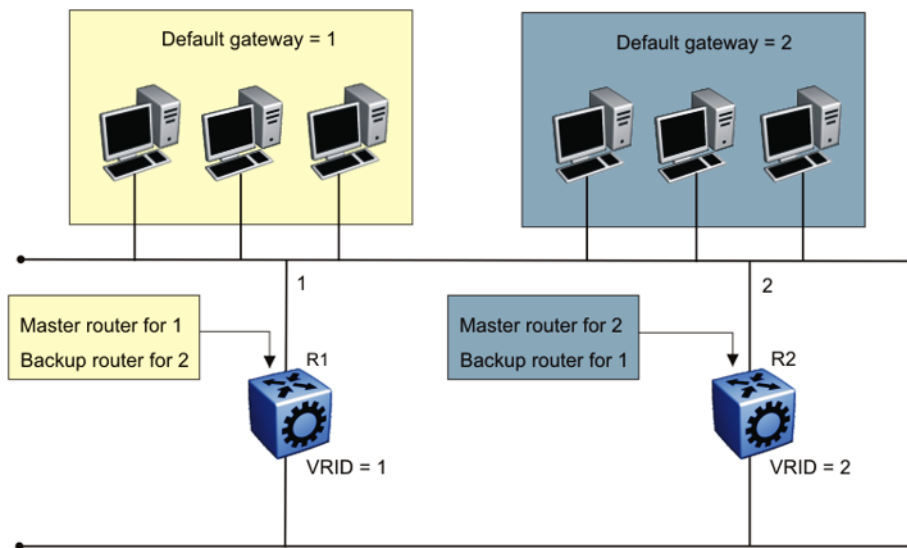

Figure 274: VRRP network configuration

The VRRP BackupMaster uses the VRRP standardized backup switch state machine. Thus, VRRP BackupMaster is compatible with standard VRRP.

Use the following best practices to implement VRRP:

- Do not configure the virtual address as a physical interface that is used on the routing switches. Instead, use a third address, for example:
 - Interface IP address of VLAN A on Switch 1 = x.x.x.2
 - Interface IP address of VLAN A on Switch 2 = x.x.x.3
 - Virtual IP address of VLAN A = x.x.x.1

Note

The switch software does not support a VRRP virtual IP address that is the same as the local physical address of the device.

- Configure the VRRP holddown timer with enough time that the Interior Gateway Protocol (IGP) routing protocol has time to update the routing table. In some cases, configuring the VRRP holddown timer to a minimum of 1.5 times the IGP convergence time is sufficient. For OSPF, as a best practice, use a value of 90 seconds if you use the default OSPF timers.

- Implement VRRP BackupMaster for an active-active configuration (BackupMaster works across multiple switches that participate in the same VRRP domain).
- Configure VRRP priority as 200 to configure VRRP Master.
- Stagger VRRP Masters between switches in the core to balance the load between switches.
- If you implement VRRP Fast, you create additional control traffic on the network and also create a greater load on the CPU. To reduce the convergence time of VRRP, the VRRP Fast feature allows the modification of VRRP timers to achieve subsecond failover of VRRP. Without VRRP Fast, normal convergence time is approximately 3 seconds.
- Do not use VRRP BackupMaster and critical IP at the same time. Use one or the other.

VRRP and spanning tree

The switch can use one of two spanning tree protocols: Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP).

VRRP protects clients and servers from link or aggregation switch failures. Configure the network to limit the amount of time a link is out of service during VRRP convergence. The following figure shows two possible configurations of VRRP and spanning tree; configuration A is optimal and configuration B is not.

Figure 275: VRRP and STG configurations

In this figure, configuration A is optimal because VRRP convergence occurs within 2 to 3 seconds. In configuration A, three spanning tree instances exist and VRRP runs on the link between the two routers. Spanning tree instance 2 exists on the link between the two routers, which separates the link between the two routers from the spanning tree instances found on the other devices. All uplinks are active.

In configuration B, VRRP convergence takes between 30 and 45 seconds because it depends on spanning tree convergence. After initial convergence, spanning tree blocks one link (an uplink), so only one uplink is used. If an error occurs on the uplink, spanning tree reconverges, which can take up to 45 seconds. After spanning tree reconvergence, VRRP can take a few more seconds to fail over.

VRRP for IPv6

For IPv6 hosts on a LAN to learn about one or more default routers, IPv6-enabled routers send router advertisements using the IPv6 ND protocol. The routers multicast these router advertisements every few minutes.

The ND protocol uses a mechanism called neighbor unreachability detection to detect the failure of a neighbor node (router or host) or the failure of the forwarding path to a neighbor. Nodes can monitor the health of a forwarding path by sending unicast ND neighbor solicitation messages to the neighbor node. To reduce traffic, nodes only send neighbor solicitations to neighbors to which they actively send traffic and only after the node receives no positive indication that the neighbors are up for a period of time. A host takes a minimum of 5 seconds to learn that a router is unreachable before it switches to another default router, but this minimum value increases ND traffic. This delay can cause service disruption.

VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol. With VRRP for IPv6, a backup router can take over for a failed default router in approximately three seconds (using default parameters). The switchover is accomplished without interaction with the hosts and with a minimum amount of VRRP traffic.

The IPv6 VRRP implementation is similar to the existing IPv4 VRRP operation, including support for holddown timer, critical IP, fast advertisements, and backup master. With backup master enabled, the backup switch routes all traffic according to its routing table. The backup master switch does not perform Layer 2 switching for the traffic to the VRRP master.

You must specify a link-local address to associate with the virtual router. Optionally, you can also assign global unicast IPv6 addresses to associate with the virtual router. Network prefixes for the virtual router are derived from the global IPv6 addresses assigned to the virtual router.

One active master switch exists for each IPv6 network prefix. All other VRRP interfaces in a network are in backup mode.

VRRP for IPv6 operation

VRRP uses a virtual IP address shared between two or more routers connecting the common network prefix to the enterprise network. With the virtual IP address as the default gateway on end hosts, VRRP provides dynamic default gateway redundancy in the event of failover.

The VRRP router with higher priority is called the master router. In case of equal priority the router with higher link-local address becomes the master router. The master router forwards packets sent to the virtual router IP addresses.

The following figure shows the minimum VRRP topology.

Figure 276: VRRP network topology

Traffic flows between users A and users B.

Router A uses VRRP global addresses as next hops for users B, and Router B for users A.

The VRRP master forwards the traffic and sends VRRP advertisements in the VLAN to announce to the backups that it is the master. If the master is no longer available, the backup takes over and becomes master. The only change occurs to the state of VRRP.

The VRRP router then transitions to the controlling state.

Note

The VRRP virtual IP address cannot be same as the local IP address of the port or VLAN on which VRRP is enabled.

In the controlling state, the VRRP router functions as the forwarding router for the IP addresses associated with the virtual router. The router responds to ND neighbor solicitation and ND router solicitation messages for these IP addresses, forwards packets with a destination MAC address equal to the virtual router MAC address, and accepts packets addressed to IP addresses associated with the virtual router.

If you initialize the VRRP router and the priority is not 255, the router transitions to the backup state to ensure that all Layer 2 switches in the downstream path relearn the new origin of the VRRP MAC addresses.

In the backup state, a VRRP router monitors the availability and state of the master router. The backup does not respond to ND neighbor solicitation and ND router solicitation messages for virtual router IP addresses and discards packets with a MAC address equal to the virtual router MAC address. The backup does not accept packets addressed to IP addresses associated with the virtual router. If a shutdown occurs, it transitions back to the initialize state. If the master router goes down, the backup router sends the VRRP advertisement and unsolicited ND neighbor advertisements and ND router advertisements described in the preceding paragraphs and transitions to the controlling state.

VRRP advertisements and master router failover

When you initialize a VRRP router, the master router continues to send advertisement messages at the advertisement interval period.

Note

The VRRP virtual IP address cannot be same as the local IP address of the port or VLAN on which VRRP is enabled.

The other VRRP routers transition to the backup state in the following situations:

- if the priority in the received advertisement is greater than the local priority
- if the priority in the received advertisement is the same as the local priority and the primary IP address of the sender is greater than the local primary IP address

The backup routers use the advertisements from the master router as a keepalive to monitor the health of the master router. If the backup router does not receive an advertisement during the master downtime interval, calculated as $3 * \text{advertisement interval}$, then the master router is declared down.

If a shutdown occurs, the master router sends a VRRP advertisement with a priority of 0 and transitions to the initialize state

The priority value 0 indicates that the master router has stopped participating in VRRP. This value triggers the backup router to transition to the master state without waiting for the current master to time out.

Critical IPv6 address and holddown timer

The critical IPv6 address is an interface that has primary impact on VRRP. If you enable critical IPv6 and the status of the critical IP changes, the master and backup relationship also changes.

If you configure and enable critical IPv6 address, the master transitions to backup if the critical IPv6 is down, and the backup becomes the master. After the critical IPv6 address of the original master resumes, if the hold-down timer is configured to 0, it becomes the master immediately. Otherwise, the original master transitions to the master state after the hold-down timer time out.

You can specify the local router IP interface uplink from the VRRP router to the network as the critical IP address. This ensures that, if the local uplink interface fails, VRRP initiates a master router failover to one of the backup routers.

The critical address can be one of the global unicast IPv6 addresses assigned to any local IPv6 interfaces.

The holddown timer is a proprietary enhancement to VRRP.

After a master transitions to backup by critical IP changing, one of the backup routers will be elected as the master router. After the critical IPv6 of the original master is restored, the original master remains in the backup state for a period of time that you configure by using the **holddown-timer** parameter.

The router becomes the master immediately if you use the command **ipv6 vrrp <1-255> action preempt**.

The holddown timer allows the master router enough time to detect and update the dynamic routes. The timer delays the preemption of the master over the backup, when the master becomes available. If the hold-timer is configured to 0, it becomes the master router immediately. Otherwise, it transitions to the master state only after the holddown timer times out.

The holddown timer does not apply during failovers caused by VRRP router priority change. The holddown timer applies only to failovers caused by a critical IP failure.

Configure all of your routers to use identical values for the holddown timer.

**Important**

Do not use VRRP backup master and critical IP at the same time. Use one or the other. The critical IP address must be a local address.

VRRP backup master with triangular SMLT

The standard implementation of VRRP supports one active master switch for each IPv6 subnet. All other VRRP interfaces in a network are in backup mode.

A deficiency occurs when VRRP-enabled switches use SMLT. If VRRP switches are aggregated into two SMLT switches, the end host traffic is load-shared on all uplinks to the aggregation switches (based on the Multilink Trunk [MLT] traffic distribution algorithm).

However, VRRP usually has only one active routing interface enabled. All other VRRP routers are in backup mode. Therefore, all traffic that reaches the backup VRRP router is forwarded over Virtual Inter-Switch Trunk (vIST) toward the master VRRP router. In this case, vIST potentially does not have enough bandwidth to carry all the aggregated traffic.

To resolve this issue, assign the backup router as the backup master router. The backup master router can actively load-share the routing traffic with a master router.

Because the two VRRP peer nodes exchange MAC address tables, the VRRP backup master can forward traffic directly, on behalf of the master router. The switch in the backup master state routes all traffic received on the backup master IP interface according to its routing table. The backup master switch does not perform Layer 2 switching for the traffic to the VRRP master.

If you enable SMLT on the backup master router, the incoming host traffic is forwarded over the SMLT links as usual.

**Important**

Do not use VRRP backup master and critical IP at the same time. Use one or the other.

Fast advertisement

You can configure the advertisement time interval (in seconds) between sending advertisement messages. This interval permits fast network convergence with standardized VRRP failover. However, losing connections to servers for more than a second can result in missing critical failures. Customer network uptime in many cases requires faster network convergence, which means network problems must be detected within hundreds of milliseconds.

To meet these requirements, the fast advertisement interval are provided.

The fast advertisement interval is similar to the advertisement interval parameter except for the unit of measure and the range. The fast advertisement interval is expressed in milliseconds and the range is from 200 to 1,000 milliseconds. This unit of measure must be in multiples of 200 milliseconds.

To configure fast advertisement, you must specify a fast advertisement interval and explicitly enable the fast advertisement option. After you enable fast advertisement, the fast advertisement interval is used instead of the advertisement interval.

If you enable fast advertisement, VRRP can only communicate with other products that have the same configuration.

Accept-mode

When you configure VRRP for IPv6 on an interface you can configure the `accept-mode` parameter, which controls whether the VRRP master or backup master accepts packets destined for the IPv6 address associated with the virtual router.

By default, `accept-mode` is disabled. The `accept-mode` parameter does not affect the Neighbor Discovery packets. The master router forwards packets with a destination link-layer MAC address that matches the virtual MAC address, and accepts packets forwarded over the virtual interswitch trunk (vIST) toward the master router, if `accept-mode` is enabled. If you disable `accept-mode`, you cannot ping the virtual IPv6 address. If you enable `accept-mode`, the master router accepts packets addressed to the IPv6 address that is associated with the virtual router.

When you configure VRRP for IPv6 on an interface, you can configure the `accept-mode` parameter. By default, `accept-mode` is disabled. If you disable `accept-mode`, the master router does not drop neighbor solicitations or neighbor advertisements. The master router forwards packets with a destination link-layer MAC address that matches the virtual MAC address. If you disable `accept-mode`, you cannot ping the virtual IPv6 address.

Note

The VRRP virtual IP address cannot be same as the local IP address of the port or VLAN on which VRRP is enabled.

VRRPv3

VRRPv3 is a combined protocol for both IPv4 and IPv6. It specifies an election protocol that dynamically assigns responsibility for a virtual router to one of the VRRP routers on a LAN. The VRRP router that controls the IPv4 or IPv6 addresses associated with a virtual router is called the Master, and it forwards packets sent to these IPv4 or IPv6 addresses. VRRP Backups wait for a Master and take ownership when the Master is no longer detected.

The election protocol provides dynamic failover in the forwarding responsibility when the Master is unavailable. VRRP for IPv4 gains a higher-availability default path without configuring dynamic routing

or router discovery protocols on every end-host. VRRP for IPv6 gains a quick switch-over to Backup routers compared to the standard IPv6 Neighbor Discovery mechanisms.

Note

The VRRP IPv6 link-local address must be the same for all VRRP routers sharing the same link and the same virtual router ID, that is, the same VRRP instance. It is the address the VRRP advertisements are sent from. Also, the Router Advertisement packets from the VRRP interface are transmitted using this address, so, when IPv6 Stateless Address Autoconfiguration is used, this address is added to host Default Router List and is used as a gateway.

The software supports VRRPv3 for IPv4 and VRRPv3 for IPv6. VRRPv3 for IPv6 is compliant to RFC 5798. The software also supports VRRPv2 for IPv4.

VRRPv3 guidelines

The switch also supports VRRPv2 for IPv4. If you configure VRRP IPv6 on an interface, it runs independently of the IPv4 version. Configure the version of the VRRP IPv4 on the interface before you configure any other IPv4 VRRP attributes. By default, the version is not configured to a particular value. However, when sourcing older configuration files that do not have the version saved, the router configures the version to VRRPv2 by default. If you change the version, all IPv4 configuration under that interface is automatically removed, and you are prompted for a confirmation before this operation.

Perform the CLI configuration through **ip vrrp** or **ipv6 vrrp** nodes; CLI commands for IPv4 are common for version 2 and version 3.

The following list identifies the features that make both IPv4 and IPv6 VRRPv3 features compliant to RFC 5798:

- Advertisement vs Fast-advertisement — Prior to RFC 5798, the minimum advertisement interval was 1 second, with Fast-advertisement a sub-second interval could be configured. When this feature is enabled, the VRRP ADVERTISEMENT packets are sent with type 7 instead of 1. With RFC 5798 the sub-second interval is standardised, and the switch sends all packets for VRRPv3 with type 1. The use of Fast-advertisement remains the same. VRRPv2 packets send with type 7, if Fast-advertisement is enabled.
- Add Master-advertisement-interval — Prior to RFC 5798 compliance, all virtual routers on the same VLAN had the same Advertisement-Interval configured. RFC 5798 states that you can use different Advertisement Intervals on the Master and Backup. On the Master, the Master-advertisement-interval and the Advertisement-Interval have the same value. On the Backup, the Master-advertisement-interval is used to calculate the timers, and the locally configured Advertisement-Interval is ignored until the Backup transitions to Master. The Master-advertisement-interval value is put in the advertisement packet type sent by the Master
- Transition to master as specified in RFC 5798 — Prior to RFC 5798, if a Backup receives an advertisement with a lower priority (or same priority but lower IP), it immediately sends its own advertisement and transitions to Master. However, RFC 5798 states that such packets must be discarded, which means it will transition to Master after the Master_Down_Timer expires
- Add skew-time — RFC 5798 states that skew-time is calculated depending on the priority, and Master-advertisement-interval assures that the Backup with highest priority sends the first advertisement when the Master goes down

Skew time is calculated using the formula: $((256 - \text{priority}) * \text{Master_Adver_Interval}) / 256$.

- Add preempt-mode — Preempt-mode is different from the **ipv6 vrrp <vrid> action preempt** command, which is an operational command issued when you want to stop the hold-down timer. RFC 5798 states that preempt-mode should be set to false when you do not want a higher priority Backup to transition to Master. By default, it is set to true

Note

Accept-mode is not fully implemented for IPv4 VRRPv3. You can only ping the virtual IP address, the same way as it is for IPv4 VRRPv2.

VRRP Configuration Using the CLI

One active master switch exists for each IP subnet. All other VRRP interfaces in a network are in backup mode.

Virtual Router Redundancy Protocol (VRRP) eliminates the single point of failure that can occur after the single static default gateway router for an end station is lost. VRRP introduces the concept of a virtual IP address shared between two or more routers connecting the common subnet to the enterprise network.

Note

The VRRP virtual IP address cannot be same as the local IP address of the port or VLAN on which VRRP is enabled.

Important

The switch, when it acts as a VRRP master, does not reply to Simple Network Management Protocol (SNMP) Get requests to the VRRP virtual interface address. However, if the switch acts as a VRRP master, and receives SNMP Get requests to its physical IP address, then it does respond.

The Simple Network Management Protocol (SNMP) provides facilities to manage and monitor network resources. An SNMP manager and agent communicate through the SNMP protocol. The manager sends queries and the agent responds. An SNMP Get request is a message that requests the values of one or more objects.

Note

The VRRP IP address responds only to ICMP-based traceroute requests. It does not respond to UDP-based traceroute requests.

When you use the fast advertisement interval option to configure a master and backup device, you must enable the fast advertisement interval option on both systems for VRRP to work correctly. If you configure one device with the regular advertisement interval, and the other device with the fast advertisement interval, it causes an unstable state and drops advertisements.

Configuring VRRP on a port or a VLAN

About This Task

Configure VRRP on a port or a VLAN to forward packets to the virtual IP addresses associated with the virtual router and customize the VRRP configuration.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a backup VRRP address:

```
ip vrrp address <1-255> <A.B.C.D>
```

3. Configure VRRP on a port:

```
ip vrrp <1-255> enable
```

4. Show the global VRRP configuration:

```
show ip vrrp
```

Example

```
Switch:1> enable  
Switch:1# configure terminal  
Switch:1(config)# interface gigabitethernet 1/2
```

Configure a backup VRRP address:

```
Switch:1(config-if)# ip vrrp address 28 192.0.2.1
```

Configure VRRP on a port:

```
Switch:1(config-if)# ip vrrp 28 enable
```

Show the global VRRP configuration:

```
Switch:1(config-if)# show ip vrrp
```

Variable definitions

Use the data in the following table to use the **ip vrrp** command.

