</tr>
<tr>
<td>diffie-hellman-group1-sha1 exchange key (authentication)</td>
<td>Non-approved, but allowed for key exchange</td>
<td></td>
</tr>
</tbody>
</table>

**Priority with Multiple Security Modes**

Multiple modes can be in effect at the same time for certain applications (for example, all modes are applicable for SSH).

The precedence from highest priority to the lowest:

1. Secure mode
2. FIPS mode
3. Default mode

Example: If for SSH, FIPS mode and Secure Mode are both enabled, Secure mode takes precedence over FIPS mode.

**Using Safe Defaults Mode**

When you take your switch from the box and set it up for the first time, you set the safe defaults mode. You should use the safe defaults mode, which disables Telnet, STP (Spanning Tree Protocol), and SNMP. All ports are enabled in the factory default setting; you can choose to have all unconfigured ports disabled on reboot using the interactive questions. Also, STPD (Spanning Tree Domain) s0 is enabled on the default VLAN; you have the option to disable STPD in safe defaults mode.

After you connect to the console port of the switch, or after you run `unconfigure switch {all}` or `configure safe-default-script`, you can change management access to your device to enhance security.

1. Connect the console and log in to the switch.

   This switch currently has some management methods enabled for convenience reasons. Please answer these questions about the security settings you would like to use. You may quit and accept the default settings by entering 'q' at any time.

   !!!!  NOTE: Spanning Tree default changed in ExtremeXOS 22.2  !!!!

   Multiple Spanning Tree Protocol (MSTP) is enabled by default to prevent broadcast storms

   Would you like to disable MSTP? [y/N/q]:

2. Type y (to disable) or n (to enable ) MSTP (Multiple Spanning Tree Protocol).

   The switch offers an enhanced security mode. Would you like to read more, and have the choice to enable this enhanced security mode? [y/N/q]:

   If you select "no," go to 4 on page 906.
3 If you select "yes," the following appears:

Enhanced security mode configures the following defaults:

* Disable Telnet server.
* Disable HTTP server.
* Disable SNMP server.
* Remove all factory default login accounts.
* Force creation of a new admin (read-write) account.
* Lockout accounts for 5 minutes after 3 consecutive login failures.
* Plaintext password entry will not be allowed.
* Generate an event when the logging memory buffer exceeds 90% of capacity.
* Only admin privilege accounts are permitted to run "show log".
* Only admin privilege accounts are permitted to run "show diagnostics".

Would you like to use this enhanced security mode? [Y/n/q]:

If you select "yes," enhanced security mode is enabled. Go to step 8 on page 906.

4 If you select "no," you are prompted to disable Telnet:

Telnet is enabled by default. Telnet is unencrypted and has been the target of security exploits in the past.

Would you like to disable Telnet? [y/N/q]:

5 You are prompted to enable SNMPv1/v2c:

SNMP access is disabled by default.
SNMPv1/v2c uses no encryption, SNMPv3 can be configured to eliminate this problem.

Would you like to enable SNMPv1/v2c? [y/N/q]: Yes

6 You are prompted to set up the community string:

SNMP community string is a text string that is used to authenticate SNMPv1/v2c messages.
It is required for managing the switch using SNMPv1/v2c.
Would you like to configure a read-only and read-write community string? [Y/n/q]: Yes

Read-only community string:
Re-enter read-only community string:
Read-write community string:
Re-enter read-write community string:

7 You are prompted to enable SNMPv3:

Would you like to enable SNMPv3? [y/N/q]: Yes

SNMPv3 uses usernames/passwords to authenticate and encrypt SNMP messages.
Would you like to create an SNMPv3 user? [Y/n/q]: Yes

User name: admin
Authentication password:
Reenter authentication password:
Privacy password:
Reenter privacy password:

SNMPv3 user 'admin' was created with authentication protocol SHA and privacy protocol AES-128.

8 Reboot the switch.

**MAC Security**

The switch maintains a database of all media access control (MAC) addresses received on all of its ports.
The switch uses the information in this database to decide whether a frame should be forwarded or filtered. MAC security (formerly known as MAC address security) allows you to control the way the FDB (forwarding database) is learned and populated. For more information, see FDB on page 561.

MAC security includes several types of control. You can:

- Limit the number of dynamically learned MAC addresses allowed per virtual port. For more information, see Limiting Dynamic MAC Addresses on page 916.
- "Lock" the FDB entries for a virtual port, so that the current entries will not change, and no additional addresses can be learned on the port. For information, see MAC Address Lockdown on page 919.

**Note**
You can either limit dynamic MAC FDB entries or lockdown the current MAC FDB entries, but not both.

- Set a timer on the learned addresses that limits the length of time the learned addresses will be maintained if the devices are disconnected or become inactive. For more information, see MAC Address Lockdown with Timeout on page 919.

**Note**
When limit-learning is configured in the port which is also associated with some other vlan where learning is disabled, then few packets with new MAC address beyond learning limit will get flooded. This flooding will take place for fraction of second until new black-hole entry is created in hardware.

- Use ACLS to prioritize or stop packet flows based on the source MAC address of the ingress virtual LAN (VLAN) or the destination MAC address of the egress VLAN. For more information about ACL policies, see Security on page 900.
- Enhance security, depending on your network configuration, by disabling Layer 2 flooding. For more information about enabling and disabling Layer 2 flooding, see Managing Egress Flooding on page 569.

## MAC Locking

MAC locking helps prevent unauthorized access to the network by limiting access based on a device’s MAC address. MAC locking enables the binding of specific MAC addresses to specific ports on a switch. MAC locking locks a port to one or more MAC addresses, preventing connection of unauthorized devices via a port. With MAC locking enabled, the only frames forwarded on a MAC locked port are those with the configured or dynamically selected MAC addresses for that port.

Frames received on a port with a Source MAC address not bound to the port are discarded or optionally allowed to dynamically bind to the port, up to a user-controlled maximum number of MAC addresses per port.

There are two different types of MAC locking:

- **Static MAC locking** - Locking one or more specified MAC addresses to a port.

- **First Arrival MAC locking** - Locking one or more MAC addresses to a port based on first arrival of received frames after First Arrival MAC locking is enabled. The configuration specifies the maximum number of end users that will be allowed. As each new end user is identified, it is MAC locked up to the
maximum number of users. Once the maximum number of users has been MAC locked, all other users will be denied access to the port until a MAC locked address is either aged, if aging is configured, or the session for that user ends.

The MAC locking feature is disabled in the device, by default. MAC locking must be enabled both globally and on port level. Once enabled, ports can be configured for static and First Arrival MAC locking.

Existing limit learning and lock learning features are supported on a port-VLAN combination. The MAC locking feature implemented in ExtremeXOS 15.7 supports MAC locking functionality on a port basis.

**MAC Locking Limitations**

The following limitations exist for the MAC locking feature:

- MAC locking cannot be enabled along with existing limit learning and lock learning features.
- MAC locking is supported on ports in the VPLS service VLAN.

**MAC Locking Functionality**

This feature provides a global enable/disable control and controls per port. Additional controls are provided to create, destroy, enable and disable static MAC to interface bindings. The MAC and port, together are required to be unique (the same MAC may be bound to multiple ports).

The configuration of a maximum number of static and dynamic entries (each individually) is provided per port. First Arrival bindings (also known as first arrival MAC locking stations) are not persistent through a device reset. Static bindings (also known as static MAC locking stations) are maintained through a device reset. First Arrival bindings are removed in the event of link loss, or after the FDB entry with the MAC locked MAC ages out. A port, may have both the static and dynamic entries, at any instance.

Dynamic locking may be disabled by setting the maximum number of First Arrival MAC addresses to zero.

Controls are provided per port to convert all current first arrival entries to static entries. This converts only the first arrival MAC bindings to static bindings. This is not to be confused with MAC locking where all dynamic FDB entries are converted to static permanent locked FDB entries and further learning is disabled. Controls are provided to clear current (both static and dynamic) bindings. Each port is configurable to support the aging of dynamically locked bindings.

The device keeps a record of the number of MAC locked stations and when the configured threshold is reached, a threshold SNMP trap/notification and/or a log message is issued based on the per-port configuration. The Source MAC Address of the frame causing the last invalid attempt is also recorded. In the event that the device is so configured, a violation SNMP Trap/Notification and/or a violation log message is issued – these controls will be exercised per port.

**Configuring MAC Locking**

The following content describes the MAC locking commands:

**Enabling and Disabling MAC Locking Globally**

To enable or disable the MAC locking feature, use the following commands:
• enable mac-locking
• disable mac-locking

**Enabling and Disabling MAC Locking on Ports**
To enable MAC locking on specific ports, use the following command:
• enable mac-locking ports [all| port_list]

To Disable MAC locking on specific ports, use the following command:
• disable mac-locking ports [all| port_list]

**Configuring First-arrival/Dynamic MAC Locking Limit**
To configure first arrival MAC locking on a port, use the following command:
• configure mac-locking ports port_list first-arrival limit-learning learn_limit

When the configured limit is reached, no further entries are learnt. However, if the learnt entries are aged out, new MAC addresses can be learned.

By default, Aging is disabled for first arrival MAC locking entries on a configured port. When the FDB entries are aged out, they are removed from the FDB, but they are retained in the MAC locking table. So when the first arrival limit is reached, only those entries in the MAC locking table can be learned again if these devices start sending out traffic. Any new MAC addresses cannot be learned.

The maximum number of dynamic MAC addresses that can be locked on a port is 600.

---

**Note**
There is no command to unconfigure first arrival or static MAC locking limit. The value can be reset giving the default learn limit specified in the help text. When First arrival MAC locking is configured to a value that is lower than the number of MACs that are locked, all the MAC locking bindings on the port are cleared.

**Configuring Static MAC Locking Limit**
To configure static MAC locking on a port, use the following command:
• configure mac-locking ports port_list static limit-learning learn_limit

When the configured limit is reached, no further entries are learned (either black holed or not further learned depending on the configured action). However, if the learned entries are cleared or deleted, new MAC addresses can be created and learned. The maximum number of MAC addresses that will be locked on a port configured for static MAC locking is 64. Aging is not applicable for the static MAC locking entries.

---

**Note**
There is no command to unconfigure first arrival or static MAC locking limit. The value can be reset giving the default learn limit specified in the help text. CLI doesn't allow changing the static MAC locking limit value to a value lower than the number of MACs locked in the MAC lock station table. Some or all of the created MAC locking stations should be removed to change the limit to a lower value.
Note
Assume that port 2:22 is enabled for MAC Locking. The maximum static entry limit value is configured to 5 on port 2:22. If the user wants to configure the maximum static entry limit value to 3,

1. The device will display an error, as maximum number of static stations already locked on the port and the value cannot be reduced.
2. In the same example, the port 2:22 has only 1 static station locked. If the maximum static entry limit value is reduced to 3, the device will allow to reduce the value.

Scenario A:

* Slot-1 DUT1.94 # show mac-locking ports 2:22

MAC locking is globally enabled.

* Slot-1 DUT1.110 # configure mac-locking ports 2:22 static limit-learning 3

* Slot-1 DUT1.111 # show mac-locking ports 2:22

MAC locking is globally enabled.
### Create/Enable/Disable static MAC Locking Entries

To create a static MAC locking entry (also known as MAC locking station) and enable or disable MAC locking for the specific MAC address and port, use the following command:

```
configure mac-locking ports port_list static [add | enable | disable] station station_mac_address
```

**Note**

A static MAC locking station is enabled by default.

To disable the static MAC locking station, use the following command.

```
configure mac-locking ports port_list static disable station station_mac_address
```

When created and enabled, a static MAC lock configuration allows only the end station designated by the MAC address to participate in forwarding of traffic.

The disabled entries are also counted when calculating the total number of locked stations. Static MAC locking stations that are disabled are only shown in “show mac-locking stations static” command. When “static” keyword is not given in “show mac-locking stations”, the disabled entries are not shown.

### Enable/Disable Aging of First-arrival MAC Addresses

To enable or disable first arrival MAC address aging, use the following command.

```
configure mac-locking ports port_list first-arrival aging [enable | disable]
```

Dynamic MAC locking mode MAC address aging is disabled by default.
This is applicable only to MAC addresses locked by first-arrival locking and not to MAC addresses locked by static locking.

When First arrival aging is disabled, MAC locking stations are retained even when the corresponding FDB entry ages out.

When First arrival aging is enabled, MAC locking station starts aging when all the FDB entries corresponding to the station MAC are removed. MAC lock stations do not start aging when FDB entries are present.

When “first arrival aging” is configured to be enabled in first-arrival locking, when an FDB entry ages out, the entry is no more locked and so new MAC addresses can be learned till the configured first-arrival limit is reached.

**Note**
First arrival Aging – Age out time for First Arrival MAC locking station is same as FDB aging time that is configured using `configure fdb agingtime`.

### Move First-arrival MACs to Static Entries

To move all current first-arrival MACs to static entries on a port, use the following command:

```
configure mac-locking ports port_list first-arrival move-to-static
```

This command converts dynamic MAC locked stations to static MAC locked stations. There is no change to FDB entries.

The static MAC locked station entries are saved in configuration and so are preserved across reboots.

**Note**
Ensure the static limit can accommodate the entries before moving them from dynamic. Otherwise, the device may throw the following error: `Error: Some dynamic stations could not be converted to static stations for port <port_list>`.

**Note**
An FDB entry created from the CLI will not be removed when a static MAC lock station is created and disabled for the corresponding MAC address. It is necessary to delete the FDB entry from the CLI. MAC-Locking does not remove user created FDB entries.

### Managing MAC Locking

#### Enable/Disable Clearing First-arrival MACs on Link Change

To manage the behavior of first arrival MAC locking on link state change, use the following command.

```
configure mac-locking ports port_list first-arrival link-down-action [clear-macs | retain-macs]
```

Clear MAC on link change is enabled by default.
When the link goes down, by default, all the first arrival MAC locking addresses will be removed. When link-down-action is configured to “retain-macs”, the first arrival MAC locking addresses will be retained even when the link goes down.

**Disable/Enable port when MAC threshold is reached**

This command is used to configure the disabling of ports when the configured MAC threshold is met. This is used for both “first arrival” and “static” MAC locking methods.

`configure mac-locking ports port_list learn-limit-action [disable-port | remain-enabled]`

The port is disabled when the configured MAC threshold is met. All the FDB entries learned on this port are flushed as the port is disabled. This configuration can be reset using the `clear mac-locking disabled-state ports port_list` command. When MAC locking is disabled on the port, the port comes back up.

**Clearing the Disabled-state of a Port**

This command is used to return the behavior of first arrival MAC locking with link state change to its default value of enabled.

`clear mac-locking disabled-state ports port_list`

**Delete Static MAC Locking Entries**

To delete MAC locking for all static MAC address or the specified static MAC address on the given port, use the following command:

`configure mac-locking ports port_list static delete station [station_mac_address | all]`

**Clearing MAC Locking entries**

The following command is used to clear MAC locking station entries for the given parameters:

`clear mac-locking station [all | {mac station_mac_address} {first-arrival | static} {ports port_list}]`

This command clears MAC locking configuration by port/mac/first arrival/static etc.

---

**Note**

Clearing static MAC locking stations will remove them from the configuration. The cleared static MAC locking stations will not be saved across reboots.

**Displaying MAC Locking Information**

This command is used to display the status of MAC locking on one or more ports.

`show mac-locking {ports port_list}`

---

**Note**

In MLAG, the mac-locking entries shown in this command’s output are only natively learned FDB entries on the switch.
If port is not specified, MAC locking status will be displayed for all ports.

Sample output:

```
Slot-1 Stack.2 # show mac-locking

MAC locking is globally enabled.

<table>
<thead>
<tr>
<th>Port</th>
<th>MAC Address</th>
<th>Status</th>
<th>State</th>
<th>Aging</th>
</tr>
</thead>
<tbody>
<tr>
<td>1:1</td>
<td>00:22:33:44:55:66</td>
<td>active</td>
<td>static</td>
<td>false</td>
</tr>
<tr>
<td>1:2</td>
<td>00:22:33:44:55:77</td>
<td>active</td>
<td>static</td>
<td>false</td>
</tr>
<tr>
<td>1:3</td>
<td>00:22:33:44:55:88</td>
<td>active</td>
<td>static</td>
<td>false</td>
</tr>
<tr>
<td>1:4</td>
<td>00:22:33:44:55:99</td>
<td>active</td>
<td>static</td>
<td>false</td>
</tr>
</tbody>
</table>
```

Legend:
- Stat - Status
- Lock Thr|Viol - Threshold | Violation
- Max Stc - Max Static Count
- dis - Disabled
- retain - Retain MACs
- Limit Action Cfg - If port should be disabled when learnt limit is exceeded
- Limit Action Stat - Port status on exceeding learn limit

The following command displays MAC locking stations for different parameters:

```
show mac-locking stations {first-arrival | static} {ports port_list}
```

**MAC Locking Configuration Example**

The following command enables MAC locking both globally for the device (stack) and at the port level for ports 2:1 through 2:5:

```
Slot-1 Stack.1 # enable mac-locking
-slot-1 Stack.2 # enable mac-locking ports 2:1-2:5
```

The following command lines enable port 2:1 for a maximum of 3 static MAC address entries. This is followed by four static MAC address creation entries. The fourth entry fails because the maximum allowed has been set to 3.

```
* Slot-1 Stack.3 # configure mac-locking ports 2:1 static limit-learning 3
* Slot-1 Stack.4 # configure mac-locking ports 2:1 static add station 00:22:33:44:55:66
* Slot-1 Stack.5 # configure mac-locking ports 2:1 static add station 00:22:33:44:55:77
* Slot-1 Stack.6 # configure mac-locking ports 2:1 static add station 00:22:33:44:55:88
* Slot-1 Stack.7 # configure mac-locking ports 2:1 static add station 00:22:33:44:55:99
  Error: Station 00:22:33:44:55:99 cannot be added as maximum static limit of 3 is already reached on port 2:1.
```

```
* Slot-1 Stack.10 # show mac-locking stations static ports 2:1
Port | MAC Address | Status | State | Aging |
-----|-------------|--------|-------|-------|
| 2:1 | 00:22:33:44:55:66 | active | static | false |
| 2:1 | 00:22:33:44:55:77 | active | static | false |
| 2:1 | 00:22:33:44:55:88 | active | static | false |
```
The following commands configure ports 2:2 through 2:5 for dynamic MAC locking with a maximum of 15 users on each port. This is followed by a line enabling MAC locking trap messaging on ports 2:1 through 5:

```bash
* Slot-1 Stack.12 # configure mac-locking ports 2:2-2:5 first-arrival limit-learning 15
* Slot-1 Stack.13 # configure mac-locking ports 2:2-2:5 trap on
* Slot-1 Stack.14 # show mac-locking ports 2:1-2:5
```

MAC locking is globally enabled.

### Limiting Dynamic MAC Addresses

You can set a predefined limit on the number of dynamic MAC addresses that can participate in the network.

After the FDB reaches the MAC limit, all new source MAC addresses are blackholed at both the ingress and egress points. These dynamic blackhole entries prevent the MAC addresses from learning and responding to ICMP (Internet Control Message Protocol) and address resolution protocol (ARP) packets.

**Note**

Blackhole FDB entries added due to MAC security violations are removed after each FDB aging period regardless of whether the MAC addresses in question are still sending traffic. If the MAC addresses are still sending traffic, the blackhole entries will be re-added after they have been deleted.
Configuring Limit Learning

- To limit the number of dynamic MAC addresses that can participate in the network, use the `limit-learning` option in the following command:

```
configure ports port_list {tagged tag} vlan vlan_name | vlan_list
  [limit-learning number {action [blackhole | stop-learning]} | lock-learning | unlimited-learning | unlock-learning]
```

This command specifies the number of dynamically learned MAC entries allowed for these ports in this VLAN. The range is 0 to 500,000 addresses.

When the learned limit is reached, all new source MAC addresses are blackholed at the ingress and egress points. This prevents these MAC addresses from learning and responding to `ICMP` and `ARP` packets.

Dynamically learned entries still get aged and can be cleared. If entries are cleared or aged out after the learning limit has been reached, new entries will then be able to be learned until the limit is reached again.

Permanent static and permanent dynamic entries can still be added and deleted using the `create fdb` and `disable flooding ports` commands. These override any dynamically learned entries.

For ports that have a learning limit in place, the following traffic still flows to the port:
- Packets destined for permanent MAC addresses and other non-blackholed MAC addresses
- Broadcast traffic
- `EDP (Extreme Discovery Protocol)` traffic

Traffic from the permanent MAC and any other non-blackholed MAC addresses still flows from the virtual port.

- To remove the learning limit, use the `unlimited-learning` option.

```
configure ports port_list {tagged tag} vlan vlan_name | vlan_list
  [limit-learning number {action [blackhole | stop-learning]} | lock-learning | unlimited-learning | unlock-learning]
```

The MAC limit-learning feature includes a stop-learning argument that protects the switch from exhausting `FDB` resources with blackhole entries. When limit-learning is configured with stop-learning, the switch is protected from exhausting FDB resources by not creating blackhole entries. Any additional learning and forwarding is prevented, but packet forwarding is not impacted for existing FDB entries.

Display Limit Learning Information

- To verify the configuration, enter the commands:

```
show vlan vlan_name security
```

This command displays the MAC security information for the specified `VLAN`.

```
show ports {mgmt | portlist} info {detail}
```

This command displays detailed information, including MAC security information, for the specified port.
Example of Limit Learning

In Figure 105, three devices are connected through a hub to a single port on the Extreme Networks device.

If a learning limit of three is set for that port, and you connect a fourth device to the same port, the switch does not learn the MAC address of the new device; rather, the switch blackholes the address.

![Figure 105: Switch Configured for Limit Learning](image)

Limiting MAC Addresses with ESRP Enabled

If you configure a MAC address limit on VLANs that participate in an ESRP (Extreme Standby Router Protocol) domain, you should add an additional back-to-back link (that has no MAC address limit on these ports) between the ESRP-enabled switches.

Doing so prevents ESRP protocol data units (PDUs) from being dropped due to MAC address limit settings.

Figure 106 is an example of configuring a MAC address limit on a VLAN participating in an ESRP domain.

![Figure 106: MAC Address Limits and VLANs Participating in ESRP](image)
S2 and S3 are ESRP-enabled switches, while S1 is an ESRP-aware (regular Layer 2) switch. Configuring a MAC address limit on all S1 ports might prevent ESRP communication between S2 and S3. To resolve this, you should add a back-to-back link between S2 and S3. This link is not needed if MAC address limiting is configured only on S2 and S3, but not on S1.

**MAC Address Lockdown**

- In contrast to limiting learning on virtual ports, you can lockdown the existing dynamic FDB entries and prevent any additional learning using the `lock-learning` option from the following command:

  ```
  configure ports port_list {tagged tag} vlan vlan_name | vlan_list
  [limit-learning number {action [blackhole | stop-learning]} | lock-learning | unlimited-learning | unlock-learning]
  ```

  This command causes all dynamic FDB entries associated with the specified VLAN and ports to be converted to locked static entries. It also sets the learning limit to 0, so that no new entries can be learned. All new source MAC addresses are blackholed.

  **Note**

  Blackhole FDB entries added due to MAC security violations are removed after each FDB aging period regardless of whether the MAC addresses in question are still sending traffic. If the MAC addresses are still sending traffic, the blackhole entries will be re-added after they have been deleted.

  Locked entries do not get aged, but can be deleted like a regular permanent entry.

  For ports that have lock-down in effect, the following traffic still flows to the port:
  - Packets destined for the permanent MAC and other non-blackholed MAC addresses
  - Broadcast traffic
  - EDP traffic
  - Traffic from the permanent MAC still flows from the virtual port.

  - Remove MAC address lockdown, use the `unlock-learning` option.

  ```
  configure ports port_list {tagged tag} vlan vlan_name | vlan_list
  [limit-learning number {action [blackhole | stop-learning]} | lock-learning | unlimited-learning | unlock-learning]
  ```

  When you remove the lockdown using the unlock-learning option, the learning-limit is reset to unlimited, and all associated entries in the FDB are flushed.

  - Display the locked entries on the switch.

  ```
  show fdb
  ```

  Locked MAC address entries have the "I" flag.

**MAC Address Lockdown with Timeout**

The MAC address lockdown with timeout feature provides a timer for aging out MAC addresses on a per port basis and overrides the FDB aging time. That is, when this feature is enabled on a port and the port goes down/restarted, MAC addresses learned on that port age out based on the MAC lockdown security.
timeout corresponding to the port, not based on the FDB aging time. By default, the MAC address lockdown timer is disabled.

**Note**
MAC address lockdown is not supported on NetLogin Dot1x non-policy mode.

When this feature is enabled on a port, MAC addresses learned on that port remain locked for the MAC lockdown timeout duration corresponding to the port, even when the port goes down. As a result, when a device is directly connected to the switch and then disconnected, the MAC address corresponding to the device will be locked up for the MAC lockdown timeout duration corresponding to that port. If the same device reconnects to the port before the MAC lockdown timer expires and sends traffic, the stored MAC address becomes active and the MAC lockdown timer is restarted. If the device is not reconnected for the MAC lockdown timeout duration, the MAC entry is removed.

MAC lockdown timeout entries are dynamically learned by the switch, which means these entries are not saved or restored during a switch reboot. If the switch reboots, the local MAC entry table is empty, and the switch needs to relearn the MAC addresses.

MAC address lockdown with timeout is configured by individual ports. The lockdown timer and address learning limits are configured separately for a port.

**Note**
You cannot enable the lockdown timeout feature on a port that already has MAC address lockdown enabled. For more information about MAC address lockdown, see [MAC Address Lockdown](#) on page 919.

MAC address learning limits and the lockdown timer work together in the following ways:

- When the learning limit has been reached on a port, a new device attempting to connect to the port has its MAC address blackholed.
- As long as the timer is still running for a MAC entry, a new device cannot connect in place of the device that entry represents. That is, if a device has disconnected from a port, a new device cannot replace it until the lockdown timer for the first device has expired. This condition is true if the limit on the port is set to 1 or if the limit (greater than 1) on the port has been reached.
- If a learning limit is already configured on a port when you enable the lockdown timeout feature, the configured limit will continue to apply. Existing blackholed entries are therefore not affected. If you enable this feature on a port with no configured learning limit, the default maximum learning limit (unlimited learning) is used.

**Understanding the Lockdown Timer**

The lockdown timer works in the following ways:

- When you enable this feature on a port, existing MAC entries for the port begin aging out based on the configured MAC lockdown timer value.
- If you move a device from one port to another, its MAC address entry is updated with the new port information, including the lockdown timer value configured for that port.
- If this feature is enabled on a port and you decrease the lockdown timer value for that port, all of the MAC FDB entries for that port will time out and be removed at the next polling interval.
• When you disable the lockdown timer on a port, existing MAC address entries for the port will time out based on the FDB aging period.
• The MAC lockdown timer takes effect when the port goes down/restarted.

Examples of Active and Inactive Devices

Figure 107 shows three devices (A, B, and C) connected through a hub to an Extreme Networks device with MAC lockdown timeout configured on the ports.

When each device starts sending traffic, the source MAC address of the device is learned and FDB entries are created. The MAC lockdown timer is set at 100 seconds.

![Figure 107: Devices Using MAC Address Lockdown](image)

**Device Inactivity for Less than the MAC Lockdown Timer**

As long as a device continues to send traffic, the MAC entry for that device is refreshed, and the MAC lockdown timer corresponding to the MAC entry is refreshed.

Therefore, as long as the device is active, the timer does not expire. The traffic can be continuous or can occur in bursts within the MAC lockdown timeout duration for the port.

In this example, Device A starts sending traffic. When the MAC address of Device A is learned and added to the FDB, the MAC lockdown timer is started for this entry.

Device A stops sending traffic; Devices B and C continue sending traffic. After 100 seconds, the MAC entry for Device A is removed from the FDB. Because Devices B and C have continued to send traffic, their MAC entries continue to be refreshed and their MAC lockdown timers continue to be restarted.

**Device Inactivity for Longer than the MAC Lockdown Timer**

When a device stops sending traffic and does not resume within the MAC lockdown timer interval for the port, the MAC lockdown timer expires, and the MAC entry is removed from the FDB.

In this example, Devices A, B, and C start sending traffic. As each MAC address is learned, the MAC lockdown timer is started for each entry.

Device A stops sending traffic; Devices B and C continue sending traffic. After 100 seconds, the MAC lockdown timer for the Device A entry is removed from the FDB. Because Devices B and C have continued to send traffic, their MAC entries continue to be refreshed and their MAC lockdown timers continue to be restarted.
Examples of Disconnecting and Reconnecting Devices

Figure 108 shows Device A connected to an Extreme Networks device with MAC lockdown timeout configured for the ports.

When Device A starts sending traffic, the source MAC address is learned on the port, the **FDB** entry is created, and the MAC lockdown timer is started for the entry. The MAC lockdown timer is set at 3,000 seconds.

![Device A](image)

**Figure 108: Single Device with MAC Lockdown Timeout**

**Disconnecting a Device**

In this example, Device A is disconnected from the port, triggering a port-down action.

The MAC entry for Device A is removed from the hardware FDB; however, the MAC entry for the device is maintained in the software. The MAC lockdown timer for this entry starts when the port goes down.

After 3,000 seconds, the MAC entry for Device A is removed from the software.

**Disconnecting and Reconnecting a Device**

When Device A is disconnected from the port, the resulting port-down action causes the MAC entry for Device A to be removed from the hardware FDB.

The MAC entry in software is maintained, and the MAC lockdown timer is started for the port.

After only 1,000 seconds have elapsed, Device A is reconnected to the same port and starts sending traffic. A MAC entry is created in the hardware FDB, and the MAC lockdown timer is restarted for the MAC entry in the software.

If Device A is reconnected but does not send any traffic for 3,000 seconds, no MAC entry is created in the hardware FDB, and the MAC lockdown timer will expire after reaching 3,000 seconds.

**Disconnecting and Reconnecting Devices with MAC Limit Learning**

In this example, a MAC learning limit of 1 has also been configured on the ports in addition to the MAC lockdown timer of 3000 seconds.

When Device A is disconnected, the resulting port-down action removes the MAC entry for Device A from the hardware FDB. The MAC entry for Device A is maintained in the software, and the MAC lockdown timer for this entry is restarted when the port goes down.

After 1000 seconds, a different device is connected to the same port and starts sending traffic. Because the MAC learning limit is set to 1 and the MAC lockdown timer is still running, the MAC address of the new device is not learned. Instead, the new MAC address is blackholed in the hardware.

When the MAC lockdown timer for Device A expires, its MAC entry is removed from the software. If the new device is still connected to the same port and sends traffic, the MAC address for the new device is
learned and added to the FDB. The MAC lockdown timer for the new device is started, and the
blackhole entry that was created for this device is deleted.

Example of Port Movement

Figure 109 shows Device A connected to port X.

Port X has a MAC lockdown timer setting of 100 seconds, and port Y has a MAC lockdown timer setting
of 200 seconds.

![Figure 109: Port Movement with MAC Lockdown Timeout](image)

Device A starts sending traffic on port X. The MAC address for Device A is learned and added to the
FDB, and the MAC lockdown timer (100 seconds) is started for this entry.

After 50 seconds, Device A is disconnected from port X and connected to port Y where it begins
sending traffic. When Device A starts sending traffic on port Y, the existing MAC entry for Device A is
refreshed, and port X in the entry is replaced with port Y. At the same time, the MAC lockdown timer for
the entry is restarted for a duration of 200 seconds (the configured MAC lockdown timer setting for
port Y).

Configuring MAC Address Lockdown with Timeout

- Configure the MAC lockdown timeout value on one or more specified ports, or on all ports using the
  following command:

  ```
  configure mac-lockdown-timeout ports [all | port_list] aging-time seconds
  ```

Enabling and Disabling MAC Address Lockdown with Timeout

- Enable the MAC lockdown timeout feature on one or more specified ports, or on all ports. using the
  command:

  ```
  enable mac-lockdown-timeout ports [all | port_list]
  ```

- Disable the MAC lockdown timeout feature on one or more specified ports, or on all ports using the
  command:

  ```
  disable mac-lockdown-timeout ports [all | port_list]
  ```

Displaying MAC Address Lockdown Information

- Display configuration information about the MAC lockdown timeout feature using the command:

  ```
  show mac-lockdown-timeout ports [all | port_list]
  ```

  Output from this command includes the configured timeout value and whether the feature is
  enabled or disabled.

- Display the MAC entries learned on one or more ports, or on all ports using the command:

  ```
  show mac-lockdown-timeout fdb ports [all | port_list]
  ```
DHCP Server

ExtremeXOS has DHCP (Dynamic Host Configuration Protocol) support.

In simple terms, a DHCP server dynamically manages and allocates IP addresses to clients. When a client accesses the network, the DHCP server provides an IP address to that client. The client is not required to receive the same IP address each time it accesses the network. A DHCP server with limited configuration capabilities is included in the switch to provide IP addresses to clients.

After ExtremeXOS DHCP server assigns the IP addresses to the clients, the entry is not removed until a DHCP release is received by the client. After the lease timer expires, the entry appears in the expired state. If the DHCP server enabled port goes down or the DHCP server is disabled on the port, the entries are not removed from the DHCP server table. Also, if the client computer moved to another VLAN, the entries are not removed until the lease timer expires.

For example:

```
Slot-1 Stack.32 # show dhcp-server
VLAN "v1":
  DHCP Address Range : 1.1.1.100->1.1.1.200
  Netlogin Lease Timer : Not configured (Default = 10 seconds)
  DHCP Lease Timer : 100 seconds
  Default Gateway : 1.1.1.1
  Primary DNS Server : 12.1.2.1
  Ports DHCP Enabled : 2:24

<table>
<thead>
<tr>
<th>IP</th>
<th>MAC</th>
<th>State</th>
<th>Lease Time Left</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.1.1.100</td>

<td>00:0c:29:11:e2:b7</td>
<td>Expired</td>
<td>0000:00:00</td>
</tr>
</tbody>
</table>

The entries can be cleared by using the command: `clear vlan 1 dhcp-address-allocation all`

Enabling and Disabling DHCP

DHCP is enabled on a per port, per VLAN basis.

- Enable or disable DHCP on a port in a VLAN using the commands:
  
  ```
  enable dhcp ports port_list vlan vlan_name
  disable dhcp ports port_list vlan vlan_name
  ```

Configuring the DHCP Server

The following commands allow you to configure the DHCP server included in the switch.

**Note**

Configuring both the DHCP server and the DHCP client on the same VLAN and the same ports is not recommended.

The parameters available to configure include the IP address range, IP address lease, and multiple DHCP options. Until ExtremeXOS 15.1, the DHCP server had a limited set of known DHCP options it could send out on request, i.e., Default Gateway, DNS, and WINS server(s). General option support has been added in ExtremeXOS 15.2. This allows you to add support for any option needed, with no ExtremeXOS code changes. The three options mentioned above can also be overwritten to support a larger number of servers, if needed. This feature allows the switch administrator to add an option based on DHCP option code value, and support various was of setting the value.

1. Configure the range of IP addresses assigned by the DHCP server using the command:
   ```
   configure vlan vlan_name dhcp-address-range ipaddress1 - ipaddress2
   ```

2. Remove the address range information using the command:
   ```
   unconfigure vlan vlan_name dhcp-address-range
   ```
3 Set how long the IP address lease assigned by the server exists using the command:

```
configure vlan vlan_name dhcp-lease-timer lease-timer
```

**Note**
The ExtremeXOS DHCP server allows the configuration of a DHCP lease timer value greater than two seconds only. The timer value range is 3–4294967295. If the DHCP lease timer is not configured, the ExtremeXOS DHCP server offers an IP address with the default lease time of 7200 seconds.

**Note**
The maximum number of DHCP leases supported by the ExtremeXOS DHCP server is limited by the number of VLANs and IP address range configured on that VLAN, and there is no hardware/software limit for the DHCP leases.

**Note**
The maximum number of DHCP servers supported by ExtremeXOS is limited by the number of VLANs the ExtremeXOS switch supports.

4 To set the generic DHCP option code, default gateway, Domain Name Servers (DNS) addresses, or Windows Internet Naming Service (WINS) server, use the following command:

```
configure {vlan} vlan_name dhcp-options [code option_number [16-bit value1 [value2 [value3 [value4]]]] | 32-bit value1 [value2 [value3 [value4]]] | flag [on | off] | hex string_value | ipaddress ipaddress1 [ipaddress2 [ipaddress3 [ipaddress4]]] | string string_value] [default-gateway | dns-server {primary | secondary} | wins-server] ipaddress
```

5 To remove the generic DHCP option code, default gateway, DNS server addresses, and WINS server information for a particular VLAN, use the following command:

```
unconfigure {vlan} vlan_name dhcp-options { [default-gateway | dns-server {primary | secondary} | wins-server]}
```

6 Remove all the DHCP information for a particular VLAN using the command:

```
unconfigure vlan vlan_name dhcp
```

You can clear the DHCP address allocation table selected entries, or all entries.

7 Clear entries using the command:

```
clear vlan vlan_name dhcp-address-allocation [ [all {offered | assigned | declined | expired}] | ipaddress]
```

You would use this command to troubleshoot IP address allocation on the VLAN.

**Displaying DHCP Information**

- Display the DHCP configuration, including the DHCP range, DHCP lease timer, network login lease timer, DHCP-enabled ports, IP address, MAC address, and time assigned to each end device using the command:

```
show dhcp-server {vlan vlan_name}
```
• View only the address allocation of the DHCP server on a VLAN using the command:
  `show {vlan} vlan_name dhcp-address-allocation`

• View only the configuration of the DHCP server on a VLAN using the command:
  `show {vlan} vlan_name dhcp-config`

### IP Security

This section describes a collection of IP security features implemented in ExtremeXOS software.

If you configure any of the features described in this section, you can enhance your network security by controlling which hosts are granted or not granted access to your network.

**Figure 110** displays the dependencies of IP security. Any feature that appears directly above another feature depends on it. For example, to configure ARP validation, you must configure DHCP snooping and trusted DHCP server.

![Image of IP Security Dependencies]

**IP Security Dependencies**

**Note**
IP security features are supported on link aggregation ports with the exception of DHCP snooping with the `block-mac` option and source IP lockdown. You can enable IP security on pre-existing trunks, but you cannot make IP security-enabled ports into trunks without first disabling IP security.

### DHCP Snooping and Trusted DHCP Server

A fundamental requirement for most of the IP security features described in this section is to configure DHCP snooping and trusted DHCP server.

DHCP snooping enhances security by filtering untrusted DHCP messages and by building and maintaining a DHCP bindings database. Trusted DHCP server also enhances security by forwarding DHCP packets from only configured trusted servers within your network.

The DHCP bindings database contains the IP address, MAC Address, VLAN ID, and port number of the untrusted interface or client. If the switch receives a DHCP ACK message and the IP address does not exist in the DHCP bindings database, the switch creates an entry in the DHCP bindings database. If the switch receives a DHCP RELEASE, NAK or DECLINE message and the IP address exists in the DHCP bindings database, the switch removes the entry.

You can enable DHCP snooping on a per port, per VLAN basis and trusted DHCP server on a per-vlan basis. If configured for DHCP snooping, the switch snoops DHCP packets on the indicated ports and builds a DHCP bindings database of IP address and MAC address bindings from the received packets. If...
configured for trusted DHCP server, the switch forwards only DHCP packets from the trusted servers. The switch drops DHCP packets from other DHCP snooping-enabled ports.

In addition, to prevent rogue DHCP servers from farming out IP addresses, you can optionally configure a specific port or set of ports as trusted ports. Trusted ports do not block traffic; rather, the switch forwards any DHCP server packets that appear on trusted ports. When configured to do so, the switch drops packets from DHCP snooping-enabled ports and causes one of the following user-configurable actions: disables the port temporarily, disables the port permanently, blocks the violating MAC address temporarily, blocks the violating MAC address permanently, and so on.

**Note**
When IP security DHCP snooping is enabled on a VLAN, if ports are removed from the VLAN, the IP security snooping configuration is removed. If ports are added back to the VLAN, you must manually enable the IP security snooping configuration again. This is true for both plain and LAG ports.

Also, if LAG is unconfigured, the IP security configuration is removed for those ports.

Also, if a new port is added to a VLAN that has IP security snooping enabled on it already for other ports, you must manually enable IP security snooping again for the new added port. IP security commands are not automatically applied to added ports to a VLAN. They must be manually configured again.

### Configuring DHCP Snooping

**DHCP** snooping is disabled on the switch by default.

- To enable DHCP snooping on the switch, use the command:

  ```
  enable ip-security dhcp-snooping {vlan} vlan_name ports [all | ports] violation-action [drop-packet [ [block-mac | block-port] [duration duration_in_seconds | permanently] | none]] {snmp-trap}
  ```

**Note**
Snooping IP fragmented DHCP packets is not supported.

The violation action setting determines what action(s) the switch takes when a rogue DHCP server packet is seen on an untrusted port or the IP address of the originating server is not among those of the configured trusted DHCP servers.

The DHCP server packets are DHCP OFFER, ACK and NAK. The following list describes the violation actions:

- **block-mac** The switch automatically generates an ACL to block the MAC address on that port. The switch does not blackhole that MAC address in the FDB. The switch can either temporarily or permanently block the MAC address.

- **block-port** The switch blocks all traffic on that port by disabling the port either temporarily or permanently.

- **none** The switch takes no action to drop the rogue DHCP packet or block the port, and so on. In this case, DHCP snooping continues to build and manage the DHCP bindings database and DHCP
forwarding will continue in hardware as before. This option can be used when the intent is only to monitor the IP addresses being assigned by the DHCP server.

**Note**
You must enable DHCP snooping on both the DHCP server port as well as on the client port. The latter ensures that DHCP client packets (DHCP Request, DHCP Release etc.) are processed appropriately.

**Note**
DHCP snooping does not work when the client and server are in different VRs and server reachability is established by inter-VR leaked routes on client VR.

Any violation that occurs causes the switch to generate an EMS log message. You can configure to suppress the log messages by configuring EMS log filters. For more information about EMS, see Using the Event Management System/Logging on page 472.

- To disable DHCP snooping on the switch, use the command:

  `disable ip-security dhcp-snooping {vlan} vlan_name ports [all | ports]`

**Configuring Trusted DHCP Server**

- Configure a trusted DHCP server on the switch using the command:

  `configure trusted-servers {vlan} vlan_name add server ip_address trust-for dhcp-server`

  If you configure one or more trusted ports, the switch assumes that all DHCP server packets on the trusted port are valid. You can configure a maximum of eight trusted DHCP servers on the switch.

  For more information about configuring trusted ports, see Configuring Trusted DHCP Ports on page 929.

- Delete a trusted DHCP server using the command:

  `configure trusted-servers vlan vlan_name delete server ip_address trust-for dhcp-server`

**Configuring Trusted DHCP Ports**

Trusted ports do not block traffic; rather, the switch forwards any DHCP server packets that appear on trusted ports. Depending on your DHCP snooping configuration, the switch drops packets and can disable the port temporarily, disable the port permanently, block the MAC address temporarily, block the MAC address permanently, and so on.

- Enable trusted ports on the switch using the command:

  `configure trusted-ports [ports] all trust-for dhcp-server`

- Disable trusted ports on the switch using the command:

  `unconfigure trusted-ports [ports all] trust-for dhcp-server`

**Displaying DHCP Snooping and Trusted Server Information**

- Display the DHCP snooping configuration settings using the command:

  `show ip-security dhcp-snooping {vlan} vlan_name`
DHCP Snooping enabled on ports: 1:2, 1:3, 1:4, 1:7, 1:9
Trusted Ports: 1:7
Trusted DHCP Servers: None

<table>
<thead>
<tr>
<th>Port</th>
<th>Violation-action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1:2</td>
<td>none</td>
</tr>
<tr>
<td>1:3</td>
<td>drop-packet</td>
</tr>
<tr>
<td>1:4</td>
<td>drop-packet, block-mac permanently</td>
</tr>
<tr>
<td>1:7</td>
<td>none</td>
</tr>
<tr>
<td>1:9</td>
<td>drop-packet, snmp-trap</td>
</tr>
</tbody>
</table>

- Display the DHCP bindings database using the command:

```
show ip-security dhcp-snooping entries {vlan} vlan_name
```

Below is sample output from this command:

<table>
<thead>
<tr>
<th>Vlan: dhcpVlan</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Server</th>
<th>Client</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP Addr</td>

<tr>
<td>--------</td>
<td>--------</td>
</tr>
<tr>
<td>172.16.100.9</td>
<td>00:90:27:c6:b7:65</td>
</tr>
</tbody>
</table>

Clearing DHCP Snooping Entries

- To clear existing DHCP snooping entries, use the command:

```
clear ip-security dhcp-snooping entries {vlan} vlan_name
```

Note
This will also clear any associated source IP lockdown and DHCP secured ARP entries.

Configuring the DHCP Relay Agent Option (Option 82) at Layer 2

This section describes how to configure the DHCP Relay agent option for Layer 2 forwarded DHCP packets.

The DHCP relay agent option feature inserts a piece of information, called option 82, into any DHCP request packet that is to be relayed by the switch. Similarly, if a DHCP reply received by the switch contains a valid relay agent option, the option will be stripped from the packet before it is relayed to the client. This is a Layer 2 option that functions only when the switch is not configured as a Layer 3 BOOTP relay.

The Agent remote ID sub-option always contains the Ethernet MAC address of the relaying switch. You can display the Ethernet MAC address of the switch by issuing the show switch command.

The contents of the inserted option 82 sub-options is as follows:
Table 100: Contents of the Inserted Option 82 Sub-options

<table>
<thead>
<tr>
<th>Code (1 byte)</th>
<th>Length (1 byte)</th>
<th>Sub-Option (1 byte)</th>

</table>

To enable the DHCP relay agent option at Layer 2, use the following command:
```
configure ip-security dhcp-snooping information option
```

Note
When DHCP relay is configured in a DHCP snooping environment, the relay agent IP address should be configured as the trusted server.

When DHCP option 82 is enabled, two types of packets need to be handled:

- **DHCP Request**: When the switch (relay agent) receives a DHCP request, option 82 is added at the end of the packet. If the option has already been enabled, then the action taken depends on the configured policy (drop packet, keep existing option 82 value, or replace the existing option). Unless configured otherwise using the `configure ip-security dhcp-snooping information circuit-id vlan-information vlan_info (vlan) [vlan_name | all]`, the vlan_info portion of the circuit ID added will be the VLAN ID of the ingress VLAN.

- **DHCP Reply**: When the option 82 information check is enabled, the packets received from the DHCP server are checked for option 82 information. If the remote ID sub-option is the switch's MAC address, the packet is sent to the client; if not, the packet is dropped. If the check is not enabled, the packets are forwarded as-is.

To disable the DHCP relay agent option, use the following command:
```
unconfigure ip-security dhcp-snooping information option
```

In some instances, a DHCP server may not properly handle a DHCP request packet containing a relay agent option.

To prevent DHCP reply packets with invalid or missing relay agent options from being forwarded to the client, use the following command:
```
configure ip-security dhcp-snooping information check
```

To disable checking of DHCP replies, use this command:
```
unconfigure ip-security dhcp-snooping information check
```

A DHCP relay agent may receive a client DHCP packet that has been forwarded from another relay agent.

If this relayed packet already contains a relay agent option, then the switch will handle this packet according to the configured DHCP relay agent option policy. The possible actions are to replace the option information, to keep the information, or to drop packets containing option 82 information. To configure this policy, use the following command:
```
configure ip-security dhcp-snooping information policy [drop | keep | replace]
```
The default relay policy is replace.

To configure the policy to the default, use this command:

```
unconfigure ip-security dhcp-snooping information policy
```

The Layer 2 relay agent option allows you to configure the circuit ID on a VLAN or port basis. The Circuit-ID can contain a variable length (up to 32 bytes long) ASCII string with the following format:

```
<VLAN Info>-<Port Info>
```

If the configuration of either VLAN Info or Port Info causes the total string length of <VLAN Info>-<Port Info> to exceed 32 bytes, then it is truncated to 32 bytes. The string is not NULL terminated, since the total circuit ID length is being specified.

For a DHCP client packet ingressing on a VLAN with the VLAN ID equal to 200 and the ingress port at 3:5, the following are true:

- When neither VLAN Info or Port Info is specified, circuit ID value is = 200-3005
- When VLAN Info is configured to SomeInfo and Port Info is not specified, the circuit ID value is SomeInfo-3005
- When VLAN Info is not specified and Port Info is configured to User1, the circuit ID value is 200-User1
- When VLAN Info is configured to SomeInfo and Port Info to User1, the circuit ID value is SomeInfo-User1

VLAN Info is configurable per VLAN.

When not explicitly configured for a VLAN, VLAN Info defaults to the ASCII string representation of the ingress VLAN ID. To configure the circuit ID on a VLAN, use the following command:

```
configure ip-security dhcp-snooping information circuit-id vlan-information vlan_info {vlan} [vlan_name | all]
```

To unconfigure the circuit ID on a VLAN, use the following command:

```
unconfigure ip-security dhcp-snooping information circuit-id vlan-information {vlan} [vlan_name | all]
```

Port Info is configurable.

When not explicitly configured for a port, port info defaults to the ASCII representation of the ingress port’s SNMP ifIndex. To configure the port information portion of the circuit-ID, use the following command:

```
configure ip-security dhcp-snooping information circuit-id port-information port_info port
```

To unconfigure the port information portion of the circuit-ID, use the following command:
unconfigure ip-security dhcp-snooping information circuit-id port-information ports [port_list | all]

Note
When this feature is enabled, all DHCP traffic must be forwarded in slowpath only, which means that this feature functions only in the context of IP Security and only on interfaces where DHCP snooping is enabled in enforcement (violation-action of ‘drop’) mode. In other words, with DHCP snooping not configured with a violation-action of ‘none’ (which is pure monitoring mode).

Configuring DHCP Binding

The DHCP bindings database contains the IP address, MAC address, VLAN ID, and port number of the client. You can add or delete the static IP to the MAC DHCP binding entries using the following commands:

configure ip-security dhcp-bindings add

configure ip-security dhcp-bindings delete

You can specify the storage details of the DHCP binding database. Use the following commands to specify the DHCP binding database location, filename, write-interval, and write threshold limits:

configure ip-security dhcp-bindings storage filename

configure ip-security dhcp-bindings storage location

configure ip-security dhcp-bindings storage

You can upload the DHCP binding database periodically by enabling the DHCP binding restoration. Binding write intervals occur in minutes, 5 to 1440 (24 hours). The default is 30 minutes.

Upload the latest DHCP binding database using the upload command:

enable ip-security dhcp-bindings restoration

You can also upload the DHCP binding database by the number of DHCP entries (the write-threshold is 25 to 200).

The periodic backup of the DHCP binding database can be disabled using the following command:

disable ip-security dhcp-bindings restoration

Note
There is no command to unconfigure the DHCP binding storage server details. To disable the DHCP binding storage server details, use the preceding command.
For information about configuring option 82 at Layer 3, see Configuring the DHCP Relay Agent Option (Option 82) at Layer 3 on page 1366.

---

**Note**

When configuring static DHCP binding entries, DHCP binding restoration needs to be configured.

---

**Example of Option 82 Configuration**

The following example describes Option 82 configuration for circuit ID fields.

```bash
create vlan v1
conf v1 add ports 21
enable ip-security dhcp-snooping v1 ports all violation-action drop-packet
configure trusted-ports 21 trust-for dhcp-server
conf ip-security dhcp-snooping information option
conf ip-security dhcp-snooping information check
conf ip-security dhcp-snooping information circuit-id vlan-information ServiceProvider-1 v1
conf ip-security dhcp-snooping information circuit-id port-information customer-1 port 1
conf ip-security dhcp-snooping information circuit-id port-information customer-2 port 2

```
Source IP Lockdown

Another type of IP security prevents IP address spoofing by automatically placing source IP address filters on specified ports. This feature, called source IP lockdown, allows only traffic from a valid DHCP-assigned address obtained by a DHCP snooping-enabled port to enter the network. In this way, the network is protected from attacks that use random source addresses for their traffic. With source IP lockdown enabled, end systems that have a DHCP address assigned by a trusted DHCP server can access the network, but traffic from others, including those with static IP addresses, is dropped at the switch.

Source IP lockdown is linked to the "DHCP snooping" feature. The same DHCP bindings database created when you enable DHCP snooping is also used by source IP lockdown to create ACLs that permit traffic from DHCP clients. All other traffic is dropped. In addition, the DHCP snooping violation action setting determines what action(s) the switch takes when a rogue DHCP server packet is seen on an untrusted port.

When source IP lockdown is enabled on a port, a default ACL is created to deny all IP traffic on that port. Then an ACL is created to permit DHCP traffic on specified ports. Each time source IP lockdown is enabled on another port, the switch creates ACLs to allow DHCP packets and to deny all IP traffic for that particular port.

Source IP lockdown is enabled on a per-port basis; it is not available at the VLAN level. If source IP lockdown is enabled on a port, the feature is active on the port for all VLANs to which the port belongs.

Note
The source IP lockdown feature works only when hosts are assigned IP address using DHCP; source IP lockdown does not function for statically configured IP addresses.

Note
Source IP lockdown cannot be enabled on Load sharing ports.
The source IP lockdown ACLs listed in table are applied per port (in order of precedence from highest to lowest).

Table 101: Source IP Lockdowns Applied Per-port

<table>
<thead>
<tr>
<th>ACL Name</th>
<th>Match Condition</th>
<th>Action</th>
<th>When Applied</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>esSrcIpLockdown_&lt;portIfIndex&gt;_&lt;source IP in hex&gt;</td>
<td>Source IP</td>
<td>Permit</td>
<td>Runtime</td>
<td>Multiple ACLs of this type can be applied, one for each permitted client.</td>
</tr>
<tr>
<td>esSrcIpLockdown_&lt;portIfIndex&gt;._1</td>
<td>Proto UDP, Dest Port 67</td>
<td>Permit</td>
<td>Configuration time</td>
<td></td>
</tr>
<tr>
<td>esSrcIpLockdown_&lt;portIfIndex&gt;._2</td>
<td>Proto UDP, Dest Port 68</td>
<td>Permit</td>
<td>Configuration time</td>
<td></td>
</tr>
<tr>
<td>esSrcIpLockdown_&lt;portIfIndex&gt;._3</td>
<td>Ethertype ARP</td>
<td>Permit</td>
<td>Configuration time</td>
<td></td>
</tr>
<tr>
<td>esSrcIpLockdown_&lt;portIfIndex&gt;._4</td>
<td>All</td>
<td>Deny + count</td>
<td>Configuration time</td>
<td></td>
</tr>
</tbody>
</table>

The counter has the same name as that of the rule of the catch-all ACL, so the counter is also named esSrcIpLockdown_<portIfIndex>._4.

Configuring Source IP Lockdown

To configure source IP lockdown, you must enable DHCP snooping on the ports connected to the DHCP server and DHCP client before you enable source IP lockdown. You must enable source IP lockdown on the ports connected to the DHCP client, not on the ports connected to the DHCP server.

- Enable DHCP snooping using the command:

  ```bash
  enable ip-security dhcp-snooping {vlan} vlan_name ports [all | ports] violation-action [drop-packet { [block-mac | block-port] [duration duration_in_seconds | permanently] | none}] {snmp-trap}
  
  For more information about DHCP snooping see, Configuring DHCP Snooping on page 928.

  Source IP lockdown is disabled on the switch by default.

- To enable source IP lockdown, use the command:

  ```bash
  enable ip-security source-ip-lockdown ports [all | ports]
  ```

- To disable source IP lockdown, use the command

  ```bash
  disable ip-security source-ip-lockdown ports [all | ports]
  ```

Displaying Source IP Lockdown Information

- Display the source IP lockdown configuration on the switch using the command:

  ```bash
  show ip-security source-ip-lockdown
  ```

Below is sample output from this command:

<table>
<thead>
<tr>
<th>Ports</th>
<th>Locked IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>23</td>
<td>10.0.0.101</td>
</tr>
</tbody>
</table>
Clear Source IP Lockdown Information

- Remove existing source IP lockdown entries on the switch using the command:
  
  clear ip-security source-ip-lockdown entries ports [ports | all]

ARP Learning

The address resolution protocol (ARP) is part of the TCP/IP suite used to dynamically associate a device’s physical address (MAC address) with its logical address (IP address).

The switch broadcasts an ARP request that contains the IP address, and the device with that IP address sends back its MAC address so that traffic can be transmitted across the network. The switch maintains an ARP table (also known as an ARP cache) that displays each MAC address and its corresponding IP address.

By default, the switch builds its ARP table by tracking ARP requests and replies, which is known as ARP learning. You can disable ARP learning so that the only entries in the ARP table are either manually added or those created by DHCP secured ARP; the switch does not add entries by tracking ARP requests and replies. By disabling ARP learning and adding a permanent entry or configuring DHCP secured ARP, you can centrally manage and allocate client IP addresses and prevent duplicate IP addresses from interrupting network operation.

Configuring ARP Learning

As previously described, ARP learning is enabled by default. The switch builds its ARP table by tracking ARP requests and replies.

- Disable ARP learning on one or more ports in a VLAN using the command:
  
  disable ip-security arp learning learn-from-arp {vlan} vlan_name ports [all | ports]

- Re-enable ARP learning on one or more ports in a VLAN using the command:
  
  enable ip-security arp learning learn-from-arp {vlan} vlan_name ports [all | ports]

Adding a Permanent Entry to the ARP Table

If you disable ARP learning, you must either manually add a permanent entry to the ARP table or configure DHCP secured ARP to populate the ARP table.

- Manually add a permanent entry to the ARP table using the command:
  
  configure iparp add ip_addr {vr vr_name} mac

For more detailed information about this command and IP routing, see IPv4 Unicast Routing on page 1327.

Configuring DHCP Secured ARP

Before you configure DHCP secured ARP, you must enable DHCP snooping on the switch.

Another method available to populate the ARP table is DHCP secured ARP. DHCP secured ARP requires that ARP entries be added to or deleted from the ARP table only when the DHCP server assigns or reassigns an IP address. These entries are known as a secure ARP entry. If configured, the switch adds the
MAC address and its corresponding IP address to the ARP table as a permanent ARP entry. Regardless of other ARP requests and replies seen by the switch, the switch does not update secure ARP entries.

DHCP secured ARP is linked to the “DHCP snooping” feature. The same DHCP bindings database created when you enabled DHCP snooping is also used by DHCP secured ARP to create secure ARP entries. The switch only removes secure ARP entries when the corresponding DHCP entry is removed from the trusted DHCP bindings database.

**Note**
If you enable DHCP secured ARP on the switch without disabling ARP learning, ARP learning continues which allows insecure entries to be added to the ARP table.

- Enable DHCP snooping using the command:
  ```
  enable ip-security dhcp-snooping {vlan} vlan_name ports [all | ports]
  violation-action [drop-packet {block-mac | block-port} [duration duration_in_seconds | permanently] | none}] {snmp-trap}
  ```

  For more information about DHCP snooping see, Configuring DHCP Snooping on page 928.

- Enable DHCP secured ARP learning is disabled by default.

  ```
  enable ip-security arp learning learn-from-dhcp {vlan} vlan_name ports
  ```

  DHCP Secured ARP must be enabled on the DHCP server port as well as the DHCP client ports.