Variable	Value
<i>1-255</i>	Specifies the number of the VRRP to create or modify.
<i>action {none preempt}</i>	<p>Causes the virtual router to disregard the timer and transition to Master state immediately, provided the hold-down timer is running.</p> <p>Note: You can use this parameter only if the hold-down timer is active.</p> <p>To set this option to the default value, use the default operator with this command.</p>
<i>action {none preempt}</i>	<p>Enables the choice option to manually override the hold-down timer and force preemption.</p> <p>You can configure <i>none preempt</i> to preempt the timer or configure it as <i>none</i> to allow the timer to keep working.</p> <p>To configure this option to the default value, use the default operator with this command.</p>
<i>address <1-255> <A.B.C.D></i>	<p>Configures the IP address of the VRRP physical interface that forwards packets to the virtual IP addresses associated with the virtual router.</p> <p><i>A.B.C.D</i> is the IP address of the master VRRP.</p> <p>Use the no operator to remove the IP address of the VRRP physical interface: <code>no ip vrrp address <1-255> <A.B.C.D></code>. To configure this option to the default value, use the default operator with this command.</p>
<i>adver-int <1-255></i>	<p>Configures the the time interval between sending VRRP advertisement messages. The range is between 1 and 255 seconds. This value must be the same on all participating routers. The default is 1.</p> <p>To configure this option to the default value, use the default operator with this command.</p>
<i>backup-master enable</i>	<p>Enables the VRRP backup master.</p> <p>Use the no operator to disable the VRRP backup master: <code>no ip vrrp <1-255> backup-master enable</code>. To configure this option to the default value, use the default operator with this command.</p> <p>When backup master functionality is enabled, the VRRP router will IP-forward packets destined to the VRRP MAC even when the router is not the VRRP Master.</p> <p>Important: Do not enable backup master if you enable critical IP.</p>

Variable	Value
<code>critical-ip-addr</code> <code><A.B.C.D></code>	Configures the critical IP address for VRRP. <i>A.B.C.D</i> is the IP address on the local router, which is configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding. Note: In this context, <i>local</i> implies an address from the same VRF as the IP interface where VRRP is being configured.
<code>critical-ip enable</code>	Enables the critical IP address option. Use the no operator to disable the critical IP address option: <code>no ip vrrp <1-255> critical-ip enable</code> . To configure this option to the default value, use the default operator with this command. Important: Do not enable Critical IP if backup master is enabled.
<code>enable</code>	Enables VRRP on the port. Use the no operator to disable VRRP on the port: <code>no ip vrrp <1-255> enable</code> . To configure this option to the default value, use the default operator with this command.
<code>fast-adv enable</code>	Enables the Fast Advertisement Interval. The default is disabled. Use the no operator to disable VRRP on the port: <code>no ip vrrp <1-255> fast-adv enable</code> . To configure this option to the default value, use the default operator with this command.
<code>fast-adv-int <200-1000></code>	Configures the Fast Advertisement Interval, the time interval between sending VRRP advertisement messages. <i>200-1000</i> is the range in milliseconds, and must be the same on all participating routers. The default is 200. You must enter values in multiples of 200 milliseconds. To configure this option to the default value, use the default operator with this command.

Variable	Value
<code>holddown-timer <0-21600></code>	<p>Specifies the time interval (in seconds) for which the transition of virtual router to Master state is delayed in case of the following conditions:</p> <ul style="list-style-type: none"> The VRRP hold-down timer runs only when the VRRP virtual router transitions from initialization to backup to master. This occurs only on a system startup. The VRRP hold-down timer does not run if the amount of time passed since VRRP virtual router initialization is greater than preset hold-down time. In such a case, VRRP virtual router transitions to Master happens irrespective of the hold-down timer. The VRRP hold-down timer also applies to the VRRP BackupMaster feature. <p><code>0-21600</code> is the time interval range (in seconds). To configure this option to the default value, use the default operator with this command. The default value for hold-down timer is 0, that is, the timer is disabled by default.</p>
<code>priority <1-255></code>	<p>Configures the port VRRP priority.</p> <p><code>1-255</code> is the value used by the VRRP router. The default is 100. Assign the value 255 to the router that owns the IP address associated with the virtual router.</p> <p>To configure this option to the default value, use the default operator with this command.</p>

Showing VRRP information

About This Task

Show VRRP port or VLAN information to view configuration details and operational status.

Procedure

- Enter Privileged EXEC mode:
`enable`
- Display basic VRRP configuration information about the specified port, all ports, or the VLAN:
`show ip vrrp address [vrid <1-255>] [addr <A.B.C.D>] [vrf WORD<1-16>] [vrfids WORD<0-512>]`
- Displaying the VRRPv3 configuration:
`show ip vrrp address version <2-3>`
- Displaying version based VRRP configuration for the specified VRF:
`show ip vrrp address vrf WORD<1-16> version <2-3>`
- Displaying version based VRRP configuration for the specified VRF ID:
`show ip vrrp address vrfids WORD<0-512> version <2-3>`

Example

```
Switch:1#show ip vrrp address
```

```
=====
```

```

Variable definitions

Use the data in the following table to use the **show ip vrrp address** command.

Variable	Value
<i>addr</i> <A.B.C.D>	Specifies the physical local address of the master VRRP.
<i>vrf</i> WORD<1-16>	Specifies the name of the VRF.
<i>vrid</i> <1-255>	Specifies a unique integer value that represents the virtual router ID in the range 1–255. The virtual router acts as the default router for one or more assigned addresses.
<i>vrfids</i> WORD<0-512>	Specifies the ID of the VRF and is an integer in the range of 0–512.
<i>version</i> <2-3>	Specifies the VRRP version (2 or 3) to be shown.

Use the data in the following table to interpret the **show ip vrrp address** command output.

Table 298: Field descriptions

Name	Description
ADV	Indicates the Advertisement Interval, in seconds, between sending advertisement messages.
BACKUP MASTER	Indicates if the Backup-Master feature is disabled or enabled.
BACKUP MASTER STATE	Indicates if the Backup-Master is up. If the switch is in Master state but Backup-Master is enabled, then the BACKUP MASTER STATE will be down.

Table 298: Field descriptions (continued)

Name	Description
CONTROL	Indicates the virtual router function. Configure the value to enabled to transition the state of the router from initialize to backup. Configure the value to disabled to transition the router from master or backup to initialize.
CRITICAL IP	Indicates the IP address of the interface that is critical to VRRP. If that IP interface is down, the VRRP state will transition to Backup, even if it has higher priority.
CRITICAL IP (ENABLED)	Indicates if the critical IP feature is enabled.
FAST ADV	Indicates the Fast Advertisement Interval, in milliseconds, between sending advertisement messages. When the Fast Advertisement Interval is enabled, the Fast Advertisement Interval is used instead of the regular advertisement interval.
FAST ADV (ENABLED)	Indicates the state of fast advertisement.
HLD DWN	Specifies the time interval (in seconds) the Hold-down timer has until it expires. If the value is 0, it means the Hold-down timer is not running. This timer will delay the transition from Backup to Master only on a system startup (the VRRP comes from INIT to Backup and determines it should become Master). <ul style="list-style-type: none"> • The VRRP hold-down timer runs when the system transitions from initialization to backup to master. This occurs only on a system startup • The VRRP hold-down timer does not run under the following condition: In a nonstartup condition, the backup system becomes master after the Master Downtime Interval (3 * hello interval), if the master virtual router goes down • The VRRP hold-down timer also applies to the VRRP BackupMaster feature
IP	Indicates the assigned IP addresses that a virtual router backs up.
MAC	Indicates the virtual MAC address of the virtual router in the format 00-00-5E-00-01-<vrrpid>, where the first three octets consist of the IANA OUI; the next two octets indicate the address block of the VRRP protocol; and the remaining octets consist of the vrrpid.
MASTER	Indicates the master router real (primary) IP address.
PRIO	Indicates the priority for the virtual router with respect to other virtual routers that are backing up one or more associated IP addresses. Higher values indicate higher priority. A priority of 255 cannot be configured and it is set for the VRRP router that has the same IP as the physical IP addresses (is Address Owner).
P/V	Indicates the P(ort)/V(lan) on which the VRRP was configured.
STATE	Indicates the current state of the virtual router. initialize—waiting for a startup event backup—monitoring the state or availability of the master router master—forwarding IP addresses associated with this virtual router.
UP TIME	Indicates the time interval since this virtual router exited the INIT state.

Table 298: Field descriptions (continued)

Name	Description
VRRP ID	Indicates the virtual router ID on a VRRP router.
VERSION	Indicates the VRRP version.

Showing extended VLAN VRRP

Perform this procedure to display the extended VRRP configuration for all VLANs or a specified VLAN on the device.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Show the extended VRRP configuration for all VLANs on the device or for the specified VLAN:

```
show ip vrrp interface vlan [<1-4059>] [portList] verbose [vrf WORD<1-16>] [vrffids WORD<0-512>]
```

Example

```
Switch:1#show ip vrrp interface vlan
=====
                                Vlan Vrrp
=====
VLAN VRF          VRRP IP          VIRTUAL
ID  NAME          ID  ADDRESS         MAC ADDRESS
-----
200 GlobalRouter  17  9.9.9.42        00:00:5e:00:01:11

All 1 out of 1 Total Num of Vlan Vrrp displayed
```

Variable definitions

Use the data in the following table to use the **show ip vrrp interface vlan** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<i>portList</i>	Specifies the slot or port number of a range of ports.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies the name of the VRF.
<code>vrfids WORD<0-512></code>	Specifies the ID of the VRF and is an integer in the range of 0-512.

Use the data in the following table to use the **show ip vrrp interface vlan [<1-4059>] [portList] verbose [vrf WORD<1-16>] [vrfids WORD<0-512>]** command output.

Variable	Value
VLAN ID	Indicates the VLAN ID.
STATE	Indicates the current state of the virtual router. <ul style="list-style-type: none"> initialize—waiting for a startup event backup—monitoring the state or availability of the master router master—forwarding IP addresses associated with this virtual router
CONTROL	Indicates the virtual router function. Configure the value to enabled to transition the state of the router from initialize to backup. Configure the value to disabled to transition the router from master or backup to initialize.
PRIORITY	Indicates the priority for the virtual router (for example, master election) with respect to other virtual routers that are backing up one or more associated IP addresses. Higher values indicate higher priority. A priority of 0, which you cannot configure, indicates that this router ceased to participate in VRRP and a backup virtual router transitions to become a new master. Use a priority of 255 for the router that owns the associated IP addresses.
MASTER IPADDR	Indicates the master router real (primary) IP address. The master IP address is listed as the source in the VRRP advertisement last received by this virtual router.
ADVERTISE INTERVAL	Indicates the time interval, in seconds, between sending advertisement messages. Only the master router sends VRRP advertisements.
CRITICAL IPADDR	Indicates the IP address of the interface that causes a shutdown event.
HOLDDOWN_TIME	Indicates the configured time (in seconds) that the system waits before it preempts the current VRRP master.
ACTION	Indicates the trigger for an action on this VRRP interface. Options include none and preemptHoldDownTimer.
CRITICAL IP ENABLE	Indicates that a user-defined critical IP address is enabled. No indicates the use of the default IP address (0.0.0.0).
BACKUP MASTER	Indicates the state of designating a backup master router.
BACKUP MASTER STATE	Indicates the state of the backup master router.
FAST ADV INTERVAL	Indicates the time interval, in milliseconds, between sending Fast Advertisement messages. When the Fast Advertisement Interval is enabled, the Fast Advertisement Interval is used instead of the regular advertisement interval.
FAST ADV ENABLE	Indicates the Fast Advertisement Interval status.

Showing VRRP interface information

About This Task

If you enter a virtual router ID or an IP address when showing VRRP interface information, the system displays the information only for that virtual router ID or for that interface.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display VRRPv3 information about the specified interface:
show ip vrrp interface version <2-3>
3. Display additional VRRPv3 information about the specified interface:
show ip vrrp interface verbose version <2-3>
4. Display VRRPv3 information for the specified VRF:
show ip vrrp interface vrf WORD<1-16> version <2-3>
5. Display VRRPv3 information for the specified virtual router:
show ip vrrp interface vrfids WORD<0-512> [version <2-3>]

Example

```
Switch:1#show ip vrrp interface

Variable definitions

Use the data in the following table to use the **show ip vrrp interface** command.

Variable	Value
<i>gigabitethernet {slot/port[-slot/port]}[,...]</i>	Specifies to show the VRRP information of which interface.
<i>verbose</i>	Specifies to show all available information about the VRRP interfaces.
<i>vlan</i>	Specifies the VLAN that contains the VRRP.
<i>vrf WORD<1-16></i>	Specifies the name of the VRF.
<i>vrid <1-255></i>	Specifies a unique integer value that represents the virtual router ID in the range 1-255. The virtual router acts as the default router for one or more assigned addresses.

Variable	Value
<code>vrfids WORD<0-512></code>	Specifies the ID of the VRF and is an integer in the range of 0-512.
<code>version<2-3></code>	Specifies the VRRP version (2 or 3) configured.

Viewing IP VRRPv3 Statistics

Use the following procedure to view IP VRRPv3 statistics to monitor network performance.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Enter the following command to view VRRP statistics:
`show ip vrrp statistics version <2-3>`
3. Enter the following command to view VRRP statistics for the specified VRF:
`show ip vrrp statistics vrf WORD<1-16> version <2-3>`
4. Enter the following command to view VRRP statistics for the specified virtual router:
`show ip vrrp statistics vrfids WORD<0-512> version <2-3>`

Example

View IP VRRPv3 statistics:

```
Switch:1#show ip vrrp statistics

```

VRRP ID	P/V	AUTHTYPE_ERR	PACKLEN_ERR	VERSION
3	3	0	0	2
2	1/1	0	0	3

Variable Definitions

Use the data in the following table to use the **ip vrrp version** command.

Variable	Value
<i>version</i>	Configures the VRRP version on the specified interface.
<2-3>	Specifies the version of VRRP (2 or 3) to be configured on the specified interface.
<i>vrf WORD<1-16></i>	Specifies the name of the VRF.
<i>vrfids WORD<0-512></i>	Specifies the ID of the VRF, and is an integer in the range of 0-512.

Enable Ping to a Virtual IP Address

Use the following procedure to enable ping to a virtual IP address. The default is enabled.

Procedure

- Enter VRRP Router Configuration mode:

```
enable

configure terminal

router vrrp
```
- Enable ping to a virtual IP address:

```
ping-virtual-address enable [vrf WORD<1-16>]

default ping-virtual-address enable [vrf WORD<1-16>]
```
- Display the configuration:

```
show ip vrrp [vrf WORD<1-16>]
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrrp
Switch:1(config-vrrp)#ping-virtual-address enable vrf mgmtrouter
Switch:1(config)#show ip vrrp vrf mgmtrouter

=====
VRRP Global Settings - VRF mgmtrouter
=====
ping-virtual-address : enabled
send-trap : enabled
```

Variable definitions

Use the data in the following table to use the `ping-virtual-address enable` and `show ip vrrp` commands.

Variable	Value
<code>enable</code>	Enables ping to a virtual IP address.
<code>vrf WORD<1-16></code>	Specifies the VRF.

Configure VRRP Notification Control

Use the following procedure to enable VRRP notification control. The generation of SNMP traps for VRRP events is enabled, by default.

About This Task

You can configure traps by creating SNMPv3 trap notifications, creating a target address to send the notifications, and specify target parameters. For more information about how to configure trap notifications, see [Logs and Traps](#) on page 2260.

Procedure

1. Enter VRRP Router Configuration mode:

```
enable

configure terminal

router vrrp
```
2. Enable a trap for VRRP events:

```
send-trap enable [vrf WORD<1-16>]
```
3. Disable a trap for VRRP events:

```
no send-trap enable [vrf WORD<1-16>]
```
4. Configure a trap for VRRP events to the default:

```
default send-trap enable [vrf WORD<1-16>]
```
5. Display the configuration:

```
show ip vrrp [vrf WORD<1-16>]
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrrp
Switch:1(config-vrrp)#send-trap enable vrf mgmtrouter
Switch:1(config)#show ip vrrp vrf mgmtrouter

=====
VRRP Global Settings - VRF mgmtrouter
=====
ping-virtual-address : enabled
send-trap : enabled
```

Variable definitions

Use the data in the following table to use the **send-trap** and **show ip vrrp** commands.

Variable	Value
<code>enable</code>	Enables generation of SNMP traps.
<code>vrf WORD<1-16></code>	Configures the send-trap for a particular VRF.

Configuring VRRP version on an interface

About This Task

Use the following command to configure the VRRP version on an interface.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Use the following command to configure the VRRP version:
3. Use the following command to set the VRRP version to default:

```
ip vrrp version <2-3>
```

```
default ip vrrp version
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/2
```

Configure VRRP version for the specified interface:

```
Switch:1(config-if)# ip vrrp version 3
```

Variable definitions

Use the data in the following table to use the **ip vrrp version** command.

Variable	Value
<code>version <2-3></code>	Configures the VRRP version (2 or 3) on the specified interface

Enabling IPv4 VRRP preempt-mode

You can configure VRRP to preempt the existing router. If a new VRRP router is added to the network with a higher priority than the existing routers, then the new router becomes the master. If preempt-mode is disabled, then the new router does not become a master, it transitions to master only when the current master is down, that is when it does not receive any advertisement packets from the current master. By default, preempt-mode is enabled.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enter the following command:

```
ip vrrp <vrid> preempt-mode enable
```

3. Use the following command to set the preempt-mode to its default value:

```
default ip vrrp <vrid> preempt-mode
```

4. Use the following command to disable the preempt-mode:

```
no ip vrrp <vrid> preempt-mode enable
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/2
```

Enabling preempt-mode on interface 1/2:

```
Switch:1(config-if)# ip vrrp 1 preempt-mode enable
```

Variable definitions

Use the data in the following table to use the **ip vrrp <vrid>** command.

Variable	Value
<i>preempt-mode enable</i>	Enables preempt-mode for VRRPv3 for IPv4.
<i>default ip vrrp <vrid> preempt-mode</i>	Sets the default preempt-mode value for VRRPv3 for IPv4.
<i>no ip vrrp <vrid> preempt-mode enable</i>	Disables preempt-mode for VRRPv3 for IPv4.

IPv6 VRRP Configuration using CLI

Configuring the VRRP interface

Configure VRRP to provide fast failover of a default router for IPv6 LAN hosts, in order to create a VRRP instance.

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.
- You must specify a link-local address to associate with the virtual router.

About This Task

VRRP supports a virtual IPv6 address shared between two or more routers that connect the common subnet to the enterprise network.

VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol.

Perform this procedure to also configure the additional addresses for which the virtual router acts as a backup.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Associate an address with the virtual router for either link-local or global:

- `ipv6 vrrp address <1-255> link-local WORD <0-127>`
- `ipv6 vrrp address <1-255> global WORD <0-255>`

Note

You must configure the link-local address before you configure the global address.

3. Enable VRRP for the interface:

```
ipv6 vrrp <1-255> enable
```

Example

Associate a link-local address with the virtual router ID 12:

```
Switch:1(config-if)#ipv6 vrrp address 12 link-local fe80::1234
```

Associate a global address with the virtual router ID 12

```
Switch:1(config-if)#ipv6 vrrp address 12 global 3333::1234/64
```

Enable VRRP for the interface:

```
Switch:1(config-if)#ipv6 vrrp 12 enable
```

Variable Definitions

Use the data in the following table to use the **ipv6 vrrp address** command.

Variable	Value
<1-255>	Specifies the virtual router ID. The virtual router acts as the default router for one or more associated addresses.
<i>enable</i>	Enables IPv6 VRRP. The default is disabled.
global WORD <0-255>	Specifies a global IPv6 address and mask to associate with the virtual router.
<i>link-local</i> WORD <0-127>	Specifies a link-local IPv6 address to associate with the virtual router.

Use the data in the following table to use the **interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{ <i>slot/port</i> [/ <i>sub-port</i>] [- <i>slot/port</i> [/ <i>sub-port</i>]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View VRRP Information

Display VRRP port or VLAN information to verify your configuration. Show VRRP information by IPv6 address or virtual router ID. If you enter a virtual router ID or an IPv6 address when you view VRRP information, the information applies only to that virtual router ID or for that interface.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the configuration information for all interfaces:

```
show ipv6 vrrp interface [verbose] [vrf WORD<1-16> | vrfids WORD<0-512>]
```

- View the configuration information for one or more ports:

```
show ipv6 vrrp interface gigabitethernet {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]} [verbose] [vrf WORD<1-16> | vrfids WORD<0-
512>]
```

- View the configuration information for one or more VLANs:

```
show ipv6 vrrp interface vlan [<1-4059>] [verbose] [vrf WORD<1-16> |
vrfids WORD<0-512>]
```

- View the configuration information for one or more virtual router IDs:

```
show ipv6 vrrp interface vrid <1-255> [verbose] [vrf WORD<1-16> |
vrfids WORD<0-512>]
```

- View VRRP address information:

```
show ipv6 vrrp address [vrf WORD<1-16> | vrfids WORD<0-512>]
```

- View VRRP address information for a link-local address:

```
show ipv6 vrrp address link-local WORD<0-127> [verbose] [vrf WORD<1-
16> | vrfids WORD<0-512>]
```

- View VRRP address information for a virtual router ID:

```
show ipv6 vrrp address vrid <1-255> [vrf WORD<1-16> | vrfids WORD<0-
512>]
```

Example

```
Switch:1>show ipv6 vrrp address
```

```

Variable Definitions

Use the data in the following table to use the **show ipv6 vrrp** commands.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>link-local WORD<0-127></i>	Displays information by link-local IPv6 address.
<i>verbose</i>	Displays extended information.
<i>vlan [<1-4059>]</i>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<i>vrid <1-255></i>	Displays information by virtual router ID.
<i>vrf WORD<1-16></i>	Specifies the VRF name.
<i>vrfids WORD<0-512></i>	Specifies the VRF ID.

Configuring VRRP notification control

Perform this procedure to configure VRRP notification control.

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.

About This Task

By default, generation of SNMP traps for VRRP events is enabled.

Procedure

1. Enter VRRP Router Configuration mode:

```
enable
configure terminal
router vrrp
```
2. Enable the VRRP-router to generate SNMP traps for events:

```
ipv6 send-trap enable
```

Example

Disable generation of SNMP traps for VRRP events:

```
Switch:1(config-vrrp)#no ipv6 send-trap enable
```

Configuring additional VRRP parameters for an interface

Configure VRRP to provide fast failover of a default router for IPv6 LAN hosts. VRRP supports a virtual IPv6 address shared between two or more routers that connect the common subnet to the enterprise network. VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol.

Configure the parameters in this procedure if the default values do not meet your requirements.

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.

About This Task

A switch that acts as a VRRP master does not reply to SNMP get requests to the VRRP virtual interface address. The switch will, however, respond to SNMP get requests to the physical IP address.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the accept mode of the master router:

```
ipv6 vrrp <1-255> accept-mode enable
```

3. Determine if the router overrides the holddown timer:

```
ipv6 vrrp <1-255> action <none|preempt>
```

4. Configure the interval between advertisement messages:

```
ipv6 vrrp <1-255> adver-int <1-40>
```

5. Enable the backup VRRP switch for traffic forwarding:

```
ipv6 vrrp <1-255> backup-master enable
```

6. Configure the IP interface on the local router:

```
ipv6 vrrp <1-255> critical-ipv6-addr WORD<0-46> [critical-ipv6 enable]
```

7. Configure the fast advertisement interval:

```
ipv6 vrrp <1-255> fast-adv enable [fast-adv-int <200-1000>]
```

8. Configure the holddown timer:

```
ipv6 vrrp <1-255> holddown-timer <0-21600>
```
9. Configure the priority for the VRRP router:

```
ipv6 vrrp <1-255> priority <1-255>
```

Example

Configure the fast advertisement interval:

```
Switch:1(config-if)#ipv6 vrrp 12 fast-adv enable fast-adv-int 400
```

Configure the holddown timer:

```
Switch:1(config-if)#ipv6 vrrp 12 holddown-timer 30
```

Variable Definitions

Use the data in the following table to use the **ipv6 vrrp** command.

Variable	Value
<1-255>	Specifies a number that uniquely identifies a virtual router on a VRRP router. The virtual router acts as the default router for one or more assigned addresses.
<i>accept-mode enable</i>	Controls whether the VRRP master or backup master accepts packets (other than neighbor discovery packets) destined to the IPv6 address associated with the virtual router. The default value is disable.
<i>action <none preempt></i>	Lists options to override the holddown timer manually and force preemption: <ul style="list-style-type: none"> • <i>none</i> does not override the timer. • <i>preempt</i> preempts the timer. This parameter applies only if the holddown timer is active.
<i>adver-int <1-40></i>	Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second. Only the master router sends advertisements.
<i>backup-master enable</i>	Uses the backup VRRP switch for traffic forwarding. This option reduces the traffic on the v1ST. The default is disabled.
<i>critical-ipv6 enable</i>	Enables or disables the use of critical IP. When disabled, the VRRP ignores the availability of the address configured as critical IP. This address must be a local address. The default is disabled.
<i>critical-ipv6-addr WORD<0-46></i>	Specifies an IP interface on the local router configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding.
<i>fast-adv enable</i>	Enables or disables the fast advertisement interval. When disabled, the regular advertisement interval is used. The default is disable.
<i>fast-adv-int <200-1000></i>	Configures the interval between VRRP advertisement messages. You must configure the same value on all participating routers. This unit of measure must be in multiples of 200 milliseconds. The default is 200.

Variable	Value
<i>holddown-timer</i> <0-21600>	Configures the amount of time, in seconds, to wait before preempting the current VRRP master. The default is 0.
<i>priority</i> <1-255>	Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.

Viewing IPv6 VRRP Statistics

View IPv6 VRRP statistics to monitor network performance

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View statistics for the device and for all interfaces:

```
show ipv6 vrrp statistics [link-local WORD<0-127>]] [vrid <1-255>]
```

Example

View IPv6 VRRP statistics for VRID 1.

```
Switch:1(config)#show ipv6 vrrp statistics vrid 1

```

Variable Definitions

Use the data in the following table to use the **show ipv6 vrrp statistics** command.

Variable	Value
<i>link-local</i> WORD<0-127>	Shows statistics for a specific link-local address.
<i>vrid</i> <1-255>	Shows statistics for a specific VRID.

Enabling IPv6 VRRP preempt-mode

You can configure IPv6 VRRP to preempt the existing router. If a new VRRP router is added to the network with a higher priority than the existing routers, then the new router becomes the master. If preempt-mode is disabled, then the new router does not become a master, it transitions to master only when the current master is down. By default, preempt-mode is enabled.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enter the following command:

```
ipv6 vrrp <vrid> preempt-mode enable
```

3. Use the following command to set the IPv6 VRRP preempt-mode to its default value:

```
default ipv6 vrrp <vrid> preempt-mode
```

4. Use the following command to disable the IPv6 VRRP preempt-mode:

```
no ipv6 <vrid> preempt-mode enable
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/2
```

Enabling IPv6 VRRP preempt-mode for interface 1/2