- Disable DHCP secured ARP learning is disabled by default.

  ```
  disable ip-security arp learning learn-from-dhcp {vlan} vlan_name ports [all | ports]
  ```

  **Note**
  You must enable DHCP secured ARP on the DHCP server as well as on the client ports.

  DHCP snooping, as always, must also be enabled on both the server and client ports.

**Displaying ARP Information**

- Display how the switch builds an ARP table and learns MAC addresses for devices on a specific VLAN and associated member ports using the command:
  ```
  show ip-security arp learning {vlan} vlan_name
  ```

  Below is sample output from this command:

<table>
<thead>
<tr>
<th>Port</th>
<th>Learn-from</th>
</tr>
</thead>
<tbody>
<tr>
<td>2:1</td>
<td>ARP</td>
</tr>
<tr>
<td>2:2</td>
<td>DHCP</td>
</tr>
<tr>
<td>2:3</td>
<td>ARP</td>
</tr>
<tr>
<td>2:4</td>
<td>None</td>
</tr>
<tr>
<td>2:5</td>
<td>ARP</td>
</tr>
<tr>
<td>2:6</td>
<td>ARP</td>
</tr>
<tr>
<td>2:7</td>
<td>ARP</td>
</tr>
<tr>
<td>2:8</td>
<td>ARP</td>
</tr>
</tbody>
</table>
• View the ARP table, including permanent and DHCP secured ARP entries using the command:

```
show iparp {ip_address | mac | vlan {vlan_name | vlan_list} | permanent} {vr vr_name}
```

---

**Note**

DHCP secured ARP entries are stored as static entries in the ARP table.

---

**Gratuitous ARP Protection**

When a host sends an ARP request to resolve its own IP address it is called *gratuitous ARP*. A gratuitous ARP request is sent with the following parameters:

• Destination MAC address—FF:FF:FF:FF:FF:FF (broadcast)
• Source MAC address—Host’s MAC address
• Source IP address = Destination IP address—IP address to be resolved

In a network, gratuitous ARP is used to:

• Detect duplicate IP address.

In a properly configured network, there is no ARP reply for a gratuitous ARP request. However, if another host in the network is configured with the same IP address as the source host, then the source host receives an ARP reply.

• Announce that an IP address has moved or bonded to a new network interface card (NIC).

If you change a system NIC, the MAC address to its IP address mapping also changes. When you reboot the host, it sends an ARP request packet for its own IP address. All of the hosts in the network receive and process this packet. Each host updates their old mapping in the ARP table with this new mapping.

• Notify a Layer 2 switch that a host has moved from one port to another port.

However, hosts can launch man-in-the-middle attacks by sending out gratuitous ARP requests for the router’s IP address. This results in hosts sending their router traffic to the attacker, and the attacker forwarding that data to the router. This allows passwords, keys, and other information to be intercepted.

To protect against this type of attack, the router sends out its own gratuitous ARP request to override the attacker whenever a gratuitous ARP request broadcast packet with the router’s IP address as the source is received on the network.

If you enable both DHCP secured ARP and gratuitous ARP protection, the switch protects its own IP address and those of the hosts that appear as secure entries in the ARP table.

**Configuring Gratuitous ARP**

You enable the gratuitous ARP feature on a per VLAN basis, not on a per port basis. The validation is done for all gratuitous ARP packets received on a VLAN in which this feature is enabled irrespective of the port in which the packet is received.

When enabled, the switch generates gratuitous ARP packets when it receives a gratuitous ARP request where either of the following is true:
• The sender IP is the same as the switch VLAN IP address and the sender MAC address is not the switch MAC address.
• The sender IP is the same as the IP of a static entry in the ARP table and the sender MAC address is not the static entry’s MAC address.

When the switch generates an ARP packet, the switch generates logs and traps.
• Enable gratuitous ARP protection using the command:
  ```
  enable ip-security arp gratuitous-protection {vlan} [all | vlan_name]
  ```
• In addition, to protect the IP addresses of the hosts that appear as secure entries in the ARP table, use the following commands to enable DHCP snooping, DHCP secured ARP, and gratuitous ARP on the switch:
  ```
  enable ip-security dhcp-snooping {vlan} vlan_name ports [all | ports] violation-action [drop-packet [block-mac | block-port] [duration duration_in_seconds | permanently | none]] {snmp-trap}
  ```
  ```
  enable ip-security arp learning learn-from-dhcp {vlan} vlan_name ports [all | ports]
  ```
  ```
  enable ip-security arp gratuitous-protection {vlan} [all | vlan_name]
  ```
• Disable gratuitous ARP protection using the command:
  ```
  disable ip-security arp gratuitous-protection {vlan} [all | vlan_name]
  ```
• In ExtremeXOS 11.5 and earlier, you enable gratuitous ARP protection using the following command:
  ```
  enable iparp gratuitous protect vlan vlan-name
  ```
• In ExtremeXOS 11.5 and earlier, you disable gratuitous ARP protection with the following command:
  ```
  disable iparp gratuitous protect vlan vlan-name
  ```

**Displaying Gratuitous ARP Information**

• Display information about gratuitous ARP using the command:
  ```
  show ip-security arp gratuitous-protection
  ```

Below is sample output from this command:

```
Gratuitous ARP Protection enabled on following VLANs:
Default, test
```

**ARP Validation**

ARP validation is also linked to the “DHCP snooping” feature. The same DHCP bindings database created when you enabled DHCP snooping is also used to validate ARP entries arriving on the specified ports.
### Validation Option

<table>
<thead>
<tr>
<th>ARP Request Packet Type</th>
<th>ARP Response Packet Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DHCP</td>
<td>Source IP is not present in the DHCP snooping database OR is present but Source Hardware Address doesn’t match the MAC in the DHCP bindings entry.</td>
</tr>
<tr>
<td>IP</td>
<td>Source IP == Mcast OR Target IP == Mcast OR Source IP is not present in the DHCP snooping database OR Source IP exists in the DHCP bindings database but Source Hardware Address doesn’t match the MAC in the DHCP bindings entry.</td>
</tr>
<tr>
<td>Source-MAC</td>
<td>Ethernet source MAC does not match the Source Hardware Address.</td>
</tr>
<tr>
<td>Destination-MAC</td>
<td>Ethernet destination MAC does not match the Target Hardware Address.</td>
</tr>
</tbody>
</table>

Depending on the options specified when enabling ARP validation, the following validations are done. Note that the 'DHCP' option does not have to be specified explicitly, it is always implied when ARP validation is enabled.

#### Configuring ARP Validation

Before you configure ARP validation, you must enable DHCP snooping on the switch.

- Enable DHCP snooping using the command:
  ```
  enable ip-security dhcp-snooping {vlan} vlan_name ports {all | ports} violation-action {drop-packet {[block-mac | block-port] [duration_in_seconds | permanently] | none]} {snmp-trap}
  ```
  For more information about DHCP snooping see, Configuring DHCP Snooping on page 928.
  ARP validation is disabled by default.

- Enable and configure ARP validation using the command:
  ```
  enable ip-security arp validation {destination-mac} {source-mac} {ip} {vlan} vlan_name {all | ports} violation-action {drop-packet {[block-port] [duration duration_in_seconds | permanently]}} {snmp-trap}
  ```
  The violation action setting determines what action(s) the switch takes when an invalid ARP is received. Any violation that occurs causes the switch to generate an EMS log message. You can configure to suppress the log messages by configuring EMS log filters. For more information about EMS, see the section Using the Event Management System/Logging on page 472.

- Disable ARP validation using the command:
  ```
  disable ip-security arp validation {vlan} vlan_name {all | ports}
  ```

#### Displaying ARP Validation Information

- Display information about ARP validation using the command:
  ```
  show ip-security arp validation {vlan} vlan_name
  ```

Below is sample output from this command:

```
----------------------------------------------------------------
```
Denial of Service Protection

A Denial-of-Service (DoS) attack occurs when a critical network or computing resource is overwhelmed and rendered inoperative in a way that legitimate requests for service cannot succeed.

In its simplest form, a DoS attack is indistinguishable from normal heavy traffic. There are some operations in any switch or router that are more costly than others, and although normal traffic is not a problem, exception traffic must be handled by the switch’s CPU in software.

**Note**

DoS protection is not supported for IPv6.

Some packets that the switch processes in the CPU software include:

- Traffic resulting from new MAC learning. (Only the Summit family switches learn in hardware.)

**Note**

When certain features such as Network Login are enabled, hardware learning is disabled to let software control new MAC learning.

- Routing and control protocols including ICMP, BGP (Border Gateway Protocol), OSPF (Open Shortest Path First), STP, EAPS (Extreme Automatic Protection Switching), ESRP, etc.

- Switch management traffic (switch access by Telnet, SSH, HTTP, SNMP, etc.)

- Other packets directed to the switch that must be discarded by the CPU

If any one of these functions is overwhelmed, the CPU may be too busy to service other functions and switch performance will suffer. Even with very fast CPUs, there will always be ways to overwhelm the CPU with packets that require costly processing.

DoS Protection is designed to help prevent this degraded performance by attempting to characterize the problem and filter out the offending traffic so that other functions can continue. When a flood of CPU bound packets reach the switch, DoS Protection will count these packets. When the packet count nears the alert threshold, packets headers are saved. If the threshold is reached, then these headers are analyzed, and a hardware **ACL** is created to limit the flow of these packets to the CPU. This ACL will remain in place to provide relief to the CPU. Periodically, the ACL will expire, and if the attack is still occurring, it will be re-enabled. With the ACL in place, the CPU will have the cycles to process legitimate traffic and continue other services.

**Note**

User-created ACLs take precedence over the automatically applied DoS protect ACLs.

DoS Protection sends a notification when the notify threshold is reached.

You can also specify some ports as trusted ports, so that DoS protection is not applied to those ports.
Configuring Simulated Denial of Service Protection

The conservative way to deploy DoS protection is to use the simulated mode first. In simulated mode, DoS protection is enabled, but no ACLs are generated.

- Enable the simulated mode using the command:
  ```
  enable dos-protect simulated
  ```

  This mode is useful to gather information about normal traffic levels on the switch. This will assist in configuring denial of service protection so that legitimate traffic is not blocked.

  The following topics describe how to configure DoS protection, including alert thresholds, notify thresholds, ACL expiration time, and so on.

Configuring Denial of Service Protection

- Enable or disable DoS protection using the command:
  ```
  enable dos-protect
  disable dos-protect
  ```

  After enabling DoS protection, the switch will count the packets handled by the CPU and periodically evaluate whether to send a notification and/or create an ACL to block offending traffic.

  You can configure a number of the values used by DoS protection if the default values are not appropriate for your situation.

  The values that you can configure are:
  - **interval**—How often, in seconds, the switch evaluates the DoS counter (default: 1 second)
  - **alert threshold**—The number of packets received in an interval that will generate an ACL (default: 4000 packets)
  - **notify threshold**—The number of packets received in an interval that will generate a notice (default: 3500 packets)
  - **ACL expiration time**—The amount of time, in seconds, that the ACL will remain in place (default: 5 seconds)
  - Configure the interval at which the switch checks for DoS attacks using the command:
    ```
    configure dos-protect interval seconds
    ```
  - Configure the alert threshold using the command:
    ```
    configure dos-protect type l3-protect alert-threshold packets
    ```
  - Configure the notification threshold using the command:
    ```
    configure dos-protect type l3-protect notify-threshold packets
    ```
  - Configure the ACL expiration time using the command:
    ```
    configure dos-protect acl-expire seconds
    ```

Configuring Trusted Ports

Traffic from trusted ports will be ignored when DoS protect counts the packets to the CPU. If we know that a machine connected to a certain port on the switch is a safe “trusted” machine, and we know that we will not get a DoS attack from that machine, the port where this machine is connected to can be configured as a trusted port, even though a large amount of traffic is going through this port.
• Configure the trusted ports list using the command:

```bash
```

**Displaying DoS Protection Settings**

• Display the DoS protection settings using the command:

```bash
show dos-protect {detail}
```

**Protocol Anomaly Protection**

The Extreme chipsets contain built-in hardware protocol checkers that support port security features for security applications, such as stateless DoS protection.

The protocol checkers allow users to drop the packets based on the following conditions, which are checked for ingress packets prior to the L2/L3 entry table:

- SIP = DIP for IPv4/IPv6 packets.
- TCP_SYN Flag = 0 for IPv4/IPv6 packets
- TCP Packets with control flags = 0 and sequence number = 0 for IPv4/IPv6 packets
- TCP Packets with FIN, URG & PSH bits set & seq. number = 0 for IPv4/IPv6 packets
- TCP Packets with SYN & FIN bits are set for IPv4/IPv6 packets
- TCP Source Port number = TCP Destination Port number for IPv4/IPv6 packets
- First TCP fragment does not have the full TCP header (less than 20 bytes) for IPv4/IPv6 packets
- TCP header has fragment offset value as 1 for IPv4/IPv6 packets
- UDP Source Port number = UDP Destination Port number for IPv4/IPv6 packets
- ICMP ping packets payload is larger than programmed value of `ICMP` max size for IPv4/IPv6 packets
- Fragmented ICMP packets for IPv4/IPv6 packets

The protocol anomaly detection security functionality is supported by a set of anomaly-protection enable, disable, configure, clear, and show CLI commands. For further details, see the *ExtremeXOS 22.6 Command Reference Guide*.

**Flood Rate Limitation**

Flood rate limitation, or storm control, is used to minimize the network impact of ingress flooding traffic. You can configure ports to accept a specified rate of packets per second. When that rate is exceeded, the port blocks traffic and drops subsequent packets until the traffic again drops below the configured rate.

• Configure the rate limit.

```bash
configure ports port_list rate-limit flood [broadcast | multicast | unknown-destmac] [no-limit | pps]
```
• Display rate limiting statistics.

```
show ports {port_list} rate-limit flood {no-refresh}
```

**Note**

ExtremeXOS switches implement rate limiting granularity at millisecond intervals. The traffic bursts are monitored at millisecond intervals and the actions are performed within sub-seconds (when applicable). When the switch evaluates the traffic pattern for bursts against the configured value in pps, the value is calibrated on a per-millisecond interval. For example, using the `configure port 1 rate-limit flood broadcast 1000` command would be equivalent to 1 packet per millisecond.

---

**Authenticating Management Sessions Through a TACACS+ Server**

You can use a Terminal Access Controller Access Control System Plus (TACACS+) server to authenticate management sessions for multiple switches.

A TACACS+ server allows you to centralize the authentication database, so that you do not have to maintain a separate local database on each switch. TACACS+ servers provide the following services:

- Username and password authentication
- Command authorization (the TACACS+ server validates whether the user is authorized to execute each command within the subset of commands, based on login privilege level)

**Note**

Command usage that should be restricted for a user account by TACACS with CLI authorization enabled may not occur when users are logged in by Chalet or when using the XML API directly. To use Chalet securely, create only read-only users on the switch, and then access Chalet with those user accounts.

- Accounting service (tracks authentication and authorization events)

**Note**

You can use a local database on each switch as a backup authentication service if the TACACS+ service is unavailable. When the TACACS+ service is operating, privileges defined on the TACACS+ server take precedence over privileges configured in the local database.

To use TACACS+ server features, you need the following components:

- TACACS+ client software, which is included in the ExtremeXOS software.
- A TACACS+ server, which is a third-party product.

**Note**

TACACS+ provides many of the same features provided by RADIUS (Remote Authentication Dial In User Service). You cannot use RADIUS and TACACS+ at the same time.
TACACS+ is a communications protocol that is used between client and server to implement the TACACS+ service. The TACACS+ client component of the ExtremeXOS software should be compatible with any TACACS+ compliant server product.

Note
The switch allows local authentication when the client IP is excluded in TACACS+ server by default. To disallow local authentication when the client IP is excluded in TACACS+ server the local authentication disallow option should be used.

For information on installing, configuring, and managing a TACACS+ server, see the product documentation for that server.

The following describes how to configure the ExtremeXOS TACACS+ client component in the ExtremeXOS software: Configuring the TACACS+ Client for Authentication and Authorization on page 946.

Configuring the TACACS+ Client for Authentication and Authorization

Changing the TACACS+ Server

Use the following steps to change TACACS+ server configuration to avoid service interruption of authentication and authorization.

1. Unconfigure the existing primary TACACS+ server.

   Note
   The command disable tacacs is not required while changing TACACS+ servers.

   If only a single TACACS+ server is configured, you must disable TACACS authorization (if enabled) before reconfiguring TACACS+ server:

   disable tacacs-authorization

   To unconfigure the existing primary TACACS+ server:

   unconfigure tacacs server [primary | secondary]

   Note
   After this step, TACACS+ will failover to secondary server.

2. Configure the new primary TACACS+ server:

   configure tacacs [primary | secondary] server [ipaddress | hostname] {tcp_port} client-ip ipaddress {vr vr_name}

3. Configure the shared-secret password for primary TACACS+ server:
configure tacacs [primary | secondary] shared-secret {encrypted}
string

**Note**
Only after configuring shared-secret password for primary server, TACACS+ will fallback to primary server from secondary.

4 Unconfigure existing secondary TACACS+ server:

unconfigure tacacs server [primary | secondary]

5 Configure new secondary TACACS+ server:

configure tacacs [primary | secondary] server [ipaddress | hostname]
{tcp_port} client-ip ipaddress {vr vr_name}

6 Configure shared-secret password for secondary TACACS+ server:

configure tacacs [primary | secondary] shared-secret {encrypted}
string

**Specifying TACACS+ Server Addresses**
Before the TACACS+ client software can communicate with a TACACS+ server, you must specify the server address in the client software. You can specify up to two TACACS+ servers, and you can use either an IP address or a host name to identify each server.

- To configure the TACACS+ servers in the client software, use the following command:
  
  configure tacacs [primary | secondary] server [ipaddress | hostname]
  {tcp_port} client-ip ipaddress {vr vr_name}

  To configure the primary TACACS+ server, specify **primary**. To configure the secondary TACACS+ server, specify **secondary**.

**Configuring the TACACS+ Client Timeout Value**

- To configure the timeout if a server fails to respond, use the following command:
  
  configure tacacs timeout seconds

  To detect and recover from a TACACS+ server failure when the timeout has expired, the switch makes one authentication attempt before trying the next designated TACACS+ server or reverting to the local database for authentication. In the event that the switch still has IP connectivity to the TACACS+ server, but a TCP session cannot be established, (such as a failed TACACS+ daemon on the server), fail over happens immediately regardless of the configured timeout value.

  For example, if the timeout value is set for three seconds (the default value), it will take three seconds to fail over from the primary TACACS+ server to the secondary TACACS+ server. If both the primary and the secondary servers fail or are unavailable, it takes approximately six seconds to revert to the local database for authentication.

**Configuring the Shared Secret Password for TACACS+ Communications**

The shared secret is a password that is configured on each network device and TACACS+ server. The shared secret is used to verify communication between network devices and the server.
To configure the shared secret for client communications with TACACS+ servers, use the following command:

```
configure tacacs [primary | secondary] shared-secret {encrypted} string
```

To configure the shared secret for a primary TACACS+ server, specify `primary`. To configure the shared secret for a secondary TACACS+ server, specify `secondary`.

Do not use the `encrypted` keyword to set the shared secret. The `encrypted` keyword prevents the display of the shared secret in the `show configuration` command output.

**Enabling and Disabling the TACACS+ Client Service**

The TACACS+ client service can be enabled or disabled without affecting the client configuration. When the client service is disabled, the client does not communicate with the TACACS+ server, so authentication must take place through another service such as the local database or a RADIUS server.

**Note**

You cannot use RADIUS and TACACS+ at the same time.

- To enable the TACACS+ client service, use the following command: `enable tacacs`
- To disable the TACACS+ client service, use the following command: `disable tacacs`

**Requiring the Privilege Level Attribute for Authentication**

You can require that the privilege level attribute (priv-lvl) must be specified for TACACS authentication to occur. Setting the privilege level attribute as required does not change any behavior associated with values received in the priv-lvl attribute, only the presence/absence of the attribute.

To require that the priv-lvl is set to allow authentication, use the following command:

```
configure tacacs priv-lvl [required | optional]
```

**TACACS+ Configuration Example**

This section provides a sample TACACS+ client configuration that:

- Specifies the primary TACACS+ server.
- Specifies the shared secret for the primary TACACS+ server.
- Specifies the secondary TACACS+ server.
- Specifies the shared secret for the secondary TACACS+ server.
- Enables the TACACS+ client on the switch.

All other client configuration features use the default settings as described Configuring the TACACS+ Client for Authentication and Authorization on page 946 or in the ExtremeXOS 22.6 Command Reference Guide.

```
configure tacacs primary server 10.201.31.238 client-ip 10.201.31.85 vr "VR-Default"
configure tacacs primary shared-secret purple
configure tacacs secondary server 10.201.31.235 client-ip 10.201.31.85 vr "VR-Default"
configure tacacs secondary shared-secret purple
enable tacacs
```
To display the TACACS+ client configuration, use the `show tacacs` command. Below is sample output from this command:

```
TACACS+: enabled
TACACS+ Authorization: disabled
TACACS+ Accounting : disabled
TACACS+ Server Connect Timeout sec: 3
Primary TACACS+ Server:
  Server name : 
  IP address : 10.201.31.238
  Server IP Port: 49
  Client address: 10.201.31.85 (VR-Default)
  Shared secret : purple
Secondary TACACS+ Server:
  Server name : 
  IP address : 10.201.31.235
  Server IP Port: 49
  Client address: 10.201.31.85 (VR-Default)
  Shared secret : purple
Primary TACACS+ Accounting Server:Not configured
Secondary TACACS+ Accounting Server:Not configured
```

### Configuring the TACACS+ Client for Accounting

#### Specifying the Accounting Server Addresses

Before the TACACS+ client software can communicate with a TACACS+ accounting server, you must specify the server address in the client software. You can specify up to two accounting servers, and you can use either an IP address or a host name to identify each server.

- To specify TACACS+ accounting servers, use the following command:

  ```
  configure tacacs-accounting [primary | secondary] server [ipaddress | hostname] [udp_port] client-ip ipaddress {vr vr_name}
  ```

  To configure the primary TACACS+ accounting server, specify `primary`. To configure the secondary TACACS+ accounting server, specify `secondary`.

#### Configuring the TACACS+ Client Accounting Timeout Value

- To configure the timeout if a server fails to respond, use the following command:

  ```
  configure tacacs-accounting timeout seconds
  ```

  To detect and recover from a TACACS+ accounting server failure when the timeout has expired, the switch makes one authentication attempt before trying the next designated TACACS+ accounting server or reverting to the local database for authentication. In the event that the switch still has IP connectivity to the TACACS+ accounting server, but a TCP session cannot be established, (such as a failed TACACS+ daemon on the accounting server), failover happens immediately regardless of the configured timeout value. If the user does not have a local account or the user is disabled locally, the user's login will fail.

  For example, if the timeout value is set for three seconds (the default value), it takes three seconds to failover from the primary TACACS+ accounting server to the secondary TACACS+ accounting server. If both the primary and the secondary servers fail or are unavailable, it takes approximately six seconds to revert to the local database for authentication.
Configuring the Shared Secret Password for TACACS+ Accounting Servers

The shared secret is a password that is configured on each network device and TACACS+ accounting server. The shared secret is used to verify communication between network devices and the server.

- To configure the shared secret for client communications with TACACS+ accounting servers, use the following command:
  
  ```
  configure tacacs-accounting [primary | secondary] shared-secret {encrypted} string
  ```

  To configure the primary TACACS+ accounting server, specify `primary`. To configure the secondary TACACS+ accounting server, specify `secondary`.

  Do not use the `encrypted` keyword to set the shared secret. The `encrypted` keyword prevents the display of the shared secret in the `show configuration` command output.

Enabling and Disabling TACACS+ Accounting

After you configure the TACACS+ client with the TACACS+ accounting server information, you must enable accounting in the TACACS+ client before the switch begins transmitting the information. You must enable TACACS+ authentication in the client for accounting information to be generated. You can enable and disable accounting without affecting the current state of TACACS+ authentication.

- To enable TACACS+ accounting, use the following command:
  
  ```
  enable tacacs-accounting
  ```

- To disable TACACS+ accounting, use the following command:
  
  ```
  disable tacacs-accounting
  ```

TACACS+ Accounting Configuration Example

This section provides a sample TACACS+ client configuration for TACACS+ accounting that:

- Specifies the primary TACACS+ accounting server.
- Specifies the shared secret for the primary TACACS+ accounting server.
- Specifies the secondary TACACS+ accounting server.
- Specifies the shared secret for the secondary TACACS+ accounting server.
- Enables TACACS+ accounting on the switch.

All other client configuration features use the default settings as described Configuring the TACACS+ Client for Authentication and Authorization on page 946 or in the ExtremeXOS 22.6 Command Reference Guide.

```plaintext
configure tacacs-accounting primary server 10.201.31.238 client-ip 10.201.31.85 vr "VR-Default"
configure tacacs-accounting primary shared-secret purple
configure tacacs-accounting secondary server 10.201.31.235 client-ip 10.201.31.85 vr "VR-Default"
config tacacs-accounting secondary shared-secret purple
enable tacacs-accounting
```
To display the TACACS+ client accounting configuration, use the `show tacacs` or the `show tacacs-accounting` command. The following is sample output from the `show tacacs` command:

```
TACACS+: enabled
TACACS+ Authorization: enabled
TACACS+ Accounting : enabled
TACACS+ Server Connect Timeout sec: 3
Primary TACACS+ Server:
  Server name : 
  IP address : 10.201.31.238
  Server IP Port: 49
  Client address: 10.201.31.85 (VR-Default)
  Shared secret : purple
Secondary TACACS+ Server:
  Server name : 
  IP address : 10.201.31.235
  Server IP Port: 49
  Client address: 10.201.31.85 (VR-Default)
  Shared secret : purple
TACACS+ Acct Server Connect Timeout sec: 3
Primary TACACS+ Accounting Server:
  Server name : 
  IP address : 10.201.31.238
  Server IP Port: 49
  Client address: 10.201.31.85 (VR-Default)
  Shared secret : purple
Secondary TACACS+ Accounting Server:
  Server name : 
  IP address : 10.201.31.235
  Server IP Port: 49
  Client address: 10.201.31.85 (VR-Default)
  Shared secret : purple
```

### Authenticating Management Sessions Through a RADIUS Server

You can use a Remote Authentication Dial In User Service (RADIUS) server to authenticate management sessions for multiple switches. A RADIUS server allows you to centralize the authentication database, so that you do not have to maintain a separate local database on each switch. RADIUS servers provide the following services for management sessions:

- Username and password authentication
- Command authorization (the RADIUS server validates whether the user is authorized to execute each command)

**Note**

Command usage that should be restricted for a user account by RADIUS with CLI authorization may not occur when users are logged in by Chalet or when using the XML API directly. To use Chalet securely, create only read-only users on the switch, and then access Chalet with those user accounts.

- Accounting service (tracks authentication and authorization events)

**Note**

You can use a local database on each switch as a backup authentication service if the RADIUS service is unavailable. When the RADIUS service is operating, privileges defined on the RADIUS server take precedence over privileges configured in the local database.

To use RADIUS server features, you need the following components:
- RADIUS client software, which is included in the ExtremeXOS software.
- A RADIUS server, which is a third-party product.

Note
RADIUS provides many of the same features provided by TACACS+. You cannot use RADIUS and TACACS+ at the same time.

RADIUS is a communications protocol (RFC 2865) that is used between client and server to implement the RADIUS service.

The RADIUS client component of the ExtremeXOS software should be compatible with any RADIUS compliant server product.

Note
The switch allows local authentication when the client IP is excluded in RADIUS server.

The following sections provide more information on management session authentication:
- How Extreme Switches Work with RADIUS Servers on page 952
- Configuration Overview for Authenticating Management Sessions on page 953

How Extreme Switches Work with RADIUS Servers
When configured for use with a RADIUS server, an ExtremeXOS switch operates as a RADIUS client. In RADIUS server configuration, the client component is configured as a client or as a Network Access Server (NAS). Typically, an ExtremeXOS NAS provides network access to supplicants such as PCs or phones.

When a supplicant requests authentication from a switch that is configured for RADIUS server authentication, the following events occur:
1. The switch sends an authentication request in the form of a RADIUS Access-Request message.
2. The RADIUS server looks up the user in the users file.
3. The RADIUS server accepts or rejects the authentication and returns a RADIUS Access-Accept or Access-Reject message.

Note
A user rejected by the Radius/TACACS server can not be authenticated via local database.

4. If authentication is accepted, the Access-Accept message can contain standard RADIUS attributes and Vendor Specific Attributes (VSAs) that can be used to configure the switch.
5. If authentication is accepted, the Access-Accept message can enable command authorization for that user on the switch. Command authorization uses the RADIUS server to approve or deny the execution of each command the user enters.

The ExtremeXOS switch initiates all communications with the RADIUS server. For basic authentication, the switch sends the Access-Request message, and communications with the RADIUS server is complete when the switch receives the Access-Accept or Access-Reject message. For command authorization, communications starts each time a user configured for command authorization enters a switch command. RADIUS server communications ends when command use is allowed or denied.
A key component of RADIUS server management is the attributes and VSAs that the RADIUS server can be configured to send in Access-Accept messages. VSAs are custom attributes for a specific vendor, such as Extreme Networks. These attributes store information about a particular user and the configuration options available to the user. The RADIUS client in ExtremeXOS accepts these attributes and uses them to configure the switch in response to authentication events. The RADIUS server does not process attributes; it simply sends them when authentication is accepted. It is the switch that processes attributes.

User authentication and attributes are managed on a RADIUS server by editing text files. On the FreeRADIUS server, the user ID, password, attributes, and VSAs are stored in the users file, and VSAs are defined in the dictionary file. The dictionary file associates numbers with each attribute. When you edit the users file, you specify the text version of each attribute you define. When the RADIUS server sends attributes to the switch, it sends the attribute type numbers to reduce the network load. Some attribute values are sent as numbers too.

Command authorization is also managed on a RADIUS server by editing text files. On a FreeRADIUS server, the profiles file is divided into sections called profiles. Each profile lists command access definitions. In the users file, you can use the Profile-Name attribute to select the command profile that applies to each user managed by command authorization.

The ExtremeXOS software supports backup authentication and authorization by eight total servers for redundancy.

RADIUS servers can be optionally configured to work with directory services such as LDAP or Microsoft Active Directory. Because ExtremeXOS switches operate with RADIUS servers, they can benefit from the pairing of the RADIUS server and a directory service. Some guidelines for configuring FreeRADIUS with LDAP are provided later in this chapter. Since the use of the directory service requires configuration of the RADIUS server and directory service, the appropriate documentation to follow is the documentation for those products.

### Configuration Overview for Authenticating Management Sessions

To configure the switch RADIUS client and the RADIUS server to authenticate management sessions, do the following:

1. Configure the switch RADIUS client for authentication as described in Configuring the RADIUS Client for Authentication and Authorization on page 961.
2. If you want to use RADIUS accounting, configure the switch RADIUS accounting client as described in Configuring the RADIUS Client for Accounting on page 963.
3. Configure the RADIUS server for authentication as described in Configuring User Authentication (Users File) on page 964.
4. If you want to use RADIUS accounting, configure a RADIUS accounting server as described in the documentation for your RADIUS product.

### Authenticating Network Login Users Through a RADIUS Server

You can use a RADIUS server to authenticate network login users and supply configuration data that the switch can use to make dynamic configuration changes to accommodate network login users.
A RADIUS server allows you to centralize the authentication database, so that you do not have to maintain a separate local database on each switch. RADIUS servers provide the following services for network login sessions:

- Username and password authentication
- Standard RADIUS attributes and Extreme Networks VSAs that the switch can use for dynamic configuration
- Accounting service (tracks authentication and authorization events)

To use RADIUS server features, you need the following components:
- RADIUS client software, which is included in the ExtremeXOS software.
- A RADIUS server, which is a third-party product.

**Note**

RADIUS provides many of the same features provided by TACACS+, but the network login feature does not work with TACACS+.

The following sections provide more information on network login session authentication:

- Differences Between Network Login Authentication and Management Session Authentication on page 954
- Configuration Overview for Authenticating Network Login Users on page 954

**Differences Between Network Login Authentication and Management Session Authentication**

Network login authentication is very similar to management session authentication.

The differences are:

- Network login authentication grants network access to devices connected to a switch port, and management session authentication grants management access to the switch for configuration and management.
- The user name for network login authentication can be a MAC address.
- Standard RADIUS attributes and Extreme Networks VSAs can be used with the network login and universal port features to configure switch ports and general switch configuration parameters.
- Command authorization is not applicable because network login controls network access, not management session access.

Except for the above differences, network login authentication is the same as described in How Extreme Switches Work with RADIUS Servers on page 952.

**Configuration Overview for Authenticating Network Login Users**

To configure the switch RADIUS client and the RADIUS server to authenticate network login users, do the following:

1. Configure the switch RADIUS client for authentication as described in Configuring the RADIUS Client for Authentication and Authorization on page 961.
2 If you want to use RADIUS accounting, configure the switch RADIUS accounting client as described in Configuring the RADIUS Client for Accounting on page 963.

3 Configure network login on the switch as described in Security.

4 Configure the RADIUS server for authentication and Extreme Networks VSAs as described in Configuring User Authentication (Users File) on page 964.

5 If you want to use the universal port feature to run configuration scripts at authentication, configure the switch universal port feature as described in Universal Port on page 330.

6 If you want to use RADIUS accounting, configure a RADIUS accounting server as described in the documentation for your RADIUS product.

Authentication

The RADIUS client software sends authentication requests using standard mechanisms for PAP, CHAP (RFC 2865 (13)) and EAP (RFC 3579 (12)).

Authentication Retransmission Algorithm

Two retransmission algorithms are used in combination: Back-off Round Robin, and simple Round Robin. The focus of this retransmission algorithm is to provide for server redundancy.

Note

The reason for using a combination of back-off and round-robin rather than the standard back-off algorithm where all configured transmissions occur to server 1 before transmitting to server 2 is to allow for more than one server to be tried prior to 802.1x timeout when EAP authentication is occurring.

The standard algorithm is as described in Figure 111 and is a combination of back-off and round-robin. This algorithm always uses the highest priority server first regardless of past transaction history. If the highest priority server can handle the entire load all, transactions will go to that server. Consider three RADIUS servers – 1, 2 and 3 with the configurable number of retries set to 2:
This figure shows the entire retransmission algorithm for a single RADIUS transaction if none of the servers were to respond. No more transmissions will occur for this transaction if a response is received by the RADIUS client software within the configurable timeout period.

The round-robin retransmission algorithm is depicted in Figure 112 and is simply round-robin.

The configurable round-robin retransmission algorithm for RADIUS authentication aims to spread the load among all the configured servers. In large-scale deployments with high rates of authentication this algorithm will provide for better performance than the default algorithm. The initial transmission for each potential authentication will go to the next server in the list. If 999 sessions were to be authenticated across three servers and no timeouts were to occur, then 333 responses would be sent to each server.

Consider three RADIUS servers: 1, 2 and 3 with the configurable number of retries set to 2 and where the prior session sent its initial request to server 1:
Figure 112: Authentication Retransmission Algorithm for a Single RADIUS Transaction (No Servers Responding 2)

This figure shows the entire retransmission algorithm for a single RADIUS transaction if none of the servers were to respond. No more transmissions will occur for this transaction if a response is received by the RADIUS client software within the configurable timeout period. All servers are considered the same priority when using this transmission algorithm with each server taking its turn receiving the initial transmission.

Accounting

Accounting Start and Stop requests are sent for user sessions in accordance with RFC 2866 (7).

Accounting Retransmission Algorithm

The RADIUS client accounting software uses the standard back-off retransmission algorithm. Since accounting transactions generally do not require timeliness this algorithm focuses on redundancy rather than expediency. The highest priority server is always tried first regardless of past transaction history. Consider three accounting servers – 1, 2 and 3 each with the configurable number of retries set to 2:
Figure 113: Accounting Retransmission Algorithm (No Servers Responding)

This figure shows the entire retransmission algorithm for a single RADIUS accounting transaction if none of the servers were to respond. All of the transactions to each of the servers are attempted before another server is attempted. If the initial server can handle the entire accounting transmission load, then all transactions will go to that server.

**Authentication NMS Realm**

The NMS realm type is supported in addition to the management and network realms. These servers are used for the Extreme Network Virtualization or Virtual Machine Tracking feature. This realm only supports the existing subset of two servers (primary and secondary).

**Per Realm Authentication Enable/Disable**

*RADIUS* authentication can be enabled on a per realm basis for the management and network realms.
Supported RADIUS Attributes

The following is a list of RADIUS attributes.

Note
Although this is the list of attributes that is supported by the RADIUS software, usage of these attributes is dependent on the features provided by the system as a whole.

Table Legend:
- PRQ—PAP Authentication Request
- CRQ—CHAP Authentication Request
- EARQ—EAP Authentication Request
- AC—Access Challenge
- AA—Access Accept
- AR—Access Reject

Configuring the RADIUS Client

For information on installing, configuring, and managing a RADIUS server, see the product documentation for that server and the guidelines in RADIUS Server Configuration Guidelines on page 964.

Configuring the RADIUS Client for Authentication and Authorization

Specifying the RADIUS Server Addresses

Before the RADIUS client software can communicate with a RADIUS server, you must specify the server address in the client software. You can specify up to eight RADIUS servers, and you can use either an IP address or a host name to identify each server.

- To configure the RADIUS servers in the client software, use the following command:
  ```
  configure radius {mgmt-access | netlogin} [primary | secondary | index] server [host_ipaddr | host_ipV6addr | hostname] {udp_port} client-ip [client_ipaddr | client_ipV6addr] {vr vr_name} {shared-secret {encrypted} secret}
  ```

Note

It is recommended to enable loopback mode on the VLAN associated with RADIUS if the radius connectivity is established via a front panel port on a summit stack.
The default port value for authentication is 1812. The client IP address is the IP address used by the RADIUS server for communicating back to the switch.

To configure the primary RADIUS server, specify `primary`. To configure the secondary RADIUS server, specify `secondary`.

By default, switch management and network login use the same primary and secondary RADIUS servers for authentication. To specify one pair of RADIUS servers for switch management and another pair for network login, use the `mgmt-access` and `netlogin` keywords.

**Configuring the RADIUS Client Timeout Value**

- To configure the timeout if a server fails to respond, use the following command:

  ```
  configure radius {mgmt-access {primary | secondary} | netlogin {primary | secondary} | index } timeout sec
  ```

  If the timeout expires, another authentication attempt is made. After three failed attempts to authenticate, the alternate server is used. After six failed attempts, local user authentication is used. If the user does not have a local account or the user is disabled locally, the user’s login will fail.

  If you do not specify the `mgmt-access` or `netlogin` keyword, the timeout interval applies to both switch management and netlogin RADIUS servers.

**Configuring the Shared Secret Password for RADIUS Communications**

The shared secret is a password that is configured on each network device (RADIUS client) and RADIUS server. The shared secret is used to verify communication between network devices and the server.

- To configure the shared secret for client communications with RADIUS servers, use the following command:

  ```
  configure radius {mgmt-access | netlogin} [primary | secondary] shared-secret [encrypted] string
  ```

  To configure the shared secret for a primary RADIUS server, specify `primary`. To configure the shared secret for a secondary RADIUS server, specify `secondary`.

  If you do not specify the `mgmt-access` or `netlogin` keyword, the secret applies to both the primary and secondary switch management and network login RADIUS servers.

  Do not use the `encrypted` keyword to set the shared secret. The `encrypted` keyword prevents the display of the shared secret in the `show configuration` command output.

**Enabling and Disabling the RADIUS Client Service**

The RADIUS client service can be enabled or disabled without affecting the client configuration. When the client service is disabled, the client does not communicate with the RADIUS server, so authentication must take place through the another service such as the local database or a TACACS+ server.

**Note**

You cannot use RADIUS and TACACS+ at the same time.
To enable the RADIUS client service, use the following command:
```
enable radius {mgmt-access | netlogin}
```

To disable the RADIUS client service, use the following command:
```
disable radius {mgmt-access | netlogin}
```

If you do not specify the `mgmt-access` or `netlogin` keywords, RADIUS authentication is enabled or disabled on the switch for both management and network login.

### Configuring the RADIUS Client for Accounting

#### Specifying the RADIUS Accounting Server Addresses

Before the RADIUS client software can communicate with a RADIUS accounting server, you must specify the server address in the client software. You can specify up to two accounting servers, and you can use either an IP address or a host name to identify each server.

To specify RADIUS accounting servers, use the following command:
```
configure radius-accounting { mgmt-access | netlogin } [ primary | secondary | index ] server [ host_ipaddr | host_ipV6addr | hostname] {udp_port} client-ip [ client_ipaddr | client_ipV6addr] {vr vr_name} {shared-secret {encrypted} secret}
```

The default port value for accounting is 1813. The client IP address is the IP address used by the RADIUS server for communicating back to the switch.

To configure the primary RADIUS accounting server, specify `primary`. To configure the secondary RADIUS accounting server, specify `secondary`.

By default, switch management and network login use the same primary and secondary RADIUS servers for accounting. To specify one pair of RADIUS accounting servers for switch management and another pair for network login, use the `mgmt-access` and `netlogin` keywords.

#### Configuring the RADIUS Client Accounting Timeout Value

To configure the timeout if a server fails to respond, use the following command:
```
configure radius-accounting { mgmt-access {primary | secondary} | netlogin {primary | secondary} | index } timeout sec
```

If the timeout expires, another authentication attempt is made. After three failed attempts to authenticate, the alternate server is used.

#### Configure the Shared Secret Password for RADIUS Accounting Servers

The shared secret is a password that is configured on each network device (RADIUS client) and RADIUS accounting server. The shared secret is used to verify communication between network devices and the server.
To configure the shared secret for client communications with RADIUS accounting servers, use the following command:

```
configure radius-accounting {mgmt-access | netlogin} [primary | secondary] shared-secret {encrypted} string
```

To configure the primary RADIUS accounting server, specify `primary`. To configure the secondary RADIUS accounting server, specify `secondary`.

If you do not specify the `mgmt-access` or `netlogin` keywords, the secret applies to both the primary and secondary switch management and network login RADIUS accounting servers.

Do not use the `encrypted` keyword to set the shared secret. The `encrypted` keyword prevents the display of the shared secret in the `show configuration` command output.

Enabling and Disabling RADIUS Accounting

After you configure the RADIUS client with the RADIUS accounting server information, you must enable accounting in the RADIUS client before the switch begins transmitting the information. You must enable RADIUS authentication in the client for accounting information to be generated. You can enable and disable accounting without affecting the current state of RADIUS authentication.

- To enable RADIUS accounting, use the following command:
  ```
  enable radius-accounting {mgmt-access | netlogin}
  ```

- To disable RADIUS accounting, use the following command:
  ```
  disable radius-accounting {mgmt-access | netlogin}
  ```

If you do not specify a keyword, RADIUS accounting is enabled or disabled on the switch for both management and network login.

RADIUS Server Configuration Guidelines

**Note**

For information on how to use and configure your RADIUS server, refer to the documentation that came with your RADIUS server.

**Note**

When configuring RADIUS/TACACS servers with the IP address received from a DHCP server, the IP address should be reserved for the switch in the DHCP server to avoid conflicts after rebooting.

Configuring User Authentication (Users File)

User authentication is configured in the users file on a FreeRADIUS server. Other RADIUS servers might use a different name and a different syntax for configuration, but the basic components of the users file and user authentication are the same.

For Extreme Networks switches, there are three types of users file entries:

- Session management entries
Network login user entries

Network login MAC address entries

Note
The “users” file is case-sensitive, and punctuation is very important for FreeRADIUS.

Session Management Entries
The following is an example of a session management entry for read-write access:

```
eric
Cleartext-Password := "eric"
Service-Type = Administrative-User,
Extreme-CLI-Authorization = Enabled
```

The key components of the example above are the user name, password, service-type, and Extreme-CLI-Authorization VSA. For simple authentication, you only need to enter the user name (“eric” in this example) and a password as described in the RADIUS server documentation.

Enter the attributes for each user and separate them from the others with commas as described in the RADIUS server documentation.

For more information on the Extreme-CLI-Authorization VSA, see Extreme Networks VSAs on page 968.

Network Login User Entries
The following is an example of a network login user entry:

```
Jim
Auth-Type := EAP, Cleartext-Password == "12345"
Session-Timeout = 60,
Termination-Action = 1,
Extreme-Security-Profile = "user-auth LOGOFF-PROFILE=avaya-
remove;qos="QP1";",
Extreme-Netlogin-Vlan = voice-avaya
```

The key components of the example above are the user name, password, attributes, and Extreme Networks VSAs. For simple authentication, you only need to enter the user name (Jim in this example) and a password as described in the RADIUS server documentation.

Enter the attributes for each user and separate them from the others with commas as described in the RADIUS server documentation.

In the example above, the Session-Timeout and Termination-Action attributes are examples of standard RADIUS attributes, and these are described in Standard RADIUS Attributes Used by Extreme Switches on page 966.

The Extreme-Security-Profile and Extreme-Netlogin-Vlan attributes are examples of Extreme Networks VSAs and are described in Extreme Networks VSAs on page 968.
Network Login MAC Address Entries

The following is an example of a network login MAC address entry:

```
00040D9D12AF
Auth-Type := Local,
Cleartext-Password == "00040D9D12AF"
Session-Timeout = 60,
Termination-Action = 1,
Extreme-Security-Profile = "user-auth LOGOFF-PROFILE=avaya remove;qos="QP1";",
Extreme-Netlogin-Vlan = voice-avaya
```

The key components of the example above are the MAC address, password (which is set to the MAC address), attributes, and Extreme Networks VSAs. For simple authentication, you only need to enter the MAC address (00040D9D12AF in this example) and a password as described in the RADIUS server documentation.

Enter the attributes for each user and separate them from the others with commas as described in the RADIUS server documentation.

In the example above, the Session-Timeout and Termination-Action attributes are examples of standard RADIUS attributes, and these are described in Standard RADIUS Attributes Used by Extreme Switches on page 966.

The Extreme-Security-Profile and Extreme-Netlogin-VLAN attributes are examples of Extreme Networks VSAs and are described in Extreme Networks VSAs on page 968.

Standard RADIUS Attributes Used by Extreme Switches

The ExtremeXOS software uses standard RADIUS attributes to send information in an Access-Request message to a RADIUS server.

The software also accepts some standard RADIUS attributes in the Access-Accept message that the RADIUS server sends to the switch after successful authentication. The switch ignores attributes that it is not programmed to use.

Table 104 lists the standard RADIUS attributes used by the ExtremeXOS software.

### Table 104: Standard RADIUS Attributes Used by Network Login

<td>String</td>
<td>Access-Request</td>
<td>Specifies a password for authentication.</td>
</tr>
</tbody>
</table>

Attribute 6: Service Type

Extreme Networks switches have two levels of user privilege:
• read-only
• read-write

Because no command line interface (CLI) commands are available to modify the privilege level, access rights are determined when you log in. For a RADIUS server to identify the administrative privileges of a user, Extreme Networks switches expect a RADIUS server to transmit the Service-Type attribute in the Access-Accept packet, after successfully authenticating the user.
Extreme Networks switches grant a RADIUS-authenticated user read-write privilege if a Service-Type value of 6 is transmitted as part of the Access-Accept message from the RADIUS server. Other Service-Type values or no value, result in the switch granting read-only access to the user. Different implementations of RADIUS handle attribute transmission differently. You should consult the documentation for your specific implementation of RADIUS when you configure users for read-write access.

**Extreme Networks VSAs**

Table 105 contains the Vendor Specific Attribute (VSA) definitions that a RADIUS server can send to an Extreme switch after successful authentication.

These attributes must be configured on the RADIUS server along with the Extreme Networks Vendor ID, which is 1916.

### Table 105: VSA Definitions for Web-Based, MAC-Based, and 802.1X Network Login

<table>
<thead>
<tr>
<th>VSA</th>
<th>Attribute Type</th>
<th>Format</th>
<th>Sent-in</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extreme-CLI-Authorization</td>
<td>201</td>
<td>Integer</td>
<td>Access-Accept</td>
<td>Specifies whether command authorization is to be enabled or disabled for the user on the ExtremeXOS switch.</td>
</tr>
<tr>
<td>Extreme-Netlogin-VLAN-Name</td>
<td>203</td>
<td>String</td>
<td>Access-Accept</td>
<td>Name of destination VLAN after successful authentication (must already exist on switch).</td>

<td>Specifies the ID or tag of the destination VLAN for the VM. Example: 101</td>
</tr>
<tr>
<td>EXTREME_VM_VR_Name</td>
<td>217</td>
<td>String</td>
<td>Access-AcCEPT</td>
<td>Specifies the VR in which the destination VLAN is to be placed. Example: UserVR1</td>
</tr>
</tbody>
</table>

The examples in the following sections are formatted for use in the FreeRADIUS users file. If you use another RADIUS server, the format might be different.

**Note**

For information on how to use and configure your RADIUS server, refer to the documentation that came with your RADIUS server.

For untagged VLAN movement with 802.1X netlogin, you can use all current Extreme Networks VLAN VSAs: VSA 203, VSA 209, and VSA 211.

**VSA 201: Extreme-CLI-Authorization**

This attribute specifies whether command authorization is to be enabled or disabled for the user on the ExtremeXOS switch.

If command authorization is disabled, the user has full access to all CLI commands. If command authorization is enabled, each command the user enters is accepted or rejected based on the contents of the profiles file on the RADIUS server.

When added to the RADIUS users file, the following example enables command authorization for the associated user:

**Extreme: Extreme-CLI-Authorization = enabled**

When added to the RADIUS users file, the following example disables command authorization for the associated user:

**Extreme: Extreme-CLI-Authorization = disabled**

**VSA 203: Extreme-Netlogin-VLAN-Name**

This attribute specifies a destination VLAN name that the RADIUS server sends to the switch after successful authentication.
The VLAN must already exist on the switch. When the switch receives the VSA, it adds the authenticated user to the VLAN.

The following describes the guidelines for VSA 203:

- For untagged VLAN movement with 802.1X netlogin, you can use all current Extreme Networks VLAN VSAs: VSA 203, VSA 209, and VSA 211.
- To specify the VLAN name, use an ASCII string.
- When using this VSA, do not specify whether the VLAN is tagged or untagged.

Because the RADIUS server can identify a target VLAN with multiple attributes, the switch selects the appropriate VLAN or VLANs using the order:

- Extreme-Netlogin-Extended-VLAN (VSA 211)
- Extreme-Netlogin-VLAN-Name (VSA 203)
- Extreme-Netlogin-VLAN-ID (VSA 209)
- Tunnel-Private-Group-ID, but only if Tunnel-Type == VLAN(13) and Tunnel-Medium-Type == 802 (6) (see Standard RADIUS Attributes Used by Extreme Switches on page 966)

If none of the previously described attributes are present ISP mode is assumed, and the client remains in the configured VLAN.

When added to the RADIUS users file, the following example specifies the destination VLAN name, purple, for the associated user:

```
Extreme: Extreme-Netlogin-VLAN-Name = purple
```

**VSA 204: Extreme-Netlogin-URL**

The Extreme-NetLogin-Url attribute specifies a web page URL that the RADIUS server sends to the switch after successful authentication. When the switch receives the attribute in response to a web-based network login, the switch redirects the web client to display the specified web page. If a login method other than web-based is used, the switch ignores this attribute.

The following describes the guidelines for VSA 204:

- To specify the URL to display after authentication, use an ASCII string.
- If you do not specify a URL, the network login infrastructure uses the default redirect page URL, or the URL that you configured using the `configure netlogin redirect-page` command.
- VSA 204 applies only to the web-based authentication mode of Network Login.

The following example specifies the redirection URL to use after successful authentication.

To configure the redirect URL as `http://www.myhomepage.com`, add the following line:

```
Extreme: Netlogin-URL = http://www.myhomepage.com
```

**VSA 205: Extreme-Netlogin-URL-Desc**

The Extreme-NetLogin-Url-Desc attribute provides a redirection description that the RADIUS server sends to the switch after successful authentication. When the switch receives this attribute in response to a web-based network login, the switch temporarily displays the redirect message while the web client is redirected to the web page specified by attribute 204. If a login method other than web-based is used, the switch ignores this attribute.
The following describes the guidelines for VSA 205:

- To let the user know where they will be redirected to after authentication (specified by VSA 204), use an ASCII string to provide a brief description of the URL.
- VSA 205 applies only to the web-based authentication mode of Network Login.

The following example specifies a redirect description to send to the switch after successful authentication:

```
Extreme: Netlogin-URL-Desc = "Authentication successful. Stand by for the home page."
```

**VSA 206: Extreme-Netlogin-Only**

The Extreme-Netlogin-Only attribute can be used to allow normal authentication or restrict authentication to only the network login method.

When this attribute is assigned to a user and authentication is successful, the RADIUS server sends the configured value back to the switch. The configured value is either disabled or enabled.

The Extreme switch uses the value received from the RADIUS server to determine if the authentication is valid. If the configured value is disabled, all normal authentication processes are supported (Telnet and SSH, for example), so the switch accepts the authentication. If the configured value is enabled, the switch verifies whether network login was used for authentication. If network login was used for authentication, the switch accepts the authentication. If an authentication method other than network login was used, the switch rejects the authentication.

Add the following line to the RADIUS server users file for users who are not restricted to network login authentication:

```
Extreme:Extreme-Netlogin-Only = Disabled
```

Add the following line to the RADIUS server users file for users who are restricted to network login authentication:

```
Extreme:Extreme-Netlogin-Only = Enabled
```

To reduce the quantity of information sent to the switch, the RADIUS server sends either a 1 for the enabled configuration or a 0 for the disabled configuration.

These values must be configured in the RADIUS dictionary file as shown in Configuring the Dictionary File on page 974.

**VSA 209: Extreme-Netlogin-VLAN-ID**

This attribute specifies a destination VLAN ID (or VLAN tag) that the RADIUS server sends to the switch after successful authentication.

The VLAN must already exist on the switch. When the switch receives the VSA, it adds the authenticated user to the VLAN.

The following describes the guidelines for VSA 209:

- For untagged VLAN movement with 802.1X netlogin, you can use all current Extreme Networks VLAN VSAs: VSA 203, VSA 209, and VSA 211.
- To specify the VLAN ID, use an ASCII string.
- When using this VSA, do not specify whether the VLAN is tagged or untagged.
Because the RADIUS server can identify a target VLAN with multiple attributes, the switch selects the appropriate VLAN or VLANS using the order:

- Extreme-Netlogin-Extended-VLAN (VSA 211)
- Extreme-Netlogin-VLAN-Name (VSA 203)
- Extreme-Netlogin-VLAN-ID (VSA 209)
- Tunnel-Private-Group-ID, but only if Tunnel-Type == VLAN(13) and Tunnel-Medium-Type == 802 (6) (see Standard RADIUS Attributes Used by Extreme Switches on page 966)

If none of the previously described attributes are present ISP mode is assumed, and the client remains in the configured VLAN.

When added to the RADIUS users file, the following example specifies the destination VLAN ID, 234, for the associated user:

```
Extreme:Extreme-Netlogin-VLAN-ID = 234
```

**VSA 211: Extreme-Netlogin-Extended-Vlan**

This attribute specifies one or more destination VLANS that the RADIUS server sends to the switch after successful authentication.

You can specify VLANS by VLAN name or ID (tag). The VLANS may either already exist on the switch or, if you have enabled dynamic VLANS and a non-existent VLAN tag is given, the VLAN is created.

When the switch receives the VSA, it does the following:

- Unauthenticates the user on all VLANS where it is currently authenticated during reauthentication.
- Authenticates the user on all VLANS in the VSA, or none of them.

In cases where the client is already authenticated, if a single VLAN move fails from a list of VLANS in the VSA and the move-fail-action is **authenticate**, then it is left as-is. If the client is not already authenticated (first time authentication), then it is authenticated on learnedOnVlan if possible. If move-fail-action is **deny** then the client is unauthenticated from all the VLANS where it is currently authenticated. There is no partial success.

**Note**

If there is one or more invalid VLAN in the VSA, the supplicant is not authenticated on any one of them.

For example, if the VSA is Uvoice;Tdata and the VLAN **data** does not have a tag or the VLAN does not exist, then the port movement fails. Even if a single VLAN in the list is invalid the entire list is discarded and the action taken is based on move-fail-action configuration.

The following describes the guidelines for VSA 211:

- For tagged VLAN movement with 802.1X netlogin, you must use VSA 211.
- To specify the VLAN name or the VLAN ID, use an ASCII string; however, you cannot specify both the VLAN name and the VLAN ID at the same time. If the string only contains numbers, it is interpreted as the VLAN ID.
- A maximum of 10 VLANS are allowed per VSA.
- For tagged VLANS, specify **T** for tagged before the VLAN name or VLAN ID.
- For untagged VLANS, specify **U** for untagged before the VLAN name or VLAN ID.
For movement based on the incoming port’s traffic, specify the wildcard * before the VLAN name or VLAN ID. The behavior can be either tagged or untagged, based on the incoming port’s traffic, and mimics the behavior of VSA 203 and VSA 209, respectively.

- Multiple VLAN names or VLAN IDs are separated by semicolons. When multiple vlans are defined in single VSA 211, the wildcard * is not allowed.
- There cannot be more than one untagged VLAN in a single VSA.
- The same VLAN cannot be both untagged and tagged in a single VSA.
- A client or supplicant can be authenticated in a only one untagged VLAN.
- The ports configured for an untagged VLAN different from the netlogin VLAN can never be added tagged to the same VLAN.
- A port can be in more than one untagged VLAN when MAC-based VLANs are enabled.

When added to the RADIUS users file, the following examples specify VLANs for the switch to assign after authentication:

<table>
<thead>
<tr>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tagged VLAN named voice</td>
<td>Extreme-Netlogin-Extended-VLAN = Tvoice</td>
</tr>
<tr>
<td>Untagged VLAN named data</td>
<td>Extreme-Netlogin-Extended-VLAN = Udata</td>
</tr>
<tr>
<td>VLAN named orange, tagging dependent on incoming traffic</td>
<td>Extreme-Netlogin-Extended-VLAN = *orange</td>
</tr>
<tr>
<td>Tagged VLAN with ID 229</td>
<td>Extreme-Netlogin-Extended-VLAN = T229</td>
</tr>
<tr>
<td>Untagged VLAN with ID 4091</td>
<td>Extreme-Netlogin-Extended-VLAN = U4091</td>
</tr>
<tr>
<td>VLAN with ID 145, tagging dependent on incoming traffic</td>
<td>Extreme-Netlogin-Extended-VLAN = *145</td>
</tr>
</tbody>
</table>

In FreeRADIUS, a tagged VLAN voice and a tagged VLAN mktg would be configured as the following:

```
Extreme-Netlogin-Extended-VLAN = "Tvoice;Tmktg;"
```

An untagged VLAN data and a tagged VLAN mktg is configured as the following:

```
Extreme-Netlogin-Extended-VLAN = "Udata;Tmktg;"
```

A tagged VLAN with VLAN ID 229 and a tagged VLAN with VLAN ID 227 is configured in FreeRADIUS as the following:

```
Extreme-Netlogin-Extended-VLAN = "T229;T227;"
```

An untagged VLAN with VLAN ID 4091 and a tagged VLAN with VLAN ID 2001 is configured as the following:

```
Extreme-Netlogin-Extended-VLAN = "U4091;T2001;"
```

**VSA 212: Extreme-Security-Profile**

This attribute specifies a profile name that the RADIUS server sends to the switch after successful authentication. The switch uses this profile name to run a special type of script called a profile. The profile is stored on the switch and can be used to modify the switch configuration in response to authentication. Profiles are created using the Universal Port feature, which is described in Universal Port on page 330.

The following describes the guidelines for VSA 212:

- This VSA must contain a profile name.
- This VSA can include optional variables for use in profile execution.
- The variable entry format is: \(<\text{var1}>\text{=\text{value1}}>;<\text{var2}>\text{=\text{value2}}>;\ldots\)
- Each profile variable must be separated from the others by a semicolon.
When added to the RADIUS users file, the following example provides to the switch the profile name p1, variable QOS=QP8, and variable LOGOFF-PROFILE=P2:

```
EXTREME-SECURITY-PROFILE= "p1 QOS="QP8";LOGOFF-PROFILE=P2;"
```

**VSA 213: EXTREME_VM_NAME**

This VSA is used in context with the Extreme Network Virtualization (XNV) feature, especially with the NMS authentication of VMs. Use this VSA to specify the name of the VM that is being authenticated. An example would be: MyVM1

**VSA 214: EXTREME_VM_VPP_NAME**

This VSA is used in context with the XNV feature, especially with the NMS authentication of VMs. Use this VSA to specify the VPP to which the VM is to be mapped. An example would be: nvpp1

**VSA 215: EXTREME_VM_IP_ADDR**

This VSA is used in context with the XNV feature, especially with the NMS authentication of VMs. Use this VSA to specify the IP address of the VM. An example would be: 11.1.254

**VSA 216: EXTREME_VM_VLAN_ID**

This VSA corresponds to XNV with Dynamic VLANs. Use this VSA to specify the ID or tag of the destination VLAN for the VM. An example would be: 101

**VSA 217: EXTREME_VM_VR_NAME**

This VSA corresponds to XNV with Dynamic VLANs. Use this VSA to specify the VR in which the destination VLAN is to be placed. An example would be: UserVR1

### Configuring the Dictionary File

Before you can use Extreme Networks VSAs on a RADIUS server, you must define the VSAs.

On the FreeRADIUS server, you define the VSAs in the dictionary file in the `/etc/raddb` directory. You must define the vendor ID for Extreme Networks, each of the VSAs you plan to use, and the values to send for the VSAs. The following example shows the entries to add to a FreeRADIUS server dictionary file for Extreme Networks VSAs:

```
VENDOR          Extreme         1916
ATTRIBUTE    Extreme-CLI-Authorization      201  integer     Extreme
ATTRIBUTE    Extreme-Shell-Command          202   string     Extreme
ATTRIBUTE    Extreme-Netlogin-Vlan          203   string     Extreme
ATTRIBUTE    Extreme-Netlogin-Url           204   string     Extreme
ATTRIBUTE    Extreme-Netlogin-Url-Desc      205   string     Extreme
ATTRIBUTE    Extreme-Netlogin-Only          206  integer     Extreme
ATTRIBUTE    Extreme-User-Location          208   string     Extreme
ATTRIBUTE    Extreme-Netlogin-Vlan-Tag      209  integer     Extreme
ATTRIBUTE    Extreme-Netlogin-Extended-Vlan 211   string     Extreme
ATTRIBUTE    Extreme-Security-Profile       212   string     Extreme
VALUE        Extreme-CLI-Authorization   Disabled       0
VALUE        Extreme-CLI-Authorization   Enabled        1
VALUE        Extreme-Netlogin-Only       Disabled       0
VALUE        Extreme-Netlogin-Only       Enabled        1
# End of Dictionary
```
The lines that begin with VALUE provide the integers that the RADIUS server sends to the switch when the corresponding text is configured in the RADIUS users file. For example, if the Extreme-CLI-Authorization attribute is set to Enabled for a particular user, the RADIUS server sends the value 1 to the switch (which reduces total bytes transferred). The ExtremeXOS software is designed to interpret the integer values as shown above, so be sure to use these values.

**Change-of-Authorization (Dynamic Authorization) Overview**

The RADIUS protocol, defined in (RFC2865), does not support unsolicited messages sent from the RADIUS server to the Network Access Server (NAS). However, it may be desirable for changes to be made to session characteristics, without requiring the NAS to initiate the exchange. For example, it may be desirable for administrators to be able to terminate user session(s) in progress. Alternatively, if the user changes authorization level, this may require that authorization attributes be added/deleted from user session(s). To overcome these limitations, several vendors have implemented additional RADIUS commands to enable unsolicited messages to be sent to the NAS. These extended commands provide support for Disconnect and Change-of-Authorization (CoA) packets.

**Disconnect Request**

Disconnect Requests are sent from the DA initiator to the DA controller when it is determined that a session will be terminated. The request is sent to UDP port 3799.

When a Disconnect Request packet is received, it is determined whether it is an authorized request from a configured server. The source IP address of the packet is used to check for a match of the configured Dynamic Authorization Servers. If the source IP address has not been configured, then the request is immediately dropped with no further validation. If the IP address is present in the configuration, a validation of the Message-Authenticator attribute occurs as indicated in RFC2869. If validation is not successful, then the packet is dropped with no further processing. If it is determined that this is a retry, the packet is also dropped with no further processing.

The authorized request indicates which DA controller the message is for, as well as which session should be terminated. If the DA controller indicated by the included attributes in the packet does not match the receiver, then the request is responded to with a Disconnect-NAK. The appropriate DA controller receiving this RADIUS extension packet identifies the session using the attributes provided and immediately terminates the session.

---

**Note**

In order to use CoA/Disconnect, ONEPolicy must be enabled with NetLogin.

**NAS Identification**

These attributes provided by the RADIUS extension packets are used to determine the DA Controller that is to disconnect the session:

- NAS-IP-Address—This IPV4 address must match the primary IP address of the default interface for a match to occur.

If all of these attributes do not match, the request is responded to with a Disconnect-NAK response.
**User Session Identification**

The following attributes are used to determine the Layer 2 sessions that are to be terminated:

- **NAS-Port**—the interface index of the port that the session is connected to.
- **Calling-Station-Id**—The ASCII representation of the MAC address of the session to be terminated. If no NAS-Port attribute is present, then all sessions with the specified MAC address are terminated regardless of what port(s) the sessions are connected to.
- **Enterasys Auth-Client-Type**—One or more of these vendor-specific attributes (VSA) can be specified to indicate which authentication clients are to be affected. Valid values are: 1-dot1x, 2-pwa, 3-macauth. If this attribute is not present, then all sessions with the specified MAC address and/or port are affected.

All included attributes must match for the request to be processed. Additional attributes that are not understood by the DA controller in this context cause a failure of this disconnect request.

**Disconnect Responses**

If the Disconnect Request is determined to be of appropriate format and matching session(s) are present and terminated appropriately, then a Disconnect-Ack is sent in response. If all the attributes in the packet are not understood within this context or do not result in a matching DA controller and session, then the DA controller sends a Disconnect-NAK in response. If the DA controller is unable to appropriately terminate the matching session(s) for some reason, a Disconnect-NAK is sent in response.

**Security**

Using the RADIUS protocol to push both changes and terminations of existing sessions does have some security issues.

---

**Caution**

In this implementation in ExtremeXOS of RFC5176, some level of trust is required on the upstream portion of the local network. Network administrators should not enable this functionality if they are not comfortable with this level of security. See Limitations on page 976.

---

**Limitations**

The following features of Change-of-Authorization (RFC5176) are not implemented in ExtremeXOS:

- **Reverse Path Forwarding Check**—Typically this is used in a proxy scenario. This check is used to determine if the IP address indicated by the RADIUS attributes is a routable destination address for a request sent by the switch software.
- **IPSEC encryption**—End-to-end encryption of both the RADIUS requests and responses.
- **Disconnect-Request and Change-of-Authorization packets identifying sessions with anything other than the Calling-Station-Id attribute containing a properly formatted MAC address. In addition to the Calling-Station-Id attribute, you can also use a NAS-Port attribute, which indicates the index of the specific port the session is connected to.
- **Acct-Session-Id attribute**—This is an alternate means of session identification. Sessions are currently uniquely identified by port and MAC address pair.
- **Retransmissions of Disconnect-Request or Change-of-Authorization ACK and NAK packets**—Retransmissions of packets is the responsibility of the device initiating the dynamic authorization transactions.
Change of Authorization

Change of Authorization requests are sent from the DA initiator to the DA controller when it is determined that a session’s authorization parameters will be changed. The request is sent to UDP port 3799.

When a Change-of-Authorization (CoA) packet is received, it is determined whether it is an authorized request from a configured server. The source IP address of the packet is used to check for a match of the configured Dynamic Authorization Servers. If the source IP address has not been configured, then the request is immediately dropped with no further validation. If the IP address is present in the configuration, a validation of the Message-Authenticator attribute occurs as indicated in RFC2869. If validation is not successful, then the packet is dropped with no further processing. If it is determined that this is a retry, the packet is also dropped with no further processing.

The message indicates which DA controller the message is for, as well as, which session should be terminated. If the DA controller indicated by the included attributes in the packet does not match the receiver, then the request is responded to with a Change-of-Authorization-NAK. The appropriate DA controller receiving this RADIUS extension packet identifies the session(s) using the attributes provided and attempts to change the authorization level of the user as newly defined in the request packet.

DA Controller Identification

The DA controller is identified for CoA Requests in the same way that Disconnect Request identification occurs.

User Session Identification

Session identification for CoA occur in the same way that Disconnect Request identification does.

Supported Authorization Attributes

Policy authorization levels can be changed using this functionality. These attributes are the same ones that are used to define the initial authorization level of a session when authenticated by the DA controller. The processing of these attributes will result in the same authorization conditions that would have occurred if they were to have been received as the initial authorization level.

- Filter-Id —The filter ID identifies the name of the policy profile that is used for the session.
- RFC3580 Attributes—Three attributes are used to determine the RFC3580 authorization levels: Tunnel-Type, Tunnel-Medium-Type, and Tunnel-Private-Group-Id.

These values are used in concert with local policy settings to determine both the correct policy profile and VLAN settings for the session.

Change-of-Authorization Responses

If the CoA request is determined to be of appropriate format, matching session(s) are found, and their authorization levels are changed appropriately, then a Change-Of-Authorization-Ack is sent in response. If all the attributes in the packet are not understood within this context or do not result in a matching DA controller and session, then the DA controller sends a Change-Of-Authorization-NAK in response. If the DA controller is unable to appropriately change the matching session(s) authorization level for some reason, a Change-Of-Authorization-NAK is sent in response.
**Retry Detection**

To minimize the potential for replay attacks, the DA controller needs to support retry detection. This involves remembering source UDP port and *RADIUS* packet identifier pairs that have been received on a per DA Initiator basis. This information needs to be remembered for a reasonable period of time so that an attacker resending an identical frame to the DA controller does not cause undue harm to the switch. This functionality used in conjunction with the Event-Timestamp attribute limits the validity of replay attacks.

**New Attribute Support**

### Table 106: New CoA Attribute Support

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Defining RFC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event-Timestamp</td>
<td>The Event-Timestamp attribute is used to minimize the effect of network replay attacks. RFC5176 recommends incorporating this attribute when not using more complex security measures to encrypt the <em>RADIUS</em> packet data. The DA controller does not process Disconnect Request or CoA requests that do not include this attribute. The timestamp sent in this attribute must be within 300 seconds of the current time for the request to be processed. Response frames to either Disconnect request or CoA requests contain this attribute.</td>
<td>RFC2869</td>
</tr>
<tr>
<td>Proxy-State</td>
<td>When one or more of these attributes are included in either Disconnect request or request frames they must be included unedited in the responses to those packets.</td>
<td>RFC2865</td>
</tr>
<tr>
<td>Message-Authenticator</td>
<td>The Message-Authenticator attribute is used to both authenticate and integrity check <em>RADIUS</em> packets. It is used in lieu of more complex security measures to authorize and/or encrypt the <em>RADIUS</em> control packets. The DA controller does not process packets with invalid Message-Authenticator attribute values.</td>
<td>RFC2869</td>
</tr>
<tr>
<td>Error-Cause</td>
<td>The Error-Cause attribute is used to give the DA Initiator more information regarding the cause of the failure to process either a Disconnect request or a CoA request. The DA controller uses this attribute when it responds with the Disconnect-Request-NAK or the Change-Of-Authorization-NAK messages.</td>
<td>RFC5176</td>
</tr>
<tr>
<td>Enterasys Auth-Client-Type</td>
<td>The Enterasys Auth-Client-Type vendor-specific attribute (VSA) is used to indicate which authentication client sessions are to be affected by either the CoA or Disconnect Requests. The vendor ID used for this VSA is the IANA assigned private enterprise number for Enterasys—5624. The Enterasys attribute type number for this attribute is 1. Valid values are: 1-dot1x, 2-pwa, 3-macauth, 4-cep, 5-radsnoop, 6-auto-tracking and 7-quarantine-agent.</td>
<td>N/A</td>
</tr>
</tbody>
</table>
Additional RADIUS Configuration Examples

Installing and Testing the FreeRADIUS Server

RADIUS is a client/server protocol based on UDP.

The example presented in this section describes a RADIUS server that is a daemon process running on a Linux server.

The following example shows how to install and test a FreeRADIUS server:

```
tar -zxvf freeradius-1.0.2.tar.gz        (extract with gunzip and tar)
./configure
make
make install                             (run this command as root)
radiud                                  (start RADIUS server, or...)
radiud -X                               (start RADIUS server in debug mode)
radtest test test localhost 0 testing123 (test RADIUS server)
```

If radtest receives a response, the FreeRADIUS server is up and running.

Note

RADIUS server software can be obtained from several sources. This solution uses the FreeRADIUS software available on the following URLs: [www.freeradius.org](http://www.freeradius.org) and [www.redhat.com](http://www.redhat.com). Another free tool, NTRadPing, can be used to test authentication and authorization requests from Windows clients. NTRadPing displays detailed responses such as attribute values sent back from the RADIUS server.

Configuring the FreeRADIUS Server

Configuring the RADIUS server involves configuring the RADIUS server and the RADIUS client (for authentication and authorization). FreeRADIUS configuration files are usually stored in the /etc/raddb folder. The following example demonstrates how to configure the FreeRADIUS server for authentication and LDAP support:

1. Modify the radiusd.conf file global settings:
   
<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_auth</td>
<td>yes</td>
</tr>
<tr>
<td>log_auth_badpass</td>
<td>no</td>
</tr>
<tr>
<td>log_auth_goodpass</td>
<td>no</td>
</tr>
</tbody>
</table>

2. Modify LDAP Settings:

   ```
   modules {
     ldap {
       server = "ldaptest.extremenetworks.com"
       basedn = "o=ldaptestdemo,dc=extremenetworks,dc=com"
       filter = "{(cn=%{Stripped-User-Name:-%{User-Name}})}"
       base_filter = "{objectclass=radiusprofile}"
       start_tls = no
       dictionary_mapping = ${raddbdir}/ldap.attrmap
       authtype = ldap
       ldap_connections_number = 5
       timeout = 4
       timelimit = 3
       net_timeout = 1
   }
   ```
3 Uncomment LDAP from the authorize section:

```
authorize {
  preprocess
  chap
  mschap
  suffix
  ldap
  eap
  files
}
```

4 Uncomment LDAP from the authenticate section:

```
authenticate {
  Auth-Type PAP {
    pap
  }
  Auth-Type CHAP {
    chap
  }
  Auth-Type MS-CHAP {
    mschap
  }
  unix
  ldap
  eap
}
```

An Extreme Networks edge switch serves as a network access server (NAS) for workstations and as a RADIUS client for the RADIUS server.

RADIUS clients are configured in `/etc/raddb/clients.conf`. There are two ways to configure RADIUS clients. Either group the NAS by IP subnet or list the NAS by host name or IP address.

5 Configure the RADIUS client using the second method.

```
client 192.168.1.1 {
  secret = extreme1
  shortname = ldap-demo
}
```

**Configuring the RADIUS-to-LDAP Attribute Mappings**

Attributes are configured in `/etc/freeradius/ladp.attrmap`. This file maps RADIUS attributes to LDAP attributes. Samba has NT/LM password hashes. Hence, the default mapping for LM-Password and NT-Password must be changed.

- Configure attribute mappings.

```
checkItem User-Password userPassword.
checkItem LMPassword sambaLMPassword
checkItem NTPassword sambaNTPassword
replyItem Tunnel-Type radiusTunnelType
replyItem Tunnel-Medium-Type radiusTunnelMediumType
replyItem Tunnel-Private-Group-Id radiusTunnelPrivateGroupId
```
Configuring Additional Attributes Mappings

Attributes are configured in `/etc/freeradius/ladp.attrmap`:

<table>
<thead>
<tr>
<th>#</th>
<th>Attribute Description</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Extreme Security Profile</td>
<td>1.3.6.1.4.1.3317.4.3.1.61</td>
</tr>
<tr>
<td>2</td>
<td>Extreme Netlogin Vlan Tag</td>
<td>1.3.6.1.4.1.3317.4.3.1.62</td>
</tr>
<tr>
<td>3</td>
<td>Extreme Netlogin Extended Vlan</td>
<td>1.3.6.1.4.1.3317.4.3.1.63</td>
</tr>
</tbody>
</table>

Modifying the RADIUS Schema

Additional attributes for RADIUS must be configured to extend the RADIUS-LDAP-V3.schema under the `/etc/openldap` directory:

- Use the following commands to modify the RADIUS schema:

```bash
attributetype ( 1.3.6.1.4.1.3317.4.3.1.61
NAME 'radiusExtremeSecurityProfile'
DESC ''
EQUALITY caseIgnoreIA5Match
SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 )
attributetype ( 1.3.6.1.4.1.3317.4.3.1.62
NAME 'radiusExtremeNetloginVlanTag'
DESC ''
EQUALITY caseIgnoreIA5Match
SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 )
attributetype ( 1.3.6.1.4.1.3317.4.3.1.63
NAME 'radiusExtremeNetloginExtendedVlan'
DESC ''
EQUALITY caseIgnoreIA5Match
SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 )
```

Configuring the Authentication Method for Supplicants

The authentication method is configured in `/etc/raddb/eap.conf`. The authentication method used by FreeRADIUS is the PEAP (Protected EAP) method. To activate PEAP, a TLS tunnel is required to encrypt communication between supplicant and RADIUS server. This means that server certificates are required.

- Configure the authentication method:

```bash
peap {
  default_eap_type = mschapv2
}
tls {
  private_key_password = whatever
  private_key_file = ${raddbdir}/certs/cert-srv.pem
  certificate_file = ${raddbdir}/certs/cert-srv.pem
  CA_file = ${raddbdir}/certs/demoCA/cacert.pem
  dh_file = ${raddbdir}/certs/dh
  random_file = ${raddbdir}/certs/random
  fragment_size = 1024
  include_length = yes
}
```
### Starting the FreeRADIUS Server

- Start RADIUS in the foreground with debugging enabled.
  ```
  radiusd -X -f
  ```

### Implementation Notes for Specific RADIUS Servers

#### Cistron RADIUS

Cistron Radius is a popular server, distributed under GPL. Cistron Radius can be found at:

When you configure the Cistron server for use with Extreme switches, you must pay close attention to the users file setup. The Cistron Radius dictionary associates the word Administrative-User with Service-Type value 6, and expects the Service-Type entry to appear alone on one line with a leading tab character.

The following is a user file example for read-write access:

```
adminuser   Auth-Type = System
Service-Type = Administrative-User,
Filter-Id = "unlim"
```

#### RSA Ace

For users of Cistron’s RSA SecureID® product, RSA offers RADIUS capability as part of their RSA/Ace Server® server software. It is mandatory to configure a matching shared-secret key on the switch and RSA Ace server for successful authentication.

#### Steel-Belted Radius

For users who have the Steel-Belted Radius (SBR) server from Juniper Networks, it is possible to limit the number of concurrent login sessions using the same user account. This feature allows the use of shared user accounts, but limits the number of simultaneous logins to a defined value. Using this feature requires Steel-Belted Radius for RADIUS authentication and accounting. To limit the maximum concurrent login sessions under the same user account:

1. Configure RADIUS and RADIUS-Accounting on the switch.
   The RADIUS and RADIUS-Accounting servers used for this feature must reside on the same physical RADIUS server. Standard RADIUS and RADIUS-Accounting configuration is required as described earlier in this chapter.
2. Modify the SBR vendor.ini file and user accounts.
   a. To configure the SBR server, the file vendor.ini must be modified to change the Extreme Networks configuration value of ignore-ports to yes as shown in the example below:

   ```
   vendor-product       = Extreme Networks
dictionary           = Extreme
ignore-ports          = yes
port-number-usage     = per-port-type
help-id               = 2000
   ```
   b. After modifying the vendor.ini file, the desired user accounts must be configured for the Max-Concurrent connections. Using the SBR Administrator application, enable the check box for Max-Concurrent connections and fill in the desired number of maximum sessions.
Microsoft IAS

To use Extreme Networks VSAs with the Internet Authentication Service (IAS) in Microsoft® Windows Server™ 2003, you must first create a Remote Access Policy and apply it so that user authentication occurs using a specific authentication type such as EAP-TLS, PEAP, or PAP. The following procedure assumes that the Remote Access Policy has already been created and configured and describes how to define Extreme Networks VSAs in Microsoft IAS:

1. Open the IAS administration GUI application.
2. In the left window pane, select the Remote Access Policies section of the tree.
3. In the right window pane, double-click the desired Remote-Access policy name so you can edit it.
4. Click the Edit-Profile button in the lower-left corner, and then select the Advanced tab.
5. If any attributes already appear in the Parameters window, remove them by selecting the attribute and clicking the Remove button.
6. When the Parameters window is empty, proceed to the next step.
7. Click the Add button, which brings up the Add Attributes dialog window.
8. Scroll down the displayed list of RADIUS attributes and select the attribute named Vendor-Specific.
9. Double-click the Vendor-Specific attribute or click the Add button.
   The Multivalued Attribute Information dialog box should appear.
10. Click the Add button, which brings up the Vendor-Specific Attribute Information dialog window.
   a. Select the first radio button for Enter Vendor Code and enter the Extreme Networks vendor code value of 1916 in the text-box.
   b. Select the second radio button for Yes, It conforms.
   c. Verify both settings, and click the Configure Attribute button to proceed.
      The Configure VSA (RFC compliant) dialog window should now appear.
      The settings for this dialog window varies, depending on which product and attribute you wish to use in your network.
   d. In the first text-box enter the Extreme Networks VSA number for the attribute you want to configure (see Extreme Networks VSAs on page 968).
   e. Use the pull-down menu to select the Attribute format, which is the same as the attribute Type listed in Extreme Networks VSAs on page 968.

   f. Configure the desired value for the attribute.
   g. Once the desired values have been entered, click OK.
11. Click OK two more times to return to the Add Attributes dialog window.
12. Select Close, and then click OK twice to complete the editing of the Remote Access Policy profile.
13. To apply the configuration changes, stop and restart the Microsoft IAS service.

After restarting the IAS service, new authentications should correctly return the Extreme Networks VSA after successful authentication. Users who were previously authenticated have to re-authenticate to before the new VSAs apply to them.

Note
For values of format integer you will have to select the type Decimal from the pull-down menu.
14 If you experience problems with the newly configured VSAs, use the following troubleshooting guidelines:
   a. If you have multiple IAS Remote Access Policies, verify that the user is being authenticated with the correct policy.
   b. Check the IAS System Log events within Microsoft Event Viewer to verify the user is authenticated through the policy where VSA settings are configured.
   c. Check whether the VSA configuration performed above is correct. A mismatch in any of the VSA settings could cause authentication or VSA failure.
   d. Verify that attributes such as "VLAN tag" or "VLAN name" correctly match the configuration of your ExtremeXOS switch and overall network topology. Invalid, or incorrect values returned in the VSA could prevent authenticated users from accessing network resources.

Setting Up Open LDAP

To integrate an ExtremeXOS switch in an LDAP environment, a RADIUS server must be configured to communicate with the LDAP database. The following components are required to install the access control solution:

- Linux server with Linux Red Hat 4.0
- FREERADIUS 1.1.x
- OpenLDAP 2.3.x
- Extreme Networks switches
- Windows 7/Windows 8 clients

To configure Universal Port for use in an LDAP environment, use the following procedure:

1. Install and configure a RADIUS server on an existing Linux server as described in Installing and Testing the FreeRADIUS Server on page 979.
2. Install and configure OpenLDAP as described later in this section.
3. Add vendor specific attributes to the RADIUS and LDAP servers as described in Installing and Testing the FreeRADIUS Server on page 979 and later in this section.
4. Configure the edge switches as described in this guide.
5. Configure each supplicant as described in Configuring a Windows 7/Windows 8 Supplicant for 802.1X Authentication on page 988.

For complete instructions on setting up an LDAP server, see the product documentation for the LDAP server.

Installing OpenLDAP

OpenLDAP software is an open source implementation of Lightweight Directory Access Protocol. This can be obtained from the site: www.openldap.org. To install OpenLDAP packages:

1. Verify the Red Hat Linux installed releases. The release number is stored in the /etc/redhat-release file.
2. Verify the version of OpenLDAP currently installed by entering the command `rpm -qa | grep openldap` at the Linux prompt.
   ```bash
   # rpm -qa | grep openldap
   openldap-2.3.xx-x
   ```
If you have a default Red Hat Linux installation, there is at least one OpenLDAP Red Hat Package Manager (RPM) installed.

The LDAP RPMs can be found on the Red Hat CD or downloaded from one of the following RPM download sources:

www.rpmfind.net and search for openldap and select the RPM based on the distribution

www.redhat.com and select Download, and then search for openldap.

After downloading the RPMs to the Linux server, change to the download directory and start the installation using the rpm command:

# rpm -ivh openldap*

Verify that the OpenLDAP RPMs have been installed with the rpm -qa | grep openldap command at the Linux prompt.

# rpm -qa | grep openldap
openldap-2.3.xx-x
openldap-clients-2.3.xx-x
openldap-servers-2.3.xx-x

Configuring OpenLDAP

Once the build is complete, the slapd and slurpd daemons are located in /usr/local/libexec.

The config files are in /etc/openldap and ready to start the main server daemon, slapd.

Configuring slapd for Startup

Before you start slapd, edit /etc/openldap/slapd.conf to include the location to store the data and details on who is allowed to access the data.

The following configuration changes need to be made:

- Change the suffix.
- Change the rootDN.
- Use slappasswd to generate rootpw.
- Add rootpw entry.

Use the following commands to configure slapd for startup:

database (use default)
suffix "dc=xxxxxx,dc=org"
rootdn "cn=xxxx,dc=xxxxxx,dc=org"
rootpw {SSHA}c5PemO1KWqz0254r4rnFVmxKA/evs4Hu
directory /var/lib/ldap
allow bind_v2
pidfile /var/run/slapd.pid

Adding New Schemas

The RADIUS schema and Samba schema for PEAP authentication must be included into the slapd.conf file. After modifying the file, the LDAP server must be restarted to load the new schemas.
• Use the following commands to add new schemas:
  ```
  cp /usr/share/doc/freeradius-1.0.1/RADIUS-LDAPv3.schema /etc/openldap/schema/
  cp /usr/share/doc/samba-3.0.10/LDAP/samba.schema /etc/openldap/schema
  ```

• Use the following commands to modify slapd.conf:
  ```
  include /etc/openldap/schema/RADIUS-LDAPv3.schema
  include /etc/openldap/schema/samba.schema
  ```

**Populating the LDAP Database with Organization and User Entries**

• Use the following commands to make the user entry in the LDAP directory (slapd.conf):
  ```
  dn: uid=newperson3,o=ldaptestdemo,dc=extremenetworks,dc=com
  objectClass: top
  objectClass: person
  objectClass: radiusprofile << Defined in the RADIUS-LDAPv3 schema
  objectClass: sambaSamAccount
  sn: ldaptestdemo
  uid: newperson3 <<< This username given in the Odyssey client
  cn: newperson3
  radiusTunnelMediumType: IEEE-802
  radiusTunnelType: VLAN
  radiusTunnelPrivateGroupId: 2 <<< Value of the VLAN tag
  sambaNTPassword: A3A685F89364D4A5182B028FBE79AC38
  sambaLMPassword: C23413A8A1B7665FC2265B23734E0D4AC
  userPassword:: e1NIQX00MXZzNXNYbTRPaHNwUjBFU9raWdxbl1dySW89
  sambaSID: S-1-0-0-28976
  ```
  The Samba-related attributes can be populated in the LDAP server already if there is an LDAP-enabled Samba infrastructure in place.

  **Note**
  If the Samba related entries are not present, then the values for sambaNTPassword and sambaNMPPassword can be created by running the `mkntpwd` command.

  ```
  cd /usr/share/doc/samba-3.0.10/LDAP/smbldap-tools/mkntpwd
  make
  ./mkntpwd -L <password>   (provides value for sambaLMPassword attribute)
  ./mkntpwd -N <password>   (provides value for sambaNTPassword attribute)
  ```

**Restarting the LDAP Server**

• Use the following syntax to stop and start LDAP services:
  ```
  service ldap restart
  ```
  For phone authentication (which uses EAP based md5 authentication), the password is stored in clear text in the UserPassword field for the phone entries in LDAP.

**LDAP Configuration Example**

This configuration example is for Summit switches, but can also be used for other Extreme switches that support 802.1X.

Use the following commands to activate the switch for 802.1X port-based authentication:

```
create vlan voice
create vlan data
create vlan ldap
```
Configure

- **voice tag 10**
- **data tag 20**
- **ldap ipaddress 192.168.1.1/24**
- **enable ipforwarding**
- **create vlan nvlan**
- **en netlogin dot1x**
- **en netlogin port 13-24 dot1x**
- **configure radius netlogin primary server 192.168.1.2 1812 client-ip 192.168.1.1 vr VR-Default**
- **configure radius netlogin primary shared-secret extreme1**
- **enable radius netlogin**
- **enable netlogin dot1x**

Configure the ports to run a script when a user is authenticated through **RADIUS** and **LDAP**:

```
configure upm event user-authenticate profile a-avaya ports 1-23
LDAP UID entries:
```

In the LDAP phone UID entry in the users file, use the following attribute to specify a profile to run on the switch:

- **Extreme-Security-Profile**

To add the port as tagged in the voice **VLAN**, use the following attribute in the users file:

- **Extreme-Netlogin-Extended-Vlan = TVoice (use UData for a PC)**

**Note**

It depends on the end-station to determine the fields required for authentication; XP uses EAP-PEAP and must have encrypted fields for the UID password. Avaya phones authenticate with MD-5 and must have an unencrypted field in LDAP.

**Scripts**

The following a-avaya script tells the phone to configure itself in the voice VLAN, and to send tagged frames.

The script also informs the phone of the file server and call server:

```
create upm profile a-avaya
create log message Starting_UPM_Script_AUTH-AVAYA
set var callServer 10.147.12.12
set var fileServer 10.147.10.3
set var voiceVlan voice
set var CleanupProfile CleanPort
set var sendTraps false

create log message Starting_UPM_AUTH-AVAYA_Port_$EVENT.USER_PORT
#*********************************************************
# adds the detected port to the device "unauthenticated" profile port list
#*********************************************************
create log message Updating_Unauthenticated_Port_List_Port_$EVENT.USER_PORT
#configure upm event user-unauthenticated profile CleanupProfile ports $EVENT.USER_PORT
#*********************************************************
# Configure the LLDP options that the phone needs
#*********************************************************
configure lldp port $EVENT.USER_PORT advertise vendor-specific dot1 vlan-name vlan $voiceVlan
configure lldp port $EVENT.USER_PORT advertise vendor-specific avaya-extreme call-server $callServer
configure lldp port $EVENT.USER_PORT advertise vendor-specific avaya-extreme file-server
```
configure lldp port $EVENT.USER_PORT advertise vendor-specific avaya-extreme dot1q-framing tagged
#configure lldp port $EVENT.USER_PORT advertise vendor-specific med capabilities
#configure lldp port $EVENT.USER_PORT advertise vendor-specific med policy application voice vlan $voiceVlan dscp 46
if port is PoE capable, uncomment the following lines
configure lldp port $EVENT.USER_PORT advertise vendor-specific med power-via-mdi
#configure inline-power operator-limit $EVENT.DEVICE_POWER ports $EVENT.USER_PORT
create log message UPM_Script_A-AVAYA_Finished_Port_$EVENT.USER_PORT

Note
Parts of the scripts make use of the QP8 profile. This is NOT recommended because the QP8 profile is used by EAPS. For voice, use QP7 for QOS.
This script uses tagging for the phone and the ports for the voice VLAN. This is NOT necessary; use multiple supplicant and untagged for the phones.

Configuring a Windows 7/Windows 8 Supplicant for 802.1X Authentication

This section provides an overview procedure for configuring a Windows 7/Windows 8 supplicant. For complete instructions on setting up a Windows 7/Windows 8 supplicant, see the product documentation for Microsoft Windows XP.

Note
For enhanced security, install the FreeRADIUS server CA certificate (the CA that signed the certificate installed in eap.conf).

1. Open the network configuration panel, select the network card, enter the properties.
2. Click the Authentication tab.
   The Authentication dialog appears.
3. Enable 802.1X and disable authenticate as computer.
4. Choose EAP type of Protected EAP, then click Properties.
5. Deselect the Validate server certificate and select eap-mschapv2 as the authentication method.
6. Click Configure.
7. Select or clear the check box depending on whether you want to use the logon name and password, then click OK.

Hypertext Transfer Protocol

The Hypertext Transfer Protocol (HTTP) is a set of rules for transferring and exchanging information (data, voice, images, and so on) on the World Wide Web. HTTP is based on a request-response model. An HTTP client initiates requests by establishing a TCP connection to a port on a remote host (port 80 by default). An HTTP server listening on that port waits for and then responds to the request; in many instances, the client is requesting a specific URL or IP address. Upon receiving a request, the destination server sends back the associated file or files and then closes the connection.
The web server in ExtremeXOS allows HTTP clients to access the switch on port 80 (by default) as well as the network login page without additional encryption or security measures. For information about secure HTTP transmission, including Secure Socket Layer (SSL), see Secure Socket Layer on page 1018.

By default, HTTP is enabled on the switch.

- If you disabled HTTP access, you can re-enable HTTP access on the default port (80) using the following command:
  ```
  enable web http
  ```
- To disable HTTP, use the following command:
  ```
  disable web http
  ```

**Secure Shell 2**

Secure Shell 2 (SSH2) is a feature of the ExtremeXOS software that allows you to encrypt session data between a network administrator using SSH2 client software and the switch or to send encrypted data from the switch to an SSH2 client on a remote system.

Configuration, image, public key, and policy files can be transferred to the switch using the Secure Copy Protocol 2 (SCP2).

The ExtremeXOS SSH2 switch application works with the following clients: Putty, SSH2 (version 2.x or later) from SSH Communication Security, and OpenSSH (version 2.5 or later).

**SSH Server Overview**

SSH server in ExtremeXOS device listens for incoming connections. The server uses various services in ExtremeXOS including AAA for authentication, Policy Manager for access control, Session Manager for session reporting, and EMS for logging.

**Understanding SSH Server**

A 2,048-bit RSA Host key for the SSH server on the ExtremeXOS device is generated. Once the key is generated, the SSH server is started and listens for connections. Password and public key authentication methods are supported.

The client’s public keys are configurable through the CLI. A maximum of 100 keys can be created. A specific key can hold a maximum of 16 users, and a single user can be added to a maximum of 16 keys.

For password authentication, the configuration should be done in the AAA module, where an account must be created for the user, either as an admin or a user, and the corresponding password should be configured. The same will be used for validating the user, when exsshd (SSH server daemon/process) contacts AAA for authenticating the user.

Upon receiving a connection, it will be first validated with ACL/Policy, if configured. If the source-address from which the connection has been established, and is configured for a deny action in the acl, the connection is closed.

If the ACL permits the source-address of the client, the server proceeds with authentication steps. As part of authentication, the versions are exchanged between the client and the server. ExtremeXOS SSH server supports protocol version 2. If the client has a protocol version 1.99 or above, the same is
accepted. Otherwise, the connection is rejected. Once the versions of both the ends are accepted, key
exchange algorithms proposal of server and client are matched. Openssh-7.5p1 supports Diffie-Hellman
group 1, 14, 16, and 18 as part of the key exchange algorithms (see Diffie-Hellman Overview on page
1017). The minimal supported Diffie-Hellman group is 14 by default in Default mode, since group 1 is
considered weaker. After the key exchange algorithm is agreed upon, the ciphers are exchanged and
agreed upon. Openssh-7.5p1 supports the following ciphers and MACs:

- **Ciphers:** 3des-cbc, blowfish-cbc, aes128-cbc, cast128-cbc, aes192-cbc, aes256-cbc, arcfour, rijndael-
cbc@lysator.liu.se, aes128-ctr, aes192-ctr, aes256-ctr, arcfour256, arcfour128, chacha20-
poly1305@openssh.com

- **MACs:** hmac-md5-etm@openssh.com, hmac-sha1-etm@openssh.com, hmac-sha2-256-
etm@openssh.com, hmac-sha2-512-etm@openssh.com, hmac-ripemd160-etm@openssh.com,
hmac-sha1-96-etm@openssh.com, hmac-md5-96-etm@openssh.com, hmac-md5, hmac-sha1,
hmac-sha2-256, hmac-sha2-512, hmac-ripemd160, hmac-ripemd160@openssh.com, hmac-sha1-96,
hmac-md5-96

After the key exchanges, the local authentication methods that are supported (public key and password
authentication) are tried first. If there is a matching key or password, the AAA authentication will be
tried out. Else, the user will be considered to be unknown, and the session will be terminated.

Below are the steps that are involved between the client and the server while establishing the
connection.
Upon disabling SSH using the command `disable ssh2`, the server stops listening for new connections, but the existing connections continue to be active. When you enable the SSH server again, the key is not regenerated by default. Specific sessions or all the sessions can be closed through `clear session` command through CLI. The sessions are closed once the idle-timeout expires. By default the idle timeout is 3,600 seconds for SSH. The same can be configured through the CLI. If the session is left idle for more than the configured/default idle-timeout value in seconds, then the session is closed by the server. The idle timeout will be on per session basis. In other words, the idle timeout that is configured when the session is established, will be the one used for that particular session. If the user changes the idle timeout after the session is established, that will not be reflected on the existing sessions, but will be used for new sessions.

**SSH Default Enabled Parameters During Installation**

When installing ExtremeXOS 22.5 for the first time, the following SSH parameters are enabled by default:

In Default, FIPS, and Secure mode:
• **Diffie-Hellman groups:** 14 (2,048 bits), 16 (4,096 bits), 18 (8192 bits)

• **Public key algorithms:** ssh-rsa, x509v3-sign-rsa, x509v3-sign-dss

In Default mode:
- **Ciphers:** aes128-ctr, aes192-ctr, aes256-ctr, chacha20-poly1305@openssh.com
- **MACs:** hmac-sha1-etm@openssh.com, hmac-sha2-256-etm@openssh.com, hmac-sha2-512-etm@openssh.com, hmac-sha1, hmac-sha2-256, hmac-sha2-512

Other OpenSSH 7.5p1 supported MACs and ciphers listed in Understanding SSH Server on page 989 are disabled by default.

### Upgrading to ExtremeXOS 22.5 and Later

When upgrading from earlier releases to ExtremeXOS 22.5 and later, supported ciphers, MACs, public key algorithms, and Diffie-Hellman groups are inherited from the earlier releases.

**Note**

DSA (ssh-dss) related host key algorithms are not supported in both server and client in ExtremeXOS 22.5 and later. However, for backward compatibility, it is supported in the server after an upgrade to ExtremeXOS 22.5 and later if DSA host key is present in the earlier release.

### Enabling SSH2 for Inbound Switch Access

You must enable SSH2 on the switch before you can connect to the switch using an external SSH2 client.

Enabling SSH2 involves two steps:

1. Generate or specify an authentication key for the SSH2 sessions (see Standard Key Authentication on page 992 and User Key-Based Authentication on page 993).

2. Enable SSH2 access by specifying a TCP port to be used for communication and specifying on which virtual router (VR) SSH2 is enabled (see Enabling SSH2 on page 1001).

### Standard Key Authentication

An authentication key must be generated before the switch can accept incoming SSH2 sessions. This can be done automatically by the switch, or you can enter a previously generated key.

• To have the key generated by the switch, use the following command:

```
configure ssh2 key
```

The key generation process can take up to one minute.

For the switch to use the newly generated key, the exsshd process needs to be restarted using the `restart process [class | name (msm slot)]` command with “exsshd” for `name`.

• To use a key that has been previously created, use the following command:

```
configure ssh2 key [pregenerated]
```
The switch prompts you to enter the pregenerated key.

**Note**
The pregenerated key must be one that was generated by the switch. To get such a key, you can use the command `show ssh2 private-key` to display the key on the console. Copy the key to a text editor and remove the carriage return/line feeds. Finally, copy and paste the key into the command line. The key must be entered as one line.

The key generation process generates the SSH2 private host key. The SSH2 public host key is derived from the private host key and is automatically transmitted to the SSH2 client at the beginning of an SSH2 session.

**User Key-Based Authentication**

Public key authentication is an alternative method to password authentication that SSH uses to verify identity. You can generate a key pair consisting of a private key and a public key. The public key is used by the ExtremeXOS SSH server to authenticate the user.

In ExtremeXOS, user public keys are stored in the switch’s configuration file; these keys are then associated (or bound) to a user.

The keys are configured on the switch in one of two ways:

- By copying the key to the switch using scp2/sftp2 with the switch acting as the server.
- By configuring the key using the CLI.

RSA and DSA encryption keys are both supported.

The public key can be loaded onto the switch using SCP or SFTP, where the switch is the server. The administrator can do this by using the SCP2 or SFTP2 client software to connect to and copy the key file to the switch. The public key file must have the extension ssh; for example, id_dsa_2048.ssh. When the `.ssh` file is copied to the switch, the key is loaded into the memory. The loaded public keys are saved to the configuration file (*.cfg) when the `save` command is issued via the CLI.

The key name is derived from the file name. For example, the key name for the file `id_dsa_2048.ssh` will be `id_dsa_2048`. The file name of the key or the keyname is restricted to 32 characters in length.

The key is associated with a user either implicitly, by pre-pending the user name to the file or explicitly using the CLI.

In order for a key to be bound or associated to a user, the user must be known. In other words, that user must have an entry in the local database on the switch. Once the user is authenticated, the user’s rights (read-only or read/write) are obtained from the database.

The key can be associated with a user by pre-pending the user name to the file name. For example, `admin.id_dsa_2048.ssh`.

If the user specified in the file name does not exist on the switch, the key is still accepted, but is not associated to any user. Once the user is added, the key can be associated with the user using the CLI. If the user name is not pre-pended to the file name, the key is accepted by the switch but is not associated with any user. The key can be then be associated with the user using the command `configure sshd2 user-key key_name add user user_name`. 
You can also enter or paste the key using the command `configure ssh2 key {pregenerated}` using the `pregenerated` keyword. There cannot be any carriage returns or new lines in the key. For more information, see the `configure ssh2 key {pregenerated}` command in the ExtremeXOS 22.6 Command Reference Guide.

The host and user public keys can be written to a file in the `config` directory using the `create sshd2 key-file {host-key | user-key} key_name` command. This enables the administrator to copy the public key to an outside server.

**Public-Key Infrastructure (PKI) in Secure Shell (SSH) Overview**

The major disadvantage with user-key-based authentication is scalability. As the number of users increases, a greater number of keys must be copied and stored in the switch. This problem can be solved with the Public-Key Infrastructure (PKI). Moreover, PKI has its own advantages of added security, certificate revocation checking, avoiding manual mapping of keys with users, etc.

For the details about configuring PKI, see Using Public-Key Infrastructure (PKI) in Your Network on page 1022.

![Figure 115: Public-Key Infrastructure Login Flow Overview](image)

**Figure 115: Public-Key Infrastructure Login Flow Overview**

In Figure 115, Callout 1 is the initial series of message exchanges initiated by the Secure Shell (SSH) client. The ExtremeXOS device is providing the SSH client with the list of supported authentication methods, one of which is public key. The SSH client responds with its public key certificate.

At Callout 2, the ExtremeXOS device verifies if the extended key usage of client certificate contains ‘client authentication’. If not, the SSH PKI connection is not established. Next, the ExtremeXOS device extracts the Common-Name field from the public key certificate and validates it against the local-accounts present/configured in the switch. If there is no matching accounts/user-name, then the SSH PKI connection is not established. Next, it checks to ensure the certificate signature from SSH client matches a trusted certificate authority’s certificate present on the ExtremeXOS device.

At Callout 3, the ExtremeXOS device sends an Online Certificate Status Protocol (OCSP) request to the OCSP responder to check the validity of the Clients X.509 certificate. If the OCSP responder determines
that the certificate has not been revoked by the certificate authority, the server sends back a GOOD response. After the preceding steps are completed, then the user is logged in automatically using SSH with X509, which can be seen using the command `show session` with the output shown as follows (the Auth field has a value of x509v3, which indicates that this is a SSH login using PKI):

```
# show session
#       Login Time               User     Type    Auth   Auth Location
--------------------------------------------------------------------------------
*5          Tue Oct 18 12:24:12 2016 samar .. ssh2    x509v3 dis  10.127.3.143
```

Limitations

- Certificate-based authentication is supported only for ExtremeXOS Secure Shell (SSH) server, not for ExtremeXOS SSH client.
- Revocation check is done only for the SSH client-end certificate using OCSP only at the time of login. There are no periodic revocation checks.
- The SSH client certificate must have client authentication purpose in the extendedKeyUsage field.
- Username must be present in CommonName (CN) in the subject of the certificate. The login username and this CN must match for access to be granted.
- Supports only RSA, DSA-based SSH client certificates.

Example: Configuring PKI for SSH Secure Login Using X509v3 Certificates

The following is an example on how to use the ExtremeXOS PKI for SSH secure login using X509v3 certificates.

For example purposes, the following has been considered:

- OpenSSL is used to generate the trusted CA certificates and SSH client certificates.
- CommonIssuerModel is used for OCSP.
- OpenSSL’s OCSP utility is used.
- Roumenpetrov’s “PKIX-SSH” with X.509 v3 certificate support is used as an SSH client.

Generating Certificates Using OpenSSL

The following steps should be followed on a Linux server with OpenSSL installed to generate the X509v3 certificates.

```
$ mkdir certs crl newcerts serial private
$ touch index.txt
$ echo "01" > serial

$ openssl req -x509 -nodes -days 365 -newkey rsa:2048 -subj "/C=US/ST=NC/L=Raleigh/O=Extr/OU=Exos/CA-Exos/emailAddress=ca-exos@extremenetworks.com" -keyout exosCAkey.pem -out exosCAcert.crt
Generating a 2048 bit RSA private key
+++
writing new private key to 'exosCAkey.pem'
-----

$ openssl x509 -in exosCAcert.crt -text
Certificate:
  Data:
```
Version: 3 (0x2)
Serial Number: 1738734014905383023 (0xf14dfee96fe3b86f)

ExtremeXOS® User Guide for version 22.6
996
The next steps are to create a X509v3 certificate for a user that is signed by the above generated CA certificate "exosCAcert.crt".

In the following command, a user certificate signing request with RSA 2048 bit key, commonName as "exos-admin" is generated:

```
$ openssl req -nodes -days 365 -newkey rsa:2048 -new -subj "/C=US/ST=NC/L=Raleigh/O=Extr/OU=Exos/CN=exos-admin/emailAddress=exos-admin@extremenetworks.com" -keyout exos-admin-key.pem -out exos-admin-req.csr
Generating a 2048 bit RSA private key
.............................................+++
......................................+++ writing new private key to 'exos-admin-key.pem'
```

In the following command, the user certificate signing request that was generated in the preceding command is being signed using the CA certificate "exosCAcert.crt":

```
$ openssl ca -config openssl.cnf -extensions usr_cert -days 365 -keyfile exosCAkey.pem -cert exosCAcert.crt -in exos-admin-req.csr -out exos-admin-cert.crt
Using configuration from openssl_A.cnf
Check that the request matches the signature
Signature ok
Certificate Details:

Downloading the Trusted Certificate to the ExtremeXOS PKI and Configuring the User Accounts

The previously generated trusted CA certificate needs to be downloaded from a TFTP server using the following command. "10.127.3.236" is the TFTP server IP address:

DUT1_X450G2-24t.3 # download ssl 10.127.3.236 certificate trusted-ca /certs/exosCAcert.crt
DUT1_X450G2-24t.4 #
DUT1_X450G2-24t.4 # sh ssl trusted-ca exosCAcert.crt
--------------------- exosCAcert.crt ---------------------
Certificate:
  Data:
    Version: 3 (0x2)
    Serial Number:
    Signature Algorithm: sha256WithRSAEncryption
    Issuer: C=US, ST=NC, L=Raleigh, O=Extr, OU=Exos, CN=CA-EXOS/emailAddress=ca-
        exos@extremenetworks.com
    Validity
      Not Before: Oct 20 07:12:47 2016 GMT
      Not After : Oct 20 07:12:47 2017 GMT
    Subject: C=US, ST=NC, L=Raleigh, O=Extr, OU=Exos, CN=CA-EXOS/emailAddress=ca-
        exos@extremenetworks.com

The user needs to be created on the ExtremeXOS device with appropriate privileges. The name of the account would be the value present in the “commonName” field of the user-certificate that was generated (that is: exos-admin-cert.crt):

DUT1_X450G2-24t.1 # create account admin exos-admin exospassword

Using OpenSSL OCSP Utility

As mentioned previously, OpenSSL’s OCSP utility is used for example purposes, and the example uses the “Common Issuer Model”.

The following command should be entered in the Linux Server for OCSP Responder:

$ openssl ocsp -port 2561 -text -index index.txt -CA exosCAcert.crt
   -rkey exosCAkey.pem -rsigner exosCAcert.crt

Using Roumenpetrov’s “PKIX-SSH” SSH Client for Logging

To use the user-certificate for logging into the ExtremeXOS SSH server, you need to concatenate the key file and certificate file as a single file, and also ensure that the file does not have a very open permission level (that is, accessible by others).

$ cat exos-admin-key.pem exos-admin-cert.crt > exosadmincert.crt
$ chmod 0600 exosadmincert.crt
$ ssh -i exosadmincert.crt exos-admin@10.127.6.57

Enabling SSH2

- To enable SSH2, use the following command:

```plaintext
enable ssh2 {access-profile [access_profile | none]} {port tcp_port_number} [vr [vr_name | all | default]}
```

You can also specify a TCP port number to be used for SSH2 communication. The TCP port number is 22 by default. The switch accepts IPv6 connections.

Before you initiate a session from an SSH2 client, ensure that the client is configured for any non-default access list or TCP port information that you have configured on the switch. After these tasks are accomplished, you may establish an SSH2-encrypted session with the switch. Clients must have a valid user name and password on the switch in order to log in to the switch after the SSH2 session has been established.

Up to eight active SSH2 sessions can run on the switch concurrently. If you enable the idle timer using the `enable idletimeout` command, the SSH2 connection times out after 20 minutes of...
inactivity by default. If you disable the idle timer using the `disable idletimeout` command, the SSH2 connection times out after 60 minutes of inactivity by default. This timeout value can be modified using the `configure ssh2 idletimeout minutes` command wherein `minutes` can be from 1 to 240”. For more information please refer to the command help for “configure ssh2”.

After SSH2 has enabled, TCP port 22 is available on all virtual routers by default.

General technical information is also available at http://www.openssh.com/specs.html.

**Setting SSH2 Rekeying Interval**

Data transmission between server and client in each SSH2 session is encrypted using session keys.

Session keys are generated after negotiation between server and client using Diffie-Hellman algorithm (see [Diffie-Hellman Overview](#) on page 1017). Cryptanalysis experts advise that it is unsafe to use the same session key to encrypt data over long periods of time. With enough captured data you could analyze the traffic and compromise the key, so it is advisable to keep changing the session keys after a certain interval.

You can configure the SSHv2 session rekeying interval by specifying a time interval and/or a data limit. After the configured time interval, the SSH server forces the client to perform a key negotiation for a new session key. This new key is used for SSH communication until the next rekeying. After configuring the SSH session rekeying time interval, configured SSH idle-timeout is disabled, so the idle-timeout occurs at the globally configured idle-timeout, instead of SSH configured idle-timeout.

Default value for data limit varies depending upon the encryption algorithm being used. For algorithms with a block size of 128-bits, data-limit is 4GB; for algorithms with a block size of 64-bits, the data limit is 1GB. This is the limitation by OpenSSH. For example, if the communication is through 3-DES algorithm and the data limit is configured at 4GB, rekeying occurs after 1GB of data is transferred. If the communication is using AES algorithm with same configuration, rekeying occurs after 4GB data is transferred. This issue does not occur if you limit the range to 1GB, instead of 4GB for the data limit.

To set the rekey interval, use the following command:

```
configure ssh2 rekey [time-interval [time_interval | none] | data-limit [data_size | default]]
```

To view your selections for rekeying, use the following commands:

```
show ssh2
```

or

```
show management
```

**Enabling/Disabling DSA and X509v3 Public Key Algorithms**

You can selectively enable and disable DSA/RSA X509 public key-based algorithms: ssh-rsa, ssh-dss, x509v3-sign-rsa, x509v3-sign-dss.

To enable DSA/RSA X509 public key-based algorithms, use the following command:

```
configure ssh2 enable {pk-alg [pkalg_name | all]}
```
To disable DSA/RSA X509 public key-based algorithms, use the following command:

```
configure ssh2 disable {pk-alg [pkalg_name | all]}
```

To view which public key-based algorithms are currently enabled, use the following command:

```
show ssh2
```

### Viewing SSH2 Information

- To view the status of SSH2 sessions on the switch, use the following command:
  
  ```
  show ssh2
  ```

  The `show management` command displays information about the switch including the enable/disable state for SSH2 sessions and whether a valid key is present.

### Using ACLs to Control SSH2 Access

You can restrict SSH2 access by creating and implementing an **ACL** policy.

You configure an ACL policy to permit or deny a specific list of IP addresses and subnet masks for the SSH2 port.

The two methods to load ACL policies to the switch are:

- Use the `edit policy` command to launch a VI-like editor on the switch. You can create the policy directly on the switch.
- Use the `tftp` command to transfer a policy that you created using a text editor on another system to the switch.

For more information about creating and implementing ACLs and policies, see **Security and ACLs** on page 637.

### Sample SSH2 Policies

The following are sample policies that you can apply to restrict SSH2 access.

In the following example, named `MyAccessProfile.pol`, the switch permits connections from the subnet 10.203.133.0/24 and denies connections from all other addresses:

```
MyAccessProfile.pol
Entry AllowTheseSubnets {
  if {
    source-address 10.203.133.0 /24;
  }
  Then {
    permit;
  }
}
```
In the following example, named MyAccessProfile.pol, the switch permits connections from the subnets 10.203.133.0/24 or 10.203.135.0/24 and denies connections from all other addresses:

```plaintext
MyAccessProfile.pol
Entry AllowTheseSubnets {
  if match any {
    source-address 10.203.133.0 /24;
    source-address 10.203.135.0 /24;
  }
  Then
  {
    permit;
  }
}
```

In the following example, named MyAccessProfile_2.pol, the switch does not permit connections from the subnet 10.203.133.0/24 but accepts connections from all other addresses:

```plaintext
MyAccessProfile_2.pol
Entry dontAllowTheseSubnets {
  if {
    source-address 10.203.133.0 /24;
  }
  Then
  {
    deny;
  }
}
Entry AllowTheRest {
  If {
    ; #none specified
  }
  Then
  {
    permit;
  }
}
```

In the following example, named MyAccessProfile_2.pol, the switch does not permit connections from the subnets 10.203.133.0/24 or 10.203.135.0/24 but accepts connections from all other addresses:

```plaintext
MyAccessProfile_2.pol
Entry dontAllowTheseSubnets {
  if match any {
    source-address 10.203.133.0 /24;
    source-address 10.203.135.0 /24
  }
  Then
  {
    deny;
  }
}
Entry AllowTheRest {
  If {
    ; #none specified
  }
  Then
  {
    permit;
  }
}
```
Configuring SSH2 to Use ACL Policies

This section assumes that you have already loaded the policy on the switch. For more information about creating and implementing ACLs and policies, see Security and ACLs.

- To configure SSH2 to use an ACL policy to restrict access, use the following command:

```
enable ssh2 {access-profile [access_profile | none]} {port tcp_port_number} {vr [vr_name | all | default]}
```

Use the `none` option to remove a previously configured ACL.

In the ACL policy file for SSH2, the source-address field is the only supported match condition. Any other match conditions are ignored.

Using SCP2 from an External SSH2 Client

In ExtremeXOS, the SCP2 protocol is supported for transferring configuration, image and public key policy files to the switch from the SCP2 client. The user must have administrator-level access to the switch. The switch can be specified by its switch name or IP address. ExtremeXOS only allows SCP2 to transfer to the switch files named as follows:

- *.cfg—ExtremeXOS configuration files
- *.pol—ExtremeXOS policy files
- *.xos—ExtremeXOS core image files
- *.xmod—ExtremeXOS modular package files
- *.ssh—Public key files

In the following examples, you are using a Linux system to move files to and from the switch at 192.168.0.120, using the switch administrator account admin. You are logged into your Linux system as user.

- To transfer the primary configuration file from the switch to your current Linux directory using SCP2, use the following command:

```
[user@linux-server]# scp2 admin@192.168.0.120:primary.cfg primary.cfg
```

- To copy the policy filename test.pol from your Linux system to the switch, use the following command:

```
[user@linux-server]# scp2 test.pol admin@192.168.0.120:test.pol
```

- To copy the image file test.xos from your Linux system to the switch, use the following command:

```
[user@linux-server]# scp2 test.xos admin@192.168.0.120:test.xos
```

Now you can use the command `install image test.xos` to install the image in the switch.

- To copy the SSH image file test.xmod from your Linux system to the switch, use the following command:

```
[user@linux-server]# scp2 test.xmod admin@192.168.0.120:test.xmod
```

Now you can use the command `install image test.xmod` to install the image in the switch.

- To load the public key id_rsa.pub from your Linux system to the switch, use the following command:

```
[user@linux-server]# scp2 id_rsa.pub admin@192.168.0.120:test.ssh
```

This command loads the key into memory, which can be viewed with the command `show sshd2 user-key`. 
Understanding the SSH2 Client Functions on the Switch

An Extreme Networks switch can function as an SSH2 client. This means you can connect from the switch to a remote device running an SSH2 server and send commands to that device. You can also use SCP2 to transfer files to and from the remote device.

**Note**

ExtremeXOS 15.7.1 upgraded from openssh-3.9p1 to openssh-6.5p1. ExtremeXOS 21.1 adds the openssl-fips-ecp-2.0.9 open source library. ExtremeXOS 22.5 upgraded from openssh-6.5p1 to openssh-7.5p1.

You do not need to enable SSH2 or generate an authentication key to use the SSH2 and SCP2 commands from the ExtremeXOS CLI.

**Note**

User-created VRs are supported only on the platforms listed for this feature in the ExtremeXOS 22.6 Feature License Requirements document.

- To send commands to a remote system using SSH2, use the following command:
  
  ```
  ssh2 {cipher [cipher]} {mac mac} {compression [on | off]} {port port} {user username} {vr vr_name} user@host {remote_command}
  ```

  The remote commands can be any command acceptable by the remote system. You can specify the login user name as a separate argument or as part of the user@host specification. If the login user name for the remote system is the same as your user name on the switch, you can omit the username parameter entirely.

  For example, to obtain a directory listing from a remote Linux system with IP address 10.10.0.2 using SSH2, enter the following command:
  ```
  ssh2 admin@10.10.0.2 ls
  ```

- To initiate a file copy from a remote system to the switch using SCP2, use the following command:
  
  ```
  scp2 {cipher cipher} {mac mac} {compression [on | off]} {port port} {vr vr_name} [ user@host:file local-file | local-file user@host:file ]
  ```

  For example, to copy the configuration file test.cfg on host system1 to the switch, enter the following command:
  ```
  scp2 admin@system1:test.cfg localtest.cfg
  ```

- To initiate a file copy to a remote system from the switch using SCP2, use the following command:
  
  ```
  scp2 {cipher cipher} {mac mac} {compression [on | off]} {port port} {vr vr_name} [ user@host:file local-file | local-file user@host:file ]
  ```

  For example, to copy the configuration file engineering.cfg from the switch to host system1, enter the following command:
  ```
  scp2 engineering.cfg admin@system1:engineering.cfg
  ```

**SSH/SCP Client Upgrade Limitations**

- Only password-based authentication is supported for SSH/SCP client.
- SCP client will not support upload of Image or BootROM files (i.e, *.xos, *.xmod, and *.xtr).
- SCP client will not support download of Image or BootRom files (like *.xos, *.xmod, and *.xtr) from ExtremeXOS SCP server.
• Only supports transfer of files such as *.cfg, *.xsf, *.py, *.pol and *.ssh files to/from the switch.
• Keyboard interactive authentication will not be supported.
• Host key algorithms are not configurable.

Using SFTP from an External SSH2 Client

The SFTP protocol is supported for transferring configuration, and policy files to the switch from the SFTP client. You must have administrator-level access to the switch. The switch can be specified by its switch name or IP address.

ExtremeXOS requires that SFTP transfer to the switch files named as follows:
• *.cfg—ExtremeXOS configuration files
• *.pol—ExtremeXOS policy files
• *.xos—ExtremeXOS core image file
• *.xmod—ExtremeXOS modular package file
• *.ssh—Public key files

In the following examples, you are using a Linux system to move files to and from the switch at 192.168.0.120, using the switch administrator account admin. You are logged into your Linux system as account user.

• To transfer the primary configuration file from the switch to your current Linux directory using SCP2, use the following command:

  user@linux-server]$ sftp admin@192.168.0.120
  password: <Enter password>
  sftp> put primary.cfg

• To copy the policy filename test.pol from your Linux system to the switch, use the following command:

  user@linux-server]$ sftp admin@192.168.0.120
  password: <Enter password>
  sftp> put test.pol

• To copy the image file image.xos from your Linux system to the switch, use the following command:

  user@linux-server]$ sftp admin@192.168.0.120
  password: <Enter password>
  sftp> put image.xos

• To load the public key id_rsa.pub from your Linux system to the switch, use the following command:

  user@linux-server]$ sftp admin@192.168.0.120
  password: <Enter password>
  sftp> put id_rsa.pub id_rsa.ssh

For image file transfers, only one image file at a time can be available for installation. If you need to install an additional image (xmod):

a) Transfer image.xos into the switch using scp/sftp
b) Install the image.xos image using the "install image" command
c) Transfer the xmod into the switch using scp/sftp
d) Install the xmod modular package file using install image fname {partition} [ active | inactive] {reboot} command.
• For image file transfers using SFTP or SCP (with the switch acting as the server), once the image is copied to the switch, validation of image is done by the switch, as indicated by the following log message:

<Info:AAA.LogSsh> Validating Image file, this could take approximately 30 seconds..image.xos

You must receive the following log message before you can proceed with the installation of the image:

<Info:AAA.LogSsh> Image file successfully validated

In stacking switches, you must receive the following log message from all slots before proceeding with the installation.

For example, in a four-switch stack, the installation can be proceed only after the following log messages are received:

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Log Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>04/19/2007 17:41:09.71</td>
<td>Slot-1: Sent file &quot;image.xos&quot; info to backup slot 3</td>
</tr>
<tr>
<td>04/19/2007 17:41:09.71</td>
<td>Slot-1: Sent file &quot;image.xos&quot; info to standby slot 3</td>
</tr>
<tr>
<td>04/19/2007 17:41:09.71</td>
<td>Slot-1: Sent file &quot;image.xos&quot; info to standby slot 4</td>
</tr>
</tbody>
</table>

Disabling Unapproved Crypto Algorithms

ExtremeXOS provides a way to administratively disable unapproved crypto algorithms. This allows you to enable and disable ciphers and MAC algorithms to be used by the SSH server.

Disabling Unapproved Crypto Algorithms

SSH works on three security modes default-mode, FIPS-mode, and Secure-Mode (see Security Mode Overview on page 902). In each mode, you can configure the required ciphers and MACs from a list using the CLI. Different modes support a different list of ciphers. By default, all available ciphers and MACs in the modes are configured unless otherwise indicated (see Table 107).
### Table 107: Supported Ciphers and MACs

<table>
<thead>
<tr>
<th>Mode</th>
<th>Ciphers</th>
<th>MACs</th>
</tr>
</thead>
</table>
| Default| **Enabled** by default: aes128-ctr, aes192-ctr, aes256-ctr, chacha20-poly1305@openssh.com  
**Disabled** by default: 3des-cbc, blowfish-cbc, aes128-cbc, aes192-cbc, aes256-cbc, cast128-cbc, rijndael-cbc@lysator.liu.se, arcfour, arcfour128, arcfour256 | **Enabled** by default: hmac-shal-etm@openssh.com, hmac-sha2-256-etm@openssh.com, hmac-sha2-512-etm@openssh.com; hmac-shal, hmac-sha2-256, hmac-sha2-512  
**Disabled** by default: hmac-md5, hmac-md5-96, hmac-md5-etm@openssh.com, hmac-md5-96-etm@openssh.com, hmac-ripemd160, hmac-ripemd160@openssh.com, hmac-ripemd160-etm@openssh.com, hmac-shal-96, hmac-shal-96-etm@openssh.com |
| FIPS   | 3des-cbc, aes128-cbc, aes192-cbc, aes256-cbc, aes128-ctr, aes192-ctr, aes256-ctr, rijndael-cbc@lysator.liu.se | hmac-shal, hmac-sha2-256, hmac-sha2-512 |
| Secure | aes128-ctr, aes192-ctr, aes256-ctr | hmac-shal; hmac-sha2-256; hmac-sha2-512 |

By default, weaker ciphers/MACs are disabled, while the remaining ciphers/MACs are enabled (see Default mode in Table 107). This is the default mode of operation. A switch can move from this default mode to FIPS mode. Changing from default mode to FIPS mode requires switch reboot. Until reboot, all the SSH connections use default mode configurations. Since the configuration is already changed by the user (here FIPS mode), updated configuration is displayed. On reboot, only FIPS mode ciphers/MACs are available in SSH for configuration. Again, disabling FIPS mode requires a system reboot. Until reboot, SSH server supports only FIPS mode ciphers/MACs. Since the user configured disabling FIPS mode, the corresponding updated configuration appears. It is recommended to update the FIPS mode once all the operations are completed. None of the security related configurations are supposed to be changed after updating the FIPS mode. This is because the behavior is undefined in those scenarios.

SSH supports Secure-Mode, which is allows only highly secure ciphers/MACs. Secure-Mode is a feature of SSH alone. This has no effect on other modules that use cryptograph like FIPS-mode. Configuring Secure-Mode does not require a switch reboot. The changes are immediate. Secure-mode and FIPS-mode are not mutually exclusive. Secure-Mode supports fewer ciphers/MACs than FIPS mode, so you only have Secure-Mode ciphers/MACs available for configuration with both Secure-Mode and FIPS-Mode are enabled. Internally, Secure-Mode uses FIPS library for cryptography instead of OpenSSL library. Once Secure-Mode is disabled, the SSH server moves to either default-mode or FIPS-mode, based on FIPS-Mode configuration. However, those ciphers/MACs that are configured before enabling/disabling Secure-Mode are lost. So, for each mode update, SSH server configuration of ciphers/MACs is reset. You have to configure ciphers/MACs each time if you configured SSH server for using particular ciphers/MACs. From the list of available ciphers/MACs, you can configure the required ciphers/MACs, and disable the ciphers/MACs that are not required.

Disabling all the ciphers/MACs does not allow any incoming connection from the clients. This happens because the incoming connections are not able to negotiate for a common cipher/MAC.

---

**ExtremeXOS® User Guide for version 22.6**

1009
Configuring Unapproved Crypto Algorithms

- To configure the required ciphers/MACs with SSHv2, use the following command:
  ```
  configure ssh2 enable [cipher [cipher | all] | mac [ mac | all]]
  ```
- To disable ciphers/Message Authentication Codes (MACs) for use with SSHv2, use the following command:
  ```
  configure ssh2 disable [cipher [cipher | all] | mac [ mac | all]]
  ```
- To display the configured SSHv2 ciphers and MACs, use the following command:
  ```
  show ssh2 {ciphers | macs}
  ```

Enabling/Disabling Ciphers and MACs Configuration Examples

**Configuration Example: Enable/Disable Ciphers in Default Mode**

```bash
# show ssh2
SSH module configuration details:
SSH Access : Disabled
Key validity : Invalid
Key type : RSA 2048
TCP port : 22
VR : all
Access profile : not set
Secure Mode : Off
Diffie-Hellman Groups : 14 (2048 bits), 16 (4096 bits), 18 (8192 bits)
Max Auth Tries : 3
Idle time : 60 minutes
Keyp Interval : 4096 MB and no time limit
Ciphers : aes128-cbc, 3des-cbc, blowfish-cbc, cast128-cbc, aes192-cbc, aes256-cbc, arcfour, rijndael-cbc@lysator.liu.se, aes128-ctr, aes192-ctr, aes256-ctr, arcfour256, arcfour128, chacha20-poly1305@openssh.com
Macs : hmac-md5-etm@openssh.com, hmac-sha1-etm@openssh.com, hmac-sha2-256-etm@openssh.com, hmac-sha2-512-etm@openssh.com, hmac-ripemd160-etm@openssh.com, hmac-sha1-96-etm@openssh.com, hmac-md5-96-etm@openssh.com, hmac-sha2-256, hmac-sha2-512, hmac-ripemd160, hmac-ripemd160@openssh.com, hmac-sha1-96, hmac-md5-96
Public key algorithms : ssh-rsa, ssh-dss, x509v3-sign-rsa, x509v3-sign-dss

Key type : RSA 2048
TCP port : 22
VR : all
Access profile : not set
Secure Mode : Off
Diffie-Hellman Groups : 14 (2048 bits), 16 (4096 bits), 18 (8192 bits)
Idle time : 60 minutes
Ciphers : aes128-ctr, aes192-ctr, aes256-ctr, aes128-cbc, 3des-cbc, aes192-cbc, aes256-cbc, rijndael-cbc@lysator.liu.se
Macs : hmac-sha2-256, hmac-sha2-512

# configure ssh2 enable mac hmac-sha1

# show ssh2 macs
Macs : hmac-sha1, hmac-sha2-256, hmac-sha2-512
Configuration Example: Enable/Disable Ciphers in Secure Mode

```bash
# configure ssh2 secure-mode on
Note: All Secure mode Ciphers/MACs will be enabled

# show ssh2
SSH module configuration details:
SSH Access     : Enabled
Key validity   : Valid
Key type       : RSA 2048
TCP port       : 22
VR             : all
Access profile : not set
Secure Mode    : On
Diffie-Hellman Groups : 14 (2048 bits), 16 (4096 bits), 18 (8192 bits)
Idle time      : 60 minutes
Ciphers        : aes128-ctr, aes192-ctr, aes256-ctr
Macs           : hmac-sha1, hmac-sha2-256, hmac-sha2-512

# show ssh2 ciphers
Ciphers        : aes128-ctr, aes192-ctr, aes256-ctr

# configure ssh2 disable cipher aes128-ctr

# show ssh2 ciphers
Ciphers        : aes192-ctr, aes256-ctr

# configure ssh2 enable cipher aes128-ctr

# show ssh2 ciphers
Ciphers        : aes128-ctr, aes192-ctr, aes256-ctr
```
**Configuration Example: Enable/Disable MACs in Secure Mode**

```bash
# show ssh2
SSH module configuration details:
SSH Access : Enabled
Key validity : Valid
Key type : RSA 2048
TCP port : 22
VR : all
Access profile : not set
Secure Mode : On
Diffie-Hellman Groups : 14 (2048 bits), 16 (4096 bits), 18 (8192 bits)
Idle time : 60 minutes
Ciphers : aes128-ctr, aes192-ctr, aes256-ctr
Macs : hmac-sha1, hmac-sha2-256, hmac-sha2-512
```

```bash
# show ssh2 mac
Macs : hmac-sha1, hmac-sha2-256, hmac-sha2-512
```

```bash
# configure ssh2 disable mac hmac-sha1
```

```bash
# show ssh2 mac
Macs : hmac-sha2-256, hmac-sha2-512
```

```bash
# configure ssh2 enable mac hmac-sha1
```

```bash
# show ssh2 mac
Macs : hmac-sha1, hmac-sha2-256, hmac-sha2-512
```

**Key Exchange Algorithms—Diffie-Hellman**

```bash
# show ssh2
SSH module configuration details:
SSH Access : Enabled
Key validity : Valid
Key type : RSA 2048
TCP port : 22
VR : all
Access profile : not set
Secure Mode : On
Diffie-Hellman Groups : 14 (2048 bits), 16 (4096 bits), 18 (8192 bits)
Idle time : 60 minutes
Ciphers : aes128-ctr, aes192-ctr, aes256-ctr
Macs : hmac-sha2-256, hmac-sha2-512
```
Diffie-Hellman Overview

Diffie-Hellman (DH) is a public-key cryptography protocol that allows two parties to establish a shared secret over an unsecure communications channel. This method allows two computer users to generate a shared private key with which they can then exchange information across an insecure channel.

ExtremeXOS supports Diffie-Hellman group 1, 14, 16, and 18 as part of the key exchange algorithms. In compliance with the Network Device collaborative Protection Profile (NDPP) of Common Criteria, the TSF (Target Security Function) ensures that diffie-hellman-group14-sha1 is the only minimal allowed key exchange method used for the SSH protocol.

ExtremeXOS uses group 14 by default as the minimal supported Diffie-Hellman group as 14 to avoid using the weaker Diffie-Hellman group 1 in an SSH server.

Configuring the Diffie-Hellman Minimal Supported Group

- To configure the minimal supported Diffie-Hellman group, use the following command:

  ```
  configure ssh2 dh-group minimum [1 | 14 | 16 | 18]
  ```

- To show the SSH configuration details, including minimal supported Diffie-Hellman group, use the following command:

  ```
  show ssh2
  ```

Diffie-Hellman Minimal Supported Group Configuration Examples

Configuration Example: DH-16 Key-Exchange Algorithm

```bash
# show ssh2
SSH module configuration details:
SSH Access            : Disabled
Key validity          : Invalid
Key type              : RSA 2048
TCP port              : 22
VR                    : all
Access profile        : not set
Secure Mode           : Off
Diffie-Hellman Groups : 14 (2048 bits), 16 (4096 bits), 18 (8192 bits)
Max Auth Tries        : 3
Idle time             : 60 minutes
Rekey Interval        : 4096 MB and no time limit
Ciphers               : aes128-ctr, aes192-ctr, aes256-ctr, aes128-cbc, 3des-cbc, aes192-cbc, aes256-cbc, rijndael-cbc@lysator.liu.se
Macs                  : hmac-shal, hmac-sha2-256, hmac-sha2-512
Public key algorithms : ssh-rsa, ssh-dss, x509v3-sign-rsa, x509v3-sign-dss

# configure ssh2 dh-group minimum 16

# show ssh2
SSH module configuration details:
SSH Access            : Disabled
Key validity          : Invalid
Key type              : RSA 2048
TCP port              : 22
VR                    : all
Access profile        : not set
Secure Mode           : Off
Diffie-Hellman Groups : 16 (4096 bits), 18 (8192 bits)
Max Auth Tries        : 3
```
Idle time             : 60 minutes
Rekey Interval        : 4096 MB and no time limit
Ciphers               : aes128-ctr, aes192-ctr, aes256-ctr, aes128-cbc, 3des-cbc, aes192-cbc, aes256-cbc, rijndael-cbc@lysator.liu.se
Macs                  : hmac-sha1, hmac-sha2-256, hmac-sha2-512
Public key algorithms : ssh-rsa, ssh-dss, x509v3-sign-rsa, x509v3-sign-dss

Configuration Example: DH-1 Key-Exchange Algorithm

```bash
# configure ssh2 dh-group minimum 1
Notice: The configured key exchange algorithm(s), DH group 1, is/are weaker than what is recommended.

# show ssh2
SSH module configuration details:
SSH Access            : Disabled
Key validity          : Invalid
Key type              : RSA 2048
TCP port              : 22
VR                    : all
Access profile        : not set
Secure Mode           : Off
Diffie-Hellman Groups : 1 (1024 bits), 14 (2048 bits), 16 (4096 bits), 18 (8192 bits)
Max Auth Tries        : 3
Idle time             : 60 minutes
Rekey Interval        : 4096 MB and no time limit
Ciphers               : aes128-ctr, aes192-ctr, aes256-ctr, aes128-cbc, 3des-cbc, aes192-cbc, aes256-cbc, rijndael-cbc@lysator.liu.se
Macs                  : hmac-sha1, hmac-sha2-256, hmac-sha2-512
Public key algorithms : ssh-rsa, ssh-dss, x509v3-sign-rsa, x509v3-sign-dss
```

**Secure Socket Layer**

Secure Socket Layer (SSLv3) is a feature of ExtremeXOS that allows you to authenticate and encrypt data over an SSL connection to provide secure communication.

The existing web server in ExtremeXOS allows HTTP clients to access the network login page. By using HTTPS on the web server, clients securely access the network login page using an HTTPS enabled web browser. Since SSL encrypts the data exchanged between the server and the client, you protect your data, including network login credentials, from unwanted exposure.

HTTPS access is provided through SSL and the Transport Layer Security (TLS1.0). These protocols enable clients to verify the authenticity of the server to which they are connecting, thereby ensuring that users are not compromised by intruders.

You must upload or generate a certificate for SSL server use. Before you can upload a certificate, you must purchase and obtain an SSL certificate from an Internet security vendor. The following security algorithms are supported:

- RSA for public key cryptography (generation of certificate and public-private key pair, certificate signing). RSA key size between 1,024 and 4,096 bits.
- Symmetric ciphers (for data encryption): RC4 and 3DES.
- Message Authentication Code (MAC) algorithms: RSA Data Security, Inc. MD5 Message-Digest Algorithm and SHA.
Enabling and Disabling SSL

This section describes how to enable and disable SSL on your switch.

To use SSL with web-based login (secure HTTP access, HTTPS) you must specify the HTTPS protocol when configuring the redirect URL.

- To enable SSL and allow secure HTTP (HTTPS) access on the default port (443), use the following command:
  ```
  enable web https
  ```

- To disable SSL and HTTPS, use the following command:
  ```
  disable web https
  ```

Creating Self-Signed Certificates and Private Keys

When you generate a certificate, the certificate is stored in the configuration file, and the private key is stored in the EEPROM. The certificate generated is in PEM format. By default ExtremeXOS uses the SHA-512 hashing algorithm to create the certificate. The certificate hashing algorithm can be configured using command `configure ssl certificate hash-algorithm hash-algorithm`. ExtremeXOS supports MD5, SHA-224, SHA-256, SHA-384 and SHA-512. The configured algorithm are used to create certificates from next time onwards. Use the `show ssl` command to check the currently configured Signature hashing algorithm.

- To create a self-signed certificate and private key that can be saved in the EEPROM, use the following command:
  ```
  configure ssl certificate privkeylen length country code organization org_name common-name name
  ```

  Make sure to specify the following:
  - Country code (maximum size of 2 characters)
  - Organization name (maximum size of 64 characters)
  - Common name (maximum size of 64)

  Any existing certificate and private key is overwritten.

  The size of the certificate depends on the RSA key length (`privkeylen`) and the length of the other parameters (country, organization name, and so forth) supplied by the user. For an RSA key length of 4,096, the certificate length is approximately 2 Kb, and the private key length is approximately 3 Kb.

**Downloading a Certificate Key from a TFTP Server**

You can download a certificate key from files stored in a TFTP server. If the operation is successful, any existing certificate is overwritten. After a successful download, the software attempts to match the public key in the certificate against the private key stored. If the private and public keys do not match, the switch displays a warning message similar to the following: **Warning: The Private Key does not match with the Public Key in the certificate.** This warning acts as a reminder to also download the private key.
Downloaded certificates and keys are not saved across switch reboots unless you save your current switch configuration. After you use the `save` command, the downloaded certificate is stored in the configuration file and the private key is stored in the EEPROM.

- To download a certificate key from files stored in a TFTP server, use the following command:
  
  ```
  download ssl ipaddress certificate {ssl-cert | trusted-ca | ocsp-signature-ca} cert_file
  ```

  **Note**
  For security measures, you can only download a certificate key in the `VR-Mgmt VR`.

- To see whether the private key matches with the public key stored in the certificate, use the following command:
  
  ```
  show ssl {detail}
  ```

  This command also displays:
  
  - HTTPS port configured. This is the port on which the clients will connect.
  - Length of the RSA key (the number of bits used to generate the private key).
  - Basic information about the stored certificate.

**Downloading a Private Key from a TFTP Server**

For security reasons, when downloading private keys, we recommend obtaining a pre-generated key rather than downloading a private key from a TFTP server. See Configuring Pregenerated Certificates and Keys on page 1020 for more information.

- To download a private key from files stored in a TFTP server, use the following command:
  
  ```
  download ssl ipaddress privkey key_file
  ```

  If the operation is successful, the existing private key is overwritten. After the download is successful, a check is performed to find out whether the private key downloaded matches the public key stored in the certificate. If the private and public keys do not match, the switch displays a warning message similar to the following: Warning: The Private Key does not match with the Public Key in the certificate. This warning acts as a reminder to also download the corresponding certificate.

Downloaded certificates and keys are not saved across switch reboots unless you save your current switch configuration. After you use the `save` command, the downloaded certificate is stored in the configuration file and the private key is stored in the EEPROM.

**Configuring Pregenerated Certificates and Keys**

- To get the pregenerated certificate from the user, use the following command:
  
  ```
  configure ssl certificate pregenerated
  ```

  You can copy and paste the certificate into the command line followed by a blank line to end the command.

  This command is also used when downloading or uploading the configuration. Do not modify the certificate stored in the uploaded configuration file because the certificate is signed using the issuer’s private key.
The certificate and private key file should be in PEM format and generated using RSA as the cryptography algorithm.

- To get the pregenerated private key from the user, use the following command:
  ```
  configure ssl privkey pregenerated
  ```

  You can copy and paste the key into the command line followed by a blank line to end the command.

  This command is also used when downloading or uploading the configuration. The private key is stored in the EEPROM.

  The certificate and private key file should be in PEM format and generated using RSA as the cryptography algorithm.

### Creating Certificate Signing Requests and Private Keys

Secure Socket Layer (SSL) allows you to:

- Generate self-signed certificates, which generate private keys and self-signed X509 certificates.
- Download SSL private key/certificate using `download ssl ipaddress certificate {ssl-cert | trusted-ca | ocsp-signature-ca} cert_file` command (generally used to download CA signed certificate).
- Obtain an SSL private-key/certificate using the `configure ssl certificate pregenerated` command (generally used to obtain the CA signed certificate for copying).

Additionally, you can create certificate signing requests (CSRs)/private key pairs. The CSR can then be taken to a Certificate Authority (CA) for signing. The CA then provides the signed certificate, which can be downloaded to the switch using either of the commands listed previously.

To create a CSR, use the following command:

```
configure ssl csr privkeylen length country code organization org_name common-name name
```

To view the CSR any time after creating it, use the following command:

```
show ssl csr
```

**Note**

For enhanced security, the minimum private key length is 2,048 (previously it was 1,024). This length is enforced in both private key/self-signed certificate pairs and private key/CSR pairs.

### Displaying SSL Information

- To display whether the switch has a valid private and public key pair and the state of HTTPS access, use the following command:
  ```
  show ssl {trusted-ca | ocsp-signature-ca} [file_name | all] {manufacturing} [certificate | detail]
  ```
- To display a certificate signing request (CSR), use the following command:
  ```
  show ssl csr
  ```
Using Public-Key Infrastructure (PKI) in Your Network

The ExtremeXOS implementation of public-key infrastructure (PKI) supports the secure authentication of Syslog server and SSH client to an Extreme Networks XOS device using an X.509 certificate. Below are primary aspects of a PKI configuration (for more information about each command listed in this topic, see ExtremeXOS 22.6 Command Reference Guide):

- **Trusted CA**—The X509v3 certificates of Certificate Authority (CA) should be downloaded using the CLI: `download ssl ipaddress certificate {ssl-cert | trusted-ca | ocsp-signature-ca} cert_file` using the trusted-ca option. The CA certificate must satisfy the following criteria to successfully download:
  - Basic constraints: CA = true
  - Key usage must contain: KeyCertSign

- **Peer Certificate**—X509v3 certificate of the peer, signed by one of the above trusted CAs. The following criteria must be met for successful authentication:
  - Syslog server certificate: Extended key usage must contain `Server Authentication`.
  - SSH Client certificate:
    - Common name (CN) of the certificate subject must be same as the username with which SSH session is tried out.
    - Extended key usage must contain `Client Authentication`.

- **OCSP**—Online Certificate Status Protocol used to find the revocation status of the peer certificate on the following scenario:
  - Syslog server certificate’s OCSP status is identified when a TLS session is to be established with the Syslog server. Only if the OCSP status is GOOD is the session established.
  - SSH Client certificate’s OCSP status is identified as part of authentication. Only if the OCSP status is GOOD is the session established.

  **Note**
  OCSP processes intermediate CA certificates iteratively, one by one.

The OCSP Server’s address must be configured in the Authority Information Access (AIA) of the peer certificate. Otherwise, the PKI authentication fails. The supported OCSP responder models are:
- common issuer model, delegated trusted responder model, trusted responder model.

- **OCSP Signature CA**—The certificates of OCSP responders must be configured as OCSP signature CA and trusted CA. To support Trusted Responder Model (TRM) of OCSP, the X509v3 certificate of the OCSP responder should be downloaded using the CLI: `download ssl ipaddress certificate {ssl-cert | trusted-ca | ocsp-signature-ca} cert_file` using the ocsp-signature-ca and trusted-ca options. For example:

  ```
  download ssl 10.120.89.79 certificate trusted-ca cacert.pem
  ```

  The OCSP signature CA is only required for TRM; it is not used for DTM and common issuer. This certificate must contain a trusted use extension that permits OCSP signing. A “trusted use extension” can be appended to a certificate using OpenSSL.

  The following example appends a trusted use extension specifying an original file and the trusted file: ocsp-sig-ca.pem is the original certificate file and the output file trusted-ocsp-sig-ca.pem is the trusted file:

  ```
  openssl x509 -in ocsp-sig-ca.pem -addtrust OCSPSigning -out trusted-ocsp-sig-ca.pem
  ```
The following is an example of an original certificate followed by the OpenSSL command output trusted certificate:

---BEGIN CERTIFICATE-----
MIICgTCCAeqgAwIBAgIJA6mg4gQOMDoMAOGCSqGSIb3DQEJBQUAMGAGAxCAzAJBqNV
BAYTA1VMTrwEAYDQYJKoZIhvcNAQEBBQADggEPADCCAQoDgkleMQswkQ<String>
CzMDUETMSRwV29ybGwIBAgIJA6mg4gQOMDoMAOGCSqGSIb3DQEJBQUAMGAGAxCAzAJBqNV
BAYTA1VMTrwEAYDQYJKoZIhvcNAQEBBQADggEPADCCAQoDgkleMQswkQ<String>
-----END CERTIFICATE-----

-----BEGIN TRUSTED CERTIFICATE-----
MIICgTCCAeqgAwIBAgIJA6mg4gQOMDoMAOGCSqGSIb3DQEJBQUAMGAGAxCAzAJBqNV
BAYTA1VMTrwEAYDQYJKoZIhvcNAQEBBQADggEPADCCAQoDgkleMQswkQ<String>
-----END TRUSTED CERTIFICATE-----

• ExtremeXOS® X509v3 certificate—The certificate of the ExtremeXOS device. This is shared to the Syslog server to perform authentication there. Use the commands: `download ssl ipaddress certificate {ssl-cert | trusted-ca | ocsp-signature-ca} cert_file` with the `ssl-cert` option, and `download ssl ipaddress privkey key_file`.

Setting Up PKI

The following is the sequential workflow involved in the session establishment using PKI:

1. Generate the involved X509v3 certificates: CA certificates, OCSP Signature CA certificate, Peer certificate (for example: Syslog server or SSH client). ExtremeXOS device certificate.
2. Download the CA certificates and OCSP Signature CA certificates to the ExtremeXOS device.
3. Download the ExtremeXOS device certificate and key to ExtremeXOS device (required for establishing TLS session with Syslog server).
4. Configure the peer (Syslog server or SSH client) as required to use its own X509v3 certificate in the connection request.
5. Initiate the connection request from peer (Syslog server or SSH client) to ExtremeXOS device.
6 ExtremeXOS device performs below tasks on the received peer’s certificate and accepts/rejects the connection request:
   a Certificate chain verification.
   b Sanity checks on certificate extensions.
   c OCSP.

PKI Limitations

- All certificates should be in PEM format files.
- Downloading CA certificate chain is not supported.
- Individual CA certificates in a certificate chain should be downloaded one-by-one using the following command: `download ssl ipaddress certificate {ssl-cert | trusted-ca | ocsp-signature-ca} cert_file`
- Downloading CA certificate of size greater than 7.5KB is not recommended.
- Certification Revocation Lists (CRLs)—not supported.
- OCSP stapling—not supported.
- Nonce is always disabled in OCSP request.
- OCSP is not done for the OCSP responder certificate. Therefore, the OCSP responder certificate should satisfy any of following criteria, failing which the OCSP response is rejected:
  - OCSP responder certificate should be self-signed, OR
  - OCSP responder certificate should contain `id-pkix-ocsp-nocheck` extension.
32 CLEAR-Flow

CLEAR-Flow Overview
Configuring CLEAR-Flow
Displaying CLEAR-Flow Configuration and Activity
Adding CLEAR-Flow Rules to ACLs
CLEAR-Flow Rule Examples

This chapter offers detailed information about the ExtremeXOS’ implementation of CLEAR-Flow. This section provides an overview, as well as specific information on how to configure CLEAR-Flow, add CLEAR-Flow rules, and provides examples.

CLEAR-Flow Overview

CLEAR-Flow is a broad framework for implementing security, monitoring, and anomaly detection in ExtremeXOS software. Instead of simply looking at the source and destination of traffic, CLEAR-Flow allows you to specify certain types of traffic that require more attention. After certain criteria for this traffic are met, the switch can either take an immediate, predetermined action, or send a copy of the traffic off-switch for analysis.

CLEAR-Flow is an extension to Access Control Lists (ACLs). You create ACL policy rules to count packets of interest. CLEAR-Flow rules are added to the policy to monitor these ACL counter statistics. The CLEAR-Flow agent monitors the counters for the situations of interest to you and your network. You can monitor the cumulative value of a counter, the change to a counter over a sampling interval, the ratio of two counters, or even the ratio of the changes of two counters over an interval. For example, you can monitor the ratio between TCP SYN and TCP packets. An abnormally large ratio may indicate a SYN attack.

The counters used in CLEAR-Flow are either defined by you in an ACL entry, or can be a predefined counter. See Predefined CLEAR-Flow Counters on page 1036 for a list and description of these counters.

If the rule conditions are met, the CLEAR-Flow actions configured in the rule are executed. The switch can respond by modifying an ACL that will block, prioritize, or mirror the traffic, executing a set of CLI commands, or sending a report using a SNMP (Simple Network Management Protocol) trap or EMS log message.

Note
CLEAR-Flow is available on platforms with an Edge, Advanced Edge, or Core license. For more license information, see the ExtremeXOS 22.6 Feature License Requirements document. CLEAR-Flow is supported only on ingress. Any limitations on a given platform for a regular ACL also hold true for CLEAR-Flow.
Configuring CLEAR-Flow

CLEAR-Flow is an extension to ACL (Access Control List)s, so you must be familiar with configuring ACLs before you add CLEAR-Flow rules to your ACL policies. Creating ACLs is described in detail in the ACLs chapter. The chapter describes how to create ACL policies, the syntax of an ACL policy file, and how to apply ACL policies to the switch.

In this chapter, you will find information about the CLEAR-Flow rules that you add to ACL policies, including the CLEAR-Flow rules’ syntax and behavior.

After creating the ACLs that contain CLEAR-Flow rules, and after applying the ACLs to the appropriate interface, you enable CLEAR-Flow on the switch. When CLEAR-Flow is enabled, the agent on the switch evaluates the rules, and when any rules are triggered, the CLEAR-Flow actions are executed.

- To enable CLEAR-Flow, enter the command:
  ```plaintext
  enable clear-flow
  ```
- To disable CLEAR-Flow, enter the command:
  ```plaintext
  disable clear-flow
  ```

When you disable the CLEAR-Flow agent on the switch, CLEAR-Flow sampling stops and all rules are left in the current state.

**Note**

Any actions triggered while CLEAR-Flow is enabled will continue when CLEAR-Flow is disabled, unless explicitly stopped.

Displaying CLEAR-Flow Configuration and Activity

- Display the state of the CLEAR-Flow agent, any CLEAR-Flow policies on each interface, and the number of CLEAR-Flow rules by entering the command:
  ```plaintext
  show clear-flow
  ```
- Display the CLEAR-Flow rules and configuration by entering the command:
  ```plaintext
  show clear-flow rule
  ```
- Display all the rules by entering the command:
  ```plaintext
  show clear-flow rule-all
  ```
  When CLEAR-Flow is enabled, any rules that satisfy the threshold will trigger and take action.
- Display the CLEAR-Flow rules that have been triggered by entering the command:
  ```plaintext
  show clear-flow rule-triggered
  ```
- Display which ACLs have been modified by CLEAR-Flow rules.
  ```plaintext
  show clear-flow acl-modified
  ```

Adding CLEAR-Flow Rules to ACLs

As described in the ACLs chapter, each ACL policy file consists of a number of named entries. Each entry consists of match conditions and actions to take if the entry is matched. CLEAR-Flow builds on the ACL concept to include rules that are periodically checked, and actions to take if a rule is triggered. The CLEAR-Flow entries are similar to the ACL entries.
The syntax of a CLEAR-Flow rule entry is:

```plaintext
entry <CLFrulename> {
if <match-type> { <match-conditions>;
}
Then {
<actions>;
}
}
```

Or you can specify an optional else clause:

```plaintext
entry <CLFrulename> {
if <match-type> { <match-conditions>;
}
Then {
<actions>;
} else {
<actions>;
}
}
```

In the CLEAR-Flow rule syntax, the `CLFrulename` is the name of the rule (maximum of 31 characters). The `match-type` specifies whether the rule is triggered when any of the expressions that make up the conditions are true (logical OR), or only when all of the expressions are true (logical AND). The `match-type` is an optional element. The `match-conditions` specifies the conditions that will trigger the rule, and how often to evaluate the rule. The `actions` in the then clause is the list of actions to take when the rule is triggered, and the optional else clause `actions` is the list of actions to take after the rule is triggered, and when the `match-conditions` later become false.

**Note**

When you create an ACL policy file that contains CLEAR-Flow rules, the CLEAR-Flow rules do not have any precedence, unlike the ACL entries. Each CLEAR-Flow rule specifies how often it should be evaluated. The order of evaluation depends on the sampling time and when the CLEAR-Flow agent receives the counter statistics. The order of the CLEAR-Flow rules in the policy file does not have any significance.

### CLEAR-Flow Rule Match Type

Match types are optional; the possible choices are:

- **match all**—All the match expressions must be true for a match to occur. This is the default.
- **match any**—If any match expression is true, then a match occurs.

### CLEAR-Flow Rule Match Conditions

In a CLEAR-Flow rule, the `match-conditions` portion consists of one to four expressions, an optional global-rule statement, and an optional period statement:

```plaintext
entry <CLFrulename> {
if <match-type> { <expression>;
<expression>;
```
In the following example, the CLEAR-Flow rule (named cflow_count_rule_example) will be evaluated every ten seconds. The actions statements will be triggered if the value of counter1 (defined earlier in the ACL policy file) is greater than 1,000,000:

```plaintext
entry cflow_count_rule_example { 
if { count counter1 > 1000000 ; 
period 10 ;
} Then {
<actions>;
} else {
<actions>;
}
}
```

The global-rule statement is optional and affects how the counters are treated. An ACL that defines counters can be applied to more than one interface. You can specify the global-rule statement so that counters are evaluated for all the applied interfaces. For example, if a policy that defines a counter is applied to port 1:1 and 2:1, a CLEAR-Flow rule that used the global-rule statement would sum up the counts from both ports. Without the global-rule statement, the CLEAR-Flow rule would look at only the counts received on one port at a time.

The period `interval` statement is optional and sets the sampling interval, in seconds. This statement specifies how often the rule is evaluated by the CLEAR-Flow agent. If not specified, the default value is 5 seconds.

The five CLEAR-Flow rule expressions are: count; delta; ratio; delta-ratio; and rule. All of these expressions check the values of counters to evaluate if an action should be taken. The counters are either defined in the ACL entries that are defined on the switch, or are the predefined CLEAR-Flow counters. When you use a counter statement in an ACL, you are defining the counter used by CLEAR-Flow to monitor your system.

**Count Expression**

A CLEAR-Flow count expression compares a counter with the threshold value. The following is the syntax for a CLEAR-Flow count expression:

```plaintext
count <counterName> REL_OPER <countThreshold> ; 
hysteresis <hysteresis> ;
```

The value of `countThreshold` and `hysteresis` can be specified as floating point numbers. The count statement specifies how to compare a counter with its threshold. The `counterName` is the name of an ACL counter referred to by an ACL rule entry and the `countThreshold` is the value compared with the counter. The `REL_OPER` is selected from the relational operators for greater than, greater than or equal to, less than, or less than or equal to (`>`, `>=`, `<`, `<=`).
The hysteresis \textit{hysteresis} statement is optional and sets a hysteresis value for the threshold. After the count statement is true, the value of the threshold is adjusted so that a change smaller than the hysteresis value will not cause the statement to become false. For statements using the REL\_OPER \textgreater{} or \textgreater{}=, the hysteresis value is subtracted from the threshold; for \textless{} or \textless{}=, the hysteresis value is added to the threshold.

Following is an example of a count expression used in a CLEAR-Flow rule:

```
entry cflow_count_rule_example { 
if { count counter1 > 1000000 ; 
period 10 ; }
Then { 
<actions> ; }
}
```

Actions are discussed in CLEAR-Flow Rule Actions on page 1034.

Table 108 is an example of evaluating the CLEAR-Flow count expression above multiple times. Notice that the rule is not triggered until evaluation 3, when the value of the counter is greater than 1,000,000.

<table>

<td>Yes</td>
</tr>
</tbody>
</table>

See Count Expression Example on page 1039 for a full example of an ACL and a CLEAR-Flow rule using a count expression.

\textit{Delta Expression}

A CLEAR-Flow delta expression computes the difference from one sample to the next of a counter value.

This difference is compared with the threshold value. The following is the syntax for a CLEAR-Flow delta expression:

```
delta <counterName> REL\_OPER <countThreshold> ;
hysteresis <hysteresis> ;
```

The values of \textit{countThreshold} and \textit{hysteresis} can be specified as floating point numbers. The delta expression specifies how to compare the difference in a counter value from one sample to the next with its threshold. The \textit{counterName} is the name of an ACL counter referred to by an ACL rule entry and the \textit{countThreshold} is the value compared with the difference in the counter from one sample to the next. The REL\_OPER is selected from the relational operators for greater than, greater than or equal to, less than, or less than or equal to (\textgreater{}, \textgreater{}=, \textless{}, \textless{}=).

The hysteresis \textit{hysteresis} statement is optional and sets a hysteresis value for the threshold. After the delta statement is true, the value of the threshold is adjusted so that a change smaller than the
hysteresis value will not cause the statement to become false. For statements using the REL_OPER > or >=, the hysteresis value is subtracted from the threshold; for < or <=, the hysteresis value is added to the threshold.

For example, the following delta expression:

```plaintext
delta counter1 >= 100 ;
hysteresis 10 ;
```

will only be true after the delta of the counter reaches at least 100. At the time it becomes true, the hysteresis value is subtracted from the threshold (setting the threshold to 90). With the threshold now at 90, the condition would stay true until the delta of the counter becomes less than 90.

If the expression becomes false, the threshold is reset to its original value. You would use the hysteresis value to prevent the expression from vacillating between the true and false states if the difference between the counter values is near the threshold. If the hysteresis value is greater than the threshold value, the hysteresis value will be set to 0.

Table 109 is an example of evaluating the CLEAR-Flow delta expression above multiple times. Notice that the rule is not triggered until evaluation 4, when the delta value (the change in the counter value from one evaluation to the next) is greater than or equal to 100. After the rule is triggered, it remains triggered until the delta value is less than 90 (the original threshold minus the hysteresis), at evaluation 7. At evaluation 9, the rule is again triggered when the delta reaches 100. The rule will remain triggered until the delta drops below 90.

</table>

See Delta Expression Example on page 1040 for a full example of an ACL and a CLEAR-Flow rule using a delta expression.

**Ratio Expression**

A CLEAR-Flow ratio expression compares the ratio of two counter values with the threshold value.
The following is the syntax for a CLEAR-Flow ratio expression:

```
ratio <counterNameA> <counterNameB> REL_OPER <countThreshold> ;
min-value <min-value> ;
hysteresis <hysteresis> ;
```

The values of `countThreshold` and `hysteresis` can be specified as floating point numbers, and the ratio is computed as a floating point number. The ratio statement specifies how to compare the ratio of two counters with its threshold. To compute the ratio, the value of `counterNameA` is divided by the value of `counterNameB`. That ratio is then compared with the `countThreshold`. The REL_OPER is selected from the relational operators for greater than, greater than or equal to, less than, or less than or equal to (>, >=, <, <=).

The min-value statement is optional, and sets a minimum value for the counters. If either counter is less than the minimum value, the expression evaluates to false. If not specified, the minimum value is 1.

The hysteresis `hysteresis` statement is optional and sets a hysteresis value for the threshold. After the ratio statement is true, the value of the threshold is adjusted so that a change smaller than the hysteresis value will not cause the statement to become false. For statements using the REL_OPER > or >=, the hysteresis value is subtracted from the threshold; for < or <=, the hysteresis value is added to the threshold.

For example, the following ratio expression:

```
ratio counter1 counter2 >= 5 ;
min-value 100;
hysteresis 1 ;
```

is true only after the ratio of the counters reaches at least 5 and the counter values are at least 100. At the time it became true, the hysteresis value would be subtracted from the threshold (setting the threshold to 4). With the threshold now at 4, the condition would stay true until the ratio of the counters became less than 4.

If the statement becomes false, the threshold is reset to its original value. You can use the hysteresis value to prevent the rule from vacillating between the true and false states if the ratio between the counter values is near the threshold. If the hysteresis value is greater than the threshold value, the hysteresis value will be set to 0.

`Table 110` is an example of evaluating the CLEAR-Flow ratio expression above multiple times. Notice that the rule is not triggered at the first evaluation because both counters have not yet reached the min-value of 100. The rule first triggers at evaluation 3, when ratio of the two counters exceeds 5. After the rule is triggered, it remains triggered until the ratio value is less than 4 (the original threshold minus the hysteresis), at evaluation 5. At evaluation 7, the rule is again triggered when the ratio reaches 5. The rule will remain triggered until the ratio drops below 4.

See Ratio Expression Example on page 1040 for a full example of an ACL and a CLEAR-Flow rule using a ratio expression.

**Delta-Ratio Expression**

A CLEAR-Flow delta-ratio expression is a combination of the delta and ratio expressions.

The CLEAR-Flow agent computes the difference from one sample to the next for each of the two counters. The ratio of the differences is then compared to the threshold value. The following is the syntax for a CLEAR-Flow delta-ratio expression (note the similarity to the delta expression):

```plaintext
delta-ratio <counterNameA> <counterNameB> REL_OPER <countThreshold> ;
min-value <min-value> ;
hysteresis <hysteresis> ;
```

The values of `countThreshold` and `hysteresis` can be specified as floating point numbers, and the delta-ratio is computed as a floating point number. The delta-ratio statement specifies how to compare the ratio of the counter differences with its threshold. The difference of the sample values of `counterNameA` is divided by the difference of the sample values of `counterNameB`, to compute the ratio that is compared with the `countThreshold`. The `REL_OPER` is selected from the relational operators for greater than, greater than or equal to, less than, or less than or equal to (`>`, `>=`, `<`, `<=`).

The min-value statement is optional and sets a minimum value for the counters. If either counter is less than the minimum value, the expression evaluates to false. If not specified, the minimum value is 1.

The hysteresis `hysteresis` statement is optional, and sets a hysteresis value for the threshold. After the ratio statement is true, the value of the threshold is adjusted so that a change smaller than the hysteresis value will not cause the statement to become false. For statements using the `REL_OPER` > or >=, the hysteresis value is subtracted from the threshold; for < or <=, the hysteresis value is added to the threshold.

For example, the following delta-ratio expression:

```plaintext
delta-ratio counter1 counter2 >= 5 ;
min-value 100 ;
hysteresis 1 ;
```

will only be true after the ratio of the deltas of the counters reached at least 5. At the time it became true, the hysteresis value would be subtracted from the threshold (setting the threshold to 4). With the threshold now at 4, the condition would stay true until the ratio of the deltas of the counters became less than 4.

If the statement becomes false, the threshold is reset to its original value. You can use the hysteresis value to prevent the rule from vacillating between the true and false states if the ratio of the deltas of
the counters is near the threshold. If the hysteresis value is greater than the threshold value, the hysteresis value will be set to 0.

Table 111 is an example of evaluating the CLEAR-Flow delta-ratio expression above multiple times. Notice that the rule is not triggered at the second evaluation because both counters have not yet reached the min-value of 100. The rule first triggers at evaluation 4, when ratio of the two counters exceeds 5. After the rule is triggered, it remains triggered until the ratio value is less than 4 (the original threshold minus the hysteresis), at evaluation 6. At evaluation 8, the rule is again triggered when the ratio reaches 5. The rule will remain triggered until the ratio drops below 4.

</table>

See Delta-Ratio Expression Example on page 1041 for a full example of an ACL and a CLEAR-Flow rule using a delta-ratio expression.

**Rule-True-Count Expression**

A CLEAR-Flow rule-true-count expression compares how many times a CLEAR-Flow rule is true with a threshold value.

One use is to combine multiple rules together into a complex rule. The following is the syntax for a CLEAR-Flow rule-true-count expression:

```
rule-true-count <ruleName> REL_OPER <countThreshold> ;
```

The rule-true-count statement specifies how to compare how many times a CLEAR-Flow rule is true with the expression threshold. The `ruleName` is the name of the CLEAR-Flow rule to monitor and the `countThreshold` is the value compared with the number of times the rule is true. The `REL_OPER` is selected from the relational operators for greater than, greater than or equal to, less than, or less than or equal to (>, >=, <, <=).

For example, the following delta-ratio expression:

```
rule-true-count cflow_count_rule_example >= 5 ;
```

will only be true after the CLEAR-Flow rule cflow_count_rule_example has been true at least five times. If the rule cflow_count_rule_example becomes true and remains true, and the period for cflow_count_rule_example is the default five seconds, the rule would have to be true for at least 20
seconds before the rule-true-count expression will become true. If the period of the rule 
cflow_count_rule_example is 10 seconds, it will need to be true for at least 40 seconds before the rule-
true_count expression becomes true.

CLEAR-Flow Rule Actions

CLEAR-Flow rules specify an action to take when the rule is triggered and can optionally specify an
action to take when the expression is false.

Because more than one action can be taken in a single rule, the collection of actions is referred to as an
action list. The following sections describe the different rule actions:

- Permit/Deny on page 1034
- QoS Profile on page 1034
- Mirror on page 1034
- SNMP Trap on page 1035
- Syslog on page 1035
- CLI on page 1035

Additionally, the SNMP trap, syslog, and CLI rule actions can use keyword substitution to make the rule
actions more flexible. The keyword substitutions are described at the end of the rule action descriptions.
See Keyword Substitution on page 1035 for more information.

Permit/Deny

This action modifies an existing ACL rule to permit or block traffic that matches that rule.
- To change an ACL to permit, use the following syntax:
  
  `permit <ACLRuleName>`

- To change an ACL to deny, use the following syntax:
  
  `deny <ACLRuleName>`

QoS Profile

This action modifies an existing ACL rule to set the QoS (Quality of Service) profile for traffic that
matches that rule.
- To change the ACL to forward to QoS profile <QPx>, use the following syntax:
  
  `qosprofile <ACLRuleName> <QPx>`

  For example:
  
  `qosprofile acl_rule_1 QP3`

Mirror

This action modifies an existing ACL rule to mirror traffic that matches that rule, or to stop mirroring
that traffic. The mirroring port must be enabled when mirroring on an ACL rule is turned on. This could
be configured earlier, or use the CLI action to execute CLI commands to configure mirroring at the same
time.
- To change the ACL to mirror traffic, use the following syntax:
  
  `mirror [add|delete] <ACLRuleName>`
For example (enabling mirroring from within CLEAR-Flow rule):

```
enable mirror to port 7:4 tagged
mirror add acl_rule_1
```

**SNMP Trap**

This action sends an SNMP trap message to the trap server, with a configurable ID and message string, when the rule is triggered. The message is sent periodically with interval `period` seconds. If `period` is 0, or if this optional parameter is not present, the message is sent only once when the rule is triggered. The interval must be a multiple of the rule sampling/evaluation interval, or the value will be rounded down to a multiple of the rule sampling/evaluation interval.

- To send an SNMP trap, use the following syntax:
  ```
  snmptrap <id> <message> <period>
  ```

**Syslog**

This action sends log messages to the ExtremeXOS EMS sever. The possible values for message level are: DEBU, INFO, NOTI, WARN, ERRO, and CRIT.

The message is sent periodically with interval `period` seconds. If `period` is 0, or if this optional parameter is not present, the message is sent only once when the rule is triggered. The interval must be a multiple of the rule sampling/evaluation interval, or the value will be rounded down to a multiple of the rule sampling/evaluation interval.

- To send a log message, use the following syntax:
  ```
  syslog <message> <level> <period>
  ```

**CLI**

This action executes a CLI command. There is no authentication or checking the validity of each command. If a command fails, the CLI will log a message in the EMS log.

- To execute a CLI command, use the following syntax:
  ```
  cli <cliCommand>
  ```
  where `<cliCommand>` is a quoted string.

**Keyword Substitution**

To make the SNMP trap, syslog, and CLI actions more flexible, keyword substitutions are supported in the syslog and SNMP trap message strings, as well as in the CLI command strings.

Table 112 on page 1036 lists the keywords and their substitutions.

If a keyword is not supported, or a counter name is not found, a string of "unknownKeyword[$keyword]" will be substituted.

For the `$vlanName` and `$port` keyword, the keyword `all` will be substituted for those rules in the wildcard ACL. Some CLI commands do not support the `all` keyword, so caution must be used with CLI commands that use this feature.
A maximum of ten different counter substitutions can be used per rule, including counters used in expressions. For example, if a rule uses four counters in its expressions, then we can use six more different counters in keyword substitutions, for a total of ten.

**Table 112: Keyword Substitutions**

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Substitution</th>
</tr>
</thead>
<tbody>
<tr>
<td>$policyName</td>
<td>Replace with the policy name.</td>

<td>$ruleInterval</td>
<td>Replace with the rule sampling/evaluation interval.</td>
</tr>
<tr>
<td>$vlanName</td>
<td>Replace with the interface VLAN (Virtual LAN) name.</td>
</tr>
<tr>
<td>$port</td>
<td>Replace with the interface port number.</td>
</tr>
</tbody>
</table>

**Predefined CLEAR-Flow Counters**

A number of packet statistics are gathered by the ExtremeXOS kernel.

To allow you to use these statistics in CLEAR-Flow expressions, these kernel counters are now available for use with CLEAR-Flow. Most of the counter names are based directly on well known names from common kernel structures and MIBs. The names are modified from their familiar form by pre-pending the characters sys_ to the counter names.

**Table 113: Predefined CLEAR-Flow Counters**

<table>
<thead>
<tr>
<th>Counter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_IpInReceives</td>
<td>The total number of input IP packets received from interfaces, including those received in error.</td>
</tr>
<tr>
<td>sys_IpInHdrErrors</td>
<td>The number of input IP packets discarded due to errors in their IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, errors discovered in processing their IP options, etc.</td>
</tr>
<tr>
<td>sys_IpInAddrErrors</td>
<td>The number of input IP packets discarded because the IP address in their IP header’s destination field was not a valid address to be received at this entity. This count includes invalid addresses (for example, 0.0.0.0) and addresses of unsupported Classes (for example, Class E).</td>
</tr>
<tr>
<td>sys_IpForwDatagrams</td>
<td>The number of input IP packets for which this entity was not their final IP destination, as a result of which an attempt was made to find a route to forward them to that final destination.</td>
</tr>
<tr>
<td>sys_IpInUnknownProtos</td>
<td>The number of locally-addressed IP packets received successfully but discarded because of an unknown or unsupported protocol.</td>
</tr>
</tbody>
</table>

---

9 Most of these descriptions can be found in RFC 2011, SNMPv2 Management Information Base for the Internet Protocol using SMIv2.
### Table 113: Predefined CLEAR-Flow Counters (continued)

<table>
<thead>
<tr>
<th>Counter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_ipInDiscards</td>
<td>The number of input IP packets for which no problems were encountered to prevent their continued processing, but which were discarded (for example, for lack of buffer space). Note that this counter does not include any IP packets discarded while awaiting re-assembly.</td>
</tr>
<tr>
<td>sys_ipInDelivers</td>
<td>The total number of input IP packets successfully delivered to IP user-protocols (including ICMP (Internet Control Message Protocol)).</td>
</tr>
<tr>
<td>sys_ipOutRequests</td>
<td>The total number of IP packets which local IP user-protocols (including ICMP) supplied to IP in requests for transmission. Note that this counter does not include any IP packets counted in ipForwDatagrams.</td>
</tr>
<tr>
<td>sys_ipOutDiscards</td>
<td>The number of output IP packets for which no problem was encountered to prevent their transmission to their destination, but which were discarded (for example, for lack of buffer space). Note that this counter would include IP packets counted in ipForwDatagrams if any such packets met this (discretionary) discard criterion.</td>
</tr>
<tr>
<td>sys_ipOutNoRoutes</td>
<td>The number of IP packets discarded because no route could be found to transmit them to their destination. Note that this counter includes any packets counted in ipForwDatagrams which meet this 'no-route' criterion.</td>
</tr>
<tr>
<td>sys_ipReasmTimeout</td>
<td>The maximum number of seconds which received fragments are held while they are awaiting reassembly at this entity.</td>
</tr>
<tr>
<td>sys_ipReasmReqsds</td>
<td>The number of IP fragments received which needed to be reassembled at this entity.</td>
</tr>
<tr>
<td>sys_ipReasmOKs</td>
<td>The number of IP packets successfully re-assembled.</td>
</tr>
<tr>
<td>sys_ipReasmFails</td>
<td>The number of failures detected by the IP re-assembly algorithm (for whatever reason: timed out, errors, etc.). Note that this is not necessarily a count of discarded IP fragments since some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received.</td>
</tr>
<tr>
<td>sys_ipFragOKs</td>
<td>The number of IP packets that have been successfully fragmented at this entity.</td>
</tr>
<tr>
<td>sys_ipFragFails</td>
<td>The number of IP packets that have been discarded because they needed to be fragmented at this entity but could not be, for example, because their Don't Fragment flag was set.</td>
</tr>
<tr>
<td>sys_ipFragCreates</td>
<td>The number of IP packet fragments that have been generated as a result of fragmentation at this entity.</td>
</tr>

### CLEAR-Flow Rule Examples

In the examples that follow, one to two *ACL* rule entries are followed by a CLEAR-Flow rule entry. The examples illustrate the four CLEAR-Flow rule expressions: count, delta, ratio, and delta-ratio.

#### Count Expression Example

In the following example, every ten seconds the CLEAR-Flow agent will request the counter1 statistics from the hardware.

After it receives the counter value, it will evaluate the CLEAR-Flow rule. If the value of counter1 is greater than 1,000,000 packets, the CLEAR-Flow agent will send a trap message to the SNMP master, and change the *ACL* acl_rule1 to block traffic (acl_rule1 is modified to a deny rule).

Since there is no period configured for the snmptrap statement, the message is sent only once.

```plaintext
entry acl_rule1 {
  if {
    destination-address 192.168.16.0/24;
    destination-port 2049;
    protocol tcp;
  } then {
    count counter1;
  }
}
entry cflow_count_rule_example {
  if { count counter1 > 1000000 ;
       period 10 ;
   } Then {
    snmptrap 123 "Traffic on acl_rule1 exceeds threshold";
    deny acl_rule1;
  }
}
```
Delta Expression Example

In this example, every ten seconds the CLEAR-Flow agent will request the counter1 statistics from the hardware.

After it receives the counter value, it will then evaluate the rule. If the delta (change) of the counter1 value from the last sampled value ten seconds ago is greater than or equal to 1,000 packets, the CLEAR-Flow agent will send a trap message to the SNMP master and change the ACL acl_rule1 to move the traffic to QP3. In addition, reduce the peak rate to 5 Kbps on QP3. As long as the delta continues to be greater than or equal to 1000 packets, the CLEAR-Flow agent will repeatedly send a trap message every 120 seconds. When the delta falls below the threshold, the agent will execute the two actions in the else portion; it will send a single SNMP trap message, return the traffic to QP1, and reset QP3 to its original bandwidth.

```plaintext
entry acl_rule1 {
  if {
    destination-address 192.168.16.0/24;
    destination-port 2049;
    protocol tcp;
  } then {
    count counter1;
  }
}
entry cflow_delta_rule_example {
  if  { delta counter1 >= 100000 ;
    period 10 ;
  } then {
    snmptrap 123 "Traffic to 192.168.16.0/24 exceed rate limit" 120;
    qosprofile acl_rule1 QP3;
    cli "configure qosprofile qp3 peak_rate 5 K ports all" ;
  } else {
    snmptrap 123 "Traffic to 192.168.16.0/24 falls below rate limit";
    qosprofile acl_rule1 QP1;
    cli "configure qosprofile qp3 maxbw 100 ports all" ;
  }
}
```

Ratio Expression Example

In this example, every two seconds the CLEAR-Flow agent will request the counter1 and counter2 statistics from the hardware.