```
Switch:1(config-if)# ipv6 vrrp 1 preempt-mode enable
```

Variable definitions

Use the data in the following table to use the **ipv6 vrrp <vrid>** command.

Variable	Value
enable	Enables preempt-mode for VRRPv3 for IPv6.
vrid <1-255>	Specifies the virtual router ID.

VRRP configuration using EDM

One active master switch exists for each IP subnet. All other VRRP interfaces in a network are in backup mode.

If you have VRRP and IP routing protocols configured on the same IP physical interface, you cannot select the interface address as the VRRP virtual IP address (logical IP address). Use a separate dedicated IP address for VRRP.

To modify the behavior of the VRRP failover mechanism, use the hold-down timer to allow the router enough time to detect and update routes. The timer delays the preemption of the master over the backup, when the master becomes available. The hold-down timer has a default value of 0 seconds. Configure all of your routers to the identical number of seconds for the hold-down timer. In addition, you can manually force the preemption of the master over the backup before the delay timer expires.

Note

The VRRP virtual IP address cannot be the same as the local IP address of the port or VLAN on which VRRP is enabled.

Important

The switch, when it acts as a VRRP master, does not reply to Simple Network Management Protocol (SNMP) Get requests to the VRRP virtual interface address. However, if the switch acts as a VRRP master, and receives SNMP Get requests to its physical IP address, then it does respond.

The Simple Network Management Protocol (SNMP) provides facilities to manage and monitor network resources. An SNMP manager and agent communicate through the SNMP protocol. The manager sends queries and the agent responds. An SNMP Get request is a message that requests the values of one or more objects.

Note

The VRRP IP address responds only to ICMP-based traceroute requests. It does not respond to UDP-based traceroute requests.

Before You Begin

- Assign an IP address to the interface.
- Enable VRRP globally.

Enabling VRRP global variables

About This Task

Enable VRRP global variables to enable the VRRP function.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **VRRP**.
3. Click the **Globals** tab.
4. Configure the required features.
5. Click **Apply**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
NotificationCntl	Indicates whether the VRRP-enabled router generates SNMP traps for events. <ul style="list-style-type: none"> • enabled—SNMP traps are generated • disabled—no SNMP traps are sent The default is enabled.
PingVirtualAddrEnable	Configures whether this device responds to pings directed to a virtual router IP address. The default is enabled.

Modifying VRRP parameters for an interface

Before You Begin

- You must enable VRRP on a brouter port or VLAN.

About This Task

You can manage and configure VRRP parameters for the routing interface.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **VRRP**.
3. Click the **Interface** tab.
4. Double-click the **HoldDownTimer** field, and enter the number of seconds for the timer.

The **HoldDownState** field displays active when the hold-down timer is counting down and preemption occurs. The field displays dormant when preemption is not pending. When the hold-down timer is active, the **HoldDownTimeRemaining** field displays the seconds remaining before preemption.
5. In the **Action** check box, select an option.
6. Click **Apply**.

Interface field descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
IfIndex	Specifies the index value that uniquely identifies the interface to which this entry is applicable.
VrId	Specifies a number that uniquely identifies a virtual router on a VRRP router. The virtual router acts as the default router for one or more assigned addresses (1 to 255).
IpAddr	Specifies the assigned IP addresses that a virtual router is responsible for backing up.
VirtualMacAddr	Specifies the MAC address of the virtual router interface.
State	Specifies the state of the virtual router interface: <ul style="list-style-type: none"> • Initialize—waiting for a startup event • Backup—monitoring availability and state of the master router • Master—functioning as the forwarding router for the virtual router IP addresses.
Control	Specifies whether VRRP is enabled or disabled for the port (or VLAN). The default is enabled.
Priority	Specifies the priority value used by this VRRP router. Set a value from 1 to 255, where 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.
AdvertisementInterval	Specifies the time interval (in seconds) between sending advertisement messages. The range is 1 to 255 seconds with a default of 1 second. Only the master router sends advertisements. The default is 1.
MasterIpAddr	Specifies the IP address of the physical interface of the master virtual router that forwards packets sent to the virtual IP addresses associated with the virtual router.
VirtualRouterUpTime	Specifies the time interval (in hundredths of a second) since the virtual router was initialized.
Action	Lists options to override the delay timer manually and force preemption: <ul style="list-style-type: none"> • none does not override the timer • preemptHoldDownTimer preempts the timer
HoldDownTimer	Configures the amount of time (in seconds) to wait before preempting the current VRRP master.

Name	Description
HoldDownState	Indicates the hold-down state of this VRRP interface. If the hold-down timer is operational, this variable is set to active; otherwise, this variable is set to dormant.
HoldDownTimeRemaining	Indicates the amount of time (in seconds) left before the HoldDownTimer expires.
CriticalIpAddr	Configures the critical IP address for VRRP. This command specifies an IP interface on the local router, which is configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding. Note: In this context, <i>local</i> implies an address from the same VRF as the IP interface where VRRP is being configured.
CriticalIpAddrEnable	Configures the IP interface on the local router to enable or disable the backup. The default is disabled.
BackUpMaster	Enables the backup VRRP system traffic forwarding. The default is disabled.
BackUpMasterState	Indicates whether the backup VRRP system traffic forwarding is enabled or disabled. The default is disabled.
FasterAdvInterval	Configures the Fast Advertisement Interval between sending VRRP advertisement messages. The interval is between 200 and 1000 milliseconds, and you must enter the same value on all participating routers. The default is 200. You must enter the values in multiples of 200 milliseconds.
FasterAdvIntervalEnable	Enables or disables the Fast Advertisement Interval. When disabled, the regular advertisement interval is used. The default is disable.

Configuring VRRP on a V3 interface

Perform this procedure to configure VRRP on a V3 interface on either a brouter port or a VLAN.

Before You Begin

- Assign an IPv4 address to the interface
- Enable routing globally
- Do not configure RSMLT on the VLAN

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **VRRP**.

3. Click the **V3 Interface** tab.
4. Click **Insert**.
5. Beside the **IfIndex** field, click **Port** or **VLAN**.
6. Select a port or VLAN.
7. Click **OK**.
8. Type the virtual router ID.
9. Type the primary IP address.
10. Type the advertisement interval.
11. Click **Insert**.

Interface field descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
IfIndex	Shows the index value that uniquely identifies the interface to which this entry applies.
InetAddrType	Specifies the source network INET Address Type.
VrId	Specifies a number that uniquely identifies a virtual router on a VRRP router.
PrimaryIpAddr	Specifies the virtual address assigned to the VRRP.
VirtualMacAddr	Specifies the MAC address of the virtual router interface.
State	Shows the state of the virtual router interface. The possible states are <ul style="list-style-type: none"> • initialize—waiting for a startup event • backup—monitoring availability and state of the master router • master—functioning as the forwarding router for the virtual router IP addresses
Control	Displays whether VRRP is enabled or disabled for the port or VLAN.
Priority	Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.
AdvInterval	Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second.
MasterIpAddr	Specifies the IP address of the physical interface of the Master's virtual router.
UpTime	Indicates the time interval since this virtual router exited the INIT state.
CriticalIpAddr	Indicates the IP address of the interface that is critical to VRRP. If that IP interface is down, the VRRP state will transition to Backup, even if it has higher priority.

Name	Description
CriticalIpAddrEnabled	Enables or disables the use of critical IP. When disabled, the VRRP ignores the availability of the address configured as critical IP. This address must be a local address. The default is disabled.
BackUpMaster	Uses the backup VRRP switch for traffic forwarding. This option reduces the traffic on the v1ST. The default is disabled.
BackUpMasterState	Indicates if the Backup-Master is operational up. If the switch is in Master state but the Backup-Master is enabled, then the BACKUP MASTER STATE will be down.
FasterAdvIntervalEnabled	Enables or disables the fast advertisement interval. When disabled, the regular advertisement interval is used. The default is disable.
FasterAdvInterval	Configures the interval between VRRP advertisement messages. The default is 200. Enter the values in multiples of 200 milliseconds.
PreemptMode	Issued to preempt the existing router. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master. The default is enabled.
Action	Lists options to override the hold-down timer manually and force preemption: <ul style="list-style-type: none"> • none does not override the timer. • preemptHoldDownTimer preempts the timer. This parameter applies only if the holddown timer is active.
HoldDownTimer	Configures the amount of time, in seconds, to wait before preempting the current VRRP master. The default is 0.
HoldDownTimeRemaining	Indicates the amount of time, in seconds, left before the HoldDownTimer expires.
MasterAdvInterval	On the VRRPv3 master, the master advertisement interval is same as the advertisement interval. On the VRRPv3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet).

Configuring VRRPv3 Checksum

Perform this procedure to configure VRRPv3 checksum on either a brouter port or a VLAN.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **VRRP**.
3. Click the **V3 Checksum** tab.

4. Click **Insert**.
5. In the **Interface** field, click **Port** or **Vlan**.
6. Select a type of checksum computation.
7. Select a VRRP version.
8. Click **Insert**.

V3 Checksum field descriptions

Use the data in the following table to use the **V3 Checksum** tab.

Name	Description
Interface	Shows VRRPv3 information about a specified interface.
rclpConflfIndex	Shows the index value that uniquely identifies the interface to which this entry applies.
ChkSumComputation	Specifies the type of checksum computation, with Pseudo Header or without Pseudo Header.
VrrpVersion	Specifies the VRRP version as unspecified, v2, or v3.

Configuring Fast Advertisement Interval on a port or a VRF instance

About This Task

Configure the Fast Advertisement Interval to send VRRP advertisement messages. The interval can be between 200 and 1000 milliseconds, and it must be the same on all participating routers. The default is 200. Enter the values in multiples of 200 milliseconds.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **VRRP** tab.
5. Click **Insert**.
6. In the **Insert VRRP** dialog box, enable **FasterAdvIntervalEnable**.
7. In the **FasterAdvInterval** field, enter a value. You must set this value using multiples of 200 milliseconds.
8. Click **Insert**.

Configuring Fast Advertisement Interval on a VLAN or a VRF instance

About This Task

Configure the Fast Advertisement Interval to send VRRP advertisement messages. The interval can be between 200 and 1000 milliseconds, and it must be the same on all participating routers. The default is 200. Enter the values in multiples of 200 milliseconds.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs > Basic**.
3. Select a VLAN.
4. Click **IP**.
5. Click the **VRRP** tab.
6. Click **Insert**.
7. In the IP, VLAN, Insert VRRP dialog box, click the **FasterAdvIntervalEnable** enable option.
8. In the **FasterAdvInterval**, box, enter a value. You must set the value using multiples of 200 milliseconds.
9. Click **Insert**.

Viewing VRRP Statistics

About This Task

View VRRP statistics to monitor network performance.

Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **VRRP**.
3. Select the **Stats** tab.

Stats Field Descriptions

The following table describes parameters on the VRRP statistics tab.

Name	Description
ChecksumErrors	Specifies the number of VRRP packets received with an invalid VRRP checksum value.
VersionErrors	Specifies the number of VRRP packets received with an unknown or unsupported version number.
VrIDErrors	Specifies the number of VRRP packets received with an invalid VrID for this virtual router.

Viewing VRRP Interface Statistics

About This Task

View VRRP statistics to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **VRRP**.
3. Select the **Interface** tab.
4. Select an interface.
5. Click **Graph**.

Interface Field Descriptions

The following table describes parameters on the **Interface** tab.

Name	Description
AdvertiseRcvd	Specifies the number of VRRP advertisements received by this virtual router.
AdvertiseIntervalErrors	Specifies the number of received VRRP advertisement packets with a different interval is than configured for the local virtual router.
IPtTlErrors	Specifies the number of VRRP packets received by the virtual router with IP TTL (Time-To-Live) not equal to 255.
PriorityZeroPktsRcvd	Specifies the number of VRRP packets received by the virtual router with a priority of 0.
PriorityZeroPktsSent	Specifies the number of VRRP packets sent by the virtual router with a priority of 0.
InvalidTypePktsRcvd	Specifies the number of VRRP packets received by the virtual router with an invalid value in the 'type' field.
AddressListErrors	Specifies the packets received address list the address list does not match the locally configured list for the virtual router.
AuthTypeMismatch	Specifies the count of authentication type mismatch messages.
PacketLengthErrors	Specifies the count of packet length errors.
AuthFailures	Specifies the count of authentication failure messages.

Viewing IP VRRPv3 Statistics

About This Task

Use the following procedure to view IPv6 VRRPv3 statistics for monitoring the network performance.

Procedure

1. In the navigation pane, expand the **Configuration --> IP** folders.
2. Click **VRRP**.
3. Click the **V3 Stats** tab.

V3 Stats Field Descriptions

Use the data in the following table to interpret the **V3 Stats** tab.

Name	Description
InetAddrType	Shows that the address type of the statistical entry is IPv4.
ChecksumErrors	Specifies the total number of VRRP packets received with an invalid VRRP checksum value.
VersionErrors	Specifies the total number of VRRP packets received with an unknown or unsupported version number.
VrIdErrors	Specifies the total number of VRRP packets received with an invalid VRID for the virtual router.

Graphing IP VRRPv3 Statistics

About This Task

Use the following procedure to view and graph IP VRRPv3 statistics for monitoring the network performance.

Procedure

1. In the navigation pane, expand the **Configuration** --> **IP** folders.
2. Click **VRRP**.
3. Click the **V3 Interface** tab.
4. Select an interface, and click **Graph**.
5. Select one or more values.
6. Select a graph type, click one of the icons in the upper-left corner of the menu bar. Your choices are:
 - Line Chart
 - Area Chart
 - Bar Chart
 - Pie Chart

V3 Interface Field Descriptions

Use the data in the following table to use the **V3 Interface** tab.

Name	Description
IfIndex	Shows the index value that uniquely identifies the interface to which this entry applies.
VrId	Specifies a number that uniquely identifies a virtual router on a VRRP router.
PrimaryIpAddr	Specifies the virtual address assigned to the VRRP.
VirtualMacAddr	Specifies the MAC address of the virtual router interface.

Name	Description
State	Specifies the state of the virtual router interface: <ul style="list-style-type: none"> • Initialize—waiting for a startup event • Backup—monitoring availability and state of the master router • Master—functioning as the forwarding router for the virtual router IP addresses.
Control	Specifies whether VRRP is enabled or disabled for the port (or VLAN). The default is enabled.
Priority	Specifies the priority value used by this VRRP router. Set a value from 1 to 255, where 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.
AdvInterval	Specifies the time interval (in seconds) between sending advertisement messages. The range is 1 to 255 seconds with a default of 1 second. Only the master router sends advertisements. The default is 1.
UpTime	Specifies the time interval (in hundredths of a second) since the virtual router was initialized.
CriticalIpAddr	This command specifies an IP interface on the local router, which is configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding. Note: In this context, local implies an address from the same VRF as the IP interface where VRRP is being configured.
CriticalIpAddrEnabled	Configures the IP interface on the local router to enable or disable the backup. The default is disabled.
BackUpMaster	Enables the backup VRRP system traffic forwarding. The default is disabled.
BackUpMasterState	Indicates whether the backup VRRP system traffic forwarding is enabled or disabled. The default is disabled.
FasterAdvIntervalEnabled	Enables or disables the Fast Advertisement Interval. When disabled, the regular advertisement interval is used. The default is disabled.
FasterAdvInterval	Configures the Fast Advertisement Interval between sending VRRP advertisement messages. The interval is between 200 and 1000 milliseconds, and you must enter the same value on all participating routers. The default is 200. You must enter the values in multiples of 200 milliseconds.

Name	Description
PreemptMode	Issued to preempt the existing router. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master.
Action	Lists options to override the delay timer manually and force preemption: <ul style="list-style-type: none"> • none does not override the timer • preemptHoldDownTimer preempts the timer
HoldDownTimer	Indicates the hold-down state of this VRRP interface. If the hold-down timer is operational, this variable is set to active; otherwise, this variable is set to dormant.
HoldDownTimeRemaining	Indicates the amount of time (in seconds) left before the HoldDownTimer expires.
MasterAdvInterval	On the VRRPv3 master, the master advertisement interval is same as the advertisement interval. On the VRRPv3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet).

IPv6 VRRP Configuration using EDM

Configure VRRP for an Interface

Configure VRRP to provide fast failover of a default router for IPv6 LAN hosts. VRRP supports a virtual IPv6 address shared between two or more routers that connect the common subnet to the enterprise network. VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol.

Perform this procedure to configure VRRP on either a brouter port or a VLAN.

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.
- Change the VRF instance as required to configure a VRRP for an interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Select **VRRP**.
3. Select the following tab:
 - For VSP 8600 Series, select **Interface**.
 - For all other platforms, select **V3 Interface**.

4. Select **Insert**.
5. Beside the **IfIndex** field, click **Port** or **VLAN**.
6. In the dialog box that opens, select a port or VLAN.
7. Select **OK**.
8. Type the virtual router ID.
9. To control the packets sent to the IPv6 address associated to the virtual router, select the **AcceptMode** check box.
10. Type the primary IP address.
11. Select **Insert**.

V3 Interface or **Interface** Field Descriptions

Use the data in the following table to use the **V3 Interface** or **Interface** tab.

Name	Description
IfIndex	Shows the index value that uniquely identifies the interface to which this entry applies.
InetAddrType	Specifies the address type for the VRRP interface.
VrId	Specifies a number that uniquely identifies a virtual router on a VRRP router.
PrimaryIpAddr	Specifies the link-local address assigned to the VRRP.
VirtualMacAddr	Specifies the MAC address of the virtual router interface.
State	Shows the state of the virtual router interface. The possible states are <ul style="list-style-type: none"> • initialize—waiting for a startup event • backup—monitoring availability and state of the master router • master—functioning as the forwarding router for the virtual router IP addresses
Control	Displays whether VRRP is enabled or disabled for the port or VLAN.
Priority	Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.
AdvInterval	Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second.
MasterIpAddr	Specifies the IP address of the physical interface of the Master's virtual router.
UpTime	Indicates the time interval since this virtual router exited the INIT state.

Name	Description
CriticalIpAddr	Indicates the IP address of the interface that is critical to VRRP. If that IP interface is down, the VRRP state will transition to Backup, even if it has higher priority.
CriticalIpAddrEnabled	Enables or disables the use of critical IP. When disabled, the VRRP ignores the availability of the address configured as critical IP. This address must be a local address. The default is disabled.
BackUpMaster	Uses the backup VRRP switch for traffic forwarding. This option reduces the traffic on the v1ST. The default is disabled.
BackUpMasterState	Indicates if the Backup-Master is up. If the switch is in Master state, but Backup-Master is enabled, then the BACKUP MASTER STATE will be down.
FasterAdvIntervalEnabled	Enables or disables the fast advertisement interval. When disabled, the regular advertisement interval is used. The default is disable.
FasterAdvInterval	Configures the interval between VRRP advertisement messages. The default is 200. Enter the values in multiples of 200 milliseconds.
AcceptMode	Controls whether the VRRP master or backup master accepts packets (other than neighbor discovery packets) destined to the IPv6 address associated with the virtual router. The default value is disable.
PreemptMode	Issued to preempt the existing router. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master. The default is enabled.
Action	Lists options to override the hold-down timer manually and force preemption: <ul style="list-style-type: none"> • none does not override the timer. • preemptHoldDownTimer preempts the timer. This parameter applies only if the holddown timer is active.
HoldDownTimer	Configures the amount of time, in seconds, to wait before preempting the current VRRP master. The default is 0.
HoldDownTimeRemaining	Indicates the amount of time, in seconds, left before the HoldDownTimer expires.
MasterAdvInterval	On the VRRP master, the master advertisement interval is same as the advertisement interval. On the VRRPV3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet).

Configuring VRRP notification control

Perform this procedure to configure VRRP notification control.

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Change the VRF instance as required to configure VRRP notification control on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **VRRP**.
3. Click the **Globals** tab.
4. Select **enabled**.
5. Click **Apply**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
NotificationCntrl	Indicates whether the VRRP-enabled router generates SNMP traps for events. <ul style="list-style-type: none"> • enabled: Generate SNMP traps. • disabled: Do not generate SNMP traps. The default is enabled.

View IPv6 VRRP Statistics

View IPv6 VRRP statistics to monitor network performance.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **VRRP**.
3. Select the **Stats** tab.

Stats Field Descriptions

Use the data in the following table to use the **Stats** tab.

Name	Description
InetAddrType	Shows the type of IP address (IPv4 or IPv6).
ChecksumErrors	Shows the number of VRRP packets received with an invalid VRRP checksum value.

Name	Description
VersionErrors	Shows the number of VRRP packets received with an unknown or unsupported version number.
VrIdErrors	Shows the number of VRRP packets received with an invalid VrID for this virtual router.

Viewing IPv6 VRRP Statistics for an Interface

View IPv6 VRRP statistics for a VLAN or port.

Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Click **VRRP**.
3. Click the **Interface** tab.
4. Select an interface.
5. Click **Statistics**.

Statistics Field Descriptions

Use the data in the following table to use the **Statistics** tab.

Name	Description
MasterTransitions	Shows the total number of times that the state of this virtual router has transitioned to master. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
RcdAdvertisements	Shows the total number of VRRP advertisements received by this virtual router. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
AdvIntervalErrors	Shows the total number of VRRP advertisement packets received for which the advertisement interval is different than the one configured for the local virtual router. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
IpTtlErrors	Shows the total number of VRRP packets received by the virtual router with IPv4 TTL (for VRRP over IPv4) or IPv6 Hop Limit (for VRRP over IPv6) not equal to 255. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.

Name	Description
RcvdPriZeroPackets	Shows the total number of VRRP packets received by the virtual router with a priority of 0. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
SentPriZeroPackets	Shows the total number of VRRP packets sent by the virtual router with a priority of 0. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
RcvdInvalidTypePkts	Shows the number of VRRP packets received by the virtual router with an invalid value in the 'type' field. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
AddressListErrors	Shows the total number of packets received for which the address list does not match the locally configured list for the virtual router. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
PacketLengthErrors	Shows the total number of packets received with a packet length less than the length of the VRRP header. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
RcvdInvalidAuthentications	Shows the total number of packets received with an unknown authentication type.

Configure IPv6 VRRP Statistics

View IPv6 VRRP statistics for a VLAN or port.

Before You Begin

Change the VRF instance as required to view IPv6 VRRP statistics on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Port**.
2. Select **IPv6**.
3. Select the **VRRP** tab.
4. Select an interface.
5. Select **Statistics**.

Graphing IPv6 VRRP Statistics

About This Task

Use the following procedure to graph IPv6 VRRPv3 statistics for monitoring the network performance.

Procedure

1. In the navigation pane, expand the **Configuration** --> **IPv6** folders.
2. Click **VRRP**.
3. Click the **Stats** tab.
4. Select an interface, and click **Graph**.
5. Select one or more values.
6. Select a graph type, click one of the icons in the upper-left corner of the menu bar. Your choices are:
 - Line Chart
 - Area Chart
 - Bar Chart
 - Pie Chart

Stats Field Descriptions

Use the data in the following table to use the **Stats** tab.

Name	Description
InetAddrType	Shows the type of IP address (IPv4 or IPv6).
ChecksumErrors	Shows the number of VRRP packets received with an invalid VRRP checksum value.
VersionErrors	Shows the number of VRRP packets received with an unknown or unsupported version number.
VrldErrors	Shows the number of VRRP packets received with an invalid VrID for this virtual router.

Configuring additional addresses on the VRRP router port

Perform this procedure to configure the additional addresses for which the virtual router acts as a back up.

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **Edit** > **Port**.
2. Click **IPv6**.
3. Click the **VRRP** tab.
4. Click **AssociatedIPAddr**.
5. Click **Insert**.

6. Type the address.
7. Type the prefix length.
8. Click **Insert**.

Configuring additional addresses on the VRRP interface

Perform this procedure to configure the additional addresses for which the virtual router acts as a back up.

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.
- Change the VRF instance as required to configure additional addresses on the VRRP interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **VRRP**.
3. Click the **Interface** tab.
4. Select an interface.
5. Click **AssociatedIPAddr**.
6. Click **Insert**.
7. Type the address.
8. Type the prefix length.
9. Click **Insert**.

Address List field descriptions

Use the data in the following table to use the **Address List** tab.

Name	Description
IpAddr	Specifies an IP address that is associated with a virtual router. The number of rows on this tab equals the number of IP addresses associated (backed up) by the virtual router
IpAddrPrefixLength	Specifies the length of the prefix in bits.

VXLAN Gateway

[VXLAN Gateway Fundamentals on page 3915](#)

[VXLAN Gateway configuration using the CLI on page 3927](#)

[OVSDB protocol support for VXLAN Gateway configuration using CLI on page 3934](#)

[VXLAN Gateway configuration using EDM on page 3939](#)

[OVSDB protocol support for VXLAN Gateway configuration using EDM on page 3944](#)

[Configuration Examples on page 3947](#)

VXLAN Gateway terminates virtual extensible LAN (VXLAN) tunnels that stretch emulated Layer 2 segments over an IP network.

The following topics provide necessary concepts and procedures to configure VXLAN Gateway and Open vSwitch Database Management Protocol (OVSDB) support for VXLAN Gateway.

VXLAN Gateway Fundamentals

Table 299: VXLAN Gateway product support

Feature	Product	Release introduced
VXLAN Gateway	VSP 4450 Series	Not Supported
	VSP 4900 Series	Not Supported
	VSP 7200 Series	VOSS 6.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.0
	VSP 8400 Series	VOSS 6.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

Table 299: VXLAN Gateway product support (continued)

Feature	Product	Release introduced
OVSDB protocol support for VXLAN Gateway	VSP 4450 Series	Not Supported
	VSP 4900 Series	Not Supported
	VSP 7200 Series	VOSS 7.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 7.1
	VSP 8400 Series	VOSS 7.1
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported
ECMP support for VXLAN Gateway	VSP 4450 Series	Not Supported
	VSP 4900 Series	Not Supported
	VSP 7200 Series	VOSS 6.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.0
	VSP 8400 Series	VOSS 6.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

VXLAN Gateway terminates virtual extensible LAN (VXLAN) tunnels that stretch emulated Layer 2 segments over an IP network.

VXLAN is an encapsulation protocol for running an overlay network over an existing Layer 3 infrastructure. This tunneling scheme uses a VLAN-like encapsulation mechanism to encapsulate MAC-based traffic. The VXLAN overlays separate workloads from physical networks, which facilitates the movement of VMs in a multi-tenant environment.

For more information about VXLAN, see the Internet Engineering Task Force (IETF) standard RFC 7348.

VXLAN Gateway as a VTEP

The VXLAN Gateway feature terminates VXLAN tunnels and operates as a VXLAN tunnel endpoint (VTEP). The VXLAN Gateway is a hardware-based VTEP that allows a VXLAN to communicate with VLANs, other VXLANs, as well as Fabric Connect I-SIDs.

The following figure shows a VXLAN Gateway (labeled as VTEP Source) connecting VXLAN segments to an SPB network. This type of deployment provides a solution for VXLAN in data centers to interoperate with Fabric Connect networks (labeled as SPB).

VXLAN Segments

VXLAN tunnels are also called VXLAN segments. VXLAN segments provide the ability to separate, abstract, and decouple the physical topology from a logical or virtual topology by using encapsulated tunneling. VXLAN segments allows only VMs within the same VXLAN tunnel to communicate with each other.

VNID

Each VXLAN segment has a 24-bit segment ID called a VXLAN Network Identifier (VNID). VNID allows up to 16 million VXLAN segments to coexist within the same administrative domain, which enables VMs to migrate between servers in the same data center or between distributed data centers. Each VTEP can support multiple VNIDs. For information about maximum scaling numbers, see [VOSS Release Notes](#).

The VNID uses the inner MAC frame originated by the individual VM. Overlapping MAC addresses can cross VXLAN segments, but never have traffic crossover because the traffic is isolated using the VNID qualifier. Due to this encapsulation, only the VTEP knows the VNID and its associated VXLAN tunnel. VMs are unaware of the VXLAN.

VM Traffic

Only VMs within the same VXLAN segment can communicate with each other. The following steps show how a VM communicates with a VM on a different host within the same VXLAN segment:

1. The VM sends a MAC frame destined to the target.
2. The VTEP looks up the VNID that the VM is associated with to verify that the destination MAC is on the same segment. If the destination MAC is on the same segment, the process continues.

3. The VTEP inserts an outer header comprising an outer MAC, outer IP address, and VXLAN header in front of the original MAC frame.
4. The VTEP transmits the final packet out to the destination IP address of the remote VTEP, connecting the destination VM addressed by the inner MAC destination address.
5. The remote VTEP verifies that the VNID is valid for the destination VM.
6. If the VNID is valid, the remote VTEP strips the packet outer header and passes the packet to the destination VM. The destination VM never knows about the VNID, or that the frame transmitted with VXLAN encapsulation.

VXLAN Gateway Management Methods

Two methods are available to manage VXLAN Gateway:

- Static management using CLI and local configuration files.
- Dynamic management using OVSDB protocol support for VXLAN Gateway.

For static management, you use CLI or local configuration files to configure and manage the VXLAN Gateway hardware-based VTEP functions. You must manually configure the Source-VTEP, VNID, VNID to I-SID bindings, Remote-VTEP, and VNI to Remote-VTEP associations, and MAC learning on the VNID only occurs at the data-plane level.

For dynamic management, you use OVSDB protocol support for VXLAN Gateway to configure and manage the VXLAN Gateway hardware-based VTEP functions with Open vSwitch Database Management Protocol (OVSDB). You must configure at least one physical Network Virtualization Controller (NVC) running VMware NSX with OVSDB features. You can add a Hardware VTEP, add a logical switch, configure VNID to VTEP bindings, and configure a replication cluster in NSX. The VXLAN Gateway must have OVSDB enabled and the Network Virtualization Controller (NVC) must communicate on the OVSDB managed interface. You must manually configure the Source-VTEP and NVC IP addresses, and the VNID to I-SID binding in NSX. The NVC can manage the VNID, Remote-VTEP, and VNI to Remote-VTEP associations. The NVC distributes the hosts MAC and IP addresses learned by the VTEP over the VXLAN.

The following table shows the functional differences between the two VXLAN Gateway management methods.

Table 300: VXLAN Gateway Management Methods

Function	Static management	Dynamic management
VNID provisioning	Manually from CLI or EDM	Automatically from NVC
VNID to I-SID binding	Manually from CLI or EDM	Automatically from NVC
Remote-VTEP	Manually from CLI or EDM	MAC learning from NVC
VNID to VTEP association for replicating BUM traffic	Manually from CLI or EDM	MAC learning from NVC
MAC learning at data-plane	Not distributed to other VXLAN Gateways	Distributed from NVC to other VXLAN Gateways
ARP suppression	Not supported	Not supported

VXLAN Gateway Licensing

VXLAN Gateway requires a Premier or Premier with MACsec license. If a Premier License is not present, you cannot configure VXLAN Gateway.

VXLAN Modes

The VXLAN Gateway implementation is available in two modes: Base Interworking Mode and Full Interworking Mode. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes through a boot configuration flag.

Important

Changing the mode requires a reboot for the change to take effect, which can cause a loss of traffic.

Base Interworking Mode

Base Interworking Mode is the default mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication at line rate between VXLAN and traditional VLAN environments.

Base Interworking Mode has the following limitations:

- No support for VXLAN-to-VXLAN communication.
- No support for VXLAN-to-SPB communication.
- No support for SMLT, vIST, or Simplified vIST.
- No support for OVSDB protocol support for VXLAN Gateway.

Each VNID represents a service instance for the VXLAN Gateway. To enable a VNID to extend into the SPB network, you must use Full Interworking Mode.

Note

If your configuration does not have a VXLAN Gateway but has SMLT or vIST, you can enable VXLAN Gateway in the Full Interworking Mode only. SMLT and vIST are incompatible and mutually exclusive with the Base Interworking Mode.

Full Interworking Mode

Full Interworking Mode is not the default mode. To configure Full Interworking Mode, you must enable the **vxlan-gw-full-interworking-mode** boot flag, save the configuration, and then reboot the switch.

Full Interworking Mode supports the Base Interworking Mode communication between VXLAN and traditional VLAN environments as well as VXLAN-to-VXLAN communication and all SPB functionality including vIST and SMLT. Layer 2 and Layer 3 services extend across VXLAN, VLAN, and SPB domains using an internal loopback. In Full Interworking Mode, VXLAN traffic flows at less than full line rate and the total amount of available internal loopback bandwidth depends on the platform used.

Full Interworking Mode has the following limitations:

- No support for Simplified vIST.

- A VNID cannot have the same value as an I-SID. A consistency check ensures that this does not happen if you change the boot configuration flag to turn off Full Interworking Mode and go into Base Interworking Mode.

Types of VXLAN Gateway Deployments

VXLAN Gateway provides the following deployment solutions:

- [VXLAN-to-VLAN Layer 2 gateway deployment](#)
- [VXLAN-to-VXLAN Layer 3 gateway deployment](#)
- [VXLAN-to-SPB gateway deployment](#)

These gateways provide VXLAN tunnel termination functions for switches that could be Top of Rack (ToR) switches, access switches, or switches higher up in the data center network topology such as a core switch or even WAN edge devices. The last case (WAN edge) could involve a Provider Edge (PE) router that terminates VXLAN tunnels in a hybrid cloud environment.

VXLAN-to-VLAN Layer 2 gateway deployment

The VXLAN-to-VLAN deployment is where the VXLAN Gateway communicates between VXLAN segments and VLAN segments. Use this scenario when nodes on a VXLAN overlay network need to communicate with nodes on legacy networks that are VLAN based as shown in the following figure.

Figure 277: VXLAN-to-VLAN deployment

In this type of deployment, the VXLAN Gateway maps the VXLAN VNID to a VLAN in the following way:

- When packets traverse a VXLAN segment into the VLAN segment, the VXLAN VTEP removes the VXLAN header and forwards regular VLAN packets to a physical port based on the destination MAC address of the inner Ethernet frame.

The VTEP discards decapsulated frames with the inner VLAN ID unless you explicitly configure them to be passed on to the non-VXLAN interface. The VXLAN VNID to VLAN mapping is statically configured.

- In the reverse direction when packets traverse a VLAN segment into a VXLAN segment, the VXLAN VTEP maps the incoming frames from the non-VXLAN interfaces to a specific VXLAN overlay network based on the VLAN ID in the frame. This complies with the standard VXLAN RFC.

The VTEP also accepts both untagged and tagged inner frames and adds or replaces the tag of the inner frame with the local VLAN mapped to the VNID before sending out the frame.

The VTEP removes the VLAN ID of the original frame before it encapsulates the frame for VXLAN.

VXLAN-to-VXLAN Layer 3 gateway deployment

The VXLAN-to-VXLAN deployment is where the VXLAN Gateway communicates between VXLAN segments. Use this scenario when one VXLAN segment needs to communicate with another VXLAN segment.

When a packet traverses a VXLAN segment and enters the VXLAN Gateway, the VXLAN VTEP maps one VXLAN segment to another in the following way:

- Decapsulates the VXLAN header.
- Performs a route lookup of the customer packet.
- Identifies that the next hop VLAN is in another VXLAN segment.
- Encapsulates the packet with a new VXLAN header with a new VNID.
- Forwards the packet out.

The following figure shows two virtualized servers attached to a Layer 3 infrastructure. The servers could be on the same rack, on different racks, or across data centers within the same administrative domain.

There are four VXLAN overlay networks identified by the VNIDs: 22, 34, 74, and 98. Notice how the VMs are associated with a VNID. For example, VM1-1 in Server 1 and VM2-4 on Server 2 are on the same VXLAN overlay network identified by VNID 22.

The VMs do not know about the overlay networks and transport method because the encapsulation and decapsulation happen transparently at the VTEPs on Servers 1 and 2. The other overlay networks and the corresponding VMs are: VM1-2 on Server 1 and VM2-1 on Server 2 both on VNID 34, VM1-3 on Server 1 and VM2-2 on Server 2 on VNID 74, and finally VM1-4 on Server 1 and VM2-3 on Server 2 on VNID 98.

Figure 278: VXLAN-to-VXLAN deployment

VXLAN-to-SPB gateway deployment

The VXLAN-to-SPB deployment is where the VXLAN Gateway communicates between a VXLAN segment and an SPB domain. This type of deployment provides a solution for customers using VXLAN in their data-centers to interoperate with Fabric Connect as shown in the following figure.

Figure 279: VXLAN-to-SPB deployment

The VXLAN Gateway maps the VXLAN VNID to I-SID in the following way:

- When packets traverse a VXLAN segment into an SPB domain, the VXLAN VTEP decapsulates the VXLAN packet, encapsulates it with MAC-in-MAC encapsulation, and then forwards it into the SPB domain.
- In the reverse direction, the VXLAN VTEP decapsulates the MAC-in-MAC packet from an SPB domain, encapsulates it with a VXLAN header, and then forwards it into a VXLAN segment.

VXLAN Gateway Considerations and Limitations

Review the following considerations, limitations, and behavioral characteristics associated with VXLAN Gateway.

Unsupported Features

VXLAN Gateway does not support the following features:

- IP Multicast over Layer 3 VSN Fabric Connect traffic cannot be carried over into a VXLAN domain through a VXLAN Gateway. Layer 3 VSN Fabric Connect requires MAC-in-MAC encapsulation over VXLAN encapsulation, and the VXLAN Gateway data plane does not support double-encapsulation. However, IP Multicast over IP Shortcuts Fabric Connect can be carried over into a VXLAN domain through a VXLAN Gateway.
- SPB-PIM Gateway and VXLAN Gateway interoperability is not supported.
- VXLAN Gateway does not support Simplified vIST in any mode.

QoS and VXLAN Gateway

- If present in the packet, VXLAN Gateway honors user-configured ingress dot1p and DSCP mappings to derive the internal CoS.
- Customer packets are not remarked.
- Control packets are handled by high priority CoS queues.

- DSCP bits in the outer IP header of VXLAN-encapsulated packets are always derived from the internal QoS, irrespective of the ingress port DiffServ configuration. Customer packet IP DSCP bits are not modified as part of VXLAN encapsulation. For more information about QoS, see [Quality of Service](#) on page 2648.
- DSCP bits in the inner IP header of VXLAN-encapsulated packets change when traffic comes in on a Layer 2 Trusted or a Layer 3 Untrusted port with DiffServ enabled.

ECMP Support for VXLAN Gateway and Fabric Extend

VXLAN Gateway requires ECMP support to communicate with remote VTEPs. The software extended this ECMP support to Fabric Extend Layer 3 core tunnels. Therefore, if your switch supports VXLAN Gateway, it also supports ECMP for both VXLAN Gateway and Fabric Extend.

Base Interworking Mode Considerations and Limitations

- After associating a VNID with an I-SID (**vnid <vnid value> i-sid <isid value>**), you cannot create an I-SID with the same value as the **<vnid value>** and vice versa.
- There is no support for SMLT, vIST, or Simplified vIST in Base Interworking Mode.
- Neither Base Interworking Mode nor Full Interworking Mode support Fabric Attach endpoints.
- Base Interworking Mode does not allow SMLT and vIST configurations. If you change from Full Interworking Mode to Base Interworking Mode, make sure there are none of these configurations.
- In Base Interworking Mode, the **untagged-traffic <port >< mlt>** support is limited to untagged traffic forwarding only. No control packet forwarding is supported on this port or MLT.

LACP MLT is not supported as part of **untagged-traffic <mlt>**.

Full Interworking Mode Considerations and Limitations

- Whenever you change from Base Interworking Mode to Full Interworking Mode, you have to reboot the switch. The software automatically changes the configuration to be in line with Full Interworking Mode.
- Full Interworking Mode does not have VXLAN endpoints. Configure ELAN endpoints under the ELAN I-SID only.
- Neither Base Interworking Mode nor Full Interworking Mode support Fabric Attach endpoints.

General Configuration Guidelines

- In VXLAN environments that have an underlying IP network with SMLT deployment, you must enable RSMLT in the underlying network on vIST VTEP devices.
- If you use more than one VXLAN Gateway node for the same I-SID, you must ensure that loops are prevented.
- The VTEP remote destination IP table in the datapath hardware is shared with the Fabric Extend IP core remote tunnel destination IP table.
 - The maximum number of FE tunnel destination IP addresses is 256.
 - The maximum number of VTEP IP addresses is 500.

For every FE tunnel destination IP you configure, you must reduce the number of VTEP IPs by one. For example, if you configure the maximum number of FE tunnel destination IPs then the maximum of VTEP remote destination that you can configure is 500-256=244.

- The total number of MACs that the VTEP learns in the switch is constant and includes the MACs learned on VNID, I-SID, and on VLANs (normal and CVLANs).
 - MAC addresses that the VTEP learns from the VNID table are also learned when an I-SID is associated with the VNID. Therefore, the maximum number of MAC addresses that the VTEP can support is reduced accordingly.
 - If a VLAN is associated with an I-SID, and that I-SID is associated with a VNID, then the VTEP learns each customer MAC address from three different tables (VLAN, I-SID, and VNID). This consumes three MAC entry records. In a vIST scenario where all I-SIDs have associated VNIDs, then the max number of C-MACs that the VTEP learns is reduced by 224K divided by 3 = 74K MAC addresses.
 - If a Switched-UNI endpoint is associated with an I-SID, then the VTEP learns the C-MAC only once in the I-SID table. If this I-SID is associated with a VNID, then the VTEP learns the C-MAC twice: once in the I-SID table and once in the VXLAN VNID table.
- IP filter rules that you create do not work for VXLAN tunnel terminated packets. This restriction also applies to the Fabric Extend Layer 3 core.
- All ports in an MLT configured as a Switched-UNI endpoint or a VXLAN endpoint have the same properties as configured under the MLT interface.
- A VXLAN tunnel VTEP source IP cannot be a broadcast or multicast IP address. Configure it as a loopback IP address and not a brouter IP address.
- The VXLAN source address (**vtep-source-ip**) should be different from the SPBM IP Shortcut (**ip-source-address**) and Fabric Extend (**ip-tunnel-source-address**) source addresses.
- If you configure the loopback IP address under a VRF, the **vtep-source-ip** address must be set up under the same VRF.
- The remote VTEP IP address (**vtep <id> ip <ip address>**) cannot be local to the system.
- You can configure a maximum of 500 remote VTEPs per VNID.
- You can change the VTEP source IP and remote VTEP IP dynamically.
- VTEPs have to be reachable for the tunnel to be up.
- The tunnel ID for a VTEP has to be the same on both vIST peers.
- If the VTEP source IP is configured under a VRF, then the VRF cannot have an I-SID associated with it or vice versa.
- Two VNIDs cannot be mapped to the same I-SID.
- An I-SID associated with a VNID cannot be a T-UNI or E-Tree I-SID.
- To prevent routing loops, the platform VLANs used for VXLAN interworking should NOT be in the same VRF or GRT as the IP interfaces in the underlay network.
- You cannot delete a VTEP source IP address (**vtep-source-ip**) when VTEPs are configured.
- If an ELAN I-SID attached to a VNID has a platform VLAN associated with it, then you cannot delete the platform VLAN or change the I-SID associated with that VLAN.
- You cannot delete the loopback IP associated with a VTEP source IP.
- If the VTEP source IP is configured under a VRF, then you cannot delete the VRF.
- You cannot delete or modify the VLAN with I-SID that is associated with a VNID.
- If an ELAN I-SID attached to a VNID also has a platform VLAN associated with it, then you cannot delete the platform VLAN or change the I-SID associated with that VLAN.

OVSDB protocol support for VXLAN Gateway Considerations and Limitations

Review the following considerations, limitations, and behavioral characteristics associated with OVSDB protocol support for VXLAN Gateway.

Network Virtualization Controllers Dependencies and Restrictions

OVSDB protocol support for VXLAN Gateway requires at least one Network Virtualization Controller (NVC) that runs OVSDB:

- OVS is an open source implementation of a virtual switch and OVSDB is a standard defined in RFC 7047.
- You require at least one NVC. The NVC is an ESXi host server that runs the VMware NSX Network Virtualization and Security Platform (minimum version 6.2.4).

Note

VMware NSX 6.2.4 has known issues that can cause VXLAN discovery delays and NVC connectivity issues in certain scenarios, for more information see [VOSS Release Notes](#).

- You must configure VMware NSX. You can add a Hardware VTEP, add a logical switch, configure VNID to VTEP bindings, and configure a replication cluster in NSX.
- The NSX logical switch on the NVC is assigned a VNID. The VXLAN Gateway is assigned an OVSDB managed interface I-SID. You must configure the VNID to I-SID binding in NSX.
- SSL is the default protocol for NVC to VXLAN Gateway communications.
- You can configure more than one NVC in a controller cluster for high availability and load-balancing.
- The NVC performs MAC learning on the VXLAN tunnel.
- ARP suppression is not supported.
- One NVC manages all encapsulated Broadcast, Unknown Unicast, and Multicast (BUM) traffic. This NVC replicates the BUM traffic to all other VTEPs in the network. If connectivity to the NVC managing BUM traffic fails, a loss of BUM traffic can occur. NVC cluster NSX service node replication is not applicable for BUM traffic.

The following diagram shows an example of NVCs managing a distributed virtual network.

OVSDB protocol support for VXLAN Gateway Dependencies and Restrictions

- The VXLAN Gateway must operate in Full Interworking mode.
- You must configure at least one NVC connection to the VXLAN Gateway.
- You can configure up to three NVCs connections to one VXLAN Gateway in this release.
- The VXLAN Gateway must use the Segmented Management Instance IP address to connect with the NVCs. For more information about how to configure Segmented Management Instance, see [Segmented Management](#) on page 67.
- You cannot change or delete the VTEP source IP address when OVSDB is enabled.
- The OVSDB managed interface I-SIDs are communicated to the NVC as physical ports of the switch.
- EDM support for OVSDB is limited in this release. You can use CLI where EDM configuration is unavailable.
- The VXLAN Gateway general considerations and limitations also apply to OVSDB protocol support for VXLAN Gateway.

Note

NVC connectivity issues for SSL communication failures are not logged on the switch. You can use the logs on the NVC to troubleshoot SSL communications with the VXLAN Gateway.

OVS Modules on VXLAN Gateway

OVSDB protocol support for VXLAN Gateway uses OVS modules on the VXLAN Gateway. The switch runs the following OVS modules:

- OVSDB server – Manages the database.
- Database – Manages the OVS schema and HW VTEP schema and JSON content.

OVSDB Replication Considerations and Limitations

Note

OVSDB replication is different than NSX service node replication. Service node replication is configured and supported in NSX. OVSDB replication uses vIST and is configured and supported on the VXLAN Gateway.

- You require at least two NVCs to enable OVSDB replication.
- OVSDB replication operates in an ACTIVE-STANDBY server configuration.
- You must disable OVSDB on the standby vIST device before disabling OVSDB on the active vIST device.
- One active NVC and one standby NVC are supported by the VXLAN Gateway.
- VNID to I-SID binding, Remote VTEPs, VNI to Remote VTEPs for BUM, Remote MACs, and Local MACs are replicated across NVCs.

VXLAN Gateway configuration using the CLI

This section provides procedures to configure VXLAN Gateway using the CLI.

Configuring the VXLAN Gateway boot flag

There are two configuration modes: Base Interworking Mode and Full Interworking Mode. The Base Interworking Mode is the default mode. To switch to the Full Interworking Mode, use this procedure.

Important

After you change this boot flag, you must save the change to the configuration file and reboot the switch.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable Full Interworking Mode:
`boot config flags vxlan-gw-full-interworking-mode`
3. Save the changed configuration.
`save config`
4. Restart the switch.
`reset`
5. Verify that VXLAN Gateway is in Full Interworking Mode:
`show boot config flags`

The **true** parameter in the output indicates that Full Interworking Mode is enabled.

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags vxlan-gw-full-interworking-mode
```