After it receives the two counter values, it will then check each counter value against its minimum valid threshold, which is 1,000. If both of the counter values is greater than 1,000, it then calculates the ratio of counter1 and counter2. If the ratio is greater than 5, the agent will execute the actions in the then clause, which consists of logging a message to the syslog server. Before logging the syslog string, the agent will replace the $ruleName keyword with the string cflow_ratio_rule_example, the $ruleValue keyword with the calculated ratio value, and the $ruleThreshold keyword with a value of 5. If either of the counter values is below the minimum value of 1,000, or the ratio is below the threshold of 5, the expression is false and no action is taken.

```plaintext
entry acl_rule1 {
  if { protocol udp;
  } then {
    count counter1;
```
entry acl_rule2 {
  if {
    protocol tcp;
  } then {
    count counter2;
  }
}

entry cflow_ratio_rule_example {
  if  { ratio counter1 counter2 > 5 ;
        period 2;
        min-value 1000;
  }
  Then {
    syslog "Rule $ruleName threshold ratio $ruleValue exceeds limit $ruleThreshold";
  }
}

Delta-Ratio Expression Example

In this example, every two seconds, the CLEAR-Flow agent will request the tcpSynCounter and tcpCounter values from the hardware.

After it receives the two counter values, it will first calculate the delta for each of the counters and then check each counter’s delta value for its minimum value, which is 100. If both of the counters’ delta values are greater than 100, it then calculates the ratio of the delta of two counters. If the ratio is greater than 10, then the agent will log a warning message and deny all SYN traffic on the interface. No period value for the syslog message is given, so the message will be logged once when the expression first becomes true. When the expression transitions from true to false, a different message will be logged and the SYN traffic on the interface will be permitted again. The delta-ratio value has to fall below a threshold of 8 for the expression to be evaluated to be false.

entry acl_syn {
  if {
    protocol tcp_flags SYN;
  } then {
    count tcpSynCounter;
  }
}

entry acl_tcp {
  if {
    protocol tcp;
  } then {
    count tcpCounter;
  }
}

entry cflow_delta_ratio_rule_example {
  if  { delta-ratio tcpSynCounter tcpCounter > 10 ;
        period 2;
        min-value 100;
        threshold 8;
  }
  Then {
    syslog "Syn attack on port $port is detected" WARN;
    deny acl_syn;
  } else {
    syslog "Syn attack on port $port is no longer detected" WARN;
    permit acl_syn;
  }
This chapter provides an overview and discusses various topologies of EAPS (Extreme Automatic Protection Switching) feature. The chapter offers configuration and monitoring details, and also provides configuration examples.

**EAPS Protocol Overview**

The EAPS protocol provides fast protection switching to Layer 2 switches interconnected in an Ethernet ring topology, such as a Metropolitan Area Network (MAN) or large campus (see Figure 116).

**Figure 116: Gigabit Ethernet Fiber EAPS MAN Ring**
EAPS Benefits

EAPS offers the following benefits:

- **Fast Recovery time for link or node failures**—When a link failure or switch failure occurs, EAPS provides fast recovery times. EAPS provides resiliency for voice, video and data services.

- **Scalable network segmentation and fault isolation**—EAPS domains can protect groups of multiple VLANs, allowing scalable growth and broadcast loop protection. EAPS domains provide logical and physical segmentation, which means the failures in one EAPS ring do not impact network service for other rings and VLANs.

- **Resilient foundation for non-stop IP routing services**—EAPS provides a resilient foundation for upper level routing protocols such as OSPF (Open Shortest Path First) and BGP (Border Gateway Protocol), minimizing route-flapping and dropped neighbors within the routed IP network.

- **Predictable convergence regardless of failure location**—EAPS provides consistent and predictable recovery behavior regardless of where link failures occur. The simple blocking architecture and predictable performance of EAPS allows for enforceable Service Level Agreements (SLAs). This allows easier network troubleshooting and failure scenario analysis without lengthy testing or debugging on live production networks.

EAPS protection switching is similar to what can be achieved with the STP (Spanning Tree Protocol), but EAPS offers the advantage of converging in less than one second when a link in the ring breaks.

An Ethernet ring built using EAPS can have resilience comparable to that provided by SONET rings, at a lower cost and with fewer restraints (such as ring size). The EAPS technology developed by Extreme Networks to increase the availability and robustness of Ethernet rings is described in RFC 3619: Extreme Networks’ Ethernet Automatic Protection Switching (EAPS) Version 1.

EAPS Single Ring Topology

The simplest EAPS configuration operates on a single ring.

This section describes how this type of EAPS configuration operates. Later sections describe more complex configurations.

An EAPS domain consists of one master node and one or more transit nodes (see Figure 117), and includes one control VLAN (Virtual LAN) and one or more protected VLANs.

A domain is a single instance of the EAPS protocol that defines the scope of protocol operation. A single logical EAPS domain typically exists on a given physical ring topology (fiber or copper).
A protected VLAN is a user data VLAN that uses the ring for a protected connection between all edge ports. The protected VLAN uses 802.1q trunking on the ring ports and supports tagged and untagged edge ports.

One ring port of the master node is designated the master node’s primary port (P), and another port is designated as the master node’s secondary port (S) to the ring. In normal operation, the master node blocks the secondary port for all protected VLAN traffic, thereby preventing a loop in the ring. (The spanning tree protocol, STP, provides the same type of protection.) Traditional Ethernet bridge learning and forwarding database mechanisms direct user data around the ring within the protected VLANs.

Note

Although primary and secondary ports are configured on transit nodes, both port types operate identically as long as the transit node remains a transit node. If the transit node is reconfigured as a master node, the configured states of the primary and secondary ports apply.

The control VLAN is a dedicated 802.1q tagged VLAN that is used to transmit and receive EAPS control frames on the ring. The control VLAN can contain only two EAPS ring ports on each node. Each EAPS domain has a unique control VLAN, and control traffic is not blocked by the master node at any time. The control VLAN carries the following EAPS control messages around the ring:

- Health-check messages, which are sent from the master node primary port. Transit nodes forward health-check messages toward the master node secondary port on the control VLAN. When the master node receives a health check message on the secondary port, the EAPS ring is considered intact.
- Link-down alert messages, which are sent from a transit node to the master node when the transit node detects a local link failure.
- Flush-FDB (forwarding database) messages, which are sent by the master node to all transit nodes when ring topology changes occur. Upon receiving this control frame, the transit node clears its MAC address forwarding table (FDB) and relearns the ring topology.
When the master node detects a failure, due to an absence of health-check messages or a received link-down alert, it transitions the EAPS domain to the Failed state and unblocks its secondary port to allow data connectivity in the protected VLANs.

EAPS Multiple Ring Topology

EAPS works with multiple ring networks to support more complex topologies for interconnecting multiple EAPS domains. This allows larger EAPS end-to-end networks to be built from edge to core.

Note

Minimal EAPS support is provided at all license levels. EAPS multiple ring topologies and common link topologies are supported at higher license levels as described in the ExtremeXOS 22.6 Feature License Requirements document.

The simplest multiple ring topology uses a single switch to join two EAPS rings.

The common link feature uses two switches, which share a common link, to provide redundancy and link multiple EAPS rings.

Two Rings Connected by One Switch

Figure 118 shows how a data VLAN can span two rings interconnected by a common switch—a figure eight topology.

Figure 118: Two Rings Interconnected by One Switch

A data VLAN that spans multiple physical rings or EAPS domains and is protected by EAPS is called an overlapping VLAN. An overlapping VLAN requires loop protection for each EAPS domain to which it belongs.

In this example, there is an EAPS domain with its own control VLAN running on ring 1 and another EAPS domain with its own control VLAN running on ring 2. A data VLAN that spans both rings is added as a protected VLAN to both EAPS domains to create an overlapping VLAN. Switch S5 has two instances of EAPS domains running on it, one for each ring.
Multiple Rings Sharing an EAPS Common Link

**EAPS Common Link Operation**

Figure 119 shows an example of a multiple ring topology that uses the EAPS common link feature to provide redundancy for the switches that connect the rings.

![Diagram](image)

**Figure 119: Multiple Rings Sharing a Common Link**

An EAPS common link is a physical link that carries overlapping VLANs that are protected by more than one EAPS domain.

In the example shown earlier, switch S5 could be a single point of failure. If switch S5 were to go down, users on Ring 1 would not be able to communicate with users on Ring 2. To make the network more resilient, you can add another switch. A second switch, S10, connects to both rings and to S5 through a common link, which is common to both rings.

The EAPS common link requires special configuration to prevent a loop that spans both rings. The software entity that requires configuration is the eaps shared-port, so the common link feature is sometimes called the *shared port* feature.

**Note**

If the shared port is not configured and the common link goes down, a superloop between the multiple EAPS domains occurs.

The correct EAPS common link configuration requires an EAPS shared port at each end of the common link. The role of the shared port (and switch) at each end of the common link must be configured as either controller or partner. Each common link requires one controller and one partner for each EAPS domain. Typically the controller and partner nodes are distribution or core switches. A controller or partner can also perform the role of master or transit node within its EAPS domain.

During normal operation, the master node on each ring protects the ring as described in EAPS Single Ring Topology on page 1044. The controller and partner nodes work together to protect the overlapping VLANs from problems caused by a common link failure or a failed controller (see Figure 120).
Figure 120: Master Node Operation in a Multiple Ring Topology

If a link failure occurs in one of the outer rings, only a single EAPS domain is affected. The EAPS master detects the failure in its domain, and converges around the failure. In this case, the controller does not take any blocking action, and EAPS domains on other rings are not affected. Likewise, when the link is restored, only the local EAPS domain is affected. The controller and any EAPS domains on other rings are not affected, and continue forwarding traffic normally.

To detect common-link faults, the controller and partner nodes send segment health check messages at one-second intervals to each other through each segment. A segment is the ring communication path between the controller and partner. The common link completes the ring, but it is a separate entity from the segment. To discover segments and their up or down status, segment health-check messages are sent from controller to partner, and also from partner to controller (see Figure 121).

Figure 121: Segment Health-Check Messages

Common Link Fault Detection and Response

With one exception, when a common link fails, each master node detects the failure and unblocks its secondary port, as shown in Figure 122.
Because the secondary port of each master node is now unblocked, the new topology introduces a broadcast loop spanning the outer rings.

The controller and partner nodes immediately detect the loop, and the controller does the following:

- Selects an active-open port for protected VLAN communications. The active-open port is the port with the smallest segment-port among all segments that are in “up” state.
- Blocks protected VLAN communications on all segment ports except the active-open port.

**Note**

When a controller goes into or out of the blocking state, the controller sends a flush-fdb message to flush the FDB in each of the switches in its segments. In a network with multiple EAPS ports in the blocking state, the flush-fdb message gets propagated across the boundaries of the EAPS domains.

**Note**

If CFM is not used, it is recommended to have a direct Link connected between EAPS Controller Node and EAPS Partner Node.

The exception mentioned above occurs when the partner node is also a master node, and the shared port that fails is configured as a primary port. In this situation, the master node waits for a link-down PDU from the controller node before opening the secondary port. This delay prevents a loop that might otherwise develop if the master/partner node detects the link failure before the controller node.

**Note**

If the common link and a ring link fail, and if the common link restores before the ring link, traffic down time can be as long as three seconds. This extended delay is required to prevent loops during the recovery of multiple failed links.
Common Link Recovery

When a common link recovers, each master node detects that the ring is complete and immediately blocks their secondary ports. The controller also detects the recovery and puts its shared port to the common link into a temporary blocking state called pre-forwarding as shown in Figure 123.

Figure 123: Common Link in Pre-Forwarding State

Because the topology has changed, the EAPS nodes must learn the new traffic paths. Each master node notifies all switches in their domain to clear their FDB tables, and traditional Ethernet bridge learning and forwarding mechanisms establish the new traffic paths. Once the controller receives flush-fdb messages for all of its connected EAPS domains, the controller shared-port state for the common link changes to forwarding, the controller state changes to Ready, and traffic flows normally as shown in Figure 124.

Figure 124: Common-Link Restored
Controller and Partner Node States

EAPS controller and partner nodes can be in the following states:

- **Ready**—Indicates that the EAPS domains are running, the common-link neighbor can be reached through segment health-checks, and the common link is up.

- **Blocking**—Indicates that the EAPS domains are running, the common-link neighbor can be reached through segment health-checks, but the common-link is down. Only the controller node (and not the partner) performs blocking.

- **Preforwarding**—Indicates the EAPS domain was in a blocking state, and the common link was restored. The controller port is temporarily blocked to prevent a loop during state transition from Blocking to Ready.

- **Idle**—Indicates the EAPS common-link neighbor cannot be reached through segment health-check messages.

Spatial Reuse with an EAPS Common Link

The common-link topology supports multiple EAPS domains (spatial reuse) on each ring as shown in Figure 125.

![EAPS Common Link Topology with Spatial Reuse](image)

**Figure 125: EAPS Common Link Topology with Spatial Reuse**

Note

If you are using the older method of enabling STP instead of EAPSv2 to block the super loop in a shared-port environment, you can continue to do so. In all other scenarios, we recommend that you do not use both STP and EAPS on the same port.

Additional Common Link Topology Examples

**Basic Core Topology**

Figure 126 shows a core topology with two access rings. In this topology, there are two EAPS common links.
Right-Angle Topology

In the right-angle topology, there are still two EAPS common links, but the common links are adjacent to each other.

To configure a right-angle topology, there must be two common links configured on one of the switches. Figure 127 shows a right-angle topology.

Combined Basic Core and Right-Angle Topology

Figure 128 shows a combination basic core and right-angle topology.
Figure 128: Basic Core and Right Angle Topology

Figure 129 shows an extension of the basic core and right angle configuration.

Figure 129: Advanced Basic Core and Right Angle Topology
Large Core and Access Ring Topology

Figure 130 shows a single large core ring with multiple access rings hanging off of it. This is an extension of a basic core configuration.

![Large Core and Access Ring Topology](image)

Fast Convergence

The fast convergence mode allows EAPS to converge more rapidly. In EAPS fast convergence mode, the link filters on EAPS ring ports are turned off. In this case, an instant notification is sent to the EAPS process if a port's state transitions from up to down or vice-versa.

You must configure fast convergence for the entire switch, not by EAPS domain.

For optimum performance and convergence, it is recommended to use fiber cables.

EAPS and Hitless Failover—SummitStack Only

When you use redundancy in a SummitStack, one node assumes the role of primary and another node assumes the role of backup.

The primary node executes the switch's management functions, and the backup node acts in a standby role. Hitless failover transfers switch management control from the primary to the backup and maintains
the state of EAPS. EAPS supports hitless failover. You do not explicitly configure hitless failover support; rather, if you are operating with redundancy in a SummitStack, hitless failover is available.

**Note**
Not all platforms support hitless failover in the same software release. To verify if the software version you are running supports hitless failover, see the table in Protocol Support for Hitless Failover on page 72. For more information about protocol and platform support for hitless failover, see Understanding Hitless Failover Support on page 71.

To support hitless failover, the primary node replicates all EAPS PDUs to the backup, which allows the backup to be aware of the EAPS domain state. Since both nodes receive EAPS PDUs, each node maintains equivalent EAPS states.

By knowing the state of the EAPS domain, the EAPS process running on the backup node can quickly recover after a primary node failover. Although both nodes receive EAPS PDUs, only the primary transmits EAPS PDUs to neighboring switches and actively participates in EAPS.

**Note**
For instructions on how to manually initiate hitless failover, see Relinquishing Primary Status on page 68.

### EAPS Licensing

Different EAPS features are offered at different license levels.

For complete information about software licensing, including how to obtain and upgrade your license and what licenses are appropriate for these features, in the ExtremeXOS 22.6 Feature License Requirements document.

---

### Configuring EAPS

#### Single Ring Configuration Tasks

To configure and enable an EAPS protected ring, do the following on each ring node:

1. Create an EAPS domain and assign a name to the domain as described in Creating and Deleting an EAPS Domain on page 1056.
2. Create and add the control VLAN to the domain as described in Adding the EAPS Control VLAN on page 1056.
3. Create and add the protected VLAN(s) to the domain as described in Adding Protected VLANs on page 1057.
4. Configure the EAPS mode (master or transit) for the switch in the domain as described in Defining the Switch Mode (Master or Transit) on page 1057.
5. Configure the EAPS ring ports, including the master primary and secondary ring ports, as described in Configuring the Ring Ports on page 1058.
6. If desired, configure the polling timers and timeout action as described in Configuring the Polling Timers and Timeout Action on page 1058.
7 Enable EAPS for the entire switch as described in Enabling and Disabling EAPS on the Switch on page 1059.
8 If desired, enable Fast Convergence as described in Enabling and Disabling Fast Convergence on page 1060.
9 Enable EAPS for the specified domain as described in Enabling and Disabling an EAPS Domain on page 1060.

Note
If you configure a VMAN on a switch running EAPS, make sure you configure the VMAN attributes on all of the switches that participate in the EAPS domain. For more information about VMANs, see VMAN (PBN) and PBBN.

Creating and Deleting an EAPS Domain
Each EAPS domain is identified by a unique domain name.
• To create an EAPS domain, use the following command:

```
create eaps name
```
• To delete an EAPS domain, use the following command:

```
delete eaps name
```

Adding the EAPS Control VLAN
You must create and configure one control VLAN for each EAPS domain. For instructions on creating a VLAN, see VLANs on page 503.
• To configure EAPS to use a VLAN as the EAPS control VLAN for a domain, use the following command:

```
configure eaps name add control {vlan} vlan_name
```

Note
A control VLAN cannot belong to more than one EAPS domain. If the domain is active, you cannot delete the domain or modify the configuration of the control VLAN.
The control VLAN must NOT be configured with an IP address. In addition, only ring ports may be added to this control VLAN. No other ports can be members of this VLAN. Failure to observe these restrictions can result in a loop in the network.
The ring ports of the control VLAN must be tagged.

By default, EAPS PDUs are automatically assigned to QoS (Quality of Service) profile QP8. This ensures that the control VLAN messages reach their intended destinations. You do not need to configure a QoS profile for the control VLAN.
Adding Protected VLANs

You must add one or more protected VLANs to each EAPS domain. The protected VLANs are the data-carrying VLANs.

Note

When you configure a protected VLAN, the ring ports of the protected VLAN must be tagged (except in the case of the default VLAN).

For instructions on creating a VLAN, see VLANs on page 503.

- To configure a VLAN as an EAPS protected VLAN, use the following command:

  `configure eaps name add protected {vlan} vlan_name`

Configuring the EAPS Domain Priority

The EAPS domain priority feature allows you to select the EAPS domains that are serviced first when a break occurs in an EAPS ring. For example, you might set up a network topology with two or more domains on the same physical ring, such as in spatial reuse. In this topology, you could configure one domain as high priority and the others as normal priority. You would then add a small subset of the total protected VLANs to the high priority domain, and add the rest of the protected VLANs to the normal priority domain. The secondary port of the normal and high priority domains can be the same, or as is typically the case of spatial reuse, opposite. If a ring fault occurs in this topology, the protected VLANs in the high priority domain are the first to recover.

- To configure the EAPS domain priority, use the following command:

  `configure eaps name priority {high | normal}`

Defining the Switch Mode (Master or Transit)

We recommend keeping the loop protection warning messages enabled. If you have considerable knowledge and experience with EAPS, you might find the EAPS loop protection warning messages unnecessary.

1. Configure the EAPS switch mode for a domain using the following command:

  `configure eaps name mode [master | transit]
  
  One switch on the ring must be configured as the master node for the specified domain; all other switches on the same ring and domain are configured as transit nodes.

  If you configure a switch to be a transit node for an EAPS domain, the default switch configuration displays the following message and prompts you to confirm the command:

  WARNING: Make sure this specific EAPS domain has a Master node in the ring. If you change this node from EAPS master to EAPS transit, you could cause a loop in the network. Are you sure you want to change mode to transit? (y/n)

2. When prompted, do one of the following:

  - Enter y to identify the switch as a transit node.
  - Enter n or press [Return] to cancel the command.

For more information see, Disabling EAPS Loop Protection Warning Messages on page 1061.
Configuring the Ring Ports

Each node on the ring connects to the ring through two ring ports. The ports that you choose on each switch should be tagged and added to the control VLAN and all protected VLANs. For information on adding tagged ports to a VLAN, see VLANs on page 503.

On the master node, one ring port must be configured as the primary port, and the other must be configured as the secondary port.

We recommend that you keep the loop protection warning messages enabled. If you have considerable knowledge and experience with EAPS, you might find the EAPS loop protection warning messages unnecessary.

1 To configure a node port as primary or secondary, use the following command:

```
configure eaps name [primary | secondary] port ports
```

If you attempt to add an EAPS ring port to a VLAN that is not protected by EAPS, the default switch configuration prompts you to confirm the command with the following message:

```
Make sure <vlan_name> is protected by EAPS. Adding EAPS ring ports to a VLAN could cause a loop in the network. Do you really want to add these ports (y/n)
```

2 When prompted, do one of the following:

- Enter y to identify the switch as a transit node.
- Enter n or press [Return] to cancel the command.

For information on configuring a VLAN for EAPS, see the following sections:

- Adding the EAPS Control VLAN on page 1056
- Adding Protected VLANs on page 1057

For more information see, Disabling EAPS Loop Protection Warning Messages on page 1061.

Configuring the Polling Timers and Timeout Action

The polling timers provide an alternate way to detect ring breaks. In a ring that uses only Extreme Networks switches, the master switch learns about a ring break by receiving a link-down PDU. When the ring uses only Extreme networks switches, the polling timers are not needed and can remain configured for the default values.

In a ring that contains switches made by other companies, the polling timers provide an alternate way to detect ring breaks. The master periodically sends hello PDUs at intervals determined by the hello PDU timer and waits for a reply. If a hello PDU reply is not received before the failtime timer expires, the switch detects a failure and responds by either sending an alert or opening the secondary port. The response action is defined by a configuration command.

- Set the polling timer values the master node uses for detecting ring failures.

```
configure eaps name hellotime seconds milliseconds
configure eaps name failtime seconds milliseconds
```

Note
These commands apply only to the master node. If you configure the polling timers for a transit node, they are ignored. If you later reconfigure that transit node as the master node, the polling timer values are used as the current values.
Use the `hellotime` keyword and its associated parameters to specify the amount of time the master node waits between transmissions of health check messages on the control VLAN. The combined value for seconds and milliseconds must be greater than 0. The default value is 1 second.

Use the `failtime` keyword and its associated parameters to specify the amount of time the master node waits before the failtimer expires. The combined value for seconds and milliseconds must be greater than the configured value for `hellotime`. The default value is 3 seconds.

**Note**
Increasing the failtime value increases the time it takes to detect a ring break using the polling timers, but it can also reduce the possibility of incorrectly declaring a failure when the network is congested.

- Configure the action taken when a ring break is detected.
  
  ```bash
  configure eaps name failtime expiry-action [open-secondary-port | send-alert]
  ```

  Use the `send-alert` parameter to send an alert when the failtimer expires. Instead of going into a failed state, the master node remains in a Complete or Init state, maintains the secondary port blocking, and writes a critical error message to syslog warning the user that there is a fault in the ring. An SNMP (Simple Network Management Protocol) trap is also sent.

  Use the `open-secondary-port` parameter to open the secondary port when the failtimer expires.

**Enabling and Disabling EAPS on the Switch**

We recommend that you keep the loop protection warning messages enabled. If you have considerable knowledge and experience with EAPS, you might find the EAPS loop protection warning messages unnecessary.

- To enable the EAPS function for the entire switch, use the following command:
  
  ```bash
  enable eaps
  ```

- To disable the EAPS function for the entire switch, use the following command:
  
  ```bash
  disable eaps
  ```

  If you enter the command to disable EAPS, the default switch configuration displays the following warning message and prompts you to confirm the command:

  ```
  WARNING: Disabling EAPS on the switch could cause a loop in the network! Are you sure you want to disable EAPS? (y/n)
  ```

  - When prompted, do one of the following:
    
    a. Enter `y` to disable EAPS for the entire switch.
    b. Enter `n` or press [Return] to cancel the command.

  For more information see, Disabling EAPS Loop Protection Warning Messages on page 1061.
**Enabling and Disabling Fast Convergence**

You can enable or disable fast convergence for the entire switch to improve EAPS convergence times.

---

**Note**

Possible factors affecting EAPS fast convergence time:

- The medium type of the link being flapped (Fiber link-down events are detected faster than copper, causing better convergence).
- Number of VLANs protected by the EAPS domain (convergence time increases with the number of protected VLANs).
- Number of FDB entries present during the switch over (convergence time increases with the number of FDBs learned).
- Topology change event (link down or link up) causes the master node to send an FDB flush to all transits. In the event of a shared port failure, FDB is flushed twice, causing an increase in convergence time.
- Number of hops between the switch where the link flap happens and the master node (convergence increases with the number of hops).

---

- To enable or disable fast convergence on the switch, use the following command:

  `configure eaps fast-convergence [off | on]`

---

**Enabling and Disabling an EAPS Domain**

We recommend that you keep the loop protection warning messages enabled. If you have considerable knowledge and experience with EAPS, you might find the EAPS loop protection warning messages unnecessary.

- To enable a specific EAPS domain, use the following command:

  `enable eaps {name}`

- To disable a specific EAPS domain, use the following command:

  `disable eaps {name}`

  If you enter the `disable eaps` command, the default switch configuration displays the following warning message and prompts you to confirm the command:

  WARNING: Disabling specific EAPS domain could cause a loop in the network! Are you sure you want to disable this specific EAPS domain? (y/n)

  - When prompted, do one of the following:
    a. Enter `y` to disable EAPS for the specified domain.
    b. Enter `n` or press [Return] to cancel the command.

  For more information see, *Disabling EAPS Loop Protection Warning Messages* on page 1061.
Configuring EAPS Support for Multicast Traffic

The ExtremeXOS software provides several commands for configuring how EAPS supports multicast traffic after an EAPS topology change.

**Note**

EAPS multicast flooding must be enabled before the add-ring-ports feature will operate. For information on enabling EAPS multicast flooding, see the command:

`configure eaps multicast temporary-flooding [on | off]`

Unconfiguring an EAPS Ring Port

Unconfiguring an EAPS port sets its internal configuration state to INVALID, which causes the port to appear in the Idle state with a port status of Unknown. This occurs when you use the `show eaps {eapsDomain} {detail}` command to display the status information about the port.

We recommend that you keep the loop protection warning messages enabled. If you have considerable knowledge and experience with EAPS, you might find the EAPS loop protection warning messages unnecessary.

1. To unconfigure an EAPS primary or secondary ring port for an EAPS domain, use the following command:

   `unconfigure eaps eapsDomain [primary | secondary] port`

   To prevent loops in the network, the switch displays by default a warning message and prompts you to unconfigure the specified EAPS primary or secondary ring port.

2. When prompted, do one of the following:
   a. Enter `y` to unconfigure the specified port.
   b. Enter `n` or press [Return] to cancel this action.

   The following command example unconfigures this node’s EAPS primary ring port on the domain “eaps_1”:

   `unconfigure eaps eaps_1 primary port`

   **WARNING:** Unconfiguring the Primary port from the EAPS domain could cause a loop in the network! Are you sure you want to unconfigure the Primary EAPS Port? (y/n)

3. Enter `y` to continue and unconfigure the EAPS primary ring port. Enter `n` to cancel this action.

   The switch displays a similar warning message if you unconfigure the secondary EAPS port.

   For more information see, Disabling EAPS Loop Protection Warning Messages on page 1061.

Disabling EAPS Loop Protection Warning Messages

The switch displays by default loop protection messages when configuring the following EAPS parameters:

- Adding EAPS primary or secondary ring ports to a VLAN
- Deleting a protected VLAN
- Disabling the global EAPS setting on the switch
- Disabling an EAPS domain
- Configuring an EAPS domain as a transit node
- Unconfiguring EAPS primary or secondary ring ports from an EAPS domain
We recommend keeping the loop protection warning messages enabled. If you have considerable knowledge and experience with EAPS, you might find the EAPS loop protection warning messages unnecessary. For example, if you use a script to configure your EAPS settings, disabling the warning messages allows you to configure EAPS without replying to each interactive yes/no question.

- To disable loop protection messages, use the following command:
  ```bash
  configure eaps config-warnings off
  ```
- To re-enable loop protection messages, use the following command:
  ```bash
  configure eaps config-warnings on
  ```

**Common Link Topology Configuration Tasks**

To create a common link topology, you must configure the shared ports at each end of the common link.

**EAPS Shared Port Configuration Rules**

The following rules apply to EAPS shared port configurations:

- Each common link in the EAPS network must have a unique link ID, which is configured at the shared port at each end of the link.
- The shared port mode configured on each side of a common link must be different from the other; one must be a controller and one must be a partner.
- The controller and partner shared ports on either side of a common link must have the same link ID. The common link is established only when the shared ports at each end of the common link have the same link ID.
- There can be up to two shared ports per switch.
- There cannot be more than one controller on a switch.

Valid combinations on any one switch are:

- 1 controller
- 1 partner
- 1 controller and 1 partner
- 2 partners
- A shared port cannot be configured on an EAPS master's secondary port.

**Note**

When a common link fails, one of the segment ports becomes the active-open port, and all other segment ports are blocked to prevent a loop for the protected VLANs. For some topologies, you can improve network performance during a common link failure by selecting the port numbers to which segments connect. For information on how the active-open port is selected, see Common Link Fault Detection and Response.

**Common Link Configuration Overview**

To configure and enable a common link to serve multiple rings, do the following on the controller and partner nodes:

1. Create a shared port for the common link as described in Creating and Deleting a Shared Port on page 1063.
2. Configure the shared port as either a controller or a partner as described in Defining the Mode of the Shared Port on page 1063.
3. Configure the link ID on the shared port as described in Configuring the Link ID of the Shared Port on page 1063.
4. If desired, configure the polling timers and timeout action as described in Configuring the Shared Port Timers and Timeout Action on page 1064.
   This step can be configured at any time, even after the EAPS domains are running.
5. Configure EAPS on each ring as described in Single Ring Configuration Tasks on page 1055.

Creating and Deleting a Shared Port

To configure a common link, you must create a shared port on each switch belonging to the common link.

- To create a shared port, use the following command:
  ```
  create eaps shared-port ports
  ```
  Where `ports` is the common link port.

  **Note**
  A switch can have a maximum of two shared ports.

- To delete a shared port on the switch, use the following command:
  ```
  delete eaps shared-port ports
  ```

Defining the Mode of the Shared Port

The shared port on one end of the common link must be configured to be the controller. This is the end responsible for blocking ports when the common link fails, thereby preventing the superloop.

The shared port on the other end of the common link must be configured to be the partner. This end does not participate in any form of blocking. It is responsible for only sending and receiving health-check messages.

- To configure the mode of the shared port, use the following command:
  ```
  configure eaps shared-port ports mode controller | partner
  ```

Configuring the Link ID of the Shared Port

Each common link in the EAPS network must have a unique link ID. The controller and partner shared ports that belong to the same common link must have matching link IDs. No other instance in the network should have that link ID.

If you have multiple adjacent common links, we recommend that you configure the link IDs in ascending order of adjacency. For example, if you have an EAPS configuration with three adjacent common links, moving from left to right of the topology, configure the link IDs from the lowest to the highest value.

- To configure the link ID of the shared port, use the following command:
  ```
  configure eaps shared-port ports link-id id
  ```
  The link ID range is 1–65534.
Configuring the Shared Port Timers and Timeout Action

- To configure the shared port timers, use the following commands:

  ```
  configure eaps shared-port port common-path-timers {[health-interval | timeout] seconds}
  configure eaps shared-port port segment-timers health-interval seconds
  configure eaps shared-port port segment-timers timeout seconds
  ```

- To configure the time out action for segment timers, use the following command:

  ```
  configure eaps shared-port port segment-timers expiry-action [segment-down | send-alert]
  ```

Unconfiguring an EAPS Shared Port

- To unconfigure a link ID on a shared port, use the following command:

  ```
  unconfigure eaps shared-port ports link-id
  ```

- To unconfigure the mode on a shared port, use the following command:

  ```
  unconfigure eaps shared-port ports mode
  ```

- To delete a shared port, use the following command:

  ```
  delete eaps shared-port ports
  ```

Clearing the EAPS Counters

The EAPS counters continue to increment until you explicitly clear the information. By clearing the counters, you can see fresh statistics for the time period you are monitoring.

- To clear the counters used by EAPS, use the following commands:

  ```
  clear counters
  clear eaps counters
  ```

Displaying EAPS Information

Displaying Single Ring Status and Configuration Information

- To display EAPS status and configuration information, use the following command:

  ```
  show eaps {eapsDomain} {detail}
  ```

  **Note**
  You might see a slightly different display, depending on whether you enter the command on the master node or the transit node.

  If you specify a domain with the optional `eapsDomain` parameter, the command displays status information for a specific EAPS domain.
The display from the `show eaps detail` command shows all the information shown in the `show eaps eapsDomain` command for all configured EAPS domains.

### Displaying Domain Counter Information

- To display EAPS counter information for one or all domains, use the following command:

  ```
  show eaps counters [eapsDomain | global]
  ```

  If you specify the name of an EAPS domain, the switch displays counter information related to only that domain.

  If you specify the `global` keyword, the switch displays a list of the counter totals for all domains. To see the counters for a specific domain, you must specify the domain name.

**Note**

If a PDU is received, processed, and consumed, only the Rx counter increments. If a PDU is forwarded in slow path, both the Rx counter and Fw counter increment.

### Displaying Common Link Status and Configuration Information

Each controller and partner node can display status and configuration information for the shared port or ports on the corresponding side of the common link.

- To display EAPS common link information, use the following command:

  ```
  show eaps shared-port {port} {detail}
  ```

  If you enter the `show eaps shared-port` command without an argument or keyword, the command displays a summary of status information for all configured EAPS shared ports on the switch.

  If you specify a shared port, the command displays information about that specific port.

  You can use the `detail` keyword to display more detailed status information about the segments and VLANs associated with each shared port.

### Displaying Common Link Counter Information

Each controller and partner node can display counter information for the shared port or ports through which the switch connects to a common link.

- To display EAPS shared port counter information, use the following command:

  ```
  show eaps counters shared-port [global | port {segment-port segport {eapsDomain}}]
  ```

  If you specify the `global` keyword, the switch displays a list of counters that show the totals for all shared ports together. To view the counters for a single shared port, enter the command with the port number.
If you specify a particular EAPS segment port, the switch displays counter information related to only that segment port for the specified EAPS domain.

Configuration Examples

Migrating from STP to EAPS

This section explains how to migrate or reconfigure an existing STP network to an EAPS network.

Note
Actual implementation steps on a production network may differ based on the physical topology, switch models, and software versions deployed.

The sample STP network is a simple two-switch topology connected with two Gigabit Ethernet trunk links, which form a broadcast loop. Both Extreme Networks switches are configured for 802.1D mode STP running on a single data VLAN named Data. The sample STP network for migration to EAPS is shown in Figure 131.

![Sample STP Network for Migration to EAPS](image)

**Figure 131: Sample STP Network for Migration to EAPS**

Creating and Configuring the EAPS Domain

- The first step in the migration process is to create an EAPS Domain and configure the EAPS mode, then define the primary and secondary ports for the domain. Follow this step for both switches. Switch2 is configured as EAPS Master to ensure the same port blocking state is maintained as in the original STP topology.

Switch 1 EAPS domain configuration:

* `SWITCH#1.1 # create eaps new-eaps`
* `SWITCH#1.2 # configure new-eaps mode transit`
* `SWITCH#1.3 # configure new-eaps primary port 4:1`
* `SWITCH#1.4 # configure new-eaps secondary port 4:2`
Switch 2 EAPS domain configuration:

* SWITCH#2.1 # create eaps new-eaps
* SWITCH#2.2 # configure new-eaps mode master
* SWITCH#2.3 # configure new-eaps primary port 4:1
* SWITCH#2.4 # configure new-eaps secondary port 4:2

Creating and Configuring the EAPS Control VLAN

1. You must create the EAPS control VLAN and configure the 802.1q tag and ring ports.
2. Configure the control VLANs as part of the EAPS domain. Do this for both switches.

Switch 1 control VLAN configuration:

* SWITCH#1.5 # create vlan control-1
* SWITCH#1.6 # configure vlan control-1 tag 4001
* SWITCH#1.8 # configure vlan control-1 add port 4:1,4:2 tagged
* SWITCH#1.9 # configure eaps new-eaps add control vlan control-1

Switch 2 control VLAN configuration:

* SWITCH#2.5 # create vlan control-1
* SWITCH#2.6 # configure vlan control-1 tag 4001
* SWITCH#2.8 # configure vlan control-1 add port 4:1,4:2 tagged
* SWITCH#2.9 # configure eaps new-eaps add control vlan control-1

Enabling EAPS and Verify EAPS Status

1. Enable the EAPS protocol and the EAPS domain.
2. Confirm that the master node is in Complete state and its secondary port is blocking.

Switch 1 commands to enable EAPS and the domain:

* SWITCH#1.10 # enable eaps
* SWITCH#1.11 # enable eaps new-eaps

Switch 2 commands to enable EAPS and verify status:

* SWITCH#2.10 # enable eaps
* SWITCH#2.11 # enable eaps new-eaps
* SWITCH#2.12 # show eaps
EAPS Enabled: Yes
EAPS Fast-Convergence: Off
EAPS Display Config Warnings: On
EAPS Multicast Add Ring Ports: Off
EAPS Multicast Send IGMP Query: On
EAPS Multicast Temporary Flooding: Off
EAPS Multicast Temporary Flooding Duration: 15 sec
Number of EAPS instances: 1
# EAPS domain configuration :

<table>
<thead>
<tr>
<th>Domain</th>
<th>State</th>
<th>Mo</th>
<th>En</th>
<th>Pri</th>
<th>Sec</th>
<th>Control-Vlan VID</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>new-eaps</td>
<td>Complete</td>
<td>M</td>
<td>Y</td>
<td>4:1</td>
<td>4:2</td>
<td>control-1</td>
<td>(4001) 0</td>
</tr>
</tbody>
</table>

Configuring the STP Protected VLAN as an EAPS Protected VLAN

Configure the data VLAN (currently protected by STP as an untagged VLAN) as an EAPS protected VLAN.
1 Assign an 802.1q tag to the data VLAN, as this might not be required with the previous STP configuration.

2 Next, the data VLAN is added to the EAPS domain as a protected VLAN.

3 Configure the VLAN port changes at the end to prevent any broadcast loop from forming during the transition from STP to EAPS protection.

   A warning message is displayed on the CLI, but this can be ignored, as it is just a reminder that the ring ports have not been added to the protected VLAN yet.

4 Change the port membership for the data VLAN from untagged to 802.1q tagged trunk ports.

Switch#2 commands to add EAPS protected VLAN and tagged ports:

```
* SWITCH#2.13 # configure vlan data tag 1000
* SWITCH#2.14 # configure new-eaps add protect vlan data
WARNING: Primary port [4:1] is not tagged on vlan "data", EAPS="new-eaps"
WARNING: Secondary port [4:2] is not tagged on vlan "data", EAPS="new-eaps"
* SWITCH#2.15 # configure data add port 4:1,4:2 tagged
```

Switch#1 commands to add EAPS protected VLAN and tagged ports:

```
* SWITCH#1.13 # configure vlan data tag 1000
* SWITCH#1.14 # configure new-eaps add protect vlan data
WARNING: Primary port [4:1] is not tagged on vlan "data", EAPS="new-eaps"
WARNING: Secondary port [4:2] is not tagged on vlan "data", EAPS="new-eaps"
* SWITCH#1.15 # configure data add port 4:1,4:2 tagged
```

Verifying the EAPS Blocking State for the Protected VLAN

- To ensure there is no potential for a broadcast storm, confirm that EAPS is successfully blocking the protected VLAN, as shown in the following example:

```
* SWITCH#2.16 # show new-eaps
Name: new-eaps
State: Complete                     Running: Yes
Enabled: Yes Mode: Master
Primary port: 4:1 Port status: Up   Tag status: Tagged
Secondary port: 4:2 Port status: Blocked Tag status: Tagged
Hello timer interval: 1 sec 0 millisec
Fail timer interval: 3 sec
Fail Timer expiry action: Send alert
Last valid EAPS update: From Master Id 00:04:96:10:51:50, at Fri Sep 10 13:38:39 2004
EAPS Domain's Controller Vlan: control-1 4001
EAPS Domain's Protected Vlan(s): data 1000
Number of Protected Vlans: 1
```

After you verify that EAPS is protecting the data VLAN, you can safely remove the STP configuration.

Verifying the STP Status and Disabling STP

Once you have successfully verified that EAPS has taken over loop prevention for the data VLAN, you no longer need the STP configuration.

Now, verify whether the data VLAN is removed from the STP domain, and then disable the STP protocol.

Switch 2 commands to verify STP status and disable STP:

```
* SWITCH#2.17 # show stp s0
Stpd: s0                Stp: ENABLED            Number of Ports: 0
Rapid Root Failover: Disabled
Operational Mode: 802.1D   Default Binding Mode: 802.1D
```
Switch 1 commands to verify STP status and disable STP:

* SWITCH#1.18 # show s0 port
  Port Mode State Cost Flags Priority Port ID Designated Bridge
  Stpd: s0 Stp: ENABLED Number of Ports: 0
  Rapid Root Failover: Disabled Operational Mode: 802.1D Default Binding Mode: 802.1D
  802.1Q Tag: (none) 802.1Q Tag: (none)
  Ports: (none) Ports: (none)
  Auto-bind Vlans: Default Auto-bind Vlans: Default
  Bridge Priority: 1 Bridge Priority: 1
  BridgeID: 00:01:00:04:96:10:30:10 BridgeID: 00:01:00:04:96:10:30:10
  Designated root: 00:01:00:04:96:10:30:10 Designated root: 00:01:00:04:96:10:30:10
  RootPathCost: 0 Root Port: ---- RootPortCost: 0 Root Port: ----
  MaxAge: 20s HelloTime: 2s ForwardDelay: 15s MaxAge: 20s HelloTime: 2s ForwardDelay: 15s
  CfgBrMaxAge: 20s CfgBrHelloTime: 2s CfgBrForwardDelay: 15s CfgBrMaxAge: 20s CfgBrHelloTime: 2s CfgBrForwardDelay: 15s
  Topology Change Time: 35s Hold time: 1s Topology Change Time: 35s Hold time: 1s
  Topology Change Detected: FALSE Topology Change: FALSE Topology Change Detected: FALSE Topology Change: FALSE
  Number of Topology Changes: 2 Number of Topology Changes: 2
  Time Since Last Topology Change: 11267s
  * SWITCH#1.17 # show stp s0 po
  * SWITCH#1.18 # disable stp s0
  * SWITCH#1.19 # disable stp

The network should now be successfully migrated from STP to EAPS.

Designing and Implementing a Highly Resilient Enterprise Network Using EAPS

Network managers can design and employ a highly resilient end-to-end enterprise network using the Extreme Networks switching platform and the EAPS protocol as shown in the following figure.
EAPS can be used in the network edge to provide link resiliency for Ethernet and IP services in a partial-meshed design. In the aggregation layer, EAPS interconnects multiple edge and core domains. When combined with VRRP (Virtual Router Redundancy Protocol) and OSPF in the aggregation layer, EAPS provides the foundation for highly resilient IP routing by protecting against link and switch failures.

In the network core, EAPS is used with OSPF to provide a high-performance IP routing backbone with zero downtime or route flaps. Using EAPS and dual-homed server farms in the data center provides high availability for mission-critical server resources.

The collapsed core/aggregation layer and data center also make use of EAPS resilient ring topology to ensure network availability to all critical sources.

**Designing and Configuring the Unified Access Layer**

The unified access network layer makes use of EAPS in a partial-meshed ring topology for maximum resiliency. The edge of the network is the first point of entry for client devices such as PCs, servers, VoIP phones, wireless devices, and printers.
Utilizing EAPS and redundant uplink ports on edge switches increases network resiliency and availability. Edge switches connect their primary and secondary uplink trunk ports to one or more switches in the aggregation network layer (as shown in Figure 133). If the primary uplink port fails, traffic can use the alternate secondary uplink.

Figure 133: Converged Network Edge (Unified Access Layer)

In this sample network, each edge switch is configured with a unique EAPS domain and control VLAN. Protected VLANs can overlap across multiple EAPS domains, or remain local to their own domain.

By putting each edge switch and VLAN into a separate EAPS domain, you gain resiliency and management benefits. First, any link or switch failures in one ring do not affect the other edge switches. Also, this type of modular design allows you to add edge switches easily without impacting other parts of the network. Troubleshooting becomes easier as the scope of failures can be quickly isolated to a specific EAPS ring or switch.

This section describes how to design the access edge network switches as EAPS transit nodes to provide Ethernet L2 connectivity services. In this example, upstream aggregation switches perform Layer 3 (L3) inter-VLAN routing functions. Although not discussed in the scope of this section, the edge switches could also be configured with additional routing, QoS, WLAN (Wireless Local Area Network), or security features.
Creating and Configuring the EAPS Domain

- Create the EAPS domain, configure the switch as a transit node, and define the EAPS primary and secondary ports as shown in the following example:

* Edge-Switch#1:1 # create eaps e1-domain
* Edge-Switch#1:2 # configure eaps e1-domain mode transit
* Edge-Switch#1:3 # configure eaps e1-domain primary port 49
* Edge-Switch#1:4 # configure eaps e1-domain secondary port 50

Creating and Configuring the EAPS Control VLAN

1. Create the EAPS control VLAN and configure its 802.1q tag and ring ports.
2. Configure the control VLAN as part of the EAPS domain. The control VLAN only contains the EAPS primary and secondary ports configured earlier. The following commands accomplish these tasks:

* Edge-Switch#1:5 # create vlan control-1
* Edge-Switch#1:6 # configure vlan control-1 tag 4000
* Edge-Switch#1:8 # configure vlan control-1 add port 49,50 tagged
* Edge-Switch#1:9 # configure eaps e1-domain add control vlan control-1

Creating and Configuring EAPS Protected VLANs

1. Create at least one EAPS protected VLAN, and configure its 802.1q tag and ports.
2. Configure the protected VLAN as part of the EAPS domain. The Protect VLAN contains the EAPS primary and secondary ports as tagged VLAN ports. Additional VLAN ports connected to client devices such as a PC could be untagged or tagged. The following commands accomplish these tasks and should be repeated for all additional protected VLANs:

* Edge-Switch#1:10 # create vlan purple-1
* Edge-Switch#1:11 # configure purple-1 tag 1
* Edge-Switch#1:12 # configure purple-1 add port 49,50 tagged
* Edge-Switch#1:13 # configure purple-1 add port 1 untagged
* Edge-Switch#1:14 # configure eaps e1-domain add protect vlan purple-1

Enabling the EAPS Protocol and EAPS Domain

- Enable EAPS to run on the domain as shown in the following example:

* Edge-Switch#1:15 # enable eaps
* Edge-Switch#1:16 # enable eaps e1-domain

Verifying the EAPS Configuration and Status

- The command in the following example allows you to verify that the EAPS configuration is correct and that the EAPS state is Links-Up.

Both ring ports must be plugged in to see the Links-Up state.

* Edge-Switch#1:17 # show eaps e1-domain detail
Name: "e1-domain" (instance=0) Priority: High
State: Links-Up Running: Yes
Enabled: Yes Mode: Transit
Primary port: 49 Port status: Up Tag status: Tagged
Secondary port: 50 Port status: Up Tag status: Tagged
Hello Timer interval: 1 sec 0 millisecond
Fail Timer interval: 3 sec
Preforwarding Timer interval: 0 sec
Last valid EAPS update: From Master Id 00:04:96:10:51:50, at Sun Sep 5 23:20:10 2004
Designing and Configuring the Aggregation Layer

The network switches in the aggregation layer provide additional resiliency benefits.

In the following example, aggregation switches are typically deployed in pairs that protect against single switch failures. Each aggregation switch is physically connected to all edge switches and participates in multiple EAPS domains. The aggregation switches can serve a different role within each EAPS domain, with one switch acting as a transit node and the other as a master node.

In this example, we have a common link with overlapping domains (and protected VLANs), which includes an EAPS controller and partner configuration. The result is a partial-mesh network design of EAPS from the access edge to the aggregation layer (see Figure 134).
The aggregation switches are configured to act as multi-function EAPS nodes to provide L2 connectivity services. After EAPS and L2 connectivity is configured, additional L3 routing configuration can be added.

Using redundant aggregation switches helps protect against a single point of failure at the switch level, while EAPS domains provide fault isolation and minimize the impact that failures have on the network. With shared port configurations, the partial-mesh physical design is maintained without broadcast loops, regardless of where a failure might occur.

To configure the L2 aggregate switches, complete the tasks described in the following sections on all aggregate switches:

1. Create and configure the EAPS domains.
2. Create and configure the EAPS control VLANs.
3. Create and configure the EAPS shared ports.
4. Enable the EAPS protocol and EAPS domain.
5 Create and configure the EAPS protected VLANs.
6 Verify the EAPS configuration and operating state.

Creating and Configuring the EAPS Domains

- Create the EAPS domains for each ring (one domain for one edge switch) and configure the EAPS mode.

Define the primary and secondary ports for each domain. In this example, however, the primary port is the same as the common link. One aggregation switch has EAPS mode configured as master and partner, while the other aggregation switch is configured as transit and controller.

EAPS master node configuration:

* AGG-SWITCH#2.1 # create eaps e1-domain
* AGG-SWITCH#2.2 # create eaps e2-domain
* AGG-SWITCH#2.3 # create eaps e3-domain
* AGG-SWITCH#2.4 # create eaps e4-domain
* AGG-SWITCH#2.5 # configure eaps e1-domain mode master
* AGG-SWITCH#2.6 # configure eaps e2-domain mode master
* AGG-SWITCH#2.7 # configure eaps e3-domain mode master
* AGG-SWITCH#2.8 # configure eaps e4-domain mode master
* AGG-SWITCH#2.9 # configure eaps e1-domain primary port 2:1
* AGG-SWITCH#2.10 # configure eaps e1-domain secondary port 1:1
* AGG-SWITCH#2.11 # configure eaps e2-domain primary port 2:1
* AGG-SWITCH#2.12 # configure eaps e2-domain secondary port 1:4
* AGG-SWITCH#2.13 # configure eaps e3-domain primary port 2:1
* AGG-SWITCH#2.14 # configure eaps e3-domain secondary port 3:1
* AGG-SWITCH#2.15 # configure eaps e4-domain primary port 2:1
* AGG-SWITCH#2.16 # configure eaps e4-domain secondary port 3:2

EAPS transit node configuration:

* AGG-SWITCH#1.1 # create eaps e1-domain
* AGG-SWITCH#1.2 # create eaps e2-domain
* AGG-SWITCH#1.3 # create eaps e3-domain
* AGG-SWITCH#1.4 # create eaps e4-domain
* AGG-SWITCH#1.5 # configure eaps e1-domain mode transit
* AGG-SWITCH#1.6 # configure eaps e2-domain mode transit
* AGG-SWITCH#1.7 # configure eaps e3-domain mode transit
* AGG-SWITCH#1.8 # configure eaps e4-domain mode transit
* AGG-SWITCH#1.9 # configure eaps e1-domain primary port 2:1
* AGG-SWITCH#1.10 # configure eaps e1-domain secondary port 1:1
* AGG-SWITCH#1.11 # configure eaps e2-domain primary port 2:1
* AGG-SWITCH#1.12 # configure eaps e2-domain secondary port 1:4
* AGG-SWITCH#1.13 # configure eaps e3-domain primary port 2:1
* AGG-SWITCH#1.14 # configure eaps e3-domain secondary port 3:1
* AGG-SWITCH#1.15 # configure eaps e4-domain primary port 2:1
* AGG-SWITCH#1.16 # configure eaps e4-domain secondary port 3:2

Creating and Configuring the EAPS Control VLANs

1 Create the EAPS control VLANs (one for each domain) and configure the 802.1q tag and ring ports for each.
Configure the control VLANs as part of their respective EAPS domain.
The control VLAN only contains the EAPS primary and secondary ports configured earlier. The following commands are entered on both aggregate switches:

```
* AGG-SWITCH.17 # create vlan control-1
* AGG-SWITCH.18 # create vlan control-2
* AGG-SWITCH.19 # create vlan control-3
* AGG-SWITCH.20 # create vlan control-4
* AGG-SWITCH.21 # configure vlan control-1 tag 4001
* AGG-SWITCH.22 # configure vlan control-2 tag 4002
* AGG-SWITCH.23 # configure vlan control-3 tag 4003
* AGG-SWITCH.24 # configure vlan control-4 tag 4004
* AGG-SWITCH.29 # configure vlan control-1 add port 2:1,1:1 tagged
* AGG-SWITCH.30 # configure vlan control-2 add port 2:1,1:4 tagged
* AGG-SWITCH.31 # configure vlan control-3 add port 2:1,3:1 tagged
* AGG-SWITCH.32 # configure vlan control-4 add port 2:1,3:2 tagged
* AGG-SWITCH.33 # configure eaps e1-domain add control vlan control-1
* AGG-SWITCH.34 # configure eaps e2-domain add control vlan control-2
* AGG-SWITCH.35 # configure eaps e3-domain add control vlan control-3
* AGG-SWITCH.36 # configure eaps e4-domain add control vlan control-4
```

Creating and Configuring the EAPS Shared Ports

- Create the EAPS shared ports, which are used to connect a common-link between the aggregate switches.

On the first switch, define the shared port mode as partner, and define the link ID. Repeat this step on the other aggregate switch, but configure the shared port mode as controller. The link ID matches the value configured for the partner.

The following shows an example configuration for the partner:

```
* AGG-SWITCH#2.37 # create eaps shared-port 2:1
* AGG-SWITCH#2.38 # configure eaps shared-port 2:1 mode partner
* AGG-SWITCH#2.39 # configure eaps shared-port 2:1 link-id 21
```

Enabling the EAPS Protocol and EAPS Domain

- Enable the EAPS protocol on the switch, and enable EAPS to run on each domain created.

The following commands are entered on both aggregate switches.

```
* AGG-SWITCH.40 # enable eaps
* AGG-SWITCH.41 # enable eaps e1-domain
* AGG-SWITCH.42 # enable eaps e2-domain
* AGG-SWITCH.43 # enable eaps e3-domain
* AGG-SWITCH.44 # enable eaps e4-domain
```

Creating and Configuring the EAPS Protected VLANs

1. Create the EAPS protected VLANs for each domain.
2. Configure an 802.1q tag and the ports for each protected VLAN.
3. Configure each protected VLAN as part of the EAPS domain.

Depending on the scope of the VLAN, it could be added to multiple EAPS domains. This type of VLAN is referred to as an overlapping protected VLAN, and requires shared port configurations.

In this example, there is one overlapping protected VLAN, purple-1, while all other VLANs are isolated to a single EAPS domain (VLANs green-1, orange-1, and red-1). Protected VLAN configuration, such as 802.1q tagging, must match on the edge switch. The commands in the following example are entered on both aggregate switches.
This procedure can also be repeated for additional protected VLANs as needed:

* AGG-SWITCH.44 # create vlan purple-1
* AGG-SWITCH.45 # create vlan green-1
* AGG-SWITCH.46 # create vlan orange-1
* AGG-SWITCH.47 # create vlan red-1
* AGG-SWITCH.48 # configure purple-1 tag 1
* AGG-SWITCH.49 # configure green-1 tag 2
* AGG-SWITCH.50 # configure orange-1 tag 3
* AGG-SWITCH.51 # configure red-1 tag 4
* AGG-SWITCH.52 # configure eaps e1-domain add protect vlan purple-1
* AGG-SWITCH.53 # configure eaps e2-domain add protect vlan purple-1
* AGG-SWITCH.54 # configure eaps e3-domain add protect vlan purple-1
* AGG-SWITCH.55 # configure eaps e4-domain add protect vlan purple-1
* AGG-SWITCH.56 # configure eaps e2-domain add protect vlan green-1
* AGG-SWITCH.57 # configure eaps e3-domain add protect vlan orange-1
* AGG-SWITCH.58 # configure eaps e4-domain add protect vlan red-1
* AGG-SWITCH.59 # configure vlan purple-1 add port 2:1,1:1,1:4,3:1,3:2 tagged
* AGG-SWITCH.60 # configure vlan green-1 add port 2:1,1:4 tagged
* AGG-SWITCH.61 # configure vlan orange-1 add port 2:1,3:1 tagged
* AGG-SWITCH.62 # configure vlan red-1 add port 2:1,3:2 tagged

### Verifying the EAPS Configuration and Operating State

1. When the configuration is complete, confirm that the EAPS domain and shared port configuration is correct.
2. Verify whether the EAPS state is Complete and the shared port status is Ready.
   
   Both ring ports must be plugged in to see the Links-Up state. This verification is performed on both aggregate switches.

EAPS master and partner node status verification example:

```
* AGG-SWITCH#2.63 # show eaps
EAPS Enabled: Yes
EAPS Fast-Convergence: Off
EAPS Display Config Warnings: On
EAPS Multicast Add Ring Ports: Off
EAPS Multicast Send IGMP Query: On
EAPS Multicast Temporary Flooding: Off
EAPS Multicast Temporary Flooding Duration: 15 sec
Number of EAPS instances: 4
# EAPS domain configuration :
--------------------------------------------------------------------------------
Domain State Mo En Pri Sec  Control-Vlan VID Count

-------------------------------------
2:1 Controller 21 Y Ready 4 4 Yes None None
```

Designing and Configuring L3 Services on EAPS

This section explains how to run L3 routing services on top of EAPS as a foundation.

In this example, OSPF is used as the dynamic IP routing protocol to communicate between different VLANs. To provide redundancy at the router level, VRRP is used to protect against an aggregation switch failure. VRRP allows one aggregation switch to route IP traffic, and if it fails the other aggregation switch takes over the IP routing role. Each EAPS protected VLAN provides L3 connectivity to the clients by configuring IP addressing, OSPF routing, and VRRP on the aggregation switches.
IP routing is added to the design on the access network switches by configuring each EAPS protected VLAN as an OSPF interface. Because these are broadcast OSPF interfaces, we need to specify a Designated Router (DR) and Backup Designated Router (BDR). While the EAPS transit and controller node is not blocking any ports, it is configured as the OSPF DR.

The EAPS master and partner node is then configured as the BDR. Similarly, the EAPS transit and controller node is also configured as the VRRP master, which provides L3 routing to the hosts. The EAPS master and partner node is configured as the VRRP backup router for redundancy.

Using redundant aggregation switches with VRRP protects against a single point of failure at the switch level. Client devices receive non-stop IP routing services in the event of link or aggregation switch failure without any reconfiguration. OSPF provides fast convergence from any routing failures. EAPS provides the resilient L2 foundation and minimizes the occurrence of routing interface flaps or dropped OSPF neighbor adjacencies.