Configuring VXLAN Gateway

Use the following procedure to configure VXLAN Gateway parameters to allow SPBM to operate on the switch.

Before You Begin

Use the **show boot config flags** to verify that you are in the mode you want. The **vxlan-gw-full-interworking-mode** should be set to `false` for the Base Interworking Mode (default) and `true` for the Full Interworking Mode.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the VTEP source IP address:

```
vtep source-ip <A.B.C.D> [vrf WORD<1-16>]
```
3. Configure the remote VTEP IP address:

```
vtep <1-500> ip <A.B.C.D> [name WORD<1-64>]
```
4. Create a VNID instance:

```
vnid <1-16777215> i-sid <1-16777215>
```

Note

The command prompt changes to **#vxlan** to indicate that you are now in VXLAN Configuration mode for the VNID specified in `vnid <1-16777215>`.

5. Associate VLANs in a port or MLT list to this VNID instance:

```
c-vid <1-4094> port <{slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}>

or

c-vid <1-4094> mlt <1-4094>
```
6. Specify the ports or MLT in this VNID instance that will support untagged traffic:

```
untagged-traffic port <{slot/port[/sub-port]}>

or

untagged-traffic mlt <1-4094>
```
7. Associate VTEPs to this VNID instance:

```
vtep <1-255>
```

Example

For an example of this procedure, see [VXLAN Gateway configuration example in Base Interworking mode](#) or [VXLAN Gateway configuration example in Full Interworking mode](#).

Variable definitions

Use the data in the following table to use the **vtep** command.

Variable	Value
<code>source-ip</code> <code><A.B.C.D> [vrf</code> <code>WORD<1-16>]</code>	Specifies the VXLAN tunnel end point (VTEP) source IP address, which can be on the GRT or a VRF. Note: The VTEP source IP address must be on a loopback interface.
<code><1-500> ip</code> <code><A.B.C.D> [name</code> <code>WORD<1-64>]</code>	Specifies an index value and an IP address that uniquely identifies this remote VTEP. Optionally, you can assign a specific name to this tunnel. By default, the switch assigns a name in this format: <code>VTEP-<#ID>-<IP address></code> Note: The remote VTEP IP address cannot be a local, broadcast, or multicast IP address.

Use the data in the following table to use the **vnid** command.

Variable	Value
<code><1-16777215> i-sid</code> <code><1-16777215></code>	Uses this VNID and I-SID information to create a VNID instance and enter VXLAN Configuration Mode in the CLI. Note: A VNID must not have the same value as an I-SID.

Use the data in the following table to configure commands in the VXLAN Configuration Mode (`#vxlan`). These commands apply to the VNID instance that you specified in the `vnid <1-16777215> i-sid <1-16777215>` command.

Variable	Value
<code>c-vid <1-4094> port <{slot/port[/ sub-port] [-slot/ port[/sub-port]] [,...]}></code>	Specifies a value that uniquely identifies the customer VLAN ID and ports of this ELAN end point. The switch reserves the following VLAN IDs: <ul style="list-style-type: none"> VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs 4060 to 4094 are reserved for internal use. VLAN IDs 3500 to 3999 are reserved if you enable VRF scaling and SPBM mode. VLAN ID 4095 is not used. VLAN ID 4096 is reserved for untagged traffic.
<code>c-vid <1-4094> mlt <1-4094></code>	Specifies a value that uniquely identifies the customer VLAN ID and MLTs of this ELAN end point. The switch reserves the following VLAN IDs: <ul style="list-style-type: none"> VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs 4060 to 4094 are reserved for internal use. VLAN IDs 3500 to 3999 are reserved if you enable VRF scaling and SPBM mode. VLAN ID 4095 is not used. VLAN ID 4096 is reserved for untagged traffic.
<code>untagged-traffic port <{slot/port[/ sub-port] [-slot/ port[/sub-port]] [,...]}></code>	Specifies the ports that support untagged traffic.
<code>untagged-traffic mlt <1-4094></code>	Specifies the MLTs that support untagged traffic.
<code>vtep <1-255></code>	Lists the remote VTEP destinations to associate with the specified VNID.

Flushing the MAC forwarding table

Use this procedure to flush all the learned MAC addresses from the forwarding database of the selected VNID.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Flush the MAC FDB:

```
vnid mac-address-entry <1-16777215> flush
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# vnid mac-address-entry 100 flush
```

VXLAN Gateway show commands

Use the procedures in this section to display specific information about VXLAN Gateway on the switch.

Displaying VTEP source information

Use the following procedure to display information about the VTEP source.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display the VTEP's source IP address and the name of the VRF:
show vtep local

Example

```
Switch:1# show vtep local
=====
                        VTEP General Info
=====
vtep source-ip-address: 198.51.100.1
vtep vrf : GlobalRouter
```

Displaying remote VTEP information

Use the following procedure to display information about the remote VTEP.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display information about all of the remote VTEPs or use the option to specify a particular VTEP:
show vtep remote [<1-500>]

Example

```
Switch:1# show vtep remote
=====
                        Remote VTEP Info
=====
ID      NAME      VTEP      L3_VTEP_NEXT_HOP_INFO
  DEST-IP  PORT/MLT  VLAN      VRF
-----
1       vtep-1    198.51.100.6  Mlt78      3851      GlobalRouter
56      vtep-56   198.51.100.22 Mlt130     3855      underlay-vxlan

-----
2 out of 2 Total Num of remote vteps
-----
```

Displaying the name of the remote VTEP

Use the following procedure to display the name of the remote VTEP.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display the names of all remote VTEPs or use the option to specify a particular VTEP:
show vtep remote name [<vtepId>]

Example

```
Switch:1# show vtep remote name
=====
Remote VTEP Name
=====
ID      NAME
-----
1       vxlan_tunnel_1
2       --
3       --
-----
3 out of 3 Total Num of remote vteps
-----
```

Displaying VNID information

Use the following procedure to display information about the VNID.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display information about all the VNIDs or use the option to specify a particular VNID:
show vnid i-sid [<1-500>]

Example

```
Switch:1# show vnid i-sid
=====
vnid Info
=====
VNID      ISID      PORT          MLT          VTEP
ID        ID        INTERFACES    INTERFACES   IDS
-----
110       120       c3:1/10      -            2,56
11000060  1060     c60:1/10     -            56
11000065  1065     c65:1/10     -            56
11000066  1066     c66:1/48     -            2
.
.
.
```

Display the MAC Addresses in the VNID FDB

Use the following procedure to display the MAC addresses in the VNID forwarding database.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display all the VNIDs in the FDB table or use one of the options to specify a particular VNID:
show vnid mac-address-entry [<1-16777215> | port <{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]> | mac <0x00:0x00:0x00:0x00:0x00:0x00> | remote]

Example

```
Switch:1# show vnid mac-address-entry
=====
                          VNID Fdb Table
=====
VNID      STATUS      MAC-ADDRESS      INTERFACE      TYPE
-----
11000065  learned    00:00:5e:00:01:01  vtep_56       REMOTE
14000100  learned    a4:25:1b:51:a5:04  vtep_67       REMOTE
14000100  learned    a4:25:1b:52:a5:04  vtep_67       REMOTE
14000100  learned    a4:25:1b:52:bd:03  vtep_2        REMOTE

=====
```

Displaying the VXLAN Running Configuration

Use the following procedure to display the currently running VXLAN configuration.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display the running configuration:
show running-config module vxlan

Example

This example shows the VXLAN information only. It does not show the hardware-specific information that also the system displays it in the output for this command.

The example shows the VXLAN Gateway in Base Interworking Mode. It also shows an external loopback (see **c-vid** commands), which enables communication between the VNID and an I-SID in an SPB network.

```
Switch:1# show running-config module vxlan

#
# VTEP CONFIGURATION
#
vtep source-ip 1.1.1.1 vrf underlay-vxlan

#
# REMOTE VTEP CONFIGURATIONS
#
vtep 2 ip 1.1.1.1 name "vtep-2"
vtep 67 ip 1.1.1.67 name "vtep-67"
```

```
#
# VNID CONFIGURATION
#
vnid 12002105 i-sid 102105
c-vid 105 port 1/11
c-vid 2105 port 1/10
vtep 67
exit
```

OVSDB protocol support for VXLAN Gateway configuration using CLI

This section provides procedures to configure OVSDB protocol support for VXLAN Gateway using the Command Line Interface (CLI).

Configuring OVSDB Managed Interfaces

Use the following procedure to configure OVSDB managed interfaces on the switch.

Before You Begin

- You must enable VXLAN Gateway Full Interworking Mode. For more information, see [Configuring the VXLAN Gateway boot flag](#) on page 3927.
- You must create the required Flex UNI or CVLAN I-SIDs before you configure the OVSDB managed interface.

Procedure

1. Enter OVSDB Configuration mode:

```
enable

configure terminal

ovsdb
```
2. Configure the OVSDB managed interface:

```
managed-interface i-sids WORD<1-1024>
```

Example

The following is an example configuring two I-SIDs as OVSDB management interfaces.

```
SWITCH:1>enable
SWITCH:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SWITCH:1(config)#ovsdb
SWITCH:1(config-ovsdb)#managed-interface i-sids 300
SWITCH:1(config-ovsdb)#managed-interface i-sids 500
```

What to Do Next

Configure the OVSDB protocol support for VXLAN Gateway, see [Configuring OVSDB protocol support for VXLAN Gateway](#) on page 3935.

Variable definitions

Use the data in the following table to use the **managed-interface** command.

Variable	Value
<code>i-sids WORD<1-1024></code>	<p>Specifies the I-SID information to create an interface to manage OVSDB protocol support for VXLAN Gateway.</p> <p>Note: You must create the required Flex UNI or CVLAN I-SIDs before you configure the managed interface I-SID.</p>

Configuring OVSDB protocol support for VXLAN Gateway

Use the following procedure to configure OVSDB protocol support for VXLAN Gateway on the switch.

Before You Begin

- You must enable VXLAN Gateway Full Interworking Mode. You can use **show boot config flags** to verify the current VXLAN Gateway mode. For more information, see [Configuring the VXLAN Gateway boot flag](#) on page 3927.
- You must configure and use the Segmented Management Instance IP address on the VXLAN Gateway to establish connectivity with the NVC. For more information about Segmented Management Instance, see [Segmented Management Instance Configuration using the CLI](#) on page 85.
- You must configure an OVSDB management interface. For more information, see [Configuring OVSDB Managed Interfaces](#) on page 3934.
- You must transfer an OVSDB certificate file and private-key file to the flash storage of the switch. You can use an ovs-pki utility with SSL libraries to generate the private keys and certificates. You can use **boot config flags FTPE** and then an SCP utility to transfer the private key and certificate file to the flash storage of the switch.
- If the switch is an aggregation switch, the IST peer must support OVSDB, have the same source VTEP-IP and OVSDB managed-interface, and must communicate with the NVC management IP.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Configure the source VTEP IP address:

```
vtep source-ip <A.B.C.D> [vrf WORD<1-16>]
```
- Enter OVSDB Configuration mode:

```
ovsdb
```
- Install the OVSDB certificate file:

```
install-cert-file WORD<1-128>
```
- Install the OVSDB private key:

```
private-key WORD<1-128>
```

6. Enable OVSDB protocol support for VXLAN Gateway:

```
enable
```

7. Configure the NVC:

```
controller <1-100> ip address <A.B.C.D> protocol <ssl|tcp> [port <1-65535>]
```

Example

The following is an example of configuring a VTEP source IP, installing an OVSDB certificate file, installing an OVSDB private key, enabling OVSDB protocol support for VXLAN Gateway, and configuring the IP address, protocol, and port for one NVC.

```
SWITCH:1>enable
SWITCH:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SWITCH:1(config)#vtep source-ip 192.0.2.1 vrf vxlan-underlay
SWITCH:1(config)#ovsdb
SWITCH:1(config-ovsdb)#install-cert-file /intflash/tom/sc-cert.pem
SWITCH:1(config-ovsdb)#private-key /intflash/tom/sc-privkey.pem
SWITCH:1(config-ovsdb)#enable
SWITCH:1(config-ovsdb)#controller 1 ip address 192.0.2.2 protocol ssl port 6640
```

Note

You can configure multiple controllers for high availability. One VXLAN Gateway can support a maximum of three controllers.

Important

If you add or delete a controller, or modify the OVSDB managed interface when a controller is configured, the existing controller connections reset. Log messages generate to indicate the status changes as the controllers disconnect and reconnect.

If you change a previously configured VTEP source-ip and re-enable OVSDB, the controller sees a new VXLAN tunnel instead of updating the existing VXLAN. You must configure the VNID to I-SID binding on the controller for the new VXLAN tunnel associated with the new VTEP IP address.

Variable definitions

Use the data in the following table to use the **vtep source-ip** command.

Variable	Value
<code><A.B.C.D> [vrf WORD<1-16>]</code>	Specifies the VXLAN tunnel end point (VTEP) source IP address in IPv4 format. Optionally you can specify a VRF. Note: The VTEP source IP address must be on a loopback interface.

Use the data in the following table to use the **install-cert-file** command.

Variable	Value
<code>WORD<1-128></code>	Specifies the path and file name of the OVSDB certificate file.

Use the data in the following table to use the **private-key** command.

Variable	Value
<i>WORD</i> <1-128>	Specifies the path and file name of the OVSDB private key.

Use the data in the following table to use the **controller** command.

Variable	Value
<1-100>	Specifies the ID of the controller.
<i>ip address</i> <A.B.C.D>	Specifies the IP address of the controller in IPv4 format.
<i>protocol</i> <ssl tcp>	Specifies the networking protocol as SSL or TCP for controller communications.
port <1-65535>	Specifies the networking port of the controller.

Configuring OVSDB Replication

Use the following procedure to configure OVSDB replication to support VIST.

Before You Begin

- You must enable VXLAN Gateway Full Interworking Mode on the switch.
- You must configure an OVSDB managed interface on the switch.
- You must configure and enable OVSDB protocol support for VXLAN Gateway on the switch.
- You must have at least two NVCs configured to communicate on the managed interface network.

Procedure

1. Enter OVSDB Configuration mode:

```
enable

configure terminal

ovsdb
```
2. Configure the OVSDB replication:

```
replication peer-ip <A.B.C.D> local-ip <A.B.C.D>
```

Example

The following is an example configuring OVSDB replication to support VIST.

```
SWITCH:1>enable
SWITCH:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SWITCH:1(config)#ovsdb
SWITCH:1(config-ovsdb)#replication peer-ip 192.0.2.3 local-ip 192.0.2.2
```

Variable definitions

Use the data in the following table to use the **replication** command.

Variable	Value
<i>peer-ip</i> <A.B.C.D>	Specifies the IP address of the secondary controller for OVSDB replication support.
<i>local-ip</i> <A.B.C.D>	Specifies the IP address of the primary controller for OVSDB replication support.

Displaying the OVSDB configuration

Use the following procedure to display the OVSDB protocol support for VXLAN Gateway configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the OVSDB configuration:

```
show ovbdb config
```

Example

The following is an example of displaying the OVSDB configuration.

```
SWITCH:1>show ovbdb config
=====
                        Ovbdb Config Info
=====
                        Status - Enabled
                        Certificate - Installed
                        Private Key - Installed
                        Replication Peer NLS-IP - 192.0.2.3
                        Replication Local NLS-IP - 192.0.2.2
=====
                        Ovbdb Controller Config Info
=====

1       ssl              192.0.2.10     6640
```

Displaying the OVSDB controller status

Use the following procedure to display the OVSDB controller status.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the OVSDB controller status:

```
show ovbdb controller status
```

Example

The following is an example of displaying the OVSDB controller status.

```
SWITCH:1>show ovbdb controller status
=====
```

```

=====
OVSDB Controller Status
=====
Protocol          IP              Port      status    source

ssl               192.0.2.3      6640     Down      Learnt

2 out of 2 Total Num of Controllers displayed

```

Displaying the OVSDB replication state

Use the following procedure to display the OVSDB replication state.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the OVSDB controller status:

```
show ovbdb replication state
```

Example

The following is an example of displaying the OVSDB replication state.

```

SWITCH:1>show ovbdb replication state
=====
Ovsdb Replication Status
=====
Local NLS IP      Peer NLS IP      State
-----
192.0.2.2         192.0.2.3        ENABLED

```

Displaying the OVSDB managed interfaces

Use the following procedure to display the OVSDB managed interfaces.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the OVSDB managed interfaces:

```
show ovbdb managed-interface
```

Example

The following is an example of displaying the OVSDB managed interfaces.

```

SWITCH:1>show ovbdb managed-interface
=====
OVSDB Managed Interfaces - ISID

VXLAN Gateway configuration using EDM

This section provides procedures to configure VXLAN Gateway using the Enterprise Device Manager (EDM).

Configuring the VXLAN Gateway boot flag

There are two configuration modes: Base Interworking Mode and Full Interworking Mode. The Base Interworking Mode is the default mode. To switch to the Full Interworking Mode, use this procedure.

Important

After you change this boot flag, you must save the change to the configuration file and reboot the switch.

Procedure

1. In the navigation pane, expand the **Configuration > Edit > Chassis** folders.
2. Click the **Boot Config** tab.
3. Select **EnableVxlanGwFullInterworkingMode** to enable Full Interworking Mode.
4. Click **Apply**.

Configuring a VTEP source IP address

Use the following procedure to configure the VXLAN Gateway source IP address.

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **VTEP**.
3. Click the **Globals** tab.
4. In the **Sourcelp** field, enter the VTEP source IP address.
5. In the **Vrf** field, select `GlobalRouter` or a VRF ID.
6. Click **Apply**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
Sourcelp	Specifies the VXLAN tunnel end point (VTEP) source IP address in an A.B.C.D format.
Vrf	Specifies the VRF name used for the source IP address, which you select from the drop down menu. This IP address can be on the GRT or a VRF. Note: The VTEP source IP address must be on a loopback interface.

Configuring a remote VTEP

Use the following procedure to configure the remote VTEP destination. The total number of VTEP remote destination IPs that you can configure is 500.

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **VTEP**.
3. Click the **Vtep** tab.
4. In the **Id** field, assign a unique index value to this remote VTEP.
5. In the **IpAddr** field, enter the IP address of this remote VTEP.
6. In the **Name** field, assign a name to this remote VTEP.
7. Click **Apply**.

Vtep field descriptions

Use the data in the following table to use the **Vtep** tab.

Name	Description
Id	Specifies an index value in the range from 1 to 500 that uniquely identifies this remote VTEP.
IpAddr	Specifies an IP address that uniquely identifies this remote VTEP. Note: The remote VTEP IP address cannot be a local, broadcast, or multicast IP address.
Name	Assigns a name to this remote VTEP tunnel.
NextHopVrfName	Displays the VRF name of the next hop to reach the remote VTEP.
OvsdbConfigured	Specifies if the VTEP is configured with OVSDB protocol support for VXLAN Gateway.

Configuring a VNID

Use the following procedure to configure a VNID, which identifies one of the potential 16 million VXLAN segments that can coexist within the same administrative domain.

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **VTEP**.
3. Click the **Vnid** tab.
4. In the **Identifier** field, assign a unique value to this VNID.
5. In the **Isid** field, specify the I-SID associated with this VNID.
6. In the **Action** field, select one of the available actions: none or flush.
7. Click **Apply**.

Vnid field descriptions

Use the data in the following table to use the **Vnid** tab.

Name	Description
Identifier	Specifies a value that uniquely identifies the VNID of this VXLAN tunnel end point.
Isid	Specifies a value that uniquely identifies the I-SID associated with this VXLAN tunnel end point. Note: A VNID must not have the same value as an I-SID.
Action	Choose one of the following actions to take with the MAC FDB: <ul style="list-style-type: none"> • none: Don't take any action. This is the default. • flushMacFdb: Flush all the learned MAC addresses from the forwarding database of the selected VNID.
OvsdbConfigured	Specifies if the VNID is configured with OVSDB protocol support for VXLAN Gateway.

Configuring VNID endpoints

Use the following procedure to configure a VNID and the VXLAN tunnel end point.

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **VTEP**.
3. Click the **Vnid End Points** tab.
4. In the **Vnid** field, enter the VNID ID.
5. In the **Vtepld** field, enter the ID of the remote VTEP.
6. Click **Apply**.

Vnid End Points field descriptions

Use the data in the following table to use the **Vnid End Points** tab.

Name	Description
Vnid	Specifies a value that uniquely identifies the VNID of this VXLAN tunnel end point.
Vtepld	Specifies an index value in the range from 1 to 500 that uniquely identifies this remote VTEP.
Isid	Displays a value that uniquely identifies the I-SID associated with this VXLAN tunnel end point.

Configuring ELAN endpoints

Use the following procedure to configure information associated with ELAN end points.

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **VTEP**.
3. Click the **Elan End Points** tab.
4. In the **Vnid** field, specify the VNID associated with this ELAN.
5. In the **Cvid** field, specify the customer VLAN ID.
6. In the **IfIndex** field, specify the interface index for this ELAN endpoint.
7. Click **Apply**.

Elan End Points field descriptions

Use the data in the following table to use the **Elan End Points** tab.

Name	Description
Vnid	Specifies a value that uniquely identifies the VNID of this ELAN tunnel endpoint.
Cvid	Specifies a value that uniquely identifies the customer VLAN ID of this ELAN endpoint. The switch reserves the following VLAN IDs: <ul style="list-style-type: none"> • VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. • VLAN IDs 4060 to 4094 are reserved for internal use. • VLAN IDs 3500 to 3999 are reserved if you enable VRF scaling and SPBM mode. • VLAN ID 4095 is not used. • VLAN ID 4096 is reserved for untagged traffic.
IfIndex	Specifies the interface index for the MLT or port for this ELAN endpoint.
Isid	Specifies the I-SID associated with this VNID.

Displaying the VTEP next hop

Use the following procedure to display information about the remote VTEP.

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **VTEP**.
3. Click the **Next Hop** tab.

Next Hop field descriptions

Use the data in the following table to use the **Next Hop** tab.

Name	Description
Vtepld	Specifies an index value in the range from 1 to 500 that uniquely identifies this remote VTEP.
Ip	Specifies an IP address that uniquely identifies this remote VTEP tunnel.
IfIndex	Specifies the interface index of the next hop to reach the remote VTEP.
Vid	Specifies the VLAN ID of the next hop to reach remote VTEP.

Displaying the VNID forwarding database

Use the following procedure to display information about the VNID forwarding database (FDB).

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **VTEP**.
3. Click the **Vnid FDB** tab.

Vnid FDB field descriptions

Use the data in the following table to use the **Vnid FDB** tab.

Name	Description
Vnid	Displays the VNID IDs of the VXLAN tunnel endpoints.
Address	Displays all the learned MAC addresses in the forwarding database of the selected VNID.
Status	Displays whether or not the MAC address was learned.
InterfaceIndex	Displays the interface index name for the VNID.
Type	Displays whether the VNID is local or remote.

OVSDB protocol support for VXLAN Gateway configuration using EDM

This section provides procedures to configure OVSDB protocol support for VXLAN Gateway using the Enterprise Device Manager (EDM).

Configuring OVSDB globally

Use the following procedure to configure the OVSDB certificates, private key, and replication global settings.

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.

2. Click **OVSDB**.
3. Click the **Globals** tab.
4. Select **Enable**.
5. In the **CertificateFilename** field, type the `filepath/filename`.
6. In the **CertFileInstallAction** field, select **install**.
7. Click **Apply**.
8. In the **PrivateKeyFilename** field, type the `filepath/filename`.
9. In the **PrivateKeyInstallAction** field, select **install**.
10. Click **Apply**.
11. Select **ReplicationEnable**.
12. In the **ReplicationPeerIpAddr** field, type the IP address.
13. In the **ReplicationLocalIpAddr** field, type the IP address.
14. Click **Apply**.
15. Verify the **ReplicationState**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
Enable	Enables or disables the feature. Default is disabled (cleared).
CertificateFilename	Specifies the filename of the certificate.
CertFileInstallAction	Specifies to install or uninstall the certificate. You must have a certificate file on the switch.
PrivateKeyFilename	Specifies the filename of the private key.
PrivateKeyInstallAction	Specifies to install or uninstall the private key. You must have a private key file on the switch.
ReplicationEnable	Enables or disables replication support. Default is disabled (cleared).
ReplicationPeerIpAddr	Specifies the replication server peer IP address in A . B . C . D format.
ReplicationLocalIpAddr	Specifies the replication local IP address in A . B . C . D format.
ReplicationState	Displays the current replication status.

Configuring an OVSDB controller

Use the following procedure to configure an OVSDB controller ID, IP address, protocol, and port.

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **OVSDB**.
3. Click the **Controller** tab.

4. Click **Insert**.
5. In the **Id** field, assign a unique index value to this controller.
6. In the **IpAddr** field, enter the IP address of this controller.
7. In the **Protocol** field, select **tcp** or **ssl**.
8. In the **Port** field, enter a port number.
9. Click **Insert**.

Controller field descriptions

Use the data in the following table to use the **Controller** tab.

Name	Description
Id	Specifies an ID number for a controller. Value range of 1 to 100.
IpAddr	Specifies the IP address of a controller. Type an IP address in A . B . C . D format.
Protocol	Specifies the communications protocol for the controller. Select tcp or ssl .
Port	Specifies the communications port for the controller. Value range of 1 to 65535.

Displaying the OVSDB controller status

Use the following procedure to display status information about the OVSDB controller.

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **OSVDB**.
3. Click the **Status** tab.

Status field descriptions

Use the data in the following table to use the **Status** tab.

Name	Description
IpAddress	Displays the IP address of a controller.
Protocol	Displays the communications protocol of a controller as TCP or SSL.
Port	Displays the communications port for the controller. Value range of 1 to 65535.
Source	Displays the source of the controller as learned or configured.
OperStatus	Displays the operational status of the controller.

Configuring OVSDB managed interface

Use the following procedure to configure a I-SID interface for the OVSDB.

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **OSVDB**.
3. Click the **Interface** tab.
4. Click **Insert**.
5. In the **Isid** field, type the I-SID identifier.
6. Click **Insert**.

Interface field descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
Isid	Specifies an I-SID to use as the managed interface.

Configuration Examples

This section provides network configuration examples for VXLAN Gateway and OVSDB protocol support for VXLAN Gateway.

VXLAN Gateway configuration example

This example shows how to configure the VXLAN Gateway. Remember that there are two modes:

- Base Interworking Mode is the default mode so there is no need to set the mode boot flag. However, you should use the **show boot config flags** command to verify that the **vxlان-gw-full-interworking-mode** is set to `false`.
- Full Interworking Mode supports all SPB functionality including vIST and SMLT using an internal loopback. Full Interworking Mode is not the default mode. To configure Full Interworking mode, you must enable the **vxlان-gw-full-interworking-mode** boot flag.

Important

Changing the mode requires a reboot for the change to take effect, which can cause a loss of traffic.

OVSDB protocol support for VXLAN Gateway configuration example

This example shows how to configure OVSDB protocol support for VXLAN Gateway:

Important

OVSDB protocol support for VXLAN Gateway also requires an ESXi host running VMware NSX configured with a HW-VTEP, and a Logical Switch configured with VNID to HW-VTEP bindings to function. See VMware NSX documentation for more information.

Important

OVSDB requires full interworking mode on the VXLAN Gateway. Changing the mode requires a reboot for the change to take effect, which can cause a loss of traffic.

Port Numbering and MAC Address Assignment Reference

[Port Numbering](#) on page 3954

[Interface Indexes](#) on page 3963

[MAC Address Assignment](#) on page 3965

This section provides information about the port numbering and Media Access Control (MAC) address assignment used on the switch.

Port Numbering

A port number includes the slot location of the port in the chassis, as well as the port position. For example, the first port in the first slot is structured as 1/1. The number of slots and ports varies depending on the hardware platform. For more information about hardware, see the hardware documentation for your platform.

VSP 4450 Series

The following diagrams illustrate the components on the front panels of the VSP 4450 Series switches. Ethernet ports 1-50 on the switch are considered to be in slot 1.

VSP 4450GSX-PWR+

Figure 281: VSP 4450GSX-PWR+

1. USB port.
2. Switch LEDs for system power (PWR), switch status (Status), and redundant power supply (RPS).

- 3. 12 10/100/1000 Mbps RJ-45 ports with PoE+. LEDs indicating port activity are above the ports.
- 4. 36 100/1000 Mbps SFP ports.
- 5. Two 1/10G SFP+ ports.
- 6. Console Port.

VSP 4450GTX-HT-PWR+

Figure 282: VSP 4450GTX-HT-PWR+

- 1. USB port but without a USB or a USB device cover.

Note

The VSP 4450GTX-HT-PWR+ model does not require a USB device in the USB port for normal operation. The USB port can be used for additional storage using a USB memory stick.

- 2. Switch LEDs for system power (PWR), switch status (Status), and redundant power supply (RPS).
- 3. 48 10/100/1000 Mbps RJ-45 ports with 802.3at PoE+. LEDs indicating port activity are above the ports.
- 4. Two combo port SFP slots. Supports 1G SFPs and 100Base low speed SFPs.
- 5. Two SFP+ slots. Supports 1G SFPs and 10G SFP+s.
- 6. Console Port.
- 7. Field-replaceable 1000W AC power supply unit (PSU).
- 8. Second field-replaceable AC power supply unit for redundancy or additional PoE.

VSP 4450GSX-DC

Figure 283: VSP 4450GSX-DC

- 1. USB port.
- 2. Switch LEDs for system power (PWR), switch status (Status), and redundant power supply (RPS).
- 3. 12 10/100/1000 Mbps RJ-45 ports. LEDs indicating port activity are above the ports.

4. 36 10/100 Mbps SPF ports.
5. Two SFP+ slots. Supports 1G SFPs and 10G SFP+s.
6. Console Port.

VSP 4900 Series

The following diagrams illustrate the components on the front panels of the VSP 4900 switches.

VSP4900-48P

The following diagram illustrates the components of the front panel of the VSP4900-48P switch. Slot 1 is used for the 48 fixed ports and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

1. Mode button for port LED control. Port LED mode indicators (SYS, SPD). Switch LEDs for system power (P1, P2) and fans (F1, F2, F3). System Locator LED (LOC).

Note

Note: STK and BT port LED mode indicators are not supported.

2. One USB micro B console port. An alternative RJ-45 console port is provided on the back panel (not shown).
3. Two USB ports, for removable storage.
4. 48 10/100/1000 Mbps RJ-45 Ethernet ports that provide 802.3at PoE+. LEDs that indicate the port activity and statuses are below the ports.
5. VIM slot (shown with VIM installed). Port numbering depends on the type of VIM installed in the slot. For more information about VIM modules, see [VSP 4900 Series Switches: Hardware Installation Guide](#).

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, and hot-swappable power supply and fan units.

VSP4900-24XE

The following diagram illustrates the components on the front panel of the VSP4900-24XE switch. Slot 1 is used for the 24 fixed ports and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

1. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2) and fans (F1, F2, F3). System Locator LED (LOC).
2. One USB micro B console port. An alternative RJ-45 console port is provided on the back panel (not shown).
3. Two USB ports, for removable storage.
4. 24 1/10 Gbps ports. LEDs that indicate the port activity and statuses are below the ports.
5. VIM slot. Port numbering depends on the type of VIM installed in the slot. For more information about VIM modules, see [VSP 4900 Series Switches: Hardware Installation Guide](#).

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, Solid State Drive (SSD) slot, and hot-swappable power supply and fan units.

VSP4900-12MXU-12XE

The following diagram illustrates the components on the front panel of the VSP4900-12MXU-12XE switch. Slot 1 is used for the 24 fixed ports and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

1. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2) and fans (F1, F2, F3). System Locator LED (LOC).
2. One USB micro B console port. An alternative RJ-45 console port is provided on the back panel (not shown).
3. Two USB ports, for removable storage.
4. Ports 1 to 12 are 100 Mbps and 1/2.5/5/10 Gbps RJ-45 ports that provide PoE (60W) and ports 13-24 are 1/10 Gbps ports. LEDs that indicate the port activity and statuses are below the ports.
5. VIM slot. Port numbering depends on the type of VIM installed in the slot. For more information about VIM modules, see [VSP 4900 Series Switches: Hardware Installation Guide](#).

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, SSD slot, and hot-swappable power supply and fan units.

VSP4900-24S

The following diagram illustrates the components on the front panel of the VSP4900-24S switch. Slot 1 is used for the 24 fixed ports and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

1. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2) and fans (F1, F2, F3). System Locator LED (LOC).
2. One USB micro B console port. An alternative RJ-45 console port is provided on the back panel (not shown).
3. Two USB ports, for removable storage.
4. 24 1 Gbps ports. LEDs that indicate the port activity and statuses are below the ports.
5. VIM slot. Port numbering depends on the type of VIM installed in the slot. For more information about VIM modules, see [VSP 4900 Series Switches: Hardware Installation Guide](#).

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, and hot-swappable power supply and fan units.

VSP 7200 Series

The following figure illustrates the front view of the VSP 7200 Series switch.

When looking at the front of the switch:

- Slot 1 is the grouping of the 48 10 Gbps ports on the left.
- Slot 2 is the grouping of the 6 40 Gbps ports on the right.

1. LEDs indicating port activity are above the RJ-45 and SFP+ port. The up arrow on the left indicates the top port; the down arrow on the right indicates the bottom port.
2. 48 ports — The VSP 7254XSQ has 48 SFP/SFP+ fiber ports. The VSP 7254XTQ has 48 RJ-45 copper ports.
3. Six QSFP+ ports — The LEDs are below each port. There are four LEDs per port to support channelization. The up arrows refer to the port above.
4. USB port.
5. LEDs for system power (PWR), switch status (Status), redundant power supply (RPS), and fan modules (Fan).

VSP 7400 Series

The following diagrams illustrate the components on the front panels of the switches. For more information on hardware, see [VSP 7400 Series Switches: Hardware Installation Guide](#).

VSP 7432CQ

The following figure illustrates the components on the front panel of the VSP 7432CQ. Slot 1 is used for all of the ports.

Figure 284: VSP 7432CQ

1. 32 100-Gigabit QSFP28/QSFP+ ports each with 4 LEDs — the top row of LEDs is for the top port and the lower row of LEDs is for the lower port.
2. RJ-45 console port.
3. USB port.
4. OOB Management port — LinkSpeed LED on the left and Activity LED on the right.
5. LEDs for system power, power supply units (PSU1 and PSU2), fan modules, and system.

The VSP 7432CQ supports two internal Extreme Integrated Application Hosting (IAH) ports labeled as Insight ports, 1/s1 and 1/s2, used by IAH virtual machines. For conceptual information see [Extreme Integrated Application Hosting](#) on page 847. For configuration instructions to use internal IAH ports, see [Virtual Services Configuration using CLI](#) on page 854 and [Virtual Services Configuration using EDM](#) on page 868.

VSP 7400-48Y

The following figure illustrates the components on the front panel of the VSP 7400-48Y. Slot 1 is used for all of the ports.

Figure 285: VSP 7400-48Y

1. 48 25-Gigabit SFP28 ports.
2. 8 100-Gigabit QSFP28/QSFP+ ports each with 4 LEDs.

3. USB port.
4. RJ-45 console port.
5. OOB Management RJ-45 port — A single LinkSpeed and Activity LED on the left.

LEDs for system power, power supply units (PSU1 and PSU2), fan modules, and system are to the right of the management port.

6. Management Set sliding button.

The VSP 7400-48Y supports one internal IAH port, 1/s1, used by IAH virtual machines. For conceptual information see [Extreme Integrated Application Hosting](#) on page 847. For configuration instructions to use internal IAH ports, see [Virtual Services Configuration using CLI](#) on page 854 and [Virtual Services Configuration using EDM](#) on page 868.

VSP 8200 Series and VSP 8400 Series

The following diagrams illustrate the components on the front panels of the switches. For more information on hardware, see [Installing the Virtual Services Platform 8000 Series](#).

VSP 8200 Series

The following figure illustrates the front view of the VSP 8284XSQ switch. There are 42 ports in Slot 1 on top, and 42 ports in Slot 2 on the bottom.

Figure 286: VSP 8284XSQ front view

1. SFP+ port LEDs are in between the ports on each slot. The up arrows refer to the port above and the down arrows refer to the port below.
2. 80 SFP+ ports that support 1G SFPs and 10G SFP+s.
 - 40 ports in Slot 1 on top
 - 40 ports in Slot 2 on the bottom
3. QSFP+ port LEDs are in between the ports on each slot. The up arrows refer to the port above and the down arrows refer to the port below.
4. Four QSFP+ ports: two in Slot 1 and two in Slot 2.
5. USB port
6. Console port (10101)

7. Management port — The LEDs are on the bottom of the port.
8. LEDs for system power (PWR), switch status (Status), redundant power supply (RPS), and fan modules (Fan).

VSP 8400 Series Series

The following figure illustrates the front view of the VSP 8400 Series switch.

Figure 287: VSP 8404 front view

Looking at the front of the switch, slot numbering begins at the top row and increases from left to right. Slot 1 is the top-left slot; slot 2 is the top-right slot. Slot 3 is the bottom-left slot; slot 4 is the bottom-right slot.

Port numbering depends on the type of Ethernet Switch Module (ESM) installed in the slot. For more information about ESMs, see [Installing the Virtual Services Platform 8000 Series](#).

1. Displays the four slots to install ESMs.
2. LEDs for system power (PWR), switch status (Status), redundant power supply (RPS), and fan modules (Fan).
3. USB port
4. Console port
5. OOB management port

VSP 8600 Series

The VSP 8608 chassis provides eight slots for I/O and control (IOC) modules and three slots for switch fabric (SF) modules in a 7U vertically oriented configuration.

The following figure illustrates the front view of the VSP 8600 Series switch.

Figure 288: VSP 8608 front view

From left-to-right, slots 1 through 4 are designated for I/O and control (IOC) modules, followed by slots SF1 through SF3 for switch fabric modules, and then slots 5 through 8 for IOC modules.

The switch supports different I/O and control (IOC) module types. Port numbering depends on the type of IOC module installed in the slot. The front panel on each IOC contains an RJ-45 console port, OOB Ethernet management port, USB port, and status LED indicators. For more information about IOC modules, see [Installing the Virtual Services Platform 8600](#).

XA1400 Series

XA1440 and XA1480 Switches

The following figure illustrates the components on the rear panel of the XA1440 and XA1480. Slot 1 is used for all of the ports.

Figure 289: XA1400 Series switches rear panel

1. DC power adapter input
2. Power button
3. Micro USB console port used to connect a terminal and perform local management.
4. RJ45 Console port used to connect a terminal and perform local management.
5. USB Type A ports for access to external storage.
6. RJ45 10/100/1000BASE-T Ethernet ports
7. 10G SFP+ Ethernet ports

Interface Indexes

The Simple Network Management Protocol (SNMP) uses interface indexes to identify ports, Virtual Local Area Networks (VLAN), and Multilink Trunking (MLT).

Port Interface Index

To determine the interface index (IfIndex), you can calculate it, or use the CLI command provided in this section.

As a result of channelization support, the ifIndex of each channelization-capable port increases by 4. The number is reserved for the 3 sub-ports when channelization is enabled.

VSP 4450 Series and XA1400 Series

For switches that do not include channelization-capable ports, use the following equation to determine the IfIndex of a port:

$$(192 \times \text{slot number}) + (\text{port number} - 1)$$

For example, the interface index of port 1/50 is 241.

The VSP 4450 Series and XA1400 Series use one slot.

VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8000 Series, and VSP 8600 Series

For switches that include channelization-capable ports, use the following equations to determine the IfIndex of a port:

- If the port does not support channelization, use $(64 \times \text{slot number}) + 128 + (\text{port number} - 1)$.
- If the port supports channelization, use the following equations:
 - for the port in question: $(64 \times \text{slot number}) + 128$
 - for subsequent ports: $(64 \times \text{slot number}) + 128 + ((\text{port number} - 1) * 4)$

This equation reserves space for the creation of the 3 sub-ports on the previous port, if or when you enable channelization.

The slot numbers are 1-2 for the VSP 4900 Series.

The slot numbers are 1-2 for the VSP 7200 Series.

The slot number is 1 for the VSP 7400 Series.

The slot numbers are 1-2 for the VSP 8200 Series.

The slot numbers are 1-4 for VSP 8400 Series.

The slot numbers are 1–8 for VSP 8600 Series.

CLI command

To determine the port interface index through the CLI, use the following command:

```
show interfaces gigabitEthernet
```

The following example shows an output for this command:

```
Switch:1(config)#show interfaces gigabitEthernet
```

Port Interface									
PORT NUM	INDEX	DESCRIPTION	LINK TRAP	PORT LOCK	MTU	PHYSICAL ADDRESS	STATUS		
							ADMIN	OPERATE	
1/1/1	192	40GbCR4BoC-Channel	true	false	1950	00:c0:ff:8b:50:00	up	up	
1/1/2	193	40GbCR4BoC-Channel	true	false	1950	00:c0:ff:8b:50:01	down	down	
1/1/3	194	40GbCR4BoC-Channel	true	false	1950	00:c0:ff:8b:50:02	down	down	
1/1/4	195	40GbCR4BoC-Channel	true	false	1950	00:c0:ff:8b:50:03	down	down	
1/2	196	100GbNone	true	false	1950	00:c0:ff:8b:50:04	down	down	
1/3	200	100GbNone	true	false	1950	00:c0:ff:8b:50:08	down	down	
1/4	204	100GbNone	true	false	1950	00:c0:ff:8b:50:0c	down	down	
1/5	208	100GbNone	true	false	1950	00:c0:ff:8b:50:10	down	down

1/8	220	100GbNone	true	false	1950	00:c0:ff:8b:50:1c	down	down	
1/9	224	100GbNone	true	false	1950	00:c0:ff:8b:50:20	down	down	
1/10	228	100GbNone	true	false	1950	00:c0:ff:8b:50:24	down	down	
1/11	232	100GbNone	true	false	1950	00:c0:ff:8b:50:28	down	down	
1/12/1	236	100GbNone-Channel	true	false	1950	00:c0:ff:8b:50:2c	down	down	
1/12/2	237	100GbNone-Channel	true	false	1950	00:c0:ff:8b:50:2d	down	down	
1/12/3	238	100GbNone-Channel	true	false	1950	00:c0:ff:8b:50:2e	down	down	
1/12/4	239	100GbNone-Channel	true	false	1950	00:c0:ff:8b:50:2f	down	down	
1/13	240	100GbNone	true	false	1950	00:c0:ff:8b:50:30	down	down	
1/14	244	100GbNone	true	false	1950	00:c0:ff:8b:50:34	down	down	
1/15	248	100GbNone	true	false	1950	00:c0:ff:8b:50:38	down	down	
1/16	252	100GbNone	true	false	1950	00:c0:ff:8b:50:3c	down	down	
1/17	256	100GbNone	true	false	1950	00:c0:ff:8b:50:40	down	down	
1/18	260	100GbNone	true	false	1950	00:c0:ff:8b:50:44	down	down	
1/19	264	100GbNone	true	false	1950	00:c0:ff:8b:50:48	down	down	
1/20	268	100GbNone	true	false	1950	00:c0:ff:8b:50:4c	down	down	
1/21	272	100GbNone	true	false	1950	00:c0:ff:8b:50:50	down	down	
1/22	276	100GbNone	true	false	1950	00:c0:ff:8b:50:54	down	down	
1/23	280	100GbNone	true	false	1950	00:c0:ff:8b:50:58	down	down	
1/24	284	100GbNone	true	false	1950	00:c0:ff:8b:50:5c	down	down	

1/25	288	100GbCR4	true	false	1950	00:c0:ff:8b:50:60	down	down
1/26	292	100GbCR4	true	false	1950	00:c0:ff:8b:50:64	down	down
1/27	296	100GbNone	true	false	1950	00:c0:ff:8b:50:68	down	down
1/28	300	100GbNone	true	false	1950	00:c0:ff:8b:50:6c	down	down
1/29	301	100GbNone	true	false	1950	00:c0:ff:8b:50:6d	down	down
1/30	305	100GbNone	true	false	1950	00:c0:ff:8b:50:71	down	down
1/31	309	100GbNone	true	false	1950	00:c0:ff:8b:50:75	down	down
1/32	313	100GbNone	true	false	1950	00:c0:ff:8b:50:79	down	down
1/s1	320	10GbInsight	true	false	1950	00:c0:ff:8b:50:7d	down	down
1/s2	321	10GbInsight	true	false	1950	00:c0:ff:8b:50:7e	down	down

Note

1/s1 and 1/s2 are ports used by Extreme Integrated Application Hosting (IAH) virtual machines only.

VLAN interface index

The interface index of a VLAN is computed using the following formula:

Because the default VLAN always uses an MGID value of 1, its interface index is always 2049.

$$\text{ifIndex} = 2048 + \text{VLAN multicast group ID (MGID)}$$

MLT interface index

The interface index of a multilink trunk (MLT) is computed using the following formula:

$$\text{ifIndex} = 6143 + \text{MLT ID number}$$

MAC Address Assignment

You must understand MAC addresses assignment if you perform one of the following actions:

- Define static Address Resolution Protocol (ARP) entries for IP addresses in the switch
- Use a network analyzer to decode network traffic

Each chassis is assigned a base number of MAC addresses with a number reserved for ports and other internal purposes, and the remainder assigned to routable VLANs. The following table identifies the numbers provided by product.

Product	Base assignment	Reserved	Assigned to routable VLANs
VSP 4450 Series	256	First 128	remaining 128
VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series	1,024	First 256	remaining 768
VSP 8600 Series	4,096	First 1,024	remaining 3,072
XA1400 Series	1,024	First 8	remaining 1,016

Virtual MAC Addresses

Virtual MAC addresses are the addresses assigned to VLANs. The system assigns a virtual MAC address to a VLAN when it creates the VLAN. The MAC address for a VLAN IP address is the virtual MAC address assigned to the VLAN.

Supported Standards, RFCs, and MIBs

[Supported IEEE Standards on page 3967](#)

[Supported RFCs on page 3968](#)

[Quality of service on page 3973](#)

[Network management on page 3973](#)

[MIBs on page 3974](#)

[Standard MIBs on page 3975](#)

[Proprietary MIBs on page 3978](#)

Supported IEEE Standards

Table 301: Supported IEEE Standards

IEEE standard	Description
802.1AB	LLDP
802.1ag	Connectivity Fault Management
802.1ah	Provider Backbone Bridging
802.1aq	Shortest Path Bridging (SPB)
802.1AX	Link Aggregation
802.1D	MAC Bridges
P802.1p	Traffic Class Expediting and Dynamic Multicast Filtering
802.1Q	Virtual LANs
802.1s	Multiple Spanning Trees
802.1t	802.1D Technical & Editorial Corrections
802.1w	Rapid Spanning Tree Protocol (RSTP)
802.1X-2010	Port-based Network Access Control (NAC)
802.3 CSMA/CD Ethernet ISO/IEC 8802	International Organization for Standardization (ISO) /International Eleetrotechnical Commission (IEC) 8802-3
802.3ab	1000 Mbps Operation, implemented as 1000BASE-T Copper

Table 301: Supported IEEE Standards (continued)

IEEE standard	Description
802.3ac	Carrier sense multiple access with collision detection (CSMA/CD) frame extensions for Virtual Bridged Local Area Networks (VLAN) tagging on 802.3 networks
802.1AE	MAC Security
802.3ae	10 Gbps Operation, implemented as 10GBASE-X SFP+
802.3af 802.3at 802.3bt (Type 3 and Type 4)	Power over Ethernet (PoE)
802.3az	Energy Efficient Ethernet (EEE)
802.3ba	40 Gbps and 100 Gbps Operation, implemented as 40GBASE-QSFP+ and 100GBASE-QSFP28
802.3x	Full Duplex & Flow Control
802.3z	1000 Mbps Operation, implemented as 1000BASE-X SFP
ANSI/TIA-1057	LLDP-MED

Supported RFCs

The following table and sections list the RFCs that the switch supports.

Table 302: Supported request for comments

Request for comment	Description
draft-grant-tacacs-02.txt	TACACS+ Protocol
RFC 768	UDP Protocol
RFC 783	Trivial File Transfer Protocol (TFTP)
RFC 791	Internet Protocol (IP)
RFC 792	Internet Control Message Protocol (ICMP)
RFC 793	Transmission Control Protocol (TCP)
RFC 815	IP Datagram Reassembly Algorithm
RFC 826	Address Resolution Protocol (ARP)
RFC 854	Telnet protocol
RFC 894	A standard for the Transmission of IP Datagrams over Ethernet Networks
RFC 896	Congestion control in IP/TCP internetworks
RFC 906	Bootstrap loading using TFTP
RFC 950	Internet Standard Subnetting Procedure

Table 302: Supported request for comments (continued)

Request for comment	Description
RFC 951	BootP
RFC 959, RFC 1350, and RFC 2428	FTP and TFTP client and server
RFC 1027	Using ARP to implement transparent subnet gateways/Nortel Subnet based VLAN
RFC 1058	RIPv1 Protocol
RFC 1112	Host Extensions for IP Multicasting (IGMPv1)
RFC 1122	Requirements for Internet Hosts
RFC 1195	Use of OSI IS-IS for Routing in TCP/IP and Dual Environments
RFC 1042	Encapsulating the Internet Protocol (IP) datagrams and Address Resolution Protocol (ARP) Note: Applicable for 802.3 networks only
RFC 1253	OSPF MIB
RFC 1256	ICMP Router Discovery
RFC 1258 Note: Exception: rlogin is only supported on VSP 8600 Series.	IPv6 Rlogin server
RFC 1305	Network Time Protocol v3 Specification, Implementation and Analysis
RFC 1323	TCP Timestamp (The switch is only compliant if the TCP timestamp is enabled.)
RFC 1340	Assigned Numbers
RFC 1519	Classless Inter-Domain Routing (CIDR): an Address Assignment and Aggregation Strategy
RFC 1541	Dynamic Host Configuration Protocol
RFC 1542	Clarifications and Extensions for the Bootstrap Protocol
RFC 1587	The OSPF NSSA Option
RFC 1591	DNS Client
RFC 1723	RIP v2 — Carrying Additional Information
RFC 1812	Router requirements
RFC 1866	Hypertext Markup Language version 2 (HTMLv2) protocol
RFC 1981	Path MTU discovery

Table 302: Supported request for comments (continued)

Request for comment	Description
RFC 2068	Hypertext Transfer Protocol
RFC 2080	RIP
RFC 2131	Dynamic Host Control Protocol (DHCP)
RFC 2132	DHCP Options and BOOTP Vendor Extensions
RFC 2138	RADIUS Authentication
RFC 2139	RADIUS Accounting
RFC 2178	OSPF MD5 cryptographic authentication / OSPFv2
RFC 2233	The Interfaces Group MIB using SMIv2
RFC 2236	IGMPv2 Snooping
RFC 2358	Definitions of Managed Objects for the Ethernet-like Interface Types
RFC 2284	PPP Extensible Authentication Protocol
RFC 2328	OSPFv2
RFC 2338	VRRP: Virtual Redundancy Router Protocol
RFC 2362	PIM-SM
RFC 2407	IP Security Domain Interpretation of Internet Security Association and Key Management Protocol (ISAKMP)
RFC 2408	Internet Security Associations and Key Management Protocol (ISAKMP)
RFC 2453	RIPv2 Protocol
RFC 2460	IPv6 base stack
RFC 2462	IPv6 Stateless Address Autoconfiguration
RFC 2463	Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification
RFC 2464	Transmission of IPv6 packets over Ethernet networks
RFC 2474	Definition of the Differentiated Services Field (DS Field) in the IPv4 and IPv6 Headers
RFC 2475	An Architecture for Differentiated Services
RFC 2545	Use of BGP-4 multi-protocol extensions for IPv6 inter-domain routing
RFC 2548	Microsoft vendor specific RADIUS attributes
RFC 2579	Textual Conventions for SMI v2
RFC 2580	Conformance Statements for SMI v2
RFC 2616	Hypertext Transfer Protocol 1.1

Table 302: Supported request for comments (continued)

Request for comment	Description
RFC 2710	Multicast Listener Discovery (MLD) for IPv6
RFC 2716	PPP EAP Transport Level Security (TLS) Authentication Protocol
RFC 2737	Entity MIB (Version 2)
RFC 2819	RMON
RFC 2865	RADIUS
RFC 2874	DNS Extensions for IPv6
RFC 2918	Route Refresh Capability for BGP-4
RFC 2992	Analysis of an Equal-Cost Multi-Path Algorithm
RFC 3046	DHCP Option 82
RFC 3162	IPv6 RADIUS client
RFC 3246	An Expedited Forwarding PHB (Per-Hop Behavior)
RFC 3315	IPv6 DHCP Relay
RFC 3376	IGMPv3
RFC 3411 and RFC 2418	SNMP over IPv6 networks
RFC 3417	Transport Mappings for SNMP
RFC 3484	Default Address Selection for IPv6
RFC 3513	Internet Protocol Version 6 (IPv6) Addressing Architecture
RFC 3569	An overview of Source-Specific Multicast (SSM)
RFC 3579	RADIUS Support For Extensible Authentication Protocol (EAP)
RFC 3580	IEEE 802.1X Remote Authentication Dial In User Service
RFC 3587	IPv6 Global Unicast Address Format
RFC 3596	DNS Extensions for IPv6
RFC 3621	Power Ethernet MIB
RFC 3748	Extensible Authentication Protocol
RFC 3810	Multicast Listener Discovery Version 2 (MLDv2) for IPv6
RFC 3825	Dynamic Host Configuration Protocol Option for Coordinate-based Location Configuration Information
RFC 3879	Deprecating Site Local Addresses
RFC 3986	Uniform Resource Identifiers (URI)
RFC 4007	IPv6 Scoped Address Architecture

Table 302: Supported request for comments (continued)

Request for comment	Description
RFC 4022	MIB for TCP
RFC 4113	MIB for UDP
RFC 4133	Entity MIB (version 3)
RFC 4193	Unique Local IPv6 Unicast Address
RFC 4213	IPv6 configured tunnel
RFC 4250–RFC 4256	SSH server and client support
RFC 4291	IPv6 Addressing Architecture
RFC 4293	MIB for IP
RFC 4301	Security Architecture for IPv6
RFC 4302	IP Authentication Header (AH)
RFC 4303	IP Encapsulated Security Payload (ESP)
RFC 4305	Cryptographic algorithm implementation requirements for ESP and AH
RFC 4308	Cryptographic suites for Internet Protocol Security (IPsec)
RFC 4443	ICMP for IPv6
RFC 4541	Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping
RFC 4552	OSPFv3 Authentication and confidentiality for OSPFv3
RFC 4601	Protocol Independent Multicast - Sparse Mode (PIM-SM)
RFC 4604	Internet Group Management Protocol Version 3 (IGMPv3) and Multicast Listener Discovery Protocol Version 2 (MLDv2) for Source-Specific Multicast
RFC 4607	Source-Specific Multicast (SSM)
RFC 4649	Dynamic Host Configuration Protocol for IPv6 (DHCPv6) Relay Agent Remote-ID Option
RFC 4675	Egress VLAN
RFC 4750	OSPFv2 MIB
RFC 4760	Multiprotocol Extensions for BGP-4
RFC 4835	Cryptographic algorithm implementation for ESP and AH
RFC 4861	IPv6 Neighbor discovery
RFC 4862	IPv6 stateless address autoconfiguration
RFC 4893	BGP Support for Four-octet AS Number Space
RFC 5095	Deprecation of Type 0 Routing headers in IPv6

Table 302: Supported request for comments (continued)

Request for comment	Description
RFC 5176	Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)
RFC 5187	OSPFv3 Graceful Restart (helper-mode only)
RFC 5242	The Syslog Protocol
RFC 5321	Simple Mail Transfer Protocol
RFC 5340	OSPF for IPv6
RFC 5746	Secure SSL Renegotiation
RFC 5798	Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6
RFC 5905	Network Time Protocol Version 4: Protocol and Algorithms Specification
RFC 5997	Use of Status-Server Packets in the Remote Authentication Dial In User Service (RADIUS) Protocol
RFC 6105	IPv6 Router Advertisement Guard
RFC 6329	IS-IS Extensions supporting Shortest Path Bridging
RFC 7047	The Open vSwitch Database Management Protocol
RFC 7348	Virtual Extensible LAN (VXLAN)
RFC 7610	DHCPv6 Shield

Quality of service

Table 303: Supported request for comments

Request for comment	Description
RFC2474 and RFC2475	DiffServ Support
RFC2597	Assured Forwarding PHB Group
RFC2598	An Expedited Forwarding PHB

Network management

Table 304: Supported request for comments

Request for comment	Description
RFC1155	SMI
RFC1157	SNMP
RFC1215	Convention for defining traps for use with the SNMP

Table 304: Supported request for comments (continued)

Request for comment	Description
RFC1305	Network Time Protocol v3 Specification, Implementation and Analysis ³
RFC1350	The TFTP Protocol (Revision 2)
RFC1907	Management Information Base for Version 2 of the Simple Network Management Protocol (SNMPv2)
RFC1930	Guidelines for creation, selection, and registration of an Autonomous System (AS)
RFC2428	FTP Extensions for IPv6
RFC2541	DNS Security Operational Considerations
RFC2572	Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)
RFC2573	SNMP Applications
RFC2574	User-based Security Model (USM) for v3 of the Simple Network Management Protocol (SNMPv3)
RFC2575	View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)
RFC2576	Coexistence between v1, v2, & v3 of the Internet standard Network Management Framework
RFC2616	IPv6 HTTP server
RFC2819	Remote Network Monitoring Management Information Base
RFC 3411	Architecture for describing SNMP Management Frameworks
RFC4292	IP Forwarding Table MIB

MIBs

Table 305: Supported request for comments

Request for comment	Description
RFC1156	MIB for network management of TCP/IP
RFC1212	Concise MIB definitions
RFC1213	TCP/IP Management Information Base
RFC1398	Ethernet MIB
RFC1442	Structure of Management Information for version 2 of the Simple Network Management Protocol (SNMPv2)
RFC1450	Management Information Base for v2 of the Simple Network Management Protocol (SNMPv2)
RFC1573	Interface MIB

Table 305: Supported request for comments (continued)

Request for comment	Description
RFC1650	Definitions of Managed Objects for the Ethernet-like Interface Types
RFC1657	BGP-4 MIB using SMIv2
RFC2021	RMON MIB using SMIv2
RFC2452	IPv6 MIB: TCP MIB
RFC2454	IPv6 MIB: UDP MIB
RFC2466	IPv6 MIB: ICMPv6 Group
RFC2578	Structure of Management Information v2 (SMIv2)
RFC2787	Definitions of Managed Objects for the Virtual Router Redundancy Protocol
RFC2863	Interface Group MIB
RFC2925	Remote Ping, Traceroute & Lookup Operations MIB
RFC3416	v2 of the Protocol Operations for the Simple Network Management Protocol (SNMP)

RFC4292	IP Forwarding Table MIB
RFC4363	Bridges with Traffic MIB
RFC4673	RADIUS Dynamic Authorization Server MIB

Standard MIBs

The following table details the standard MIBs that the switch supports.

Table 306: Supported MIBs

Standard MIB name	Institute of Electrical and Electronics Engineers/Request for Comments (IEEE/RFC)	File name
STDMIB2— Link Aggregation Control Protocol (LACP) (802.3ad)	802.3ad	ieee802-lag.mib
STDMIB3—Exensible Authentication Protocol Over Local Area Networks (EAPoL) (802.1x)	802.1x	ieee8021x.mib
STDMIB4—Internet Assigned Numbers Authority (IANA) Interface Type	—	iana_if_type.mib

Table 306: Supported MIBs (continued)

Standard MIB name	Institute of Electrical and Electronics Engineers/Request for Comments (IEEE/RFC)	File name
STD MIB5—Structure of Management Information (SMI)	RFC1155	rfc1155.mib
STD MIB6—Simple Network Management Protocol (SNMP)	RFC1157	rfc1157.mib
STD MIB7—MIB for network management of Transfer Control Protocol/Internet Protocol (TCP/IP) based Internet MIB2	RFC1213	rfc1213.mib
STD MIB8—A convention for defining traps for use with SNMP	RFC1215	rfc1215.mib
STD MIB10—Definitions of Managed Objects for Bridges	RFC1493	rfc1493.mib
STD MIB11—Evolution of the Interface Groups for MIB2	RFC2863	rfc2863.mib
STD MIB12—Definitions of Managed Objects for the Ethernet-like Interface Types	RFC1643	rfc1643.mib
STD MIB15—Remote Network Monitoring (RMON)	RFC2819	rfc2819.mib
STD MIB17—Management Information Base of the Simple Network Management Protocol version 2 (SNMPv2)	RFC1907	rfc1907.mib
STD MIB21—Interfaces Group MIB using SMIv2	RFC2233	rfc2233.mib
STD MIB26b—Message Processing and Dispatching for the SNMP	RFC2572	rfc2572.mib
STD MIB26c—SNMP Applications	RFC2573	rfc2573.mib
STD MIB26d—User-based Security Model (USM) for version 3 of the SNMP	RFC2574	rfc2574.mib
STD MIB26e—View-based Access Control Model (VACM) for the SNMP	RFC2575	rfc2575.mib
STD MIB26f—Coexistence between Version 1, Version 2, and Version 3 of the Internet-standard Network Management Framework	RFC2576	rfc2576.mib
STD MIB29—Definitions of Managed Objects for the Virtual Router Redundancy Protocol	RFC2787	rfc2787.mib

Table 306: Supported MIBs (continued)

Standard MIB name	Institute of Electrical and Electronics Engineers/Request for Comments (IEEE/RFC)	File name
STDMIB31—Textual Conventions for Internet Network Addresses	RFC2851	rfc2851.mib
STDMIB32—The Interface Group MIB	RFC2863	rfc2863.mib

STDMIB36—Protocol Independent Multicast MIB for IPv4	RFC2934	rfc2934.mib
STDMIB38—SNMPv3 These Request For Comments (RFC) make some previously named RFCs obsolete	RFC3411, RFC3412, RFC3413, RFC3414, RFC3415	rfc2572.mib, rfc2573.mib, rfc2574.mib, rfc2575.mib
STDMIB39—Entity Sensor Management Information Base	RFC3433	
STDMIB40—The Advanced Encryption Standard (AES) Cipher Algorithm in the SNMP User-based Security Model	RFC3826	rfc3826.mib
STDMIB41—Management Information Base for the Transmission Control protocol (TCP)	RFC4022	rfc4022.mib
STDMIB43—Management Information Base for the User Datagram Protocol (UDP)	RFC4113	rfc4113.mib
Q-BRIDGE-MIB —Management Information Base for managing Virtual Bridged LANs	RFC4363	q-bridge.mib
LLDP-EXT-MED-MIB — LLDP-MED	ANSI/TIA-1057	lldpExtMed.mib

Proprietary MIBs

The following table details the proprietary MIBs that the switch supports.

Table 307: Proprietary MIBs

Proprietary MIB name	File name
Extreme Networks Energy Saver MIB	bayStackNes.mib
Extreme Networks Link-state tracking (LST) MIB	bayStackLinkStateTracking.mib
Extreme Networks IGMP MIB	rfc_igmp.mib
Extreme Networks IP Multicast MIB	ipmroute_rcc.mib
Extreme Networks MIB definitions	wf_com.mib
Extreme Networks PIM MIB	pim-rcc.mib
Extreme Networks RSTP/MSTP proprietary MIBs	nrrst000.mib, nrmst000.mib
Extreme Networks SLA Monitor Agent MIB	slamon.mib
Other SynOptics definitions	s5114roo.mib
Other SynOptics definitions	s5emt103.mib
Other SynOptics definitions	s5tcs112.mib
Other SynOptics definition for Combo Ports	s5ifx.mib
Other SynOptics definition for PoE	bayStackPethExt.mib

ICMPv6 Type and Code

The Internet Control Message Protocol (ICMPv6) uses many messages identified by a type and code field (see RFC 4443). Error messages use message types 0 to 127. Informational messages use message types 128 to 255. The following table provides the type and code reference.

Table 308: ICMPv6 type and code details

Type	Name	Code	Reference
1	Destination Unreachable	0—no route to destination 1—communication with destination administratively prohibited 2—(not assigned) 3—address unreachable 4—port unreachable	RFC 4443
2	Packet Too Big	N/A	RFC 4443
3	Time Exceeded	0—hop limit exceeded in transit 1—fragment reassembly time exceeded	RFC 4443
4	Parameter Problem	0—erroneous header field encountered 1—unrecognized Next Header type encountered 2—unrecognized IPv6 option encountered	RFC 4443
128	Echo Request	N/A	RFC 4443
129	Echo Reply	N/A	RFC 4443
130	Multicast Listener Query	N/A	
131	Multicast Listener Report	N/A	
132	Multicast Listener Done	N/A	
133	Router Solicitation	N/A	RFC 4861
134	Router Advertisement	N/A	RFC 4861
135	Neighbor Solicitation	N/A	RFC 4861
136	Neighbor Advertisement	N/A	RFC 4861

Table 308: ICMPv6 type and code details (continued)

Type	Name	Code	Reference
137	Redirect Message	N/A	RFC 4861
138	Router Renumbering	0—router renumbering command 1—router renumbering result 255—sequence number reset	
139	ICMP Node Information Query	N/A	
140	ICMP Node Information Response	N/A	
141	Inverse neighbor discovery Solicitation Message	N/A	RFC 3122
142	Inverse neighbor discovery Advertisement Message	N/A	RFC 3122
143	Version 2 Multicast Listener Report	N/A	RFC 3810
144	Home Agent Address Discovery Request Message	N/A	RFC 3775
145	Home Agent Address Discovery Reply Message	N/A	RFC 3775
146	Mobile Prefix Solicitation	N/A	RFC 3775
147	Mobile Prefix Advertisement	N/A	RFC 3775