To configure L3 on the aggregation switches, completed the tasks described in the following sections:
1 Configure OSPF on the EAPS protected VLANs.
2 Configure OSPF on the EAPS protected VLANs.
3 Configure VRRP on the EAPS protected VLANs.
4 Verify OSPF and VRRP configuration status.

Configuring IP Addresses on the EAPS Protected VLANs

Client host stations need the IP address configuration to match their protected VLANs. The edge switches do not require IP addresses, but this could optionally be done for management or troubleshooting purposes.

The following example shows IP address configuration:

```
* AGG-SWITCH#1.1  # configure vlan green-1 ipaddress 172.16.1.1/24
* AGG-SWITCH#1.2  # configure vlan purple-1 ipaddress 172.16.2.1/24
* AGG-SWITCH#1.3  # configure vlan orange-1 ipaddress 172.16.3.1/24
* AGG-SWITCH#1.4  # configure vlan red-1 ipaddress 172.16.4.1/24
* AGG-SWITCH#2.1  # configure vlan green-1 ipaddress 172.16.1.2/24
* AGG-SWITCH#2.2  # configure vlan purple-1 ipaddress 172.16.2.2/24
* AGG-SWITCH#2.3  # configure vlan orange-1 ipaddress 172.16.3.2/24
* AGG-SWITCH#2.4  # configure vlan red-1 ipaddress 172.16.4.2/24
```

Configuring OSPF on the EAPS Protected VLANs

Because OSPF broadcast networks are being used, configure the DR and BDR for each VLAN. Configure the EAPS transit and controller as the DR by using a higher OSPF priority value since it is not performing L2 blocking. The EAPS master and partner switch is configured as the BDR. In this example, all edge EAPS protected VLANs are placed in the OSPF backbone area, but another OSPF area could be created if desired.

Example OSPF DR configuration:

```
* AGG-SWITCH#1.5  # enable ipforwarding vlan green-1
* AGG-SWITCH#1.6  # enable ipforwarding vlan purple-1
* AGG-SWITCH#1.7  # enable ipforwarding vlan orange-1
* AGG-SWITCH#1.8  # enable ipforwarding vlan red-1
* AGG-SWITCH#1.9  # configure ospf routerid 172.16.1.1
* AGG-SWITCH#1.10 # configure ospf add vlan green-1 area 0.0.0.0
* AGG-SWITCH#1.11 # configure ospf add vlan purple-1 area 0.0.0.0
* AGG-SWITCH#1.12 # configure ospf add vlan orange-1 area 0.0.0.0
* AGG-SWITCH#1.13 # configure ospf add vlan red-1 area 0.0.0.0
* AGG-SWITCH#1.14 # configure ospf vlan green-1 priority 110
* AGG-SWITCH#1.15 # configure ospf vlan purple-1 priority 110
* AGG-SWITCH#1.16 # configure ospf vlan orange-1 priority 110
* AGG-SWITCH#1.17 # configure ospf vlan red-1 priority 110
* AGG-SWITCH#1.18 # enable ospf
```

Example OSPF BDR configuration:

```
* AGG-SWITCH#2.5  # enable ipforwarding vlan green-1
* AGG-SWITCH#2.6  # enable ipforwarding vlan purple-1
* AGG-SWITCH#2.7  # enable ipforwarding vlan orange-1
* AGG-SWITCH#2.8  # enable ipforwarding vlan red-1
* AGG-SWITCH#2.9  # configure ospf routerid 172.16.1.2
* AGG-SWITCH#2.10 # configure ospf add vlan green-1 area 0.0.0.0
* AGG-SWITCH#2.11 # configure ospf add vlan purple-1 area 0.0.0.0
* AGG-SWITCH#2.12 # configure ospf add vlan orange-1 area 0.0.0.0
* AGG-SWITCH#2.13 # configure ospf add vlan red-1 area 0.0.0.0
* AGG-SWITCH#2.14 # configure ospf vlan green-1 priority 100
* AGG-SWITCH#2.15 # configure ospf vlan purple-1 priority 100
```
Configuring VRRP on the EAPS Protected VLANs

The VRRP virtual router (VR) is configured with the virtual IP address of 172.16.x.254 for each VLAN (example VLAN green-1 = 172.16.1.254). The VRRP virtual router IP address is configured as the default gateway of each client machine. Since it is not performing L2 blocking, configure the EAPS transit and controller as VRRP master router by using a higher priority value. The EAPS master and partner switch is configured as the VRRP backup router.

Example VRRP master router configuration:

* AGG-SWITCH#1.19 # create vrrp vlan green-1 vrid 1
* AGG-SWITCH#1.20 # configure vrrp vlan green-1 vrid 1 priority 110
* AGG-SWITCH#1.21 # configure vrrp vlan green-1 vrid 1 add 172.16.1.254
* AGG-SWITCH#1.22 # enable vrrp vlan green-1 vrid 1
* AGG-SWITCH#1.23 # create vrrp vlan purple-1 vrid 1
* AGG-SWITCH#1.24 # configure vrrp vlan purple-1 vrid 1 priority 100
* AGG-SWITCH#1.25 # configure vrrp vlan purple-1 vrid 1 add 172.16.2.254
* AGG-SWITCH#1.26 # enable vrrp vlan purple-1 vrid 1
* AGG-SWITCH#1.27 # create vrrp vlan orange-1 vrid 1
* AGG-SWITCH#1.28 # configure vrrp vlan orange-1 vrid 1 priority 110
* AGG-SWITCH#1.29 # configure vrrp vlan orange-1 vrid 1 add 172.16.3.254
* AGG-SWITCH#1.30 # enable vrrp vlan orange-1 vrid 1
* AGG-SWITCH#1.31 # create vrrp vlan red-1 vrid 1
* AGG-SWITCH#1.32 # configure vrrp vlan red-1 vrid 1 priority 110
* AGG-SWITCH#1.33 # configure vrrp vlan red-1 vrid 1 add 172.16.4.254
* AGG-SWITCH#1.34 # enable vrrp vlan red-1 vrid 1

Example VRRP backup router configuration:

* AGG-SWITCH#2.19 # create vrrp vlan green-1 vrid 1
* AGG-SWITCH#2.20 # configure vrrp vlan green-1 vrid 1 priority 100
* AGG-SWITCH#2.21 # configure vrrp vlan green-1 vrid 1 add 172.16.1.254
* AGG-SWITCH#2.22 # enable vrrp vlan green-1 vrid 1
* AGG-SWITCH#2.23 # create vrrp vlan purple-1 vrid 1
* AGG-SWITCH#2.24 # configure vrrp vlan purple-1 vrid 1 priority 100
* AGG-SWITCH#2.25 # configure vrrp vlan purple-1 vrid 1 add 172.16.2.254
* AGG-SWITCH#2.26 # enable vrrp vlan purple-1 vrid 1
* AGG-SWITCH#2.27 # create vrrp vlan orange-1 vrid 1
* AGG-SWITCH#2.28 # configure vrrp vlan orange-1 vrid 1 priority 100
* AGG-SWITCH#2.29 # configure vrrp vlan orange-1 vrid 1 add 172.16.3.254
* AGG-SWITCH#2.30 # enable vrrp vlan orange-1 vrid 1
* AGG-SWITCH#2.31 # create vrrp vlan red-1 vrid 1
* AGG-SWITCH#2.32 # configure vrrp vlan red-1 vrid 1 priority 100
* AGG-SWITCH#2.33 # configure vrrp vlan red-1 vrid 1 add 172.16.4.254
* AGG-SWITCH#2.34 # enable vrrp vlan red-1 vrid 1

Verifying OSPF and VRRP Configuration Status

1. Verify the OSPF neighbor adjacencies are established and that the DR and BDR status is correct.
2. Verify that the VRRP VR is running and the VRRP master/backup status is correct.

OSPF and VRRP verification example:

* AGG-SWITCH#1.35 # show ospf neighbor
  Neighbor ID Pri State Up/Dead Time Address Interface
  172.16.1.2 100 FULL /BDR 00:18:01:08/00:00:00:00:03 172.16.3.2 orange-1
  172.16.1.2 100 FULL /BDR 00:18:01:08/00:00:00:00:03 172.16.4.2 red-1
  172.16.1.2 100 FULL /BDR 00:17:54:17/00:00:00:00:03 172.16.1.2 green-1
Designing and Configuring the Core Layer with EAPS

The core switches provide high performance backbone routing between the edge, aggregation, data center, and external Internet networks.

An additional high availability backbone ring is built that combines EAPS and OSPF. Using EAPS and OSPF together increases the stability of IP routing tables. Since EAPS provides 50-millisecond convergence for link failures, OSPF adjacencies do not flap. In this example, the backbone ring is formed by adding two core L2/L3 switches and connecting them to the two existing aggregation switches. The core switches also provide routing to the Internet using BGP (see Figure 136).
Using redundant core switches protects against a single point of failure at the switch level. OSPF provides fast convergence from any routing failures. EAPS provides the resilient L2 foundation and minimizes the occurrence of routing interface flaps or dropped OSPF neighbor adjacencies. Combining EAPS and OSPF provides the highest level of network resiliency and routing stability.

Configuring the core switches requires a new EAPS domain with a single EAPS protected VLAN with OSPF forming the backbone IP network. Additional configuration is needed on the aggregation switches to connect them to the backbone EAPS and OSPF ring. Since the steps are similar to previous configuration examples, the L2 (EAPS) and L3 (OSPF) configurations are combined. Since the BGP configuration is independent of EAPS configuration, BGP configuration is not discussed here.

To configure backbone connectivity on the core and aggregation switches, complete the tasks described in the following sections:

1. Create and configure the backbone EAPS domain.
2. Create and configure the backbone EAPS protected VLANs.
3. Configure an IP address and OSPF on the backbone VLAN.
4. Verify EAPS and OSPF configuration status.
Creating and Configuring the Backbone EAPS Domain

1. Create the backbone EAPS domains and configure the EAPS mode.
2. Define the primary and secondary ports for each domain.
   Configure on both core and aggregation switches.

Core-Switch 1 EAPS configuration:
* CORE-SWITCH#1.1 # create eaps e5-domain
* CORE-SWITCH#1.2 # configure eaps e5-domain mode transit
* CORE-SWITCH#1.3 # configure eaps e5-domain primary port 2:1
* CORE-SWITCH#1.4 # configure eaps e5-domain secondary port 2:4

Core-Switch 2 EAPS configuration:
* CORE-SWITCH#2.1 # create eaps e5-domain
* CORE-SWITCH#2.2 # configure eaps e5-domain mode master
* CORE-SWITCH#2.3 # configure eaps e5-domain primary port 2:1
* CORE-SWITCH#2.4 # configure eaps e5-domain secondary port 2:4

Agg-Switch 1 EAPS configuration:
* AGG-SWITCH#1.1 # create eaps e5-domain
* AGG-SWITCH#1.2 # configure eaps e5-domain mode transit
* AGG-SWITCH#1.3 # configure eaps e5-domain primary port 2:1
* AGG-SWITCH#1.4 # configure eaps e5-domain secondary port 2:4

Agg-Switch 2 EAPS configuration:
* AGG-SWITCH#2.1 # create eaps e5-domain
* AGG-SWITCH#2.2 # configure eaps e5-domain mode transit
* AGG-SWITCH#2.3 # configure eaps e5-domain primary port 2:1
* AGG-SWITCH#2.4 # configure eaps e5-domain secondary port 2:4

Creating and Configuring the Backbone EAPS Control VLAN

1. Create the EAPS control VLAN and configure its 802.1q tag, and ring ports.
2. Configure the control VLANs as part of the backbone EAPS domain. Enable EAPS and the backbone EAPS domain. Configure on both core and aggregation switches (EAPS is already enabled on aggregation switches).

Core-Switch#1 control VLAN configuration:
* CORE-SWITCH#1.1 # create vlan control-5
* CORE-SWITCH#1.2 # configure vlan control-5 tag 4005
* CORE-SWITCH#1.4 # configure vlan control-5 add port 2:1,2:4 tagged
* CORE-SWITCH#1.5 # configure eaps e5-domain add control vlan control-5
* CORE-SWITCH#1.6 # enable eaps
* CORE-SWITCH#1.7 # enable eaps e5-domain

Core-Switch#2 control VLAN configuration:
* CORE-SWITCH#2.1 # create vlan control-5
* CORE-SWITCH#2.2 # configure vlan control-5 tag 4005
* CORE-SWITCH#2.4 # configure vlan control-5 add port 2:1,2:4 tagged
* CORE-SWITCH#2.5 # configure eaps e5-domain add control vlan control-5
* CORE-SWITCH#2.6 # enable eaps
* CORE-SWITCH#2.7 # enable eaps e5-domain

Agg-Switch#1 control VLAN configuration:
* AGG-SWITCH#1.1 # create vlan control-5
* AGG-SWITCH#1.2 # configure vlan control-5 tag 4005
* AGG-SWITCH#1.4 # configure vlan control-5 add port 2:4,2:6 tagged
Creating and Configuring the Backbone EAPS Protected VLANs

1. Create the EAPS protected VLAN for the backbone domain.
2. Configure the 802.1q tag and ports for the protected VLANs. Because this VLAN is only used for transit routing, there are no other ports besides the ring ports.
3. Configure the protected VLAN as part of the EAPS domain. Do this configuration on both the core and aggregate switches.

Core-Switch#1 protected VLAN configuration:
* CORE-SWITCH#1.8 # create vlan backbone
* CORE-SWITCH#1.9 # configure vlan backbone tag 3000
* CORE-SWITCH#1.10 # configure vlan backbone add port 2:1,2:4 tagged
* CORE-SWITCH#1.11 # configure eaps e5-domain add protect vlan backbone

Core-Switch#2 protected VLAN configuration:
* CORE-SWITCH#2.8 # create vlan backbone
* CORE-SWITCH#2.9 # configure vlan backbone tag 3000
* CORE-SWITCH#2.10 # configure vlan backbone add port 2:1,2:4 tagged
* CORE-SWITCH#2.11 # configure eaps e5-domain add protect vlan backbone

Agg-Switch#1 protected VLAN configuration:
* AGG-SWITCH#1.7 # create vlan backbone
* AGG-SWITCH#1.8 # configure vlan backbone tag 3000
* AGG-SWITCH#1.9 # configure vlan backbone add port 2:4,2:6 tagged
* AGG-SWITCH#1.10 # configure eaps e5-domain add protect vlan backbone

Agg-Switch#2 protected VLAN configuration:
* AGG-SWITCH#2.7 # create vlan backbone
* AGG-SWITCH#2.8 # configure vlan backbone tag 3000
* AGG-SWITCH#2.9 # configure vlan backbone add port 2:4,2:6 tagged
* AGG-SWITCH#2.10 # configure eaps e5-domain add protect vlan backbone

Configuring an IP Address and OSPF on the Backbone VLAN

1. Configure an IP address and enable IP forwarding (routing) on the backbone protected VLAN.
2. OSPF is configured and because an OSPF broadcast network is used, configure the designated router and backup designated router for each VLAN. Since it is not performing L2 blocking, configure the EAPS transit core switch as the DR by using a higher OSPF priority value. The EAPS master core switch is configured as the BDR. The aggregation transit switches need not perform DR/BDR duties for the backbone VLAN, so their OSPF priority is configured at 0 to force ODR behavior.
Core-Switch#1 OSPF configuration:

* CORE-SWITCH#1.12 # configure vlan backbone ipaddress 192.168.1.1/24
* CORE-SWITCH#1.13 # enable ipforwarding vlan backbone
* CORE-SWITCH#1.14 # configure ospf routerid 192.168.1.1
* CORE-SWITCH#1.15 # configure ospf add vlan backbone area 0.0.0.0
* CORE-SWITCH#1.16 # configure ospf vlan backbone priority 110
* CORE-SWITCH#1.17 # enable ospf

Core-Switch#2 OSPF configuration:

* CORE-SWITCH#2.12 # configure vlan backbone ipaddress 192.168.1.2/24
* CORE-SWITCH#2.13 # enable ipforwarding vlan backbone
* CORE-SWITCH#2.14 # configure ospf routerid 192.168.1.2
* CORE-SWITCH#2.15 # configure ospf add vlan backbone area 0.0.0.0
* CORE-SWITCH#2.16 # configure ospf vlan backbone priority 100
* CORE-SWITCH#2.17 # enable ospf

Agg-Switch#1 OSPF configuration:

* AGG-SWITCH#1.11 # configure vlan backbone ipaddress 192.168.1.3/24
* AGG-SWITCH#1.12 # enable ipforwarding vlan backbone
* AGG-SWITCH#1.13 # configure ospf add vlan backbone area 0.0.0.0
* AGG-SWITCH#1.14 # configure ospf vlan backbone priority 0

Agg-Switch#2 OSPF configuration:

* AGG-SWITCH#2.11 # configure vlan backbone ipaddress 192.168.1.4/24
* AGG-SWITCH#2.12 # enable ipforwarding vlan backbone
* AGG-SWITCH#2.13 # configure ospf add vlan backbone area 0.0.0.0
* AGG-SWITCH#2.14 # configure ospf vlan backbone priority 0

Verifying EAPS and OSPF Configuration Status

1. Verify that the backbone EAPS domain and OSPF configuration is correct.
2. Confirm that the OSPF neighbor adjacencies and DR/BDR/ODR status are correct. Verify this status on both aggregate switches.

Core-Switch#1 EAPS and OSPF status example:

* CORE-SWITCH#1.18 # show eaps
  EAPS Enabled: Yes
  EAPS Fast-Convergence: On
  EAPS Display Config Warnings: On
  EAPS Multicast Add Ring Ports: Off
  EAPS Multicast Send IGMP Query: On

  EAPS Multicast Temporary Flooding: Off
  EAPS Multicast Temporary Flooding Duration: 15 sec
Designing and Configuring the Data Center Switches with EAPS

Building from the network core, you can expand the network with additional EAPS rings to provide resiliency to mission-critical server farms.

The core switches provide high performance backbone routing between the data center and the rest of the network, which includes both internal and external (Internet) destinations. The core switch acts as the EAPS master node for each ring, while the data center switches act as EAPS transit nodes to complete the ring. The core switch also acts as the OSPF routing node to provide gateway routing functionality to the server-farms. For an additional level of resiliency, each server is dual-homed (dual attached) to both EAPS transit L2 switches. Even if a switch or link fails, the servers are available.

The network design and configuration is similar to the edge and aggregation EAPS and OSPF layers. The modular approach is simple and scalable, and allows additional data center rings to be added to provide room for growth. In our example, server-farms are isolated into separate categories such as external and internal service groups, which yield additional security and resiliency benefits.

To configure the data center switches, you need a new EAPS domain with a single EAPS protected VLAN to form the server-farm network. In this example, two data center switches are configured as EAPS transit nodes (L2 switch only) and attach to the existing core switch acting as the EAPS master. Each server in the server-farm is dual-homed to both EAPS transit switches in the data center for additional physical resiliency. IP routing functionality is performed by the core switch via OSPF, which provides L3 connectivity to the rest of the network.
To configure data center connectivity, complete the tasks described in the following sections:

1. Create and configure the data center EAPS domain.
2. Create and configure the data center EAPS Control VLAN.
3. Create and configure the data center EAPS protected VLANs.
4. Configure an IP address and OSPF on the backbone VLAN.
5. Verify EAPS and OSPF configuration status.

**Creating and Configuring the Data Center EAPS Domain**

Create the backbone EAPS domains, configure the EAPS mode, and define the primary and secondary ports for each domain. Do this configuration on both core and aggregation switches.

Core-Switch#1 EAPS configuration:

* CORE-SWITCH#1.1 # create eaps e6-domain
* CORE-SWITCH#1.2 # configure eaps e6-domain mode master
* CORE-SWITCH#1.3 # configure eaps e6-domain primary port 4:1
* CORE-SWITCH#1.4 # configure eaps e6-domain secondary port 4:2
Data center-Switch#1 EAPS configuration:

* DC-SWITCH#1.1 # create eaps e6-domain
* DC-SWITCH#1.2 # configure eaps e6-domain mode transit
* DC-SWITCH#1.3 # configure eaps e6-domain primary port 49
* DC-SWITCH#1.4 # configure eaps e6-domain secondary port 50

Datacenter -Switch#2 EAPS configuration:

* DC-SWITCH#2.1 # create eaps e6-domain
* DC-SWITCH#2.2 # configure eaps e6-domain mode transit
* DC-SWITCH#2.3 # configure eaps e6-domain primary port 49
* DC-SWITCH#2.4 # configure eaps e6-domain secondary port 50

**Creating and Configuring the Data Center EAPS Control VLAN**

1. Create the EAPS control VLAN and configure its 802.1q tag, and ring ports.
2. Configure the control VLANs as part of the data center EAPS domain. Enable EAPS and the data center EAPS domain. You need to do this configuration on the core and data center L2 switches.

**Core-Switch#1 control VLAN configuration:**

* CORE-SWITCH#1.1 # create vlan control-6
* CORE-SWITCH#1.2 # configure vlan control-6 tag 4006
* CORE-SWITCH#1.4 # configure vlan control-6 add port 4:1,4:2 tagged
* CORE-SWITCH#1.5 # configure eaps e5-domain add control vlan control-6
* CORE-SWITCH#1.6 # enable eaps

**Data center-Switch#1 control VLAN configuration:**

* DC-SWITCH#1.1 # create vlan control-6
* DC-SWITCH#1.2 # configure vlan control-6 tag 4006
* DC-SWITCH#1.4 # configure vlan control-6 add port 49,50 tagged
* DC-SWITCH#1.5 # configure eaps e6-domain add control vlan control-6
* DC-SWITCH#1.6 # enable eaps
* DC-SWITCH#1.7 # enable eaps e6-domain

**Datacenter-Switch#2 control VLAN configuration:**

* DC-SWITCH#2.1 # create vlan control-6
* DC-SWITCH#2.2 # configure vlan control-6 tag 4006
* DC-SWITCH#2.4 # configure vlan control-6 add port 49,50 tagged
* DC-SWITCH#2.5 # configure eaps e6-domain add control vlan control-6
* DC-SWITCH#2.6 # enable eaps
* DC-SWITCH#2.7 # enable eaps e6-domain

**Create and Configure the Data Center EAPS Protected VLANS**

1. Create the EAPS protected VLAN for the data center domain.
2. Configure the 802.1q tag and ports for the protected VLANS. Because each server is dual-homed to each data center switch, add a VLAN port on each switch for each server.
3. Configure the protected VLAN as part of the EAPS domain. Do this configuration on the core and data center switches.

**Core-Switch#1 protected VLAN configuration:**

* CORE-SWITCH#1.7 # create vlan srvfarm-1
* CORE-SWITCH#1.8 # configure vlan srvfarm-1 tag 1000
* CORE-SWITCH#1.9 # configure vlan srvfarm-1 add port 4:1,4:2 tagged
* CORE-SWITCH#1.10 # configure eaps e6-domain add protect vlan srvfarm-1
Data center-Switch#1 protected VLAN configuration:

- DC-SWITCH#1.8 # create vlan srvfarm-1
- DC-SWITCH#1.9 # configure vlan srvfarm-1 tag 1000
- DC-SWITCH#1.10 # configure vlan srvfarm-1 add port 49,50 tagged
- DC-SWITCH#1.11 # configure vlan srvfarm-1 add port 1 untagged
- DC-SWITCH#1.12 # configure eaps e5-domain add protect vlan srvfarm-1

Data center-Switch#2 protected VLAN configuration:

- DC-SWITCH#2.8 # create vlan srvfarm-1
- DC-SWITCH#2.9 # configure vlan srvfarm-1 tag 1000
- DC-SWITCH#2.10 # configure vlan srvfarm-1 add port 49,50 tagged
- DC-SWITCH#2.11 # configure vlan srvfarm-1 add port 1 untagged
- DC-SWITCH#2.12 # configure eaps e5-domain add protect vlan srvfarm-1

### Configuring an IP Address and OSPF on the Backbone VLAN

Configure an IP address and enable IP forwarding (routing) on the data center protected VLAN.

This step is only performed on the core switch. Servers are configured accordingly with the core switch IP address as their default gateway. Since there are no additional routers on this VLAN, configure it as an OSPF passive interface. In this example, the data center VLAN is placed on the backbone OSPF area, but additional OSPF areas can be configured if needed.

Core-Switch#1 OSPF configuration:

- CORE-SWITCH#1.11 # configure vlan srvfarm-1 ipaddress 10.10.10.10/24
- CORE-SWITCH#1.12 # enable ipforwarding vlan srvfarm-1
- CORE-SWITCH#1.13 # configure ospf add vlan srvfarm-1 area 0.0.0.0 passive

### Verifying EAPS and OSPF Configuration Status

1. Verify that the data center EAPS domain and OSPF configuration is correct.
2. Verify whether the data center subnet is advertised to other routers through OSPF.

Core-Switch#2 route verification example:

- CORE-SWITCH#2.1 # show iproute 10.10.10.0/24
  
  | Origin (Ori): (b) BlackHole, (be) EBGP, (bg) BGP, (bi) IBGP, (bo) BOOTP |

CFM Support in EAPS

ExtremeXOS provides Connectivity Fault Management (CFM) support within EAPS protocol.
CFM reports fault connectivity failures to EAPS, and EAPS communicates with the CFM process to set up point-to-point DOWN MEPs (Management Endpoints) to monitor link connectivity. The CFM module notifies EAPS of any link-connectivity issues, and triggers EAPS to take necessary action.

802.1ag CFM supports link monitoring. It does this by sending out PDUs at designated transmit intervals. If the CFM fails to receive PDUs, it assumes the link is out of service, and notifies its clients. In this instance, EAPS acts as a CFM client.

First, you will create a down MEP within the CFM CLI. Configure the CLI to create a MEP group that associates this down MEP with a remote MEP (RMEP). There is a 1:1 relationship between a port and the down MEP, and as such, each MEP group is tied to a single port. Using the EAPS CLI, you can add the MEP groups you wish to monitor. For each MEP group added to EAPS, EAPS will receive UP/DOWN notifications from CFM when CFM detects a MEP state change for that group. Each MEP group corresponds to an EAPS ring port. Notifications from those MEP groups that are inadvertently added—that do not correspond to an EAPS ring port—are ignored in EAPS.

The CFM configuration is independent of EAPS, and MEPs and MEP groups may use different VLANs other than the EAPS control VLAN to monitor links.

When EAPS receives a CFM notification that the link failed, EAPS blocks that port on all of the EAPS control VLANs. This prevents EAPS control PDUs from being hardware forwarded on the link, in case the link is still up. Any EAPS PDUs that are received on a CFM failed port are dropped in EAPS. It is generally recommended to have the CCM interval as short as possible to detect link failures faster, which improves convergence time.

Configuring EAPS for CFM Support

- Use the following command to configure EAPS for CFM support:

```
configure eaps cfm [add | delete] group group_name
```

For additional configuration details for CFM support, refer to Configuring CFM on page 414.

Binding to a MEP Group

- To bind to a MEP Group, use the following command:

```
configure eaps cfm [add | delete] group group_name
```

This command notifies CFM that EAPS is interested in notifications for this MEP and RMEP pair. This MEP should already be bound to a physical port, so when notification is received, EAPS associates that notification with a ring-port failure.

Create MPs and the CCM Transmission Interval

Within an MA, you configure the following MPs:

- Maintenance end points (MEPs), which are one of the following types:
  - UP MEPs—transmit CCMs and maintain CCM database
  - DOWN MEPs—transmit CCMs and maintain CCM database
  - Maintenance intermediate points (MIPs)—pass CCMs through

Each MEP must have an ID that is unique for that MEP throughout the MA.
• To configure UP and DOWN MEPS and its unique MEP ID, use the following command:
  ```
  configure cfm domain domain_name association association_name [ports port_list add [[end-point [up|down] mepid (group group_name)] | [intermediate-point]]
  ```

• To change the MEP ID on an existing MEP, use the following command:
  ```
  configure cfm domain domain-name association association_name ports port_list end-point [up | down] mepid mepid
  ```

• To delete UP and DOWN MEPS, use the following command:
  ```
  configure cfm domain domain-name association association_name ports port_list delete end-point [up | down] intermediate-point
  ```

• To configure a MIP, use the following command:
  ```
  configure cfm domain domain_name association association_name [ports port_list add [[end-point [up|down] mepid {group group_name}] | [intermediate-point]]
  ```

• To delete a MIP, use the following command:
  ```
  configure cfm domain domain_name association association_name [ports port_list delete [[end-point [up|down] mepid {group group_name}] | [intermediate-point]]
  ```

• To configure the transmission interval for the MEP to send CCMs, use the following command:
  ```
  configure cfm domain domain_name association association_name {ports port_list end-point [up | down]} transmit-interval [3|10|100|1000|10000|60000|600000]
  ```

• To unconfigure the transmission interval for the MEP to send CCMs and return it to the default, use the following command:
  ```
  unconfigure cfm domain domain_name association association_name {ports port_list end-point [up | down]} transmit-interval
  ```

• To enable or disable a MEP, use the following command:
  ```
  configure cfm domain domain_name association association_name ports port_list end-point [up | down] [enable | disable]
  ```

### Displaying EAPS MEP Group Bindings

- Display EAPS MEP group bindings with the command: `show eaps cfm groups`

  ```
  # sh eaps cfm groups
  -------------------------------
  MEP Group Name    Status Port MEP ID
  -------------------------------
  eapsCfmGrp1       Up 41  11
  eapsCfmGrp2       Up 31  12
  -------------------------------
  ```

### Displaying EAPS Output Change

- Display EAPS output changes using the command `show eaps`

  The existing output places a ! next to a CFM monitored ring port if the CFM indicates the MEP group for that port is down.

  ```
  # sh eaps
  EAPS Enabled: Yes
  EAPS Fast-Convergence: Off
  ```
EAPS Display Config Warnings: Off
EAPS Multicast Add Ring Ports: Off
EAPS Multicast Send IGMP Query: On
EAPS Multicast Temporary Flooding: Off
EAPS Multicast Temporary Flooding Duration: 15 sec
Number of EAPS instances: 1

Configuration Example

Below is a sample configuration of CFM support in EAPS:

```
switch 1 # sh configuration cfm
#
# Module dot1ag configuration.
#
create cfm domain string "MD1" md-level 6
configure cfm domain "MD1" add association string "MD1v1" vlan "v1"
create cfm domain "MD1" add association string "MD1v2" vlan "v2"
configure cfm domain "MD1" association "MD1v1" ports 17 add end-point down 6
configure cfm domain "MD1" association "MD1v2" ports 17 add end-point down 5
configure cfm domain "MD1" association "MD1v1" ports 31 add end-point down 13
configure cfm domain "MD1" association "MD1v2" ports 17 add end-point down add group "eapsCfmGrp1"
configure cfm domain "MD1" association "MD1v1" ports 23 end-point down add group "eapsCfmGrp2"
configure cfm domain "MD1" association "MD1v2" ports 31 end-point down add group "eapsCfmGrp3"
configure cfm group "eapsCfmGrp1" add rmep 2
configure cfm group "eapsCfmGrp2" add rmep 4
configure cfm group "eapsCfmGrp3" add rmep 12

switch 2 # sh configuration "eaps"s
#
# Module eaps configuration.
#
enable eaps
create eaps d1
configure eaps d1 mode transit
configure eaps d1 primary port 17
configure eaps d1 secondary port 23
enable eaps d1
create eaps d2
configure eaps d2 mode transit
configure eaps d2 primary port 31
configure eaps d2 secondary port 23
enable eaps d2
configure eaps d1 add control vlan v1
configure eaps d1 add protected vlan pv1
configure eaps d2 add control vlan v2
configure eaps d2 add protected vlan pv2
create eaps shared-port 23
configure eaps shared-port 23 mode partner
configure eaps shared-port 23 link-id 100
configure eaps cfm add group eapsCfmGrp1
configure eaps cfm add group eapsCfmGrp2
configure eaps cfm add group eapsCfmGrp3
```
Limitations

CFM PDU transmit intervals are limited by the supported limits of CFM module. Platforms that do not support CFM in hardware are limited to a minimum interval of 100 ms.

The maximum number of down MEPs is limited by the CFM module. This is as low as 32 MEPs in some platforms.

Platforms Supported

All ExtremeXOS platforms support this feature; however, not all platforms support hardware-based CFM.

Platforms with no hardware-based CFM support are limited to software-based CFM transmit intervals of 100 ms or higher. Hardware-based intervals can go as low as 3.3 ms.
This chapter provides an overview to ERPS, and discusses various ERPS features. The chapter also offers configuration details, provides configuration examples, and shows you how to debug ERPS.

### ERPS Overview

The basic concept of G.8032/ERPS (Ethernet Ring Protection Switching) is that traffic may flow on all links of a ring network except on one link called the Ring Protection Link (RPL).

The RPL owner is the node that blocks the RPL, and the other node of the RPL is called the RPL neighbor node. All other nodes are called non-RPL nodes. When a link fails, the RPL owner unblocks the RPL to allow connectivity to the nodes in the ring. The G.8032/ERPS rings utilize a channel (dedicated path) for carrying their control traffic which is the R-APS messages (Ring Automatic Protection Switching).

The ring protection architecture relies on the existence of an APS protocol to coordinate ring protection actions around an Ethernet ring, as shown in Figure 138.

![Figure 138: Simple Ring with RPL, RPL Owner, RPL Neighbor, and Non-RPL Nodes](image)

More complex topologies include ladder ring networks which are called sub-rings in G.8032 terminology. In these networks, there could exist one or more rings and sub-rings which complete their connectivity through the interconnected nodes of the ring(s). Multiple ladder networks are supported only if the following conditions are met:

- R-APS channels are not shared across Ethernet ring interconnections.
- On each ring port, each traffic channel and each R-APS channel are controlled by the Ethernet Ring Protection (ERP) Control process of only one Ethernet ring.
Each major ring or sub-ring must have its own RPL.

**Note**
One important aspect of sub-rings is that they complete their channel through the virtual channel (when using the virtual channel mode), which can span the network and cross the sub-ring boundaries. This entails that the virtual channel is provisioned on all the nodes it spans across.

In **Figure 139**, the ring comprises nodes A, B, C, and D with links A–B, B–C, C–D, and D–A while the control channel for this ring has its own dedicated **VLAN (Virtual LAN)**. The sub-ring consists of nodes D, F, E, and C with links D–F, F–E, and E–C. D and C are interconnected nodes. The channel for the sub-ring spans the links C–E, E–F, and F–D and their nodes while the virtual channel comprises the links D–A, A–B, B–C and D–C and their nodes. This means that the virtual channel for the sub-ring needs to not only exist on the interconnected nodes, but also on the nodes A and B.

**Figure 139: Ring and Sub-ring Network**

When using G.8032 in networks, take care to design the virtual channel paths, since the VLAN provisioning has to exist on all the nodes through which the virtual channel can pass and which is solely dedicated to the sub-ring in question.

Sub-ring topology changes may impact flow forwarding over the domain of the other (interconnected) network, as such topology change events are signaled to the domain of the other network using the Topology Change signal.

**Supported ERPS Features**

The following are the **ERPS** features supported in the current release:

- G.8032 version 1 support.
- G.8032 version 2 support with a restricted VC option.
- Revertive mode support for version 1 and 2.
- Basic interoperability with **EAPS (Extreme Automatic Protection Switching)** with G.8032 acting as an access ring. Flush notifications will be sent Link monitoring using CFM or native local link monitoring methods.
• Support for hardware accelerated CFM in specific platforms that have this capability.
• G.8032 version 2 with no Virtual Channel support.
• Support for attaching to a CFM DOWN-MEP configured external to ERPS.

G.8032 Version 2

The concept of sub-rings is introduced to add multiple rings to the main ring. A sub-ring is an incomplete ring that completes its path through the main ring or other sub-rings. The control path for the sub-ring completes either through the implementation of a virtual channel, or by changing the flow of control packets in the sub-rings. Virtual channels are supported through the use of the sub-rings control channel being configured as a data VLAN in the main ring.

You can configure the sub-ring in “no virtual channel” mode, where the control path for the sub-ring is through all the nodes of the sub-ring (including the RPL owner and neighbor). You must be careful, however, to avoid using the sub-ring’s control channel across the main ring because that will cause a loop. ExtremeXOS supports the use of CFM, in conjunction with Manual Switch (MS), to protect the sub-rings against multiple failures in the main ring.

CFM Link Monitoring

To enable CFM to report link events, the link must first be registered with CFM. ERPS acts as a client of CFM and creates the required Management Entity Points (MEPs). For G.8032 v1/v2 implementation:

It is generally recommended to have the CCM interval as short as possible to detect link failures faster, which improves convergence time.

• Creating a DOWN-MEP is by creating the DOWN-MEP with the CFM commands, and then assigning a group name to it. This group can then be associated to the ERPS ring.

Here is an example:

```
switch # sh cfm
Domain: "erps_6", MD Level: 6
Association: "erps_MA_100", Destination MAC Type: Multicast, VLAN "v2" with 2 cfm ports
  Transmit Interval: 1000 ms
  port 27; Down End Point, mepid: 11, transmit-interval: 10000 ms (configured),
  MEP State: Enabled, CCM Message: Enabled, Send SenderId TLV: Disabled
  port 37; Down End Point, mepid: 21,
  transmit-interval: 10000 ms (configured),
  MEP State: Enabled, CCM Message: Enabled, Send SenderId TLV: Disabled
Association: "erps_MA_100", Destination MAC Type: Multicast, VLAN "v2" with 2 cfm ports
  Transmit Interval: 1000 ms
  port 27; Down End Point, mepid: 11, transmit-interval: 10000 ms (configured),
  MEP State: Enabled, CCM Message: Enabled, Send SenderId TLV: Disabled
  port 37; Down End Point, mepid: 21,
  transmit-interval: 10000 ms (configured),
  MEP State: Enabled, CCM Message: Enabled, Send SenderId TLV: Disabled
```

```
switch # show cfm detail
Domain/ Port MP Remote End-Point Remote End-Point MEP Life Flags
Association MAC Address IP Address ID time Age
```

ExtremeXOS® User Guide for version 22.6
Note
You must configure a remote MEP-ID for the local MEPs so that a specific association can be maintained between the two ends.

Limitations
CFM PDU transmit intervals are limited by the supported limits of CFM module. Platforms that do not support CFM in hardware are limited to a minimum interval of 100 ms. The maximum number of down MEPs is limited by the CFM module. This is as low as 32 MEPs in some platforms.

Revertive and Non-revertive Mode
In the revertive mode, you can revert back to the RPL being blocked once the Signal Fault has cleared. In non-revertive mode, the SF remains blocked even after the fault clears. Reversion is handled in the following way:

- The reception of an R-APS No Request (NR) message causes the RPL owner node to start the wait-to-restore (WTR) timer.
- The WTR timer is cancelled if, during the WTR period, a request with a higher priority than NR is accepted by the RPL owner node, or is declared locally at the RPL owner node.
- When the WTR timer expires, without the presence of any other higher priority request, the RPL owner node initiates reversion by blocking its traffic channel over the RPL, transmitting an R-APS (NR, RB) message over both ring ports, informing the Ethernet ring that the RPL is blocked, and performing a flush FDB (forwarding database) action. The ERPS Ring will be in the idle state.
- The acceptance of the R-APS (NR, RB) message causes all Ethernet ring nodes to unblock any blocked non-RPL link that does not have an SF condition. If it is an R-APS (NR, RB) message without a DNF indication, all Ethernet ring nodes perform a necessary flush FDB action.

In non-revertive operation, the Ethernet ring does not automatically revert when all ring links and Ethernet ring nodes have recovered and no external requests are active. Non-revertive operation is handled in the following way:

- The RPL owner node does not generate a response on reception of an R-APS (NR) messages.
- When other healthy Ethernet ring nodes receive the NR (node ID) message, no action is taken in response to the message.
Force Switch

In the absence of any failure in the ring network, an operator-initiated Force Switch (FS) results in the RPL getting unblocked, and the node on which the FS has been issued is blocked. This condition is indicated by the transmission of R-APS FS messages, which are continuous until this condition is unconfigured. Two or more Forced Switches are allowed in the Ethernet ring, but this may cause the segmentation of an Ethernet ring. It is the responsibility of the operator to prevent this effect if it is undesirable.

You can remove a Forced Switch condition by issuing a clear command to the same Ethernet ring node where the Forced Switch is presented: `configure erps ring-name dynamic-state [force-switch | manual-switch | clear] port slot:port`. The clear command removes existing local operator commands and triggers reversion in case the Ethernet ring is in revertive behavior. The Ethernet ring node where the Forced Switch was cleared continuously transmits the R-APS (NR) message on both ring ports, informing that no request is present at the Ethernet ring node.

Clear Command

The clear command is described in the *ITU-T G.8032* (*Standard for ERPS*). This command allows the ERPS ring to administratively return (revert) to idle state and trigger (on the owner) the transmission of NR,RB messages that return all other nodes back to the idle state from the pending state. If it is an R-APS (NR, RB) message without a DNF indication, all Ethernet ring nodes perform a necessary flush FDB. In the revertive-mode of operation, after the link failure is cleared in the ring, the traffic channel reverts (the RPL owner node blocks its RPL port and transmits an R-APS (NR, RB) message in both directions, repeatedly) after the expiration of a WTR timer. With the clear command, the traffic channel can be made to revert without waiting for the WTR to expire. When you issue a clear command for non-revertive mode at the RPL owner node, the non-revertive operation is cleared and the traffic channel is reverted. Upon receiving an R-APS (NR, RB) message, any blocking Ethernet ring node should unblock its non-failed ring port.

To issue the clear command, use the command:

```
configure erps ring-name dynamic-state [force-switch | manual-switch | clear] port slot:port
```

Manual Switch

Manual Switch is similar to the Force Switch except that only one Manual Switch is allowed for an Ethernet ring. The processing of which node retains the Manual Switch is based on the priority table and the node state. However only one Manual Switch is retained at the end for the ring.

Clearing the Manual Switch is done similar to the Force Switch.

Virtual Channel for Sub-rings

While the standard describes how the sub-rings can function with a virtual channel, in this implementation sub-rings will function only with the presence of virtual channels.
Channel Blocking
The R-APS control channel is blocked, as is traffic on the blocked ports for the control traffic entering on one ring port and getting forwarded to the other ring port. However, locally generated or delivered control traffic on the blocked port is supported.

Traffic Blocking
Traffic is always blocked for the protected VLANs on the blocked ports of the ring/sub-ring in a G.8032 network.

Signal Failure and Recovery
In the absence of a higher priority request in the node, the following Signal Failure (SF) actions are taken.

• An Ethernet ring node detecting an SF condition on one of its ring ports blocks the traffic channel and R-APS channel on the failed ring port.
• The Ethernet ring node detecting an SF condition transmits an R-APS message indicating SF on both ring ports. The R-APS (SF) message informs other Ethernet ring nodes of the SF condition. R-APS (SF) messages are continuously transmitted by the Ethernet ring node detecting the SF condition while this condition persists. (The Periodic timer determines the interval of sending the SF after the first three.) For sub-ring interconnection nodes, the R-APS (SF) message is transmitted on the R-APS channel of the Sub-Ring port.
• Assuming the Ethernet ring node was in an idle state before the SF condition occurred, upon detection of this SF condition the Ethernet ring node triggers a local FDB flush.
• An Ethernet ring node accepting an R-APS (SF) message unblocks any blocked ring port that does not have an SF condition. This action unblocks the traffic channel on the RPL.
• An Ethernet ring node accepting an R-APS (SF) message stops transmission of other R-APS messages.
• An Ethernet ring node accepting an R-APS (SF) message without a DNF indication performs a flush FDB.

An Ethernet ring node that has one or more ring ports in an SF condition (upon detection of clearance of the SF condition) keeps at least one of these ring ports blocked for the traffic channel and for the R-APS channel, until the RPL is blocked as a result of Ethernet ring protection reversion, or until there is another higher priority request (for example, an SF condition) in the Ethernet ring. An Ethernet ring node that has one ring port in an SF condition, and detects clearing of this SF condition, continuously transmits the R-APS (NR) message with its own Node ID as the priority information over both ring ports, informing that no request is present at the Ethernet ring node and initiates a guard timer as described in sub-clause 10.1.5. Another recovered Ethernet ring node (or Nodes) holding the link block receives the message and compares the Node ID information with its own Node ID. If the received R-APS (NR) message has the higher priority, the Ethernet ring node unblocks its ring ports. Otherwise, the block remains unchanged. There is only one link with one-end block. The Ethernet ring nodes stop transmitting R-APS (NR) messages when they accept an R-APS (NR, RB), or when another higher priority request is received.

Timers
This section discusses the various timers associated with ERPS.
Guard Timer

The guard timer is used to prevent Ethernet ring nodes from acting upon outdated R-APS messages, and to prevent the possibility of forming a closed loop. The guard timer is activated whenever an Ethernet ring node receives an indication that a local switching request has cleared (i.e., local clear SF, clear). The guard timer can be configured in 10 ms steps, between 10 ms and two seconds, with a default value of 500 ms. This timer period should be greater than the maximum expected forwarding delay in which an R-APS message traverses the entire ring. The longer the period on the guard timer, the longer an Ethernet ring node is unaware of new or existing relevant requests transmitted from other Ethernet ring nodes, and is unable to react to them.

A guard timer is used in every Ethernet ring node. Once a guard timer is started, it expires by itself. While the guard timer is running, any received R-APS Request/State and Status information is blocked and not forwarded to the Priority Logic. When the guard timer is not running, the R-APS Request/State and Status information is forwarded unchanged.

Hold-off Timer

When a new defect, or more severe defect occurs (new SF), this event is not be reported immediately to protection switching if the provisioned hold-off timer is a non-zero value. Instead, the hold-off timer is started. When the hold-off timer expires, the trail that started the timer is checked to see if a defect still exists. If one does exist, that defect is reported to protection switching. The suggested range of the hold-off timer is 0 to 10 seconds in steps of 100 ms with an accuracy of ±5 ms. The default value for a hold-off timer is 0 seconds.

Delay Timers

In revertive mode, the wait-to-restore (WTR) timer is used to prevent frequent operation of the protection switching caused by intermittent signal failure defects. The wait-to-block (WTB) timer is used when clearing Forced Switch and Manual Switch commands. As multiple Forced Switch commands are allowed to coexist in an Ethernet ring, the WTB timer ensures that clearing of a single Forced Switch command does not trigger the re-blocking of the RPL. When clearing a Manual Switch command, the WTB timer prevents the formation of a closed loop due to a possible timing anomaly where the RPL owner node receives an outdated remote MS request during the recovery process.

Interoperability with EAPS

A basic G.8032 interoperability with EAPS is supported wherein the G.8032 ring is configured as sub-ring interacting with the backbone EAPS ring.

When topology changes occur in the G.8032 ring, this initiates a ring flush in the EAPS ring. This uses the same methodology that EAPS uses today when STP requires a flush. EAPS then flushes all the VLANs in its domains.

When a failure occur in the G.8032 ring, the protocol handles it and open up the RPL link. A flush message is propagated to the EAPS ring if configured to do so using the `configure erps ring-name [add | delete] topology-change-ring-list` command.
Sample Configuration

Here is a sample configuration of the ERPS feature:

create vlan cv1
config vlan cv1 tag 10
config vlan cv1 add port 5,6 tagged

create vlan pv1
config vlan pv1 tag 1000
config vlan pv1 add port 1
config vlan pv1 add port 5,6 tagged

create erps ring1
configure erps ring1 add ring-ports east 5
configure erps ring1 add ring-ports west 6
configure erps ring1 add control “cv1”
configure erps ring1 add protected vlan “pv1”
configure erps ring1 add protection-port 5
configure erps ring1 revert enabled wait-to-restore 500
enable erps r1
enable erps

CFM DOWN-MEP Configuration to Provide Link Monitoring/Notifications

create cfm domain string “MD3” md-level 3
configure cfm domain “MD3” add association string “MD3vsub1” vlan “vsub1”
configure cfm domain “MD3” association “MD3vsub1” ports 20 add end-point down 14
configure cfm domain “MD3” association “MD3vsub1” ports 24 add end-point down 13
configure cfm domain “MD3” association “MD3vsub1” ports 20 end-point down add group “erpsDn1”
configure cfm domain “MD3” association “MD3vsub1” ports 24 end-point down add group “erpsDn2”
configure cfm group “erpsDn1” add rmep 15
configure cfm group “erpsDn2” add rmep 12
configure erps subring1 cfm port east add group erpsDn2
configure erps subring1 cfm port west add group erpsDn1

Sub-ring Configuration

First, configure a main ring on the Interconnected node:

create erps main-ring1
configure erps main-ring1 add ring-ports east 5
configure erps main-ring1 add ring-ports west 6
configure erps ring1 add control “cv1”

Next, configure a sub-ring on the interconnected node:

create erps sub-ring1
configure erps sub-ring1 add ring-ports east 10
configure erps sub-ring1 add control “subv1”
configure erps main-ring1 add sub-ring sub-ring1
enable erps main-ring1
enable erps sub-ring1

Virtual Channel for Sub-ring

configure vlan subv1 add port 5 6 tagged
configure main-ring1 add protected vlan subv1
No Virtual Channel for Sub-ring

```bash
configure erps subring1 subring-mode no-virtualChannel
```

## Configuring ERPS

### ERPS Version 1 Commands

- To create or delete an ERPS ring, use the following commands:
  ```bash
  create erps ring-name
  delete erps ring-name
  ```

- To add or delete a control VLAN on the ERPS ring, use the following commands:
  ```bash
  configure erps ring-name add control {vlan} vlan_name
  configure erps ring-name delete control {vlan} vlan_name
  ```

- To add or delete a protected VLAN on the ERPS ring, use the following commands:
  ```bash
  configure erps ring-name add protected {vlan} vlan_name
  configure erps ring-name delete protected {vlan} vlan_name
  ```

- To add ring ports on the ERPS ring (this ring's ports connect the switch to the ERPS ring), use the following command:
  ```bash
  configure erps ring-name ring-ports [east | west] port
  ```

- To add ring ports on the ERPS ring, use the following command:
  ```bash
  configure erps ring-name ring-ports [east | west] port
  ```

- To configure CFM for ERPS ring ports, use the following command:
  ```bash
  configure erps ring-name cfm port [east | west] [add | delete] group group_name
  ```

- To delete ring ports on the ERPS ring, use the following command:
  ```bash
  unconfigure erps ring-name ring-ports west
  ```

- To add or delete RPL (ring protection link) owner configuration for the ERPS ring, use the following commands:
  ```bash
  configure erps ring-name protection-port port
  unconfigure erps ring-name protection-port
  ```

- To add or delete RPL (ring protection link) neighbor configuration for the ERPS ring, use the following commands:
  ```bash
  configure erps ring-name neighbor-port port
  unconfigure erps ring-name neighbor-port
  ```

- To add or delete ERPS revert operation along with the wait-to-restore time interval, use the following commands:
  ```bash
  configure {erps} ring-name revert [ enable | disable ]
  ```

- To configure the periodic timer, use the following command:
  ```bash
  configure {erps} ring-name timer periodic [ default | milliseconds ]
  ```
• To configure the guard timer, use the following command:
  
  ```
  configure {erps} ring-name timer guard [ default | milliseconds ]
  ```

• To configure the hold-off timer, use the following command:

  ```
  configure {erps} ring-name timer hold-off [ default | milliseconds ]
  ```

• To configure the wait-to-restore timer, use the following command:

  ```
  configure {erps} ring-name timer wait-to-restore [ default | milliseconds ]
  ```

• To rename the ERPS ring/sub-ring, use the following command:

  ```
  configure erps old-ring-name name new-ring-name
  ```

• To enable or disable ERPS, use the following commands:

  ```
  enable erps
disable erps
  ```

• To enable or disable an existing ERPS ring/sub-ring, use the following command:

  ```
  enable erps ring-name
disable erps ring-name
  ```

• Run or clear force and manual switch triggers, or clear command to the ERPS ring/sub-ring.

  ```
  configure erps ring-name dynamic-state [ force-switch | manual-switch | clear ] port slot:port
  ```

• To display global information for ERPS, use the following command:

  ```
  show erps
  ```

• To display specific details about an ERPS ring, use the following command:

  ```
  show erps ring-name
  ```

• To display ERPS statistics, use the following command:

  ```
  show erps ring-name statistics
  ```

• To clear statistics on an ERPS ring, use the following command:

  ```
  clear counters erps ring-name
  ```

• To debug ERPS, use the following commands:

  ```
  debug erps [options]
ddebug erps show ring-name
  ```

**ERPS Version 2 Commands**

• To set the rings to which to propagate topology change events, use the following command:

  ```
  configure erps ring-name [ add | delete ] topology-change ring-list
  ```

• To enable or disable the ability of ERPS to allow the topology-change bit to be set (to send out Flush events), use the following commands:

  ```
  enable erps ring-name topology-change
disable erps ring-name topology-change
  ```

• To add or delete a sub-ring to the main ring, use the following command:

  ```
  configure {erps} ring-name [ add | delete ] sub-ring-name sub_ring
  ```
To configure the wait-to-block timer, use the following command:

```
configure {erps} ring-name timer wait-to-block [ default | milliseconds]
```

To add or delete an ERPS sub-ring to the EAPS domain, use the following commands:

```
configure {erps} ring-name notify-topology-change {eaps} domain_name
unconfigure {erps} ring-name notify-topology-change {eaps} domain_name
```

To configure a wait-to-block timer, use the following command:

```
configure {erps} ring-name timer wait-to-block [ default | milliseconds]
```

To configure sub-ring mode, use the following command:

```
configure erps ring_name subring-mode [no-virtualChannel | virtualChannel]
```

create erps sub_ring
```
configure erps sub_ring add control vlan c_vlan_sub
configure erps sub_ring ring-port east 2
configure erps sub_ring ring-port west 1
configure erps sub_ring protection-port 1
configure erps sub_ring cfm port east add group d5d2
configure erps sub_ring cfm port west add group d5d4
configure erps sub_ring add protected vlan p_vlan
enable erps
enable erps sub_ring

**Note**
ERPS Virtual channel is enabled in the above configuration by creating a control vlan of the sub-ring [c_vlan_sub] and added as a protected vlan in switch A, B and C’s main ring.

### Debugging ERPS

1. Check the output of `show erps ring statistics` to see if any error/dropped counters are incrementing.
   a. If they are, check the state of the ring ports and trace these links to the neighbor node to see the state of the links.
   
   The output of `show log` after turning on the filters for ERPS should provide more information on what is happening on the switch.

2. Check the output of `show erps` and `show erps ring` to see if the node state is as expected.
   In steady state, the node should be in “Idle” and the failed state ring should be in “Protected” state.

### ERPS Feature Limitations

The following are ERPS feature limitations:

- Backup failover and checkpointing for both v1 and v2 are not available in the current release.
- In platforms that do not have hardware OAM (operations and management), the optimum CFM interval recommended is one second for link monitoring, which will give rise to approximately three-second overhead in convergence times.

**Note**
For optimum performance and convergence, it is recommended to use fiber cables.

- Other than the basic EAPS interoperability stated above, all other EAPS related interoperability is not supported.
- There is no interoperability with STP (Spanning Tree Protocol) in the current release.
Using the STP (Spanning Tree Protocol) functionality of the switch makes your network more fault tolerant. This chapter explains more about STP and the STP features supported by ExtremeXOS.

**Note:**
STP is a part of the 802.1D bridge specification defined by the IEEE Computer Society. To explain STP in terms used by the IEEE 802.1D specification, the switch will be referred to as a bridge.

ExtremeXOS version 12.0 and later supports the new edition of the IEEE 802.1D standard (known as IEEE 802.1D-2004) for STP, which incorporates enhancements from the IEEE 802.1t-2001, IEEE 802.1W, and IEEE 802.1y standards. The IEEE 802.1D-2004 standard is backward compatible with the IEEE 802.1D-1998 standard. For more information, see Compatibility Between IEEE 802.1D-1998 and IEEE 802.1D-2004 STP Bridges on page 1112.

### Spanning Tree Protocol Overview

STP is a bridge-based mechanism for providing fault tolerance on networks.

STP allows you to implement parallel paths for network traffic and to ensure that redundant paths are:
- Disabled when the main paths are operational.
- Enabled if the main path fails.

**Note:**
STP and ESRP (Extreme Standby Router Protocol) cannot be configured on the same VLAN (Virtual LAN) simultaneously.
Compatibility Between IEEE 802.1D-1998 and IEEE 802.1D-2004 STP Bridges

The IEEE 802.1D-2004 compliant bridges interoperate with the IEEE 802.1D-1998 compliant bridges.

To ensure seamless operation of your STP network, read this section before you configure STP on any Extreme Networks device running ExtremeXOS 11.6 or later.

Differences in behavior between the two standards include the:

- Default port path cost
- Bridge priority
- Port priority
- Edge port behavior

This section describes the bridge behavior differences in more detail.

Default Port Path Cost

The 802.1D-2004 standard modified the default port path cost value to allow for higher link speeds.

A higher link speed can create a situation whereby an 802.1D-1998 compliant bridge could become the more favorable transit path.

For example, in Figure 141, bridge A is the root bridge running the new 802.1D-2004 standard, bridges B and C are running the old 802.1D-1998 standard, and bridges D, E, and F are running the new 802.1D-2004 standard. In addition, all ports are 100 Mbps links. The ports on bridges B and C have a default path cost of 19, and the ports on bridge A, D, E, and F have a default path cost of 200,000.
If you use the default port path costs, bridge D blocks its port to bridge E, and all traffic between bridges D and E must traverse all of bridges in the network. Bridge D blocks its port to bridge E because the path cost to the root bridge is less by going across bridges B and C (with a combined root cost of 38) compared with going across bridge E (with a root cost of 200,000). In fact, if there were 100 bridges between bridges B, C, and D running the old 802.1D-1998 standard with the default port path costs, bridge D would still use that path because the path cost is still higher going across bridge E.

As a workaround and to prevent this situation, configure the port path cost to make links with the same speed use the same path host value. In the example described above, configure the port path cost for the 802.1D-2004 compliant bridges (bridges A, D, E, and F) to 19.

**Note**
You cannot configure the port path cost on bridges B and C to 200,000 because the path cost range setting for 802.1D-1998 compliant bridges is 1 to 65,535.

To configure the port path cost, use the following command:

```
configure stpd stpd_name ports cost [auto | cost] port_list
```

**Bridge Priority**

By configuring the STPD (Spanning Tree Domain) bridge priority, you make the bridge more or less likely to become the root bridge.

Unlike the 802.1D-1998 standard, the 802.1D-2004 standard restricts the bridge priority to a 16-bit number that must be a multiple of 4,096. The new priority range is 0 to 61,440 and is subject to the multiple of 4,096 restriction. The old priority range was 0 to 65,535 and was not subject to the multiple
of 4,096 restriction (except for MSTP (Multiple Spanning Tree Protocol) configurations). The default bridge priority remains the same at 32,768.

If you have an ExtremeXOS 11.5 or earlier configuration that contains an STP or RSTP bridge priority that is not a multiple of 4,096, the switch rejects the entry and the bridge priority returns to the default value while loading the structure. The MSTP implementation in ExtremeXOS already uses multiples of 4,096 to determine the bridge priority.

To configure the bridge priority, use the following command:

```bash
configure stpd stpd_name priority priority
```

For example, to lower the numerical value of the priority (which gives the priority a higher precedence), you subtract 4,096 from the default priority: 32,768 - 4,096 = 28,672. If you modify the priority by a value other than 4,096, the switch automatically changes the priority to the lower priority value. For example, if you configure a priority of 31,000, the switch automatically changes the priority to 28,672.

**Spanning Tree Protocol (STP) Bridge Priority Incrementing/Decrementing by One**

This feature allows you to configure all STP modes (RSTP/MSTP) bridge priority in increments of 1 or 4,096. Allowing this level of granularity of the priority allows a large range of priority values for the backup root functionality.

After priority reaches 0, backup root is unable to provide for rapid recovery in a lost root situation. In that case, priority returns to its initial configured (or default) value, and the process starts again.

Loss of root should be a rare event, but this feature setting provides a buffer in situations where network downtime to reset the root is not often available.

**Supported Platforms**

**STP Loss of Root Bridge Example**

The backup root bridge becomes the root bridge when something goes wrong with the primary root bridge: root bridge failure, root bridge malfunction, or administrative errors, and the backup root bridge loses connection with the root bridge. If the priority of the root bridge is zero and backup root loses the connectivity to the root bridge, then automatic assignment of the priority value for the backup root becomes the initial configured value.

In the following example, Switch1 is the root bridge with priority 32,768. Switch2, Switch3, and Switch4 are configured with priority as 49,152, 36,864, and 40,960, respectively. When the physical link between Switch1 and Switch2 goes down, then Switch2 becomes the root bridge by changing its configured bridge priority, which will be less than Switch1's 32,768 (operational priority); in this case its priority will be 28,672 (32,768 - 4,096). When the priority value reaches 0, then automatic assignment of the priority value returns to the configured value.
To set STP bridge priority values, use the following command with the `priority-mode` set to `dot1d`:

```
configure stpd stpd_name priority-mode [dot1d | dot1t]
```

### Port Priority

The port priority value is always paired with the port number to make up the 16-bit port identifier, which is used in various STP operations and the STP state machines.

Unlike the 802.1D-1998 standard, the 802.1D-2004 standard uses only the four most significant bits for the port priority and it must be a multiple of 16. The new priority range available is 0 to 240 and is subject to the multiple of 16 restriction. The 802.1D-1998 standard uses the eight most significant bits for the port priority. The old priority range was 0 to 31 and was not subject to the multiple of 16 restriction.

To preserve backward compatibility and to use ExtremeXOS 11.5 or earlier configurations, the existing `configure stpd ports priority` command is available. If you have an ExtremeXOS 11.5 or earlier configuration, the switch interprets the port priority based on the 802.1D-1998 standard. If the switch reads a value that is not supported in ExtremeXOS 11.6 or later, the switch rejects the entry.

When you save the port priority value, the switch saves it as the command `configure stpd ports port-priority` with the corresponding change in value.

For example, if the switch reads the `configure stpd ports priority 16` command from an ExtremeXOS 11.5 or earlier configuration, (which is equivalent to the command `configure stpd ports priority 8` entered through CLI), the switch saves the value as `configure stpd ports port-priority 128`.

### Edge Port Behavior

In ExtremeXOS 11.5 or earlier, Extreme Networks had two edge port implementations: edge port and edge port with safeguard.

The 802.1D-2004 standard has a bridge detection state machine, which introduced a third implementation of edge port behavior. The following list describes the behaviors of the different edge port implementations:

- Edge port (ExtremeXOS 11.5 and earlier):
The port does not send bridge protocol data units (BPDUs).
- The port does not run a state machine.
- If BPDUs are received, the port discards the BPDU and enters the blocking state.
- If subsequent BPDUs are not received, the port remains in the forwarding state.

- **Edge port with safeguard configured (ExtremeXOS 11.5 and 11.4 only):**
  - The port sends BPDUs.
  - When configured for MSTP, the port runs a partial state machine.
  - If BPDUs are received, the port enters the blocking state.
  - If subsequent BPDUs are not received, the port attempts to enter the forwarding state.

- **Edge port running 802.1D-2004 with safeguard enabled:**
  - The port sends BPDUs.
  - The port runs a state machine.
  - If BPDUs are received, the port behaves as a normal RSTP port by entering the forwarding state and participating in RSTP.
  - If subsequent BPDUs are not received, the port attempts to become the edge port again.

Edge port with safeguard prevents accidental or deliberate misconfigurations (loops) by having edge ports enter the blocking state upon receiving a BPDU. The 802.1D-2004 standard implements a bridge detection mechanism that causes an edge port to transition to a non-edge port upon receiving a BPDU; however, if the former edge port does not receive any subsequent BPDUs during a pre-determined interval, the port attempts to become an edge port.

If an 802.1D-2004 compliant safeguard port (edge port) connects to an 802.1D-1998 compliant edge port with safeguard configured, the old safeguard port enters the blocking state. Although the new safeguard port becomes a designated port, the link is not complete (and thus no loop is formed) because one side of the link is blocked.

**Restricted Role**

In a large metro environment, to prevent external bridges from influencing the spanning tree active topology, the following commands have been introduced for Rapid Spanning Tree Protocol (RSTP) and MSTP.

- **configure stpd stpd_name ports restricted-role enable port_list**
  - This command enables restricted role on a specified port in the core network to prevent external bridges from influencing the spanning tree active topology.
  - Restricted role should not be enabled with edge mode.
  - stpd_name—Specifies an STPD name on the switch.
  - port_list—Specifies one or more ports or slots and ports.
  - Enabling restricted role causes a port to not be selected as a root port, even if it has the best spanning tree priority vector. Such a port is selected as an alternate port after the root port is selected. The restricted role is disabled by default. If set, it can cause a lack of spanning tree connectivity.
  - A network administrator enables restricted role to prevent external bridges from influencing the spanning tree active topology.

- **configure stpd stpd_name ports restricted-role disable port_list**
  - This command disables restricted role on a specified port in the core network.
  - stpd_name—Specifies an STPD name on the switch.
• port_list—Specifies one or more ports or slots and ports.
• Restricted role is disabled by default. If set, it can cause a lack of spanning tree connectivity. A network administrator enables restricted role to prevent external bridges from influencing the spanning tree active topology.

**Loop Protect**

STP depends on continuous reception of Type 2 BPDUs (RSTP/MSTP) based on the port role. The designated port transmits BPDUs and the non-designated port receives BPDUs. If one of the ports in a physical redundant topology no longer receives BPDUs, then STP assumes that the topology is loop free. This leads the blocking port from the alternate or backup port becomes designated and moves to a forwarding State causing a loop.

Loop Protect protects the network from loops. The Loop Protect feature is achieved by ports receiving BPDUs (RSTP/MSTP only) on point-to-point ISLs before their states are allowed to become forwarding. Further, if a BPDU timeout occurs on a port, its state becomes listening until a new BPDU is received. In this way, both upstream and downstream facing ports are protected. When a root or alternate port loses its path to the root bridge, due to message age expiration, it takes on the role of designated port and will not forward traffic until a BPDU is received. When a port is intended to be the designated port in an ISL, it constantly proposes and will not forward until a BPDU is received. It will revert to listening if it stops getting a response. Loop Protect also overrides the port admin setting. This protects against misconfiguration (such as disabling STP on a port) and protocol failure by the connected bridge.

Loop Protect has the capability to

• Control port forwarding state based on reception of agreement BPDUs
• Control port forwarding state based on reception of disputed BPDUs
• Disable a port based on frequency of failure events
• Communicate port non-forwarding status through traps.

**Note**

Loop Protect Traps are not supported in this ExtremeXOS 15.7.

By default, Loop Protect is disabled on all ports.

**Loop Protect Port Modes**

Ports work in two Loop Protect operational modes.

• If the port has the partner loop protect as capable then it works in full functional mode.
• If the port has the partner loop protect as incapable then it works limited functional mode.

In full mode, when RSTP/MSTP BPDUs is received in point-to-point link and the port is designated, a Loop Protect timer is set to 3 times hello time, when this timer expires then port will be moved to blocking state. Limited mode adds a further requirement that the flags field in the BPDU indicates a root role.

Message age expiration and the expiration of the Loop Protect timer are both events for which Loop Protect generates traps and a debug message. In addition, user can configure Loop Protect to forcefully disable port when one or more events occur. When the configured number of events happens within a given window of time, the port will be forced into disable and held there until you manually unlock it.
The following example shows the loop due to the misconfiguration in STP:

Figure 143 shows that Switch 1 is elected as Root. Switch 2 and Switch 3 elect the root port. Switch 3’s port connected to Switch 2 is elected as Alternate port and it is port state is in blocking state.

![Figure 143: Switch 1 Elected as Root](image)

Figure 144 shows that if the user accidentally disables the STP on Switch 2 port connected to Switch 3, Switch 2 will stop sending the BPDU to Switch 3 since STP is disabled. Switch 3 assumes that neighbor is down and it changes the port to forwarding state which will eventually create a loop.

![Figure 144: STP Disabled on Switch 2](image)

Figure 145 shows that, with loop protect enabled switch 3 will not go to forwarding state until it receives a BPDU from switch 2 and the port state will be in discarding state.

![Figure 145: STP Disabled on Switch 2](image)
Figure 145: Loop Protect Enabled

When the Loop protect feature is enabled:

- On a Point-to-point Link, BPDU must be received before going to Forwarding state.
- If a BPDU timeout occurs on a port, its state becomes DISCARDING until a BPDU is received.
- When a root or alternate port loses its path to the root bridge due to a message age expiration it takes on the role of designated port. It will not forward traffic until a BPDU is received.
- When a port is intended to be the designated port in a point-to-point link it constantly proposes and will not forward until a BPDU is received, and will revert to discarding if it fails to get a response.
- If the partner is not Loop Protect Capable (Alternate Agreement not supported), designated port will not be allowed to forward unless receiving agreements from a port with root role.
- Legacy Spanning Tree (802.1d) or shared media devices should be connected in a non-redundant fashion to avoid the possibility of looping.

You can enable the port by giving the command `enable port port-list`.

STP Filter Configuration

This new ExtremeXOS 15.7.1 CLI feature includes processing and forwarding of STP BPDU’s either by system wide or port based filter installation.

In previous releases this processing and forwarding of STP BPDU’s was based only on ports, now this has been changed to system wide (default). Prior to ExtremeXOS 15.7, blocked ports transmission of the BPDU’s was restricted, but for the Loop Protect feature when any proposal agreement BPDU is received in the blocked port, then reply for the proposal agreement is to be transmitted. Due to this MAC movement is reported and the packet was not processed. This feature prevents this issue.

You can roll back to the previous implementation (port-based) if any issues are encountered.

Backup Root

When the root bridge of spanning tree instance is lost, its information may be retained in the network until the aging mechanism causes it to be removed. This leads to a delay in convergence on for the new
root. This backup root feature is used to get faster convergence when the root bridge connectivity is lost.

Backup root feature enabled bridge port should be connected to Root with point to point link. When backup root bridge lost contact with the root bridge, automatically backup root bridge lowers its bridge priority (an increment below the priority of the lost root). This will cause the backup root bridge to become the new root with information superior to any information held by any bridge in the network. While save and reboot automatically changed priority will not be saved and restored. At the time of reboots it will have its priority restored to the original configured value by administrator.

If the priority of the root bridge is Zero and backup root has lost the connectivity of the root bridge then automatic assignment of the priority value for the backup root will be the initial configured value.

This backup root feature is activated only when there is loss of connectivity with the root bridge. Raising the priority on the root will not cause the Backup root feature to be activated.

**Configuration Recommendations:**

- Enable the Backup Root feature on both the root and backup root.
- Configure all bridges except the root and backup root with the maximum bridge priority value (61440 with 802.1t).
- Configure the root and backup root to have the next lowest priority (57344 with 802.1t).
- We also recommend having multiple links between the root and backup root. This helps prevent the Backup Root feature from activating due to a simple link failure rather than a bridge failure.
- Care must be taken when this feature is used as it may result in sub-optimal traffic forwarding paths.

Consider the following topology: 10G link connected from the edge switches to the aggregation Root while the edge switches to the Backup Root switch with 1G links to reduce the cost and acts as a backup link. In this case, when the link between aggregation Root and Backup Root fails, the traffic will now use the 1G links providing reduced performance of the network. The aggregation old root is still in the network which can be used to forward the traffic. This feature has moved the root of the stp domain.

![Figure 146: Root and Backup Root Topology](image)
Multisource Detection

Multisource Detection is a feature that prevents network disruption due to excessive topology changes caused by a full duplex port transmitting multiple BPDUs with different source MAC addresses, and different BPDU information. When a port is point-to-point, the received priority information comes from the most recently received BPDU. When a port is non-point-to-point, the received information reflects the best priority information out of all the received BPDUs. Typical scenarios for multisource detection are when a switch is connected to a device which has been improperly configured to forward received BPDUs out on other ports or has been configured to not run the Spanning Tree protocol and treats BPDUs as multicast packets by transmitting them out all other forwarding ports. In these situations, the connected port is acting as a shared media device. The way to detect shared media is the duplex setting. Since the port is full duplex it treats the connection as point-to-point.

When Loop Protect is configured for the port, if multisource detection is triggered, the port will go to the listening state and no longer be part of the active topology. Loop protect does not operate on shared media ports.

Restrict Topology Change Notification

Restricted Topology Change Notification (TCN) is a Spanning Tree Protocol feature that allows/disallows TCN propagation on specified ports. When Restricted TCN is disabled, TCN propagation is allowed. The port propagates received TCNs and topology changes to other ports.

Restrict TCN is disabled by default. When Restricted TCN is enabled, the port does not propagate received TCNs and topology changes to other ports. Enable Restricted TCN to prevent unnecessary address flushing in the core region of the network caused by activation of bridges external to the core network.

A possible reason for not allowing TCN propagation is when bridges are not under the full control of the administrator or because MAC operational state for the attached or downstream LANs transitions frequently, causing disruption throughout the network. Rapid Spanning Tree responds to TCNs by selectively flushing the filter database. Persistent TCNs are disruptive, causing persistent address flushing, which in turn causes increased flooding in the network.

Restricted TCN is a useful tool when it is not possible to remove the source of the TCNs.

BPDU Restrict on Edge Safeguard

BPDU restrict causes a port on which this feature is configured to be disabled as soon as an STP BPDU is received on that port, thus allowing you to enforce the STP domain borders and keep the active topology predictable.

Figure shows a BPDU restrict example.
In this figure, loops on the LAN access switches are not prevented since the ports towards the distribution switches are not running STP but Software Redundant Ports (SRP). Currently, ExtremeXOS software cannot run STP on ports that are configured for SRP. STP on the access switch is unaware of the alternate path and therefore cannot prevent the loop that exists across the switches. Configuring a port as an edge mode port alone cannot prevent the loop between the switches because edge ports never send BPDUs. The edge safeguard feature is not able to prevent the loops because STP does not have the information about the alternate path.

To prevent the loops across the switches, the edge safeguard feature can be configured with the BPDU restrict function. When running in BPDU restrict mode, edge safeguard ports send STP BPDUs at a rate of one every two seconds. The port is disabled as soon as an STP BPDU is received on the BPDU restrict port, thereby preventing the loop. Flexibility is provided with an option to re-enable the port after a user specified time period. If a user enables a port while STP has disabled it, the port is operationally enabled; STP is notified and then stops any recovery timeout that has started.

When an STPD is disabled for a BPDU restrict configured port, an STP port in 802.1D operation mode begins forwarding immediately, but in the RSTP or MSTP operation modes, the port remains in the disabled state.

BPDU restrict is available on all of the three operational modes of STP: 802.1D, RSTP, and MSTP.

Although edge safeguard is not available in 802.1D operation mode, when you configure BPDU restrict you do so in a similar way, that is, as an extension of edge safeguard; then only BPDU restrict is available on the port and not edge safeguard.

To configure BPDU restrict, use the command:

```plaintext
• configure {stp} stpd_name ports edge-safeguard enable port_list (bpdu-restrict) {recovery-timeout (seconds)}
• BPDU restrict can also be configured by using the following commands:
  • configure {stp} stpd_name ports bpdu-restrict [enable | disable] port_list {recovery-timeout (seconds)}
  • configure stpd stpd_name ports link-type [[auto | broadcast | point-to-point] port_list | edge port_list] {edge-safeguard [enable | disable] (bpdu-restrict) {recovery-timeout seconds}}
```

Figure 147: BPDU Restrict

In this figure, loops on the LAN access switches are not prevented since the ports towards the distribution switches are not running STP but Software Redundant Ports (SRP). Currently, ExtremeXOS software cannot run STP on ports that are configured for SRP. STP on the access switch is unaware of the alternate path and therefore cannot prevent the loop that exists across the switches. Configuring a port as an edge mode port alone cannot prevent the loop between the switches because edge ports never send BPDUs. The edge safeguard feature is not able to prevent the loops because STP does not have the information about the alternate path.

To prevent the loops across the switches, the edge safeguard feature can be configured with the BPDU restrict function. When running in BPDU restrict mode, edge safeguard ports send STP BPDUs at a rate of one every two seconds. The port is disabled as soon as an STP BPDU is received on the BPDU restrict port, thereby preventing the loop. Flexibility is provided with an option to re-enable the port after a user specified time period. If a user enables a port while STP has disabled it, the port is operationally enabled; STP is notified and then stops any recovery timeout that has started.

When an STPD is disabled for a BPDU restrict configured port, an STP port in 802.1D operation mode begins forwarding immediately, but in the RSTP or MSTP operation modes, the port remains in the disabled state.

BPDU restrict is available on all of the three operational modes of STP: 802.1D, RSTP, and MSTP.

Although edge safeguard is not available in 802.1D operation mode, when you configure BPDU restrict you do so in a similar way, that is, as an extension of edge safeguard; then only BPDU restrict is available on the port and not edge safeguard.

To configure BPDU restrict, use the command:

```plaintext
• configure {stp} stpd_name ports edge-safeguard enable port_list (bpdu-restrict) {recovery-timeout (seconds)}
• BPDU restrict can also be configured by using the following commands:
  • configure {stp} stpd_name ports bpdu-restrict [enable | disable] port_list {recovery-timeout (seconds)}
  • configure stpd stpd_name ports link-type [[auto | broadcast | point-to-point] port_list | edge port_list] {edge-safeguard [enable | disable] (bpdu-restrict) {recovery-timeout seconds}}
```
To include BPDU restrict functionality when configuring link types or edge safeguard, see Configuring Link Types on page 1141 and Configuring Edge Safeguard on page 1141.

The example below shows a BPDU restrict configuration:

```
configure s1 ports edge-safeguard enable 9 bpdu-restrict recovery-timeout 400.
```

The following is sample output from the `show s1 ports` command resulting from the configuration:

```
switch # show s1 ports
Port   Mode     State      Cost  Flags     Priority Port ID Designated Bridge
9      EMISTP   FORWARDING 20000 eDee-w-G-- 128      8009    80:00:00:04:96:26:5f:4e
Total Ports: 1
------------------------- Flags: ----------------------------
1:                e=Enable, d=Disable
2: (Port role)    R=Root, D=Designated, A=Alternate, B=Backup, M=Master
3: (Config type)  b=broadcast, p=point-to-point, e=edge, a=auto
4: (Oper. type)   b=broadcast, p=point-to-point, e=edge
5:                p=proposing, a=agree
6: (partner mode) d = 802.1d, w = 802.1w, m = mstp
7:                i = edgeport inconsistency
8:                S = edgeport safe guard configured but inactive
9:                G = edgeport safe guard bpdu restrict active in 802.1w and mstp
10:               r = Restricted Role
```

The following is sample output for STP operation mode dot1d from the `show configuration stp` command:

```
switch # show configuration stp
# Module stp configuration.
# configure mstp region region2
configure stpd s0 delete vlan default ports all
disable stpd s0 auto-bind vlan default
create stpd s1
configure stpd s1 mode dot1w
enable stpd s0 auto-bind vlan Default
configure stpd s1 add vlan v1 ports 9 emistp
configure stpd s1 ports mode emistp 9
configure stpd s1 ports cost auto 9
configure stpd s1 ports port-priority 128 9
configure stpd s1 ports link-type edge 9
configure stpd s1 ports edge-safeguard enable 9 recovery-timeout 400
configure stpd s1 ports bpdu-restrict enable 9 recovery-timeout 400
enable stpd s1 ports 9
configure stpd s1 tag 10
enable stpd s1
```

The following is sample output for STP operation mode dot1w from the `show configuration stp` command:

```
switch # show configuration stp
# Module stp configuration.
# configure mstp region 000496265f4e
configure stpd s0 delete vlan default ports all
disable stpd s0 auto-bind vlan default
create stpd s1
configure stpd s1 mode dot1w
enable stpd s0 auto-bind vlan Default
configure stpd s1 add vlan v1 ports 9 emistp
configure stpd s1 ports mode emistp 9
configure stpd s1 ports cost auto 9
configure stpd s1 ports port-priority 128 9
configure stpd s1 ports link-type edge 9
configure stpd s1 ports edge-safeguard enable 9 recovery-timeout 400
configure stpd s1 ports bpdu-restrict enable 9 recovery-timeout 400
enable stpd s1 ports 9
configure stpd s1 tag 10
enable stpd s1
```
Disable Forwarding of Spanning Tree Protocol (STP) Bridge Protocol Data Units (BPDUs)

You can disable forwarding of STP Bridge Protocol Data Units (BPDUs) when STP is disabled on a switch. When STP is disabled globally, BPDUs received on a port are forwarded to other ports that are part of same VLAN causing the switch to transparently forward STP/RSTP/MSTP BPDUs. This transparent forwarding causes one-to-many peer in the network trouble where STP disabled. To avoid this transparent forwarding of BPDUs, you can opt to discard the BDPUs when there is no STP configuration enabled on the switch.

To disable STP BDPUs, use the command:

```
configure stpd bpdu-forwarding [on | off]
```

Span Tree Domains

The switch can be partitioned into multiple virtual bridges. Each virtual bridge can run an independent Spanning Tree instance. Each Spanning Tree instance is called a STPD. Each STPD has its own root bridge and active path. After an STPD is created, one or more VLANs can be assigned to it.

A physical port can belong to multiple STPDs. In addition, a VLAN can span multiple STPDs.

The key points to remember when configuring VLANs and STP are:

- Each VLAN forms an independent broadcast domain.
- STP blocks paths to create a loop-free environment.
- Within any given STPD, all VLANs belonging to it use the same spanning tree.
- To create an STPD, use the command:
  ```
create stpd stpd_name {description stpd-description}
```
- To delete an STPD, use the command:
  ```
delete stpd stpd_name
```

User-created STPD names are not case-sensitive.

For detailed information about configuring STP and various STP parameters on the switch, see Configuring STP on the Switch on page 1166.

Member VLANs

When you add a VLAN to an STPD, that VLAN becomes a member of the STPD. The two types of member VLANs in an STPD are:

- Carrier
 Protected

Carrier VLAN

A carrier VLAN defines the scope of the STPD, which includes the physical and logical ports that belong to the STPD and if configured, the 802.1Q tag used to transport Extreme Multiple Instance Spanning Tree Protocol (EMISTP) or Per VLAN Spanning Tree (PVST+) encapsulated bridge protocol data units (BPDUs).

See Encapsulation Modes on page 1127 for more information about encapsulating STP BPDUs.

Only one carrier VLAN can exist in a given STPD, although some of its ports can be outside the control of any STPD at the same time.

If you configure EMISTP or PVST+, the STPD ID must be identical to the VLAN ID of the carrier VLAN in that STPD. See Specifying the Carrier VLAN on page 1125 for an example.

If you have an 802.1D configuration, we recommend that you configure the StpdID to be identical to the VLAN ID of the carrier VLAN in that STPD. See Basic 802.1D Configuration Example on page 1169 for an example.

If you configure Multiple Spanning Tree (MSTP—IEEE 802.1Q-2003, formerly IEEE 802.1s), you do not need carrier VLANs for MSTP operation. With MSTP, you configure a Common and Internal Spanning Tree (CIST) that controls the connectivity of interconnecting MSTP regions and sends BPDUs across the regions to communicate the status of MSTP regions. All VLANs participating in the MSTP region have the same privileges. For more information about MSTP, see Multiple Spanning Tree Protocol on page 1150.

Protected VLAN

Protected VLANs are all other VLANs that are members of the STPD.

These VLANs “piggyback” on the carrier VLAN. Protected VLANs do not transmit or receive STP BPDUs, but they are affected by STP state changes and inherit the state of the carrier VLAN. Protected VLANs can participate in multiple STPDs, but any particular port in the VLAN can belong to only one STPD. Also known as non-carrier VLANs.

If you configure MSTP, all member VLANs in an MSTP region are protected VLANs. These VLANs do not transmit or receive STP BPDUs, but they are affected by STP state changes communicated by the CIST to the MSTP regions. Multiple spanning tree instances (MSTIs) cannot share the same protected VLAN; however, any port in a protected VLAN can belong to multiple MSTIs. For more information about MSTP, see Multiple Spanning Tree Protocol on page 1150.

Specifying the Carrier VLAN

The following example:

• Creates and enables an STPD named s8.
• Creates a carrier VLAN named v5.
• Assigns VLAN v5 to STPD s8.
• Creates the same tag ID for the VLAN and the STPD (the carrier VLAN’s ID must be identical to the STPD’s ID).

```
create vlan v5
configure vlan v5 tag 100
configure vlan v5 add ports 1:1-1:20 tagged
create stpd s8
configure stpd s8 add vlan v5 ports all emistp
configure stpd s8 tag 100
enable stpd s8
```

Notice how the tag number for the VLAN v5 (100) is identical to the tag for STPD s8. By using identical tags, you have selected the carrier VLAN. The carrier VLAN’s ID is now identical to the STPD’s ID.

**STPD Modes**

An STPD has three modes of operation:

• **802.1D mode**

  Use this mode for backward compatibility with previous STP versions and for compatibility with third-party switches using IEEE standard 802.1D. When configured in this mode, all rapid configuration mechanisms are disabled.

• **802.1w mode**

  Use this mode for compatibility with Rapid Spanning Tree (RSTP). When configured in this mode, all rapid configuration mechanisms are enabled. The benefit of this mode is available on point-to-point links only and when the peer is likewise configured in 802.1w mode. If you do not select point-to-point links and the peer is not configured for 802.1w mode, the STPD fails back to 802.1D mode.

  You can enable or disable RSTP on a per STPD basis only; you cannot enable RSTP on a per port basis.

  For more information about RSTP and RSTP features, see Rapid Spanning Tree Protocol on page 1139.

• **MSTP mode**

  Use this mode for compatibility with MSTP. MSTP is an extension of RSTP and offers the benefit of better scaling with fast convergence. When configured in this mode, all rapid configuration mechanisms are enabled. The benefit of MSTP is available only on point-to-point links and when you configure the peer in MSTP or 802.1l mode. If you do not select point-to-point links and the peer is not configured in 802.1l mode, the STPD fails back to 802.1D mode.

  You must first configure a CIST before configuring any MSTIs in the region. You cannot delete or disable a CIST if any of the MSTIs are active in the system.

  You can create only one MSTP region on the switch, and all switches that participate in the region must have the same regional configurations. You can enable or disable an MSTP on a per STPD basis only; you cannot enable MSTP on a per port basis.
If configured in MSTP mode, an STPD uses the 802.1D BPDU encapsulation mode by default. To ensure correct operation of your MSTP STPDs, do not configure EMISTP or PVST+ encapsulation mode for MSTP STPDs.

For more information about MSTP and MSTP features, see Multiple Spanning Tree Protocol on page 1150.

By default:
- The STPD s0 operates in MSTP CIST mode.
- The default device configuration contains a single STPD called s0.
- User-created STPDs operate in dot1d mode.
- The default VLAN is a member of STPD s0 with autobind enabled.

To configure the mode of operation of an STPD, use the following command:

```
configure stpd stpd_name mode [dot1d | dot1w | mstp [cist | msti instance]]
```

**Note**
Starting with ExtremeXOS 22.2, STP operational mode can be changed while VLANs are associated with an STP domain. In MSTP operation mode, mode change is allowed only for CIST domains.

All STP parameters default to the IEEE 802.1D values, as appropriate.

**Encapsulation Modes**

You can configure ports within an STPD to accept specific BPDU encapsulations.

This STP port encapsulation is separate from the STP mode of operation. For example, you can configure a port to accept the PVST+ BPDU encapsulation while running in 802.1D mode.

An STP port has three possible encapsulation modes:
- **802.1D mode**

  Use this mode for backward compatibility with previous STP versions and for compatibility with third-party switches using IEEE standard 802.1D. BPDUs are sent untagged in 802.1D mode. Because of this, any given physical interface can have only one STPD running in 802.1D mode. The default port mode for user-created STP domains for Dot1d and Dot1w operation mode is Dot1d.

  This encapsulation mode supports the following STPD modes of operation: 802.1D, 802.1w, and MSTP.

  - **Extreme Multiple Instance Spanning Tree Protocol (EMISTP) mode**

    EMISTP mode is proprietary to Extreme Networks and is an extension of STP that allows a physical port to belong to multiple STPDs by assigning the port to multiple VLANs. EMISTP adds significant flexibility to STP network design. BPDUs are sent with an 802.1Q tag having an STPD instance Identifier (STPD ID) in the VLAN ID field.

    This encapsulation mode supports the following STPD modes of operation: 802.1D and 802.1w.
• Per VLAN Spanning Tree (PVST+) mode

This mode implements PVST+ in compatibility with third-party switches running this version of STP. The STPDs running in this mode have a one-to-one relationship with VLANs and send and process packets in PVST+ format.

This encapsulation mode supports the following STPD modes of operation: 802.1D and 802.1w.

These encapsulation modes are for STP ports, not for physical ports. When a physical port belongs to multiple STPDs, it is associated with multiple STP ports. It is possible for the physical port to run in different modes for different domains to which it belongs.

If configured in MSTP mode, an STPD uses the 802.1D BPDU encapsulation mode by default. To ensure correct operation of your MSTP STPDs, do not configure EMISTP or PVST+ encapsulation mode for MSTP STPDs.

• To configure the BPDU encapsulation mode for one or more STP ports, use the command:
  ```
  configure stpd stpd_name ports mode [dot1d | emistp | pvst-plus]
  port_list
  ```

• To configure the default BPDU encapsulation mode on a per STPD basis, use the command:

  ```
  configure stpd stpd_name default-encapsulation [dot1d | emistp | pvst-plus]
  ```

Instead of accepting the default encapsulation modes of dot1d for the default STPD s0 and for all other STPDs, this command allows you to specify the type of BPDU encapsulation to use for all ports added to the STPD (if not otherwise specified).

**STPD Identifier**

An StpdID is used to identify each STP domain.

When assigning the StpdID when configuring the domain, ensure that the carrier VLAN of that STPD does not belong to another STPD. Unless all ports are running in 802.1D mode, an STP with ports running in either EMISTP mode or PVST+ mode must be configured with an StpdID.

An StpdID must be identical to the VLAN ID of the carrier VLAN in that STP domain. For an 802.1D STPD, the VLAN ID can be either a user-defined ID or one automatically assigned by the switch.

**Note**

If an STPD contains at least one port not in 802.1D mode, you must configure the STPD with an StpdID.

**MSTP** uses two different methods to identify the STPDs that are part of the MSTP network. An instance ID of 0 identifies the CIST. The switch assigns this ID automatically when you configure the CIST STPD. An **MSTI (Multiple Spanning Tree Instances)** identifier (MSTI ID) identifies each STP domain that is part of an MSTP region. You assign the MSTI ID when configuring the STPD that participates in the MSTP region. In an MSTP region, MSTI IDs only have local significance. You can reuse MSTI IDs across MSTP regions. For more information about MSTP and MSTP features, see **Multiple Spanning Tree Protocol** on page 1150.
STP States

Each port that belongs to a member VLAN participating in STP exists in one of the following states:

**Blocking** A port in the blocking state does not accept ingress traffic, perform traffic forwarding, or learn MAC source addresses. The port receives STP BPDUs. During STP initialization, the switch always enters the blocking state.

**Listening** A port in the listening state does not accept ingress traffic, perform traffic forwarding, or learn MAC source addresses. The port receives STP BPDUs. This is the first transitional state a port enters after being in the blocking state. The bridge listens for BPDUs from neighboring bridge(s) to determine whether the port should or should not be blocked.

**Learning** A port in the learning state does not accept ingress traffic or perform traffic forwarding, but it begins to learn MAC source addresses. The port also receives and processes STP BPDUs. This is the second transitional state after listening. From learning, the port will change to either blocking or forwarding.

**Forwarding** A port in the forwarding state accepts ingress traffic, learns new MAC source addresses, forwards traffic, and receives and processes STP BPDUs.

**Disabled** A port in the disabled state does not participate in STP; however, it will forward traffic and learn new MAC source addresses.

Binding Ports

There are two ways to bind (add) ports to an STPD: manually and automatically. By default, ports are manually added to an STPD.

*Note*
The default VLAN and STPD S0 are already on the switch.

**Manually Binding Ports**

- To manually bind ports, use the commands:

  ```
  configure stpd stpd_name add vlan vlan_name ports [all | port_list] 
  {{dot1d | emistp | pvst-plus}}
  configure vlan vlan_name add ports [all | port_list] {tagged {tag} | untagged} stpd stpd_name {{dot1d | emistp | pvst-plus}}
  ```

  The first command adds all ports or a list of ports within the specified VLAN to an STPD. For EMISTP and PVST+, the carrier VLAN must already exist on the same set of ports. The second command adds all ports or a list of ports to the specified VLAN and STPD at the same time. If the ports are added to the VLAN but not to the STPD, the ports remain in the VLAN.

  For EMISTP and PVST+, if the specified VLAN is not the carrier VLAN and the specified ports are not bound to the carrier VLAN, the system displays an error message. If you configure MSTP on your switch, MSTP does not need carrier VLANs.

*Note*
The carrier VLAN's ID must be identical to the ID of the STP domain.

If you add a protected VLAN or port, that addition inherits the carrier VLAN's encapsulation mode, unless you specify the encapsulation mode when you execute the `configure stpd add vlan` or `configure vlan add ports stpd` commands. If you specify an encapsulation mode (dot1d, emistp, or pvst-plus), the STP port mode is changed to match; otherwise, the STP port
inherits either the carrier VLANs encapsulation mode on that port or the STPD's default encapsulation mode.

For MSTP, you do not need carrier a VLAN. A CIST controls the connectivity of interconnecting MSTP regions and sends BPDUs across the regions to communicate region status. You must use the dot1d encapsulation mode in an MSTP environment. For more information about MSTP, see the section Multiple Spanning Tree Protocol on page 1150.

- To remove ports, use the command:
  ```
  configure stpd stpd_name delete vlan vlan_name ports [all | port_list]
  ```
  If you manually delete a protected VLAN or port, only that VLAN or port is removed. If you manually delete a carrier VLAN or port, all VLANs on that port (both carrier and protected) are deleted from that STPD.

To learn more about member VLANs, see Member VLANs on page 1124. For more detailed information about these command line interface (CLI) commands, see the ExtremeXOS 22.6 Command Reference Guide.

Automatically Binding Ports

- To automatically bind ports to an STPD when the ports are added to a VLAN, use the command:
  ```
  enable stpd stpd_name auto-bind vlan vlan_name
  ```
  The autobind feature is disabled on user-created STPDs. The autobind feature is enabled on the default VLAN that participates in the default STPD S0.

For EMISTP or PVST+, when you issue this command, any port or list of ports that you add to the carrier VLAN are automatically added to the STPD with autobind enabled. In addition, any port or list of ports that you remove from a carrier VLAN are automatically removed from the STPD. This feature allows the STPD to increase or decrease its span as ports are added to or removed from a carrier VLAN.

**Note**

The carrier VLAN's ID must be identical to the ID of the STP domain.

Enabling autobind on a protected VLAN does not expand the boundary of the STPD.

If the same set of ports are members of the protected VLAN and the carrier VLAN, protected VLANs are aware of STP state changes. For example, assume you have the following scenario:

- Carrier VLAN named v1
- v1 contains ports 3:1-3:2
- Protected VLAN named v2
- v2 contains ports 3:1-3:4

Since v1 contains ports 3:1-3:2, v2 is aware only of the STP changes for ports 3:1 and 3:2, respectively. Ports 3:3 and 3:4 are not part of the STPD, which is why v2 is not aware of any STP changes for those ports.

In addition, enabling autobind on a protected VLAN causes ports to be automatically added or removed as the carrier VLAN changes.

For MSTP, when you issue this command, any port or list of ports that gets automatically added to an MSTI are automatically inherited by the CIST. In addition, any port or list of ports that you remove
from an MSTI protected VLAN are automatically removed from the CIST. For more information, see Automatically Inheriting Ports--MSTP Only on page 1131.

• To remove ports, enter the command:
  ```
  configure stpd stpd_name delete vlan vlan_name ports [all | port_list]
  ```
  If you manually delete a port from the STPD on a VLAN that has been added by autobind, ExtremeXOS records the deletion so that the port does not get automatically added to the STPD after a system restart.

To learn more about the member VLANs, see Member VLANs on page 1124. For more detailed information about these CLI commands, see the ExtremeXOS 22.6 Command Reference Guide.

Automatically Inheriting Ports--MSTP Only

In an MSTP environment, whether you manually or automatically bind a port to an MSTI in an MSTP region, the switch automatically binds that port to the CIST.

The CIST handles BPDU processing for itself and all of the MSTIs; therefore, the CIST must inherit ports from the MSTIs in order to transmit and receive BPDUs. You can only delete ports from the CIST if it is no longer a member of an MSTI.

For more information about MSTP, see Multiple Spanning Tree Protocol on page 1150.

Rapid Root Failover

ExtremeXOS supports rapid root failover for faster STP failover recovery times in STP 802.1D mode. If the active root port link goes down, ExtremeXOS recalculates STP and elects a new root port. The rapid root failover feature allows the new root port to immediately begin forwarding, skipping the standard listening and learning phases. Rapid root failover occurs only when the link goes down and not when there is any other root port failure, such as missing BPDUs.

The default setting for this feature is disabled.

• To enable rapid root failover, enter the command:
  ```
  enable stpd stpd_name rapid-root-failover
  ```

• To display the configuration, enter the command:
  ```
  show stpd {stpd_name | detail}
  ```

STP and Hitless Failover—SummitStack Only

When you are using redundancy in a SummitStack, one node assumes the role of primary and the other node assumes the role of backup. The primary executes the switch’s management functions, and the backup acts in a standby role. Hitless failover transfers switch management control from the primary to
the backup and maintains the state of STP. STP supports hitless failover. You do not explicitly configure hitless failover support; rather, if you have two nodes installed, hitless failover is available.

Note
Not all platforms support hitless failover in the same software release. To verify if the software version you are running supports hitless failover, see the following table in Managing the Switch on page 52. For more information about protocol and platform support for hitless failover, see Understanding Hitless Failover Support on page 71.

To support hitless failover, the primary node replicates STP BPDUs to the backup, which allows the nodes to run STP in parallel. Although both primary and backup node receive STP BPDUs, only the primary transmits STP BPDUs to neighboring switches and participates in STP.

Note
Before initiating failover, review the section Synchronizing Nodes on page 1631 to confirm that both primary and backup nodes are running software that supports the synchronize command.

To initiate hitless failover on a network that uses STP:
1. Confirm that the nodes are synchronized and have identical software and switch configurations using the command:
   
   ```
   show switch {detail}
   ```
   
   The output displays the status of the primary and backup nodes, with the primary node showing MASTER and the backup node showing BACKUP (InSync).

   If the primary and backup nodes are not synchronized and both nodes are running a version of ExtremeXOS that supports synchronization, proceed to 2.

   If the primary and backup nodes are synchronized, proceed to 3 on page 1132.

2. If the primary and backup nodes are not synchronized, use the synchronize command to replicate all saved images and configurations from the primary to the backup.

   After you confirm the nodes are synchronized, proceed to 3.

3. If the nodes are synchronized, use the run failover (formerly run msm-failover) command to initiate failover.

For more detailed information about verifying the status of the primary and backup nodes, and system redundancy, see Understanding System Redundancy on page 67. For more information about hitless failover, see Understanding Hitless Failover Support on page 71.

### STP Configurations

When you assign VLANs to an STPD, pay careful attention to the STP configuration and its effect on the forwarding of VLAN traffic.

This section describes three types of STP configurations:
- Basic STP
- Multiple STPDs on a single port (which uses EMISTP)
- A VLAN that spans multiple STPDs
Basic STP Configuration

This section describes a basic, 802.1D STP configuration. Figure 148 on page 1133 illustrates a network that uses VLAN tagging for trunk connections.

The following four VLANs have been defined:
- Sales is defined on switch A, switch B, and switch M.
- Personnel is defined on switch A, switch B, and switch M.
- Manufacturing is defined on switch Y, switch Z, and switch M.
- Engineering is defined on switch Y, switch Z, and switch M.
- Marketing is defined on all switches (switch A, switch B, switch Y, switch Z, and switch M).

Two STPDs are defined:
- STPD1 contains VLANs Sales and Personnel.
- STPD2 contains VLANs Manufacturing and Engineering.

The carrier and protected VLANs are also defined:
- Sales is the carrier VLAN on STPD1.
- Personnel is a protected VLAN on STPD1.
- Manufacturing is a protected VLAN on STPD2.
- Engineering is the carrier VLAN on STPD2.
- Marketing is a member of both STPD1 and STPD2 and is a protected VLAN.

Figure 148: Multiple STPDs
When the switches in this configuration boot-up, STP configures each STPD such that the topology contains no active loops. STP could configure the topology in a number of ways to make it loop-free.

In Figure 148, the connection between switch A and switch B is put into blocking state, and the connection between switch Y and switch Z is put into blocking state. After STP converges, all the VLANs can communicate, and all bridging loops are prevented.

The protected VLAN Marketing, which has been assigned to both STPD1 and STPD2, communicates using all five switches. The topology has no loops, because STP has already blocked the port connection between switch A and switch B and between switch Y and switch Z.

Within a single STPD, you must be extra careful when configuring your VLANs. Figure 149 illustrates a network that has been incorrectly set up using a single STPD so that the STP configuration disables the ability of the switches to forward VLAN traffic.

![Figure 149: Incorrect Tag-Based STPD Configuration](image)

The tag-based network in the following figure has the following configuration:

- Switch 1 contains VLAN Marketing and VLAN Sales.
- Switch 2 contains VLAN Engineering and VLAN Sales.
- Switch 3 contains VLAN Marketing, VLAN Engineering, and VLAN Sales.
- The tagged trunk connections for three switches form a triangular loop that is not permitted in an STP topology.
- All VLANs in each switch are members of the same STPD.

STP can block traffic between switch 1 and switch 3 by disabling the trunk ports for that connection on each switch.

Switch 2 has no ports assigned to VLAN Marketing. Therefore, if the trunk for VLAN Marketing on switches 1 and 3 is blocked, the traffic for VLAN Marketing will not be able to traverse the switches.

**Note**

If an STPD contains multiple VLANs, all VLANs should be configured on all ports in that domain, except for ports that connect to hosts (edge ports).
Multiple STPDs on a Port

Traditional 802.1D STP has some inherent limitations when addressing networks that have multiple VLANs and multiple STPDs.

For example, consider the sample depicted in Figure 150 on page 1135.

![Figure 150: Limitations of Traditional STPD](image)

The two switches are connected by a pair of parallel links. Both switches run two VLANs, A and B. To achieve load-balancing between the two links using the traditional approach, you would have to associate A and B with two different STPDs, called S1 and S2, respectively, and make the left link carry VLAN A traffic while the right link carries VLAN B traffic (or vice versa). If the right link fails, S2 is broken and VLAN B traffic is disrupted.

To optimize the solution, you can use the Extreme Multiple Instance Spanning (EMISTP) mode, which allows a port to belong to multiple STPDs. EMISTP adds significant flexibility to STP network design. Referring to Figure 150, using EMISTP, you can configure all four ports to belong to both VLANs.

Assuming that S1 and S2 still correspond to VLANs A and B respectively, you can fine-tune STP parameters to make the left link active in S1 and blocking in S2, while the right link is active in S2 and blocking in S1. Again, if the right link fails, the left link is elected active by the STP algorithm for S2, without affecting normal switching of data traffic.

Using EMISTP, an STPD becomes more of an abstract concept. The STPD does not necessarily correspond to a physical domain; it is better regarded as a vehicle to carry VLANs that have STP instances. Because VLANs can overlap, so do STPDs. However, even if the different STPDs share the entire topology or part of the redundant topology, the STPDs react to topology change events in an independent fashion.

VLANs Spanning Multiple STPDs

Traditionally, the mapping from VLANs to STP instances have been one-to-one or many-to-one.

In both cases, a VLAN is wholly contained in a single instance. In practical deployment there are cases in which a one-to-many mapping is desirable. In a typical large enterprise network, for example, VLANs
span multiple sites and/or buildings. Each site represents a redundant looped area. However, between any two sites the topology is usually very simple.

Alternatively, the same VLAN may span multiple large geographical areas (because they belong to the same enterprise) and may traverse a great many nodes.

In this case, it is desirable to have multiple STP domains operating in a single VLAN, one for each looped area.

The justifications include the following:

- The complexity of the STP algorithm increases, and performance drops, with the size and complexity of the network. The 802.1D standard specifies a maximum network diameter of seven hops. By segregating a big VLAN into multiple STPDs, you reduce complexity and enhance performance.
- Local to each site, there may be other smaller VLANs that share the same redundant looped area with the large VLAN. Some STPDs must be created to protect those VLANs. The ability to partition VLANs allows the large VLAN to be “piggybacked” in those STPDs in a site-specific fashion.

Figure 151 has five domains. VLANs green, blue, brown, and yellow are local to each domain. VLAN red spans all of the four domains. Using a VLAN that spans multiple STPDs, you do not have to create a separate domain for VLAN red. Instead, VLAN red is “piggybacked” onto those domains local to other VLANs.

Figure 151: VLANs Spanning Multiple STPDs

In addition, this configuration has these features:

- Each site can be administered by a different organization or department within the enterprise. Having a site-specific STP implementation makes the administration more flexible and convenient.
- Between the sites the connections usually traverse distribution switches in ways that are known beforehand to be “safe” with STP. In other words, the looped areas are already well defined.

EMISTP Deployment Constraints

Although EMISTP greatly enhances STP capability, these features must deployed with care.

This section describes configuration issues that, if not followed, could lead to an improper deployment of EMISTP. This section also provides the following restrictive principles to abide by in network design:
• Although a physical port can belong to multiple STPDs, any VLAN on that port can be in only one domain. Put another way, a VLAN cannot belong to two STPDs on the same physical port.

• Although a VLAN can span multiple domains, any LAN segment in that VLAN must be in the same STPD. VLANs traverse STPDs only inside switches, not across links. On a single switch, however, bridge ports for the same VLAN can be assigned to different STPDs. This scenario is illustrated in Figure 152.

![Figure 152: VLANs Traverse Domains Inside Switches](image)

**Figure 152: VLANs Traverse Domains Inside Switches**

• The VLAN partition feature is deployed under the premise that the overall inter-domain topology for that VLAN is loop-free. Consider the case in Figure 153, VLAN red (the only VLAN in the figure) spans STPDs 1, 2, and 3. Inside each domain, STP produces a loop-free topology. However, VLAN red is still looped, because the three domains form a ring among themselves.
A necessary (but not sufficient) condition for a loop-free inter-domain topology is that every two domains only meet at a single crossing point.

Note
You can use MSTP to overcome the EMISTP constraints described in this section.

Per VLAN Spanning Tree

Switching products that implement Per VLAN Spanning Tree (PVST) have been in existence for many years and are widely deployed.

To support STP configurations that use PVST, ExtremeXOS has an operational mode called PVST+.

Note
In this document, PVST and PVST+ are used interchangeably. PVST+ is an enhanced version of PVST that is interoperable with 802.1Q STP. The following discussions are in regard to PVST+, if not specifically mentioned.

STPD VLAN Mapping

Each VLAN participating in PVST+ must be in a separate STPD, and the VLAN number (VLAN ID) must be the same as the STPD identifier (STPD ID).

As a result, PVST+ protected VLANs cannot be partitioned.
This fact does not exclude other non-PVST+ protected VLANs from being grouped into the same STPD. A protected PVST+ VLAN can be joined by multiple non-PVST+ protected VLANs to be in the same STPD.

Note
When PVST+ is used to interoperate with other networking devices, each VLAN participating in PVST+ must be in a separate STP domain.

Native VLAN
In PVST+, the native VLAN must be peered with the default VLAN on Extreme Networks devices, as both are the only VLANs allowed to send and receive untagged packets on the physical port.

Third-party PVST+ devices send VLAN 1 packets in a special manner. ExtremeXOS does not support PVST+ for VLAN 1. Therefore, when the switch receives a packet for VLAN 1, the packet is dropped.

When a PVST+ instance is disabled, the fact that PVST+ uses a different packet format raises an issue. If the STPD also contains ports not in PVST+ mode, the flooded packet has an incompatible format with those ports. The packet is not recognized by the devices connected to those ports.

Rapid Spanning Tree Protocol
The Rapid Spanning Tree Protocol (RSTP), originally in the IEEE 802.1w standard and now part of the IEEE 802.1D-2004 standard, provides an enhanced spanning tree algorithm that improves the convergence speed of bridged networks.

RSTP takes advantage of point-to-point links in the network and actively confirms that a port can safely transition to the forwarding state without relying on any timer configurations. If a network topology change or failure occurs, RSTP rapidly recovers network connectivity by confirming the change locally before propagating that change to other devices across the network. For broadcast links, there is no difference in convergence time between STP and RSTP.

RSTP supersedes legacy STP protocols, supports the existing STP parameters and configurations, and allows for seamless interoperability with legacy STP.

RSTP Concepts

Port Roles
RSTP uses information from BPDUs to assign port roles for each LAN segment. Port roles are not user-configurable. Port role assignments are determined based on the following criteria:

- A unique bridge identifier (MAC address) associated with each bridge
- The path cost associated with each bridge port
- A port identifier associated with each bridge port

RSTP assigns one of the following port roles to bridge ports in the network, as described in Table 114.
Table 114: RSTP Port Roles

<table>
<thead>
<tr>
<th>Port Role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root</td>
<td>Provides the shortest (lowest) path cost to the root bridge. Each bridge has only one root port; the root bridge does not have a root port. If a bridge has two or more ports with the same path cost, the port with the best port identifier (lowest MAC address) becomes the root port.</td>
</tr>
<tr>
<td>Designated</td>
<td>Provides the shortest path connection to the root bridge for the attached LAN segment. To prevent loops in the network, there is only one designated port on each LAN segment. To select the designated port, all bridges that are connected to a particular segment listen to each other’s BPDUs and agree on the bridge sending the best BPDU. The corresponding port on that bridge becomes the designated port. If there are two or more ports connected to the LAN, the port with the best port identifier becomes the designated port.</td>
</tr>
<tr>
<td>Alternate</td>
<td>Provides an alternate path to the root bridge and the root port.</td>
</tr>
<tr>
<td>Backup</td>
<td>Supports the designated port on the same attached LAN segment. Backup ports exist only when the bridge is connected as a self-loop or to a shared-media segment.</td>
</tr>
<tr>
<td>Disabled</td>
<td>A port in the disabled state does not participate in RSTP; however, it will forward traffic and learn new MAC source addresses.</td>
</tr>
</tbody>
</table>

When RSTP stabilizes:
- All root ports and designated ports are in the forwarding state.
- All alternate ports and backup ports are in the blocking state.

RSTP makes the distinction between the alternate and backup port roles to describe the rapid transition of the alternate port to the forwarding state if the root port fails.

To prevent a port from becoming an alternate or backup port, use the command:

```
configure stpd stpd_name ports active-role enable port .
```

To revert to the default that allows a port to be elected to any STP port role, use the command:

```
configure stpd stpd_name ports active-role disable port
```

To view the active-role status, use the command: `show stpd ports`.

**Link Types**

With RSTP (Rapid Spanning Tree Protocol), you can configure the link type of a port in an STPD.

RSTP tries to rapidly move designated point-to-point links into the forwarding state when a network topology change or failure occurs. For rapid convergence to occur, the port must be configured as a point-to-point link.

**Table 115** describes the link types.
### Table 115: RSTP Link Types

<table>
<thead>
<tr>
<th>Port Link Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto</td>
<td>Specifies the switch to automatically determine the port link type. An auto link behaves like a point-to-point link if the link is in full-duplex mode or if link aggregation is enabled on the port. Otherwise, the link behaves like a broadcast link used for 802.1w configurations.</td>
</tr>
<tr>
<td>Edge</td>
<td>Specifies a port that does not have a bridge attached. An edge port is held in the STP forwarding state unless a BPDU is received by the port. In that case, the port behaves as a normal RSTP port. The port is no longer considered an edge port. If the port does not receive subsequent BPDUs during a pre-determined time, the port attempts to become an edge port. ExtremeXOS 11.5 or earlier—An edge port is placed and held in the STP forwarding state unless a BPDU is received by the port. In that case, an edge port enters and remains in the blocking state until it stops receiving BPDUs and the message age timer expires.</td>
</tr>
<tr>
<td>Broadcast</td>
<td>Specifies a port attached to a LAN segment with more than two bridges. A port with a broadcast link type cannot participate in rapid reconfiguration using RSTP or MSTP. By default, all ports are broadcast links.</td>
</tr>
<tr>
<td>Point-to-point</td>
<td>Specifies a port attached to a LAN segment with only two bridges. A port with point-to-point link type can participate in rapid reconfiguration. Used for 802.1w and MSTP configurations.</td>
</tr>
</tbody>
</table>

### Configuring Link Types

- To configure the ports in an STP, enter the command:

  ```
  configure stpd stpd_name ports link-type [[auto | broadcast | point-to-point] port_list | edge port_list {edge-safeguard [enable | disable] {bpdu-restrict} {recovery-timeout seconds}}]
  ```

  Where the following is true:

  - auto—Configures the ports as auto links. If the link is in full-duplex mode or if link aggregation is enabled on the port, an auto link behaves like a point-to-point link.
  - broadcast—Configures the ports as broadcast ports. By default, all ports are broadcast links.
  - point-to-point—Configures the ports for rapid reconfiguration in an RSTP or MSTP environment.
  - edge—Configures the ports as edge ports. For information about edge safeguard, see Configuring Edge Safeguard on page 1141.

- To change the existing configuration of a port in an STP, and return the port to factory defaults, enter the command:

  ```
  unconfigure stpd stpd_name ports link-type port_list
  ```

- To display detailed information about the ports in an STP, enter the command:

  ```
  show {stpd} stpd_name ports {{[detail | port_list {detail}]}}
  ```

### Configuring Edge Safeguard

Loop prevention and detection on an edge port configured for RSTP is called edge safeguard. You can configure edge safeguard on RSTP edge ports to prevent accidental or deliberate misconfigurations (loops) resulting from connecting two edge ports together or by connecting a hub or other non-STP switch to an edge port. Edge safeguard also limits the impact of broadcast storms that might occur on edge ports. This advanced loop prevention mechanism improves network resiliency but does not interfere with the rapid convergence of edge ports.
An edge port configured with edge safeguard immediately enters the forwarding state and transmits BPDUs. If a loop is detected, STP blocks the port. By default, an edge port without edge safeguard configured immediately enters the forwarding state but does not transmit BPDUs unless a BPDU is received by that edge port.

You can also configure edge safeguard for loop prevention and detection on an MSTP edge port.

- To configure an edge port and enable edge safeguard on that port, use the command:

  ```
  configure stpd stpd_name ports link-type [[auto | broadcast | point-to-point] port_list | edge port_list [edge-safeguard [enable | disable] {bpdu-restrict} {recovery-timeout seconds}]]
  ```

- If you have already configured a port as an edge port and you want to enable edge safeguard on the port, use the following command:

  ```
  configure {stpd} stpd_name ports edge-safeguard enable port_list {bpdu-restrict} {recovery-timeout {seconds}}
  ```

- To disable edge safeguard on an edge port, enter the command:

  ```
  configure {stpd} stpd_name ports edge-safeguard disable port_list {bpdu-restrict} {recovery-timeout {seconds}}
  ```

In ExtremeXOS 11.5 and earlier, ports that connect to non-STP devices are edge ports. Edge ports do not participate in RSTP, and their role is not confirmed. Edge ports immediately enter the forwarding state unless the port receives a BPDU. In that case, edge ports enter the blocking state. The edge port remains in the blocking state until it stops receiving BPDUs and the message age timer expires.

ExtremeXOS 11.6 and later support an enhanced bridge detection method, which is part of the 802.1D-2004 standard. Ports that connect to non-STP devices are still considered edge ports. However, if you have an 802.1D-2004 compliant edge port, the bridge detection mechanism causes the edge port to transition to a non-edge port upon receiving a BPDU. If the former edge port does not receive a subsequent BPDU during a pre-determined interval, the port attempts to become an edge port.

In ExtremeXOS 12.0.3 and 12.1.4 onwards, STP edge safeguard disables a port when a remote loop is detected. ExtremeXOS versions prior to 12.0.3 and 12.1.4 place the port in blocking mode. The change was made because BPDUs are still processed when a port is in a blocking state. A remote loop causes BPDUs to be exponentially duplicated which caused high CPU utilization on the switch even though the port was transitioned to a blocked state.

**Configuring Auto Edge**

This feature helps to automatically determine if a port is an edge port or non-edge port. If no BPDU is received for a period of time on auto edge enabled ports, the switch marks those ports as edge ports. If BPDU is received, the switch marks those ports as non-edge ports. By default auto edge is enabled on all ports.

**RSTP Timers**

For RSTP to rapidly recover network connectivity, RSTP requires timer expiration. RSTP derives many of the timer values from the existing configured STP timers to meet its rapid recovery requirements rather than relying on additional timer configurations.
Table 116 describes the user-configurable timers, and Table 117 on page 1143 describes the timers that are derived from other timers and are not user configurable.

### Table 116: User-Configurable Timers

<table>
<thead>
<tr>
<th>Timer</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hello</td>
<td>The root bridge uses the hello timer to send out configuration BPDUs through all of its forwarding ports at a predetermined, regular time interval. The default value is 2 seconds. The range is 1 to 10 seconds.</td>
</tr>
<tr>
<td>Forward delay</td>
<td>A port moving from the blocking state to the forwarding state uses the forward delay timer to transition through the listening and learning states. In RSTP, this timer complements the rapid configuration behavior. If none of the rapid rules are in effect, the port uses legacy STP rules to move to the forwarding state. The default is 15 seconds. The range is 4 to 30 seconds.</td>
</tr>
</tbody>
</table>

### Table 117: Derived Timers

<table>
<thead>
<tr>
<th>Timer</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCN</td>
<td>The root port uses the topology change notification (TCN) timer when it detects a change in the network topology. The TCN timer stops when the topology change timer expires or upon receipt of a topology change acknowledgement. The default value is the same as the value for the bridge hello timer.</td>
</tr>
<tr>
<td>Topology change</td>
<td>The topology change timer determines the total time it takes the forwarding ports to send configuration BPDUs. The default value for the topology change timer depends upon the mode of the port: 802.1D mode—The sum of the forward delay timer value (default value is 15 seconds; range of 4 to 30 seconds) and the maximum age timer value (default value is 20 seconds; range of 6 to 40 seconds). 802.1w mode—Double the hello timer value (default value is 4 seconds).</td>
</tr>
<tr>
<td>Message age</td>
<td>A port uses the message age timer to time out receiving BPDUs. When a port receives a superior or equal BPDU, the timer restarts. When the timer expires, the port becomes a designated port and a configuration update occurs. If the bridge operates in lw mode and receives an inferior BPDU, the timer expires early. The default value is the same as the STPD bridge max age parameter.</td>
</tr>
<tr>
<td>Hold</td>
<td>A port uses the hold timer to restrict the rate that successive BPDUs can be sent. The default value is the same as the value for the bridge hello timer.</td>
</tr>
<tr>
<td>Recent backup</td>
<td>The timer starts when a port leaves the backup role. When this timer is running, the port cannot become a root port. The default value is double the hello time (4 seconds).</td>
</tr>
<tr>
<td>Recent root</td>
<td>The timer starts when a port leaves the root port role. When this timer is running, another port cannot become a root port unless the associated port is put into the blocking state. The default value is the same as the forward delay time.</td>
</tr>
</tbody>
</table>

The protocol migration timer is neither user-configurable nor derived; it has a set value of 3 seconds. The timer starts when a port transitions from STP (802.1D) mode to RSTP (802.1w) mode and vice-versa. This timer must expire before further mode transitions can occur.

**RSTP Operation**

In an RSTP environment, a point-to-point link LAN segment has two bridges.
A switch that considers itself the unique, designated bridge for the attached LAN segment sends a "propose" message to the other bridge to request a confirmation of its role. The other bridge on that LAN segment replies with an "agree" message if it agrees with the proposal. The receiving bridge immediately moves its designated port into the forwarding state.

Before a bridge replies with an "agree" message, it reverts all of its designated ports into the blocking state. This introduces a temporary partition into the network. The bridge then sends another "propose" message on all of its designated ports for further confirmation. Because all of the connections are blocked, the bridge immediately sends an "agree" message to unblock the proposing port without having to wait for further confirmations to come back or without the worry of temporary loops.

Beginning with the root bridge, each bridge in the network engages in the exchange of "propose" and "agree" messages until they reach the edge ports. Edge ports connect to non-STP devices and do not participate in RSTP. Their role does not need to be confirmed. If you have an 802.1D-2004 compliant edge port, the bridge detection mechanism causes the edge port to transition to a non-edge port upon receiving a BPDU. If the former edge port does not receive a subsequent BPDU during a pre-determined interval, the port attempts to become an edge port.

RSTP attempts to transition root ports and designated ports to the forwarding state and alternate ports and backup ports to the blocking state as rapidly as possible.

A port transitions to the forwarding state if any of the port:

- Has been in either a root or designated port role long enough that the spanning tree information supporting this role assignment has reached all of the bridges in the network;

  **Note**
  RSTP is backward-compatible with STP, so if a port does not move to the forwarding state with any of the RSTP rapid transition rules, a forward delay timer starts and STP behavior takes over.

- Is now a root port and no other ports have a recent role assignment that contradicts with its root port role;
- Is a designated port and attaches to another bridge by a point-to-point link and receives an "agree" message from the other bridge port; or
- Is an edge port. An edge port is a port connected to a non-STP device and is in the forwarding state.

The following sections provide more information about RSTP behavior.

**Root Port Rapid Behavior**

In Figure 154 on page 1145, the diagram on the left displays the initial network topology with a single bridge having the following:

- Two ports are connected to a shared LAN segment.
- One port is the designated port.
- One port is the backup port.

The diagram on the right displays a new bridge that:

- Is connected to the LAN segment.
- Has a superior STP bridge priority.
Becomes the root bridge and sends a BPDU (Bridge Protocol Data Unit) to the LAN that is received by both ports on the old bridge.

Figure 154: Example of Root Port Rapid Behavior

If the backup port receives the BPDU first, STP processes this packet and temporarily elects this port as the new root port while the designated port’s role remains unchanged. If the new root port is immediately put into the forwarding state, there is a loop between these two ports.

To prevent this type of loop from occurring, the recent backup timer starts. The root port transition rule does not allow a new root port to be in the forwarding state until the recent backup timer expires.

Another situation may arise if you have more than one bridge and you lower the port cost for the alternate port, which makes it the new root port. The previous root port is now an alternate port. Depending on your STP implementation, STP may set the new root port to the forwarding state before setting the alternate port to the blocking state. This may cause a loop.

To prevent this type of loop from occurring, the recent root timer starts when the port leaves the root port role. The timer stops if the port enters the blocking state. RSTP requires that the recent root timer stop on the previous root port before the new root port can enter the forwarding state.

Desiganted Port Rapid Behavior

When a port becomes a new designated port, or the STP priority changes on an existing designated port, the port becomes an unsynced designated port.

For an unsynced designated port to rapidly move into the forwarding state, the port must propose a confirmation of its role on the attached LAN segment (unless the port is an edge port). Upon receiving an “agree” message, the port immediately enters the forwarding state.

If the receiving bridge does not agree and it has a superior STP priority, the receiving bridge replies with its own BPDU. Otherwise, the receiving bridge keeps silent, and the proposing port enters the forwarding state and starts the forward delay timer.

The link between the new designated port and the LAN segment must be a point-to-point link. If there is a multi-access link, the “propose” message is sent to multiple recipients. If only one of the recipients
agrees with the proposal, the port can erroneously enter the forwarding state after receiving a single “agree” message.

Receiving Bridge Behavior
The receiving bridge must decide whether or not to accept a proposal from a port.

Upon receiving a proposal for a root port, the receiving bridge:
• Processes the BPDU and computes the new STP topology.
• Synchronizes all of the designated ports if the receiving port is the root port of the new topology.
• Puts all unsynced, designated ports into the blocking state.
• Sends down further “propose” messages.
• Sends back an “agree” message through the root port.

If the receiving bridge receives a proposal for a designated port, the bridge replies with its own BPDU. If the proposal is for an alternate or backup port, the bridge keeps silent.

Propagating Topology Change Information
When a change occurs in the topology of the network, such events are communicated through the network.

In an RSTP environment, only non-edge ports entering the forwarding state cause a topology change. A loss of network connectivity is not considered a topology change; however, a gain in network connectivity must be communicated. When an RSTP bridge detects a topology change, that bridge starts the topology change timer, sets the topology change flag on its BPDUs, floods all of the forwarding ports in the network (including the root ports), and flushes the learned MAC address entries.

Rapid Reconvergence
This section describes the RSTP rapid behavior following a topology change.

In this example, the bridge priorities are assigned based on the order of their alphabetical letters; bridge A has a higher priority than bridge F.

Suppose you have a network, as shown in Figure 155 on page 1147, with six bridges (bridge A through bridge F) where the following is true:
• Bridge A is the root bridge.
• Bridge D contains an alternate port in the blocking state.
• All other ports in the network are in the forwarding state.
Figure 155: Initial Network Configuration

The network reconverges in the following way:

If the link between bridge A and bridge F goes down, bridge F detects the root port is down. At this point, bridge F:

• Immediately disables that port from the **STP**.
• Performs a configuration update.

As shown in Figure 156, after the configuration update, bridge F:

• Considers itself the new root bridge.
• Sends a BPDU message on its designated port to bridge E.

Figure 156: Down Link Detected

• Bridge E believes that bridge A is the root bridge. When bridge E receives the BPDU on its root port from bridge F, bridge E:
  • Determines that it received an inferior BPDU.
  • Immediately begins the max age timer on its root port.
  • Performs a configuration update.

As shown in Figure 157, after the configuration update, bridge E:

• Regards itself as the new root bridge.
• Sends BPDU messages on both of its designated ports to bridges F and D, respectively.
Figure 157: New Root Bridge Selected

As shown in Figure 158, when bridge F receives the superior BPDU and configuration update from bridge E, bridge F:
- Decides that the receiving port is the root port.
- Determines that bridge E is the root bridge.

Figure 158: Communicating New Root Bridge Status to Neighbors

Bridge D believes that bridge A is the root bridge. When bridge D receives the BPDU from bridge E on its alternate port, bridge D:
- Immediately begins the max age timer on its alternate port.
- Performs a configuration update.

As shown in Figure 159, after the configuration update, bridge D:
- Moves the alternate port to a designated port.
- Sends a “propose” message to bridge E to solicit confirmation of its designated role and to rapidly move the port into the designated state.
Upon receiving the proposal, bridge E (as shown in Figure 160 on page 1149):

- Performs a configuration update.
- Changes its receiving port to a root port.

The existing designated port enters the blocking state.

Bridge E then sends:

- A “propose” message to bridge F.
- An “agree” message from its root port to bridge D.

To complete the topology change (as shown in Figure 161):

- Bridge D moves the port that received the “agree” message into the forwarding state.
- Bridge F confirms that its receiving port (the port that received the “propose” message) is the root port, and immediately replies with an “agree” message to bridge E to unblock the proposing port.
Figure 161: Completing the Topology Change

Figure 162 displays the new topology.

Figure 162: Final Network Configuration

Compatibility With STP (802.1D)

RSTP interoperates with legacy STP protocols; however, the rapid convergence benefits are lost when interacting with legacy STP bridges.

Each RSTP bridge contains a port protocol migration state machine to ensure that the ports in the STPD operate in the correct, configured mode. The state machine is a protocol entity within each bridge configured to run in 802.1w mode. For example, a compatibility issue occurs if you configure 802.1w mode and the bridge receives an 802.1D BPDU on a port. The receiving port starts the protocol migration timer and remains in 802.1D mode until the bridge stops receiving 802.1D BPDUs. Each time the bridge receives an 802.1D BPDU, the timer restarts. When the port migration timer expires, no more 802.1D BPDUs have been received, and the bridge returns to its configured setting, which is 802.1w mode.

Multiple Spanning Tree Protocol

The MSTP, based on IEEE 802.1Q-2003 (formerly known as IEEE 802.1s), allows the bundling of multiple VLANs into one spanning tree topology.

This concept is not new to Extreme Networks. Like MSTP, Extreme Networks proprietary EMISTP implementation can achieve the same capabilities of sharing a virtual network topology among multiple VLANs; however, MSTP overcomes some of the challenges facing EMISTP, including enhanced loop protection mechanisms and new capabilities to achieve better scaling.
MSTP logically divides a Layer 2 network into regions. Each region has a unique identifier and contains multiple spanning tree instances (MSTIs). An MSTI is a spanning tree domain that operates within and is bounded by a region. MSTIs control the topology inside the regions. The Common and Internal Spanning Tree (CIST) is a single spanning tree domain that interconnects MSTP regions. The CIST is responsible for creating a loop-free topology by exchanging and propagating BPDUs across regions to form a Common Spanning Tree (CST).

MSTP uses RSTP as its converging algorithm and is interoperable with the legacy STP protocols: STP (802.1D) and RSTP (802.1w).

MSTP has three major advantages over 802.1D, 802.1w, and other proprietary implementations:

- To save control path bandwidth and provide improved scalability, MSTP uses regions to localize BPDU traffic. BPDUs containing information about MSTIs contained within an MSTP region do not cross that region’s boundary.
- A single BPDU transmitted from a port can contain information for up to 64 STPDs. MSTP BPDU processing utilizes less resources compared to 802.1D or 802.1w where one BPDU corresponds to one STPD.
- In a typical network, a group of VLANs usually share the same physical topology. Dedicating a spanning tree per VLAN like PVST+ is CPU intensive and does not scale very well. MSTP makes it possible for a single STPD to handle multiple VLANs.

**MSTP Concepts**

**MSTP Regions**

An MSTP network consists of either individual MSTP regions connected to the rest of the network with 802.1D and 802.1w bridges or as individual MSTP regions connected to each other.

An MSTP region defines the logical boundary of the network. With MSTP, you can divide a large network into smaller areas similar to an OSPF (Open Shortest Path First) area or a BGP (Border Gateway Protocol) Autonomous System, which contain a group of switches under a single administration. Each MSTP region has a unique identifier and is bound together by one CIST that spans the entire network. A bridge participates in only one MSTP region at a time.

An MSTP region can hide its internal STPDs and present itself as a virtual 802.1w bridge to other interconnected regions or 802.1w bridges because the port roles are encoded in 802.1w and MSTP BPDUs.

By default, the switch uses the MAC address of the switch to generate an MSTP region. Since each MAC address is unique, every switch is in its own region by default. For multiple switches to be part of an MSTP region, you must configure each switch in the region with the same MSTP region identifiers. See Configuring MSTP Region Identifiers on page 1152 for information.

In Figure 163, all bridges inside MSTP regions 1 and 2 are MSTP bridges; bridges outside of the regions are either 802.1D or 802.1w bridges.
Configuring MSTP Region Identifiers

For multiple switches to be part of an MSTP region, you must configure each switch in the region with the same MSTP configuration attributes, also known as MSTP region identifiers. The following list describes the MSTP region identifiers:

- **Region Name**—This indicates the name of the MSTP region. In the Extreme Networks implementation, the maximum length of the name is 32 characters and can be a combination of alphanumeric characters and underscores (_).
- **Format Selector**—This indicates a number to identify the format of MSTP BPDUs. The default is 0.
- **Revision Level**—An unsigned integer encoded within a fixed field of 2 octets that identifies the revision of the current MST configuration. The revision number is not incremented automatically each time that the MST configuration is committed.

The switches inside a region exchange BPDUs that contain information for MSTIs.

The switches connected outside of the region exchange CIST information. By having devices look at the region identifiers, MSTP discovers the logical boundary of a region:

- To configure the MSTP region name, use the command:
  ```
  configure mstp region regionName
  ```
  The maximum length of the region name is 32 characters and can be a combination of alphanumeric characters and underscores (_). You can configure only one MSTP region on the switch at any given time.

  If you have an active MSTP region, we recommend that you disable all active STPDs in the region before renaming the region on all of the participating switches.

- To configure the number used to identify MSTP BPDUs, use the command:
  ```
  configure mstp format format_identifier
  ```
By default, the value used to identify the MSTP BPDUs is 0. The range is 0 to 255.
If you have an active MSTP region, we recommend that you disable all active STPDs in the region before modifying the value used to identify MSTP BPDUs on all participating switches.

- To configure the MSTP revision level, use the command:
  
  `configure mstp revision revision`

  Although this command is available on the CLI, this command is reserved for future use.

**Unconfiguring an MSTP Region**

Before you unconfigure an MSTP region, we recommend that you disable all active STPDs in the region.

To unconfigure the MSTP region on the switch, use the command:

`unconfigure mstp region`

After you issue this command, all of the MSTP settings return to their default values. See Configuring MSTP Region Identifiers on page 1152 for information about the default settings.

**Common and Internal Spanning Tree**

MSTP logically divides a Layer 2 network into regions. The Common and Internal Spanning Tree (CIST) is a single spanning tree domain that interconnects MSTP regions. The CIST is responsible for creating a loop-free topology by exchanging and propagating BPDUs across regions to form a Common Spanning Tree (CST).

In essence, the CIST is similar to having a large spanning tree across the entire network. The CIST has its own root bridge that is common to all MSTP regions, and each MSTP region elects a CIST regional root that connects that region to the CIST, thereby forming a CST.

The switch assigns the CIST an instance ID of 0, which allows the CIST to send BPDUs for itself in addition to all of the MSTIs within an MSTP region. Inside a region, the BPDUs contain CIST records and piggybacked M-records. The CIST records contain information about the CIST, and the M-records contain information about the MSTIs. Boundary ports exchange only CIST record BPDUs.

All MSTP configurations require a CIST domain. You must first configure the CIST domain before configuring any MSTIs. By default, all MSTI ports in the region are inherited by the CIST. You cannot delete or disable a CIST if any of the MSTIs are active in the system.

**Configuring the CIST**

- Configure an STPD as the CIST, specifying the `mstp cist` keywords in the following command:
  
  `configure stpd stpd_name mode [dot1d | dot1w | mstp [cist | msti instance]]`

  You can enable MSTP on a per STPD basis only. By specifying the `mstp cist` keywords, you can configure the mode of operation for the STPD as MSTP and identify the STPD to be the CIST.

**CIST Root Bridge**

In a Layer 2 network, the bridge with the lowest bridge ID becomes the CIST root bridge. The parameters (vectors) that define the root bridge include the following:
- User-defined bridge priority (by default, the bridge priority is 32,768)
- MAC address

The CIST root bridge can be either inside or outside an MSTP region. The CIST root bridge is unique for all regions and non-MSTP bridges, regardless of its location.

For more information about configuring the bridge ID, see the `configure stpd priority` command.

**CIST Regional Root Bridge**

Within an MSTP region, the bridge with the lowest path cost to the CIST root bridge is the CIST regional root bridge.

The path cost, also known as the CIST external path cost, is a function of the link speed and number of hops. If there is more than one bridge with the same path cost, the bridge with the lowest bridge ID becomes the CIST regional root. If the CIST root is inside an MSTP region, the same bridge is the CIST regional root for that region because it has the lowest path cost to the CIST root. If the CIST root is outside an MSTP region, all regions connect to the CIST root via their CIST regional roots.

The total path cost to the CIST root bridge from any bridge in an MSTP region consists of the CIST internal path cost (the path cost of the bridge to the CIST regional root bridge) and the CIST external path cost. To build a loop-free topology within a region, the CIST uses the external and internal path costs, and the MSTI uses only the internal path cost.

Looking at MSTP region 1 in Figure 164, the total path cost for the bridge with ID 60 consists of an external path cost of A and an internal path cost of E.

![Figure 164: Closeup of MSTP Region 1](image)

**CIST Root Port**

The port on the CIST regional root bridge that connects to the CIST root bridge is the CIST root port (also known as the master port for MSTIs).
The CIST root port is the master port for all MSTIs in that region, and it is the only port that connects the entire region to the CIST root.

If a bridge is both the CIST root bridge and the CIST regional root bridge, there is no CIST root port on that bridge.

**Enabling the CIST**

To enable the CIST, use the following command and specify the CIST domain as the `stpd_name`:

```bash
enable stpd {stpd_name}
```

**Multiple Spanning Tree Instances**

Multiple spanning tree instances (MSTIs) control the topology inside an MSTP region. An MSTI is a spanning tree domain that operates within and is bounded by a region; an MSTI does not exchange BPDUs with or send notifications to other regions. You must identify an MSTI on a per region basis. The MSTI ID does not have any significance outside of its region so you can reuse IDs across regions. An MSTI consists of a group of VLANs, which can share the same network topology. Each MSTI has its own root bridge and a tree spanning its bridges and LAN segments.

You must first configure a CIST before configuring any MSTIs in the region. You cannot delete or disable a CIST if any of the MSTIs are active in the system.

You can map multiple VLANs to an MSTI; however, multiple MSTIs cannot share the same VLAN.

**Configuring the MSTI and the MSTI ID**

MSTP uses the MSTI ID, not an Stpd ID, to identify the spanning tree contained within the region. As previously described, the MSTI ID only has significance within its local region, so you can re-use IDs across regions.

To configure the MSTI that is inside an MSTP region and its associated MSTI ID, use the following command and specify the `mstp [msti instance]` parameters:

```bash
configure stpd stpd_name mode [dot1d | dot1w | mstp [cist | msti instance]]
```

The range of the MSTI instance ID is 1–4094.

MSTP STPDs use 802.1D BPDU encapsulation mode by default. To ensure correct operation of your MSTP STPDs, do not configure EMISTP or PVST+ encapsulation mode for MSTP STPDs. For more information, see Encapsulation Modes on page 1127.

**MSTI Regional Root Bridge**

Each MSTI independently chooses its own root bridge. For example, if two MSTIs are bounded to a region, there is a maximum of two MSTI regional roots and one CIST regional root.

The bridge with the lowest bridge ID becomes the MSTI regional root bridge. The parameters that define the root bridge include the following:

- User-defined bridge priority (by default, the bridge priority is 32,768)
- MAC address
Within an MSTP region, the cost from a bridge to the MSTI regional root bridge is known as the MSTI internal path cost. Looking at MSTP region 1 in Figure 164 on page 1154, the bridge with ID 60 has a path cost of F to the MSTI regional root bridge.

The MSTI regional root bridge can be the same as or different from the CIST regional root bridge of that region. You achieve this by assigning different priorities to the STP instances configured as the MSTIs and the CIST. For more information about configuring the bridge ID, see the configure stpd priority command in the ExtremeXOS 22.6 Command Reference Guide.

**MSTI Root Port**

The port on the bridge that has the lowest path cost to the MSTI regional root bridge is the MSTI root port.

If a bridge has two or more ports with the same path cost, the port with the best port identifier becomes the root port.

**Enabling the MSTI**

To enable the MSTI, use the following command and specify the MSTI domain as the stpd_name:

```
enable stpd {stpd_name}
```

**Note**

If two switches are configured for the same CIST and MSTI region, in order for them to understand that they are in the same region, both must also belong to the same VLAN which is added to the STP domain. If they belong to different VLANs, each switch believes that each belongs to a different region. When an MSTP BPDU is sent, it carries a VID digest created by VLAN memberships in the CIST domain and the MSTI domain.

**Boundary Ports**

Boundary ports are bridge ports that are only connected to other MSTP regions or 802.1D or 802.1w bridges.

The ports that are not at a region boundary are called internal ports. The boundary ports exchange only CIST BPDUs. A CIST BPDU originated from the CIST root enters a region through the CIST root port and egresses through boundary ports. This behavior simulates a region similar to an 802.1w bridge, which receives BPDUs on its root ports and forwards updated BPDUs on designated ports.

Figure 165 shows an MSTP network that consists of two MSTP regions. Each region has its own CIST regional root and is connected to the CIST root through master ports. The CIST regional roots in each region are the MSTP bridges having the lowest CIST external root path cost. The CIST root is the bridge with the lowest bridge ID and is an 802.1w bridge outside of either MSTP region.
MSTP Region 1 and MSTP Region 2 are connected to the CIST root through directly connected ports, identified as master ports. The bridge with ID 100 connects to the CIST root through Region 1, Region 2, or segment B. For this bridge, either Region 1 or Region 2 can be the designated region or segment B can be the designated segment. The CIST BPDUs egressing from the boundary ports carry the CIST regional root as the designated bridge. This positions the entire MSTP region as one virtual bridge.

The CIST controls the port roles and the state of the boundary ports. A master port is always forwarding for all CIST and MSTI VLANs. If the CIST sets a boundary port to the discarding state, the CIST blocks traffic for all VLANs mapped to it and the MSTIs within that region. Each MSTI blocks traffic for their member VLANs and puts their internal ports into the forwarding or blocking state depending on the MSTI port roles.

**MSTP Port Roles**

MSTP uses the same port roles as RSTP (Root, Designated, Alternate, and Backup).

In addition to these port roles, MSTP introduces a new port role: Master. A Master port is the port that connects an MSTI to the CIST root.

**MSTP Port States**

MSTP uses the same port states as RSTP (Listening, Learning, Forwarding, and Blocking).

In the Extreme Networks MSTP implementation, the listening state is not truly implemented as FDB (forwarding database) learning cannot be done when the port is not in the forwarding state. Ports in the blocking state listen but do not accept ingress traffic, perform traffic forwarding, or learn MAC source address; however, the port receives and processes BPDUs.

For more information about all of the STP port states, see STP States on page 1129.
**MSTP Link Types**

*STP* uses the same link types as *STP* and *RSTP*, respectively.

In an MSTP environment, configure the same link types for the CIST and all MSTIs.

For more information about the link types, see Link Types on page 1140.

**MSTP Edge Safeguard**

You can configure edge safeguard for loop prevention and detection on an MSTP edge port. For more information, see Configuring Edge Safeguard on page 1141.

---

**Note**

In MSTP, configuring edge safeguard at CIST will be inherited in all MSTIs.

In MSTP, an edge port needs to be added to a CIST before adding it to an MSTI.

---

**MSTP Timers**

*STP* uses the same timers as *STP* and RSTP. For more information, see RSTP Timers on page 1142.

**MSTP Hop Counts**

In an MSTP environment, the hop count has the same purpose as the maxage timer for 802.1D and 802.1w environments. The CIST hop count is used within and outside a region. The MSTI hop count is used only inside of the region. In addition, if the other end is an 802.1D or 802.1w bridge, the maxage timer is used for interoperability between the protocols.

The BPDUs use hop counts to age out information and to notify neighbors of a topology change.

To configure the hop count:

```
configure stpd stpd_name max-hop-count hopcount
```

By default, the hop count of a BPDU is 20 hops. The range is 6 to 40 hops.

**Configuring MSTP on the Switch**

To configure and enable MSTP:

1. Create the MSTP region using the following command:

```
configure mstp region regionName
```
2 Create and configure the CIST, which forms the CST, using the following commands:

```
create stpd stpd_name {description stpd-description}
configure stpd stpd_name mode mstp cist
```

**Note**

You can configure the default STPD, S0 as the CIST. No VLAN can be bound to the CIST and no ports can be added to the CIST. Therefore, the VLAN should be bound to the MSTI and the “show MSTI port” command will show the VLAN ports. The ports added to the MSTI are bound automatically to the CIST even though they are not added to it.

3 Enable the CIST using the command:

```
enable stpd {stpd_name}
```

4 Create and configure MSTIs using the commands:

```
create stpd stpd_name {description stpd-description}
configure stpd stpd_name mode mstp cist instance
```

5 Add VLANs to the MSTIs using one of the following commands:
   a Manually binding ports

```
configure stpd stpd_name add vlan vlan_name ports [all | port_list] 
   {[dot1d | emistp | pvst-plus]}
configure vlan vlan_name add ports [all | port_list] {tagged {tag} | untagged} stpd stpd_name {[dot1d | emistp | pvst-plus]}
```

   b Automatically binding ports to an STPD when ports are added to a member VLAN

```
enable stpd stpd_name auto-bind vlan vlan_name
```

6 Enable the MSTIs using the command:

```
enable stpd {stpd_name}
```

For a more detailed configuration example, see MSTP Configuration Example on page 1172.

**MSTP Operation**

To further illustrate how MSTP operates and converges, Figure 166 on page 1160 displays a network with two MSTP regions. Each region contains three MSTP bridges and one MSTI. The overall network topology also contains one CIST root bridge (Switch A, which has the lowest bridge ID), one interconnecting 802.1w bridge (Switch D), and 10 full duplex, point-to-point segments. VLAN Default spans all of the bridges and segments in the network, VLAN engineering is local to its respective region, and STPD S0 is configured as the CIST on all bridges.
MSTP Region 1 consists of the following:
- Three bridges named Switch A, Switch B, and Switch C
- One MSTI STPD named S1 with an MSTI ID of 1
- VLAN Engineering mapped to the MSTI STPD, S1
- Switch A as the CIST root bridge (this is the CIST root bridge for all regions)
- Switch A as the CIST regional root bridge
- Switch A as the MSTI regional root bridge
- Three boundary ports that connect to MSTP Region 2 and other 802.1D or 802.1w bridges

MSTP Region 2 consists of the following:
- Three bridges named Switch E, Switch F, and Switch G
- One MSTI STPD named S1 with an MSTI ID of 1
- VLAN finance mapped to the MSTI STPD, S1
- Switch E as the CIST regional root bridge
- Switch F as the MSTI regional root bridge
- One master port that connects to the CIST
- Three boundary ports that connect to MSTP Region 1 and other 802.1D or 802.1w bridges

The following sequence describes how the MSTP topology converges:
1. Determining the CIST root bridge, MSTP regions, and region boundaries.

---

**Note**
The MSTI ID does not have any significance outside of its region so you can reuse IDs across regions.
Each bridge believes that it is the root bridge, so each bridge initially sends root bridge BPDUs throughout the network. As bridges receive BPDUs and compare vectors, the bridge with the lowest Bridge ID is elected the CIST root bridge. In our example, Switch A has the lowest Bridge ID and is the CIST root bridge.

The bridges in the MSTP regions (Switches A, B, C, E, F, and G) advertise their region information along with their bridge vectors.

Segments 1, 3, and 9 receive BPDUs from other regions and are identified as boundary ports for Region 1. Similarly, segments 2, 3, and 9 are identified as boundary ports for Region 2.

2 Controlling boundary ports.

Each MSTP region has a CIST regional root bridge that communicates to the CIST root bridge. The bridge with the lowest path cost becomes the CIST regional root bridge. The port on the CIST regional root bridge that connects to the CIST root bridge is the CIST root port.

For Region 1, Switch A has the lowest cost (0 in this example) and becomes the CIST regional root. Since the bridge is both the CIST root bridge and the CIST regional root bridge, there is no CIST root port on the bridge.

For Region 2, Switch E is the CIST regional root bridge and so a port on that bridge becomes the CIST root port.

3 Identifying MSTI regional roots.

Each MSTI in a region has an MSTI regional root bridge. MSTI regional roots are selected independently of the CIST root and CIST regional root. The MSTP BPDUs have M-records for each MSTI. Bridges belonging to an MSTI compare vectors in their M-records to elect the MSTI regional root.

4 Converging the CIST.

The CIST views every region as a virtual bridge and calculates the topology using the 802.1w algorithm. The CIST calculates the topology both inside and outside of a region.

5 Converging MSTIs.

After the CIST identifies the boundary ports, each MSTI in a domain converge their own trees using 802.1w.

At this point, all CIST and MSTIs have assigned port roles (Root, Designated, Alternate, and Backup) to their respective spanning trees. All root and designated ports transition to the forwarding state while the remaining ports remain in the discarding state.

Propagating topology change information is similar to that described for RSTP.

For more information, see Propagating Topology Change Information on page 1146.

For a configuration example, see MSTP Configuration Example on page 1172.
STP and Network Login

STP and network login can be enabled on the same port. This feature can be used to prevent loops while providing redundancy and security on aggregated as well as end switches.

Note
You should be aware that an STP topology change will affect the network login clients. See STP Rules and Restrictions on page 1165 for further information.

Figure 167 shows STP and network login enabled on ports 2 and 3 of Switch 2 and Switch 3 for a typical aggregation scenario.

Figure 167: STP and Network Login Enabled

This relieves the administrator from having to configure network login on all the edge ports. All the traffic can be monitored and resiliency is provided at the aggregation side.

The Figure 168 shows a typical scenario for protecting loops and monitoring traffic on the edge side.
Figure 168: Traffic Monitoring on the Edge Side

In huge networks, it is not easy to control or prevent end users from connecting devices other than workstations to the edge ports. This feature helps prevent the network loops that occur when end users connect a switch or hub to the existing edge port in order to increase the number of end user ports.

**STP and MLAG**

You can configure MSTP and RSTP on MLAG (Multi-switch Link Aggregation Group) peers and access switches, which can prevent loops in networks containing MLAG topology. This allows third-party switches to be connected to MLAG topology (as access switches) and an MSTP or RSTP domain can span ExtremeXOS and third-party switches.

In typical MLAG deployments (see Figure 169), connections can exist between access switches, which can cause data loops. By configuring MSTP/RSTP on all the nodes, loops can be effectively prevented.

You should configure the MSTP/RSTP domain in the MLAG peers with a higher priority than the access switches, which blocks the redundant link between access switches. The LAG links in blue form one set of MLAG links and the corresponding ports at MLAG peers are associated with one MLAG index. The LAG links in red form another set of MLAG links, and the corresponding ports at MLAG peers are associated with another MLAG index.
MSTP/RSTP is supported in simple, W-MLAG, and two-tier MLAG topologies.

For the purpose of synchronization of protocol information, a master is elected for each MLAG index between MLAG peers, based on switch MAC address of peers and MLAG index. By choosing MLAG index with odd or even number, it is possible to change mastership between MLAG peers. Only the master node will transmit BPDUs and process BPDUs. Port roles and states are computed by the master node for the given MLAG index and applied on the local MLAG port. These details are check pointed to the backup node and are applied on its MLAG port.

**Recommendations for Configuring MSTP/RSTP with MLAG**

You should configure in such a way that one of the MLAG peers become root bridge (see Bridge Priority on page 1113), and also configure MLAG peers with backup root option (see Backup Root on page 1119). The former avoids less powerful access switches from becoming the root bridge; the latter facilitates faster convergence as the other MLAG peer becomes root bridge quicker. Loop protect feature (see Loop Protect on page 1117) should not be enabled on LAG ports (which are part of the MLAG topology) on access switches. This is because a multi-source condition is triggered when one of the two MLAG peers goes down. The loop protect feature prevents the port from going to the forwarding state, if configured. However, enabling this feature on MLAG ports is acceptable.

Since both MLAG peers should act like single switch, the ISC link should not be blocked, regardless of MSTP/RSTP role. Keeping this in mind, the port cost of the ISC port is chosen internally to be the lowest possible value (see Default Port Path Cost on page 1112). This helps in selecting the ISC link as the active link if there are any parallel links to the ISC. MLAG links do not have special preference over redundant connections that are in parallel to the MLAG link. The standard MST/RSTP algorithm disables both MLAG links if it has higher root path cost than the redundant link. This allows the lower cost link to be...
chosen as active link. If you configure MSTP over MLAG, both MLAG peers and access switches should be in the same MSTP region. This makes MLAG and ISC ports internal ports.

**STP Rules and Restrictions**

This section summarizes the rules and restrictions for configuring STP are:

- The carrier VLAN must span all ports of the STPD. (This is not applicable to MSTP.)
- The StpdID must be the VLAN ID of the carrier VLAN; the carrier VLAN cannot be partitioned. (This is not applicable to MSTP.)
- A default VLAN cannot be partitioned. If a VLAN traverses multiple STPDs, the VLAN must be tagged.
- An STPD can carry, at most, one VLAN running in PVST+ mode, and its STPD ID must be identical with that VLAN ID. In addition, the PVST+ VLAN cannot be partitioned.
- The default VLAN of a PVST+ port must be identical to the native VLAN on the PVST+ device connected to that port.
- If an STPD contains both PVST+ and non-PVST+ ports, that STPD must be enabled. If that STPD is disabled, the BPDUs are flooded in the format of the incoming STP port, which may be incompatible with those of the connected devices.
- The 802.1D ports must be untagged and the EMISTP/PVST+ ports must be tagged in the carrier VLAN.
- STP and network login operate on the same port as follows:
  - STP (802.1D), RSTP (802.1w), and MSTP (802.1s) support both network login and STP on the same port.
  - At least one VLAN on the intended port should be configured both for STP and network login.
  - STP and Network Login operate together in both Network Login ISP mode and campus mode starting with Extreme 22.2.
  - When STP blocks a port, network login does not process authentication requests. All network traffic, except STP BPDUs, is blocked.
  - When STP places a port in forwarding state, all network traffic is allowed and network login starts processing authentication requests.
- STP cannot be configured on the following ports:
  - FDB flush does not occur on STP- and NetLogin-enabled ports during the topology changes.
  - A mirroring target port.
  - A software-controlled redundant port.
- When you are using the older method of enabling STP instead of using EAPSv2 to block the super loop in a shared-port environment, you can continue to do so. In all other scenarios, it is not recommended to use both STP and EAPS on the same port.
- MSTP and 802.1D STPDs cannot share a physical port.
- Only one MSTP region can be configured on a switch.
- In an MSTP environment, a VLAN can belong to one of the MSTIs.
- A VLAN can belong to only one MSTP domain.
- MSTP is not interoperable with PVST+.
- No VLAN can be bound to the CIST.
- Starting with ExtremeXOS 22.2, under the following two conditions, these attributes are preserved with autobind being used to bind the STPD domain to the VLAN: STP enable, Cost, Priority,
LinkType, Edge-Sage-Guard, BPDU Restrict, Restrict Role, ActiveRole, LoopProtect, LoopProtect-Partner, AutoEdge, Restricted TCN:

- With sharing and STP configurations established, disabling sharing no longer removes the STP port configuration for the configured master port and it preserves certain configuration attributes and restores them when the port is recreated.
- Configured port's STP properties are preserved when the port is moved from one VLAN to another, provided the new port gets associated with same STP domain.
- MLAG is not supported with STP (802.1D).

### Configuring STP on the Switch

**Note**
If you are transitioning from EOS to ExtremeXOS, please note that ExtremeXOS blocks on a more granular (VLAN) level, instead of at the port level as EOS does.

To configure basic STP:

1. Create one or more STPDs using the command:
   ```
   create stpd stpd_name {description stpd-description}
   ```
2. Add one or more VLANs to the STPD using the command:
   ```
   configure stpd stpd_name add vlan vlan_name | vlan_list ports [all | port_list] {[dot1d | emistp | pvst-plus]}
   ```
3. Define the carrier VLAN using the command:
   ```
   configure stpd stpd_name tag stpd_tag
   ```
   **Note**
   The carrier VLAN's ID must be identical to the StpdID.
4. Enable STP for one or more STPDs using the command:
   ```
   enable stpd {stpd_name}
After you have created the STPD, you can optionally configure STP parameters for the STPD.

**Note**
You should not configure any STP parameters unless you have considerable knowledge and experience with STP. The default STP parameters are adequate for most networks.

The following parameters can be configured on each STPD:
- Hello time (In an MSTP environment, configure this only on the CIST.)
- Forward delay
- Max age (In an MSTP environment, configure this only on the CIST.)
- Max hop count (MSTP only)
- Bridge priority
- Domain description
- StpdID (STP, RSTP, EMISTP, and PVST+ only)
- MSTI ID (MSTP only)

The following parameters can be configured on each port:
- Path cost
- Port priority
- Port mode

**Note**
When using more than one STP domain over the same set of ports, it is recommended to turn off the L2-fast-convergence feature (`configure forwarding L2-protocol fast-convergence off`) as this feature causes unnecessary flooding during topology changes.

**Note**
The device supports the RFC 1493 Bridge MIB, RSTP-03, and Extreme Networks STP MIB. Parameters of the s0 default STPD support RFC 1493 and RSTP-03. Parameters of any other STPD support the Extreme Networks STP MIB.

If an STPD contains at least one port not in 802.1D (dot1D) mode, the STPD must be configured with an StpdID.

The following section provides more detailed STP configuration examples, including 802.1D, EMISTP, RSTP, and MSTP.

**STP FDB Flush Criteria**

When there are more than 1000 VLANs and more than 70 ports participating in STP, the number of messages exchanged between STP/FDB/HAL modules can consume a lot of system memory when trying to flush the FDB during a STP topology change. To help avoid this high consumption, you can set the flush type from the default of vlan-and-port to port-based.

To set the flush type, enter the command:

```
configure stpd flush-method [vlan-and-port | port-only]
```
Displaying STP Settings

- To display STPD settings, use the command:

  `show stpd {stpd_name | detail}

To display more detailed information for one or more STPDs, specify the `detail` option.

This command displays the following information:
- STPD name
- STPD state
- STPD mode of operation
- Domain description
- Rapid Root Failover
- Tag
- Ports
- Active VLANs
- Bridge priority
- Bridge ID
- Designated root
- STPD configuration information

If you have MSTP configured on the switch, this command displays additional information:
- MSTP Region
- Format Identifier
- Revision Level
- Common and Internal Spanning Tree (CIST)
- Total number of MST Instances (MSTI)

- To display the state of a port that participates in STP, use the command:

  `show {stpd} stpd_name ports {{detail | port_list {detail}}}

To display more detailed information for one or more ports in the specified STPD, including participating VLANs, specify the `detail` option.

This command displays the following information:
- STPD port configuration
- STPD port mode of operation
- STPD path cost
- STPD priority
- STPD state (root bridge, etc.)
- Port role (root designated, alternate, etc.)
- STPD port state (forwarding, blocking, etc.)
- Configured port link type
- Operational port link type
- Edge port settings (inconsistent behavior, edge safeguard setting)
- MSTP port role (internal or boundary)

If you have MSTP configured and specify the `detail` option, this command displays additional information:
If you have a VLAN that spans multiple STPDs, use the `show {vlan} vlan_name stpd` command to display the STP configuration of the ports assigned to that specific VLAN.

The command displays the following:
- STPD port configuration
- STPD port mode of operation
- STPD path cost
- STPD priority
- STPD state (root bridge, etc.)
- Port role (root designated, alternate, etc.)
- STPD port state (forwarding, blocking, etc.)
- Configured port link type
- Operational port link type

## STP Configuration Examples

### Note
If you are transitioning from EOS to ExtremeXOS, please note that ExtremeXOS blocks on a more granular (VLAN) level, instead of at the port level as EOS does.

### Basic 802.1D Configuration Example

The following example:
- Removes ports from the VLAN Default that will be added to VLAN Engineering.
- Creates the VLAN Engineering.
- Assigns a VLAN ID to the VLAN Engineering.

### Note
If you do not explicitly configure the VLAN ID in your 802.1D deployment, use the `show vlan` command to see the internal VLAN ID automatically assigned by the switch.

- Adds ports to the VLAN Engineering.
- Creates an STPD named Backbone_st.
- Configures the default encapsulation mode of dot1d for all ports added to STPD Backbone_st.
- Enables autobind to automatically add or remove ports from the STPD.
- Assigns the Engineering VLAN to the STPD.
Assigns the carrier VLAN.

- Enables STP.

**Note**
To assign the carrier VLAN, the StpdID must be identical to the VLAN ID of the carrier VLAN.

```bash
configure vlan default delete ports 2:5-2:10
create vlan engineering
configure vlan engineering tag 150
configure vlan engineering add ports 2:5-2:10 untagged
create stpd s1
configure stpd s1 default-encapsulation dot1d
enable stpd s1 auto-bind vlan engineering
configure stpd s1 tag 150
enable stpd s1
```

By default, the port encapsulation mode for user-defined STPDs is dot1d. In this example, you set it to dot1d.

**EMISTP Configuration Example**

*Figure 170* is an example of EMISTP.

![Figure 170: EMISTP Configuration Example](image)

**Note**
By default, all ports added to a user-defined STPD or STPD s0 are in dot1d mode, unless otherwise specified.

The following commands configure the switch located between S1 and S2:

```bash
create vlan red
create red tag 100
configure red add ports 1:1-1:4 tagged
create vlan green
configure green tag 200
configure green add ports 1:1-1:2 tagged
create vlan yellow
configure yellow tag 300
configure yellow add ports 1:3-1:4 tagged
create stpd s1
```
RSTP 802.1w Configuration Example

Figure 171 on page 1171 is an example of a network with multiple STPDs that can benefit from RSTP.

For RSTP to work:

1. Create an STPD.
2. Configure the mode of operation for the STPD.
3. Create the VLANs and assign the VLAN ID and the VLAN ports.
4. Assign the carrier VLAN.
5. Add the protected VLANs to the STPD.
6. Configure the port link types.
7. Enable STP.

Figure 171: RSTP Example

In this example, the commands configure Switch A in STPD1 for rapid reconvergence.
Use the same commands to configure each switch and STPD in the network.

```bash
create stpd stpd1
configure stpd stpd1 mode dot1w
create vlan sales
create vlan personnel
create vlan marketing
configure vlan sales tag 100
configure vlan personnel tag 200
configure vlan marketing tag 300
configure vlan sales add ports 1:1,2:1 tagged
configure vlan personnel add ports 1:1,2:1 tagged
configure vlan marketing add ports 1:1,2:1 tagged
configure stpd stpd1 add vlan sales ports all
configure stpd stpd1 add vlan personnel ports all
configure stpd stpd1 add vlan marketing ports all
configure stpd stpd1 ports link-type point-to-point 1:1,2:1
cfgure stpd stpd1 tag 100
enable stpd stpd1
```

**MSTP Configuration Example**

You must first configure a CIST before configuring any MSTIs in the region. You cannot delete or disable a CIST if any of the MSTIs are active in the system.

Figure 172 is an example with multiple STPDs that can benefit from MSTP. In this example, we have two MSTP regions that connect to each other and one external 802.1w bridge.

![MSTP Configuration Example Diagram](image)

**Figure 172: MSTP Configuration Example**

For MSTP to work, complete the following steps on all switches in Region 1 and Region 2:
1 Remove ports from the VLAN Default that will be added to VLAN Engineering.
2 Create the VLAN Engineering.
3 Assign a VLAN ID to the VLAN Engineering.

**Note**
If you do not explicitly configure the VLAN ID in your MSTP deployment, use the `show vlan` command to see the internal VLAN ID automatically assigned by the switch.

4 Add ports to the VLAN Engineering.
5 Create the MSTP region.

**Note**
You can configure only one MSTP region on the switch at any given time.

6 Create the STPD to be used as the CIST, and configure the mode of operation for the STPD.
7 Specify the priority for the CIST.
8 Enable the CIST.
9 Create the STPD to be used as an MSTI and configure the mode of operation for the STPD.
10 Specify the priority for the MSTI.
11 Assign the VLAN Engineering to the MSTI.
12 Configure the port link type.
13 Enable the MSTI.

On the external switch (the switch that is not in a region):
1 Create an STPD that has the same name as the CIST, and configure the mode of operation for the STPD.
2 Specify the priority of the STPD.
3 Enable the STPD.

**Note**
In the following sample configurations, any lines marked (Default) represent default settings and do not need to be explicitly configured. STPD s0 already exists on the switch.

In the following example, the commands configure Switch A in Region 1 for MSTP. Use the same commands to configure each switch in Region 1:

```bash
create vlan engineering
configure vlan engineering tag 2
configure vlan engineering add port 2-3 tagged
configure mstp region region1
create stpd s0 (Default)
disable stpd s0 auto-bind vlan Default
configure stpd s0 mode mstp cist (Default)
configure stpd s0 priority 32768 (Default)
enable stpd s0 (Default)
create stpd s1
configure stpd s1 mode mstp msti 1
configure stpd s1 priority 32768 (Default)
enable stpd s1 auto-bind vlan engineering
configure stpd s0 ports link-type point-to-point 2-3
enable stpd s1
```
In the following example, the commands configure Switch E in Region 2 for MSTP. Use the same commands to configure each switch in Region 2:

```plaintext
create vlan finance
configure vlan finance tag 2
configure vlan finance add port 2-3 tagged
configure mstp region region2
create stpd s0 (Default)
configure stpd s0 mode mstp cist (Default)
configure stpd s0 priority 32768 (Default)
disable stpd s0 auto-bind vlan Default
enable stpd s0 (Default)
create stpd s1
configure stpd s1 mode mstp msti 1
configure stpd s1 priority 32768 (Default)
enable stpd s1 auto-bind vlan finance
configure stpd s0 ports link-type point-to-point 2-3
```

In the following example, the commands configure switch D, the external switch. Switch D becomes the CIST root bridge:

```plaintext
create stpd s0 (Default)
disable stpd s0
configure stpd s0 mode dot1w
configure stpd s0 priority 28672
enable stpd s0 auto-bind vlan Default (Default)
configure stpd s0 ports link-type point-to-point 4-5
enable stpd s0
```
ESRP Overview

The ESRP (Extreme Standby Router Protocol™), like the Virtual Router Redundancy Protocol (VRRP), allows multiple switches to provide redundant routing services to users.

ESRP is used to eliminate the single point of failure associated with manually configuring a default gateway address on each host in a network. Without using ESRP, if the configured default gateway fails, you must reconfigure each host on the network to use a different router as the default gateway. ESRP provides a redundant path for the hosts. Using ESRP, if the default gateway fails, the backup router assumes forwarding responsibilities.

**Note**
Support for ESRP operation over IPv6 networks was added in ExtremeXOS release 12.6.

In addition to providing Layer 3 routing redundancy for IP and IPX, ESRP also provides Layer 2 redundancy features for fast failure recovery and to provide for dual-homed system design. In some instances, depending on network system design, ESRP can provide better resiliency than using Spanning Tree Protocol (STP) or Virtual Router Redundancy Protocol (VRRP (Virtual Router Redundancy Protocol)). You can use Layer 3 and Layer 2 redundancy features in combination or independently. ESRP is available only on Extreme Networks switches. An example ESRP topology is shown in Figure 173.
In this example, ESRP Core Switch #1 and ESRP Core Switch #2 are both configured with three ESRP domains. Each domain represents a separate ESRP instance and supports a unique set of VLANs. Each domain is configured to use one master VLAN (Virtual LAN) and can support additional member VLANs. The switches exchange keep-alive packets for each VLAN independently.

Unless groups are configured, each ESRP domain supports two routers, one operating in the master state, and one operating in the slave state. Within an ESRP domain, any ESRP router can become the master, but only one ESRP router can be master at a time. Only the master can actively provide Layer 3 routing and/or Layer 2 switching for each VLAN. The master handles the forwarding, ARP requests, NDP messages, and routing for a particular VLAN. The slave router stands by, ready to take over if the master is no longer available.

Each switch in an ESRP topology has its own unique IP address (or IPX NetID) and a MAC address, which are required for basic IP connectivity. For each ESRP domain, there is a shared virtual IP address or IPX NetID and a MAC address, which are used for network client communications. The virtual IP address or IPX NetID is configured on all ESRP routers in a domain, and it is configured as the default gateway address on network clients in that domain. If the master ESRP router becomes unavailable, the backup ESRP router takes over using the same virtual IP address or IPX NetID.

The topology in Figure 173 shows that one switch serves as the master for the Corpnet1 and Corpnet2 domains, and the other switch serves as master for the Corpnet3 domain. This topology demonstrates the load sharing capability of ESRP. If one switch served as master for all ESRP domains, all traffic would
be routed through that master, and the slave switch would be idle. Dividing the ESRP domain mastership between routers allows domain clients access to more bandwidth and reduces the likelihood of exceeding the capacity of a single master router.

You can use ESRP to achieve edge-level or aggregation-level redundancy.

Deploying ESRP in this area of the network allows you to simplify your network design, which is important in designing a stable network. ESRP also works well in meshed networks where Layer 2 loop protection and Layer 3 redundancy are simultaneously required.

**Note**
For complete information about platform support for ESRP, see the [ExtremeXOS 22.6 Feature License Requirements](#) document.

**ESRP Master Election**

The system determines the ESRP master switch (providing Layer 3 routing and/or Layer 2 switching services for a VLAN) using the following default factors:

- **Stickiness**—The switch with the higher sticky value has higher priority. When an ESRP domain claims master, its sticky value is set to 1 (available only in extended mode).
- **Active ports**—The switch that has the greatest number of active ports takes highest precedence.
- **Tracking information**—Various types of tracking are used to determine if the switch performing the master ESRP function has connectivity to the outside world. ExtremeXOS software supports the following types of tracking:
  - **VLAN**—Tracks any active port connectivity to one designated VLAN. An ESRP domain can track one VLAN, and the tracked VLAN should not be a member of any other ESRP domain in the system.
  - **IP unicast route table entry**—Tracks specific learned routes from the IP route table.
  - **Ping**—Tracks ICMP (Internet Control Message Protocol) ping connectivity to specified devices.
  - **Environment (health checks)**—Tracks the environment of the switch, including power supplies.

If any of the configured tracking mechanisms fail, the master ESRP switch relinquishes status as master, and remains in slave mode for as long as the tracking mechanism continues to fail.

- **ESRP priority**—This is a user-defined field. The range of the priority value is 0 to 255; a higher number has higher priority, except for 255. The default priority setting is 0. A priority setting of 255 makes an ESRP switch a standby switch that remains in slave mode until you change the priority setting. We recommend this setting for system maintenance. A switch with a priority setting of 255 will never become the master.
- **System MAC address**—The switch with the higher MAC address has higher priority.
- **Active port weight**—The switch that has the highest port weight takes precedence. The bandwidth of the port automatically determines the port weight (available only in extended mode).

You can configure the precedence order of the factors used by the system to determine the master ESRP switch. For more information about configuring the ESRP election metrics, see [ESRP Election Algorithms](#) on page 1179.
Master Switch Behavior

If a switch is master, it actively provides Layer 3 routing services to other VLANs, and Layer 2 switching between all the ports of that VLAN.

Additionally, the switch exchanges ESRP packets with other switches that are in slave mode.

Pre-Master Switch Behavior

A pre-master switch is ready to transition to master, but is going through possible loop detection before changing to the master state.

Upon entering the pre-master state, the switch sends ESRP packets to other switches on that same VLAN. If the switch finds itself superior to its neighbor, and successfully executes loop detection techniques, the switch transitions to master. This temporary state avoids the possibility of having simultaneous masters.

Slave Switch Behavior

If a switch is in slave mode, it exchanges ESRP packets with other switches on that same VLAN.

When a switch is in slave mode, it does not perform Layer 3 routing or Layer 2 switching services for the VLAN. From a Layer 3 routing protocol perspective (for example, RIP (Routing Information Protocol) or OSPF (Open Shortest Path First)), when in slave mode for the VLAN, the switch marks the router interface associated with that VLAN as down. From a Layer 2 switching perspective, no forwarding occurs between the member ports of the VLAN; this prevents loops and maintains redundancy.

If you configure the switch to use the optional ESRP Host Attach configuration, the switch continues Layer 2 forwarding to the master. For more information, see ESRP Host Attach on page 1195.

Neutral Switch Behavior

The neutral state is the initial state entered into by the switch.

In a neutral state, the switch waits for ESRP to initialize and run. A neutral switch does not participate in ESRP elections. If the switch leaves the neutral state, it enters the slave state.

Electing the Master Switch

A new master can be elected. This is done in one of the following ways:

- A communicated parameter change
- Loss of communication between master and slave(s)

If a parameter determines the master changes (for example, link loss or priority change), the election of the new master typically occurs within one second. A parameter change triggers a handshake between the routers. As long as both routers agree upon the state transition, new master election is immediate.

If a switch in slave mode loses its connection with the master, a new election occurs (using the same precedence order indicated ESRP Master Election on page 1177 or using a configured precedence order described in ESRP Election Algorithms on page 1179). The new election typically takes place in three times the defined timer cycle (8 seconds by default).
Before the switch transitions to the master state, it enters a temporary pre-master state. While in the pre-master state, the switch sends ESRP PDUs until the pre-master state timeout expires. Depending upon the election algorithm, the switch may then enter the master or slave state. Traffic is unaffected by the pre-master state because the master continues to operate normally. The pre-master state avoids the possibility of having simultaneous masters.

To configure the pre-master state timeout, use the following command:

```
configure esrp esrpDomain timer premaster seconds
```

**Caution**

Configure the pre-master state timeout only with guidance from Extreme Networks support. Misconfiguration can severely degrade the performance of ESRP and your switch.

---

**ESRP Failover Time**

ESRP failover time is largely determined by the following factors:

- ESRP hello timer setting.
- ESRP neighbor timer setting.
- The routing protocol being used for interrouter connectivity if Layer 3 redundancy is used; **OSPF** failover time is faster than **RIP** failover time.

The failover time associated with the ESRP protocol depends on the timer setting and the nature of the failure. The default hello timer setting is two seconds; the range is 2-1024 seconds. The default neighbor timer setting is eight seconds; the range is 3*hello to 1024 seconds. The failover time depends on the type of event that caused ESRP to failover. In most cases, a non-hardware failover is less than one second, and a hardware failover is eight seconds.

If routing is configured, the failover of the particular routing protocol (such as RIP V1, RIP V2, or OSPF) is added to the failover time associated with ESRP.

If you use OSPF, make your OSPF configuration passive. A passive configuration acts as a stub area and helps decrease the time it takes for recalculating the network. A passive configuration also maintains a stable OSPF core.

For more information about the ESRP timers and configuring the ESRP timers, see **ESRP Configuration Overview** on page 1185.

---

**ESRP Election Algorithms**

You configure the switch to use one of 15 different election algorithms to select the ESRP master. ESRP uses the default election policy for extended mode. If you have an ESRP domain operating in standard mode, the domain ignores the sticky and weight algorithms.

To change the election algorithm, you must first disable the ESRP domain and then configure the new election algorithm. If you attempt to change the election algorithm without disabling the domain first, an error message appears.

- To disable the ESRP domain, use the following command:

```
disable esrp (esrpDomain)
```
To modify the election algorithm, use the following command:

```
configure esrp esrpDomain add elrp-poll ports [ports | all]
```

If you attempt to use an election algorithm not supported by the switch, an error message similar to the following appears:

**ERROR:** Specified election-policy is not supported! Supported Policies:

1. sticky > ports > weight > track > priority > mac
2. ports > track > priority
3. sticky > ports > track > priority
4. ports > track > priority > mac
5. sticky > ports > track > priority > mac
6. priority > mac
7. sticky > priority > mac
8. priority > ports > track > mac
9. sticky > priority > ports > track > mac
10. priority > track > ports > mac
11. sticky > priority > track > ports > mac
12. track > ports > priority
13. sticky > track > ports > priority
14. track > ports > priority
15. sticky > track > ports > priority

**ESRP Election Algorithms**

Table 118 describes the ESRP election algorithms. Each algorithm considers the election factors in a different order of precedence. The election algorithms that use sticky and weight are only available in extended mode.

**Table 118: ESRP Election Algorithms**

<table>

</tr>
</tbody>
</table>

**Caution**

All switches in the ESRP network must use the same election algorithm; otherwise, loss of connectivity, broadcast storms, or other unpredictable behavior may occur.

**ESRP Domains**

ESRP domains allow you to configure multiple VLANs under the control of a single instance of the ESRP protocol. By grouping multiple VLANs under one ESRP domain, the ESRP protocol can scale to provide protection to large numbers of VLANs. All VLANs within an ESRP domain simultaneously share the same active and standby router and failover router, as long as one port of each member VLAN belongs to the domain master.

Depending on the election policy used, when a port in a member VLAN belongs to the domain master, the member VLAN ports are considered when determining the ESRP master. You can configure a maximum of 64 ESRP domains in a network.

If you disable an ESRP domain, the switch notifies its neighbor that the ESRP domain is going down, and the neighbor clears its neighbor table. If the master switch receives this information, it enters the neutral state to prevent a network loop. If the slave switch receives this information, it also enters the neutral state.

ESRP packets do not identify themselves to which domain they belong; you either configure a domain ID or the ESRP domain uses the 802.1Q tag (VLANid) of the master VLAN.
A domain ID in the packet clearly classifies the packet, associates a received ESRP PDU to a specific ESRP domain, and tells the receiving port where the packet came from.

**Note**
Active Ports Count (ports): Total number of active physical ports of master VLANs of the ESRP domain.

### ESRP Groups

ExtremexOS software supports running multiple instances of ESRP within the same VLAN or broadcast domain. This functionality is called an *ESRP group*. Although other uses exist, the most typical application for multiple ESRP groups is when two or more sets of ESRP switches are providing fast-failover protection within a subnet.

A maximum of seven distinct ESRP groups can be supported on a single ESRP switch, and a maximum of 32 ESRP groups can be defined within the same network broadcast domain. You can configure a maximum of 32 ESRP groups in a network.

For example, two ESRP switches provide Layer 2/Layer 3 connectivity and redundancy for the subnet, while another two ESRP switches provide Layer 2 connectivity and redundancy for a portion of the same subnet. **Figure 174** shows ESRP groups.

![ESRP Groups](image)

**Figure 174: ESRP Groups**

### ESRP Extended Mode Features

The *ESRP* extended mode is enabled by default and provides the maximum ESRP feature set.

You can use ESRP extended mode only when all switches that participate in ESRP are running ExtremexOS software.
The following list describes the ESRP extended mode features that are not available in standard mode:

- **Handshaking**

  In standard mode, events such as link flapping cause the ESRP master switch to generate a large number of packets and to increase processing time.

  To prevent this, extended mode supports handshaking, which occurs when a switch requests a state change, forces its neighbor to acknowledge the change, and the neighbor sends an acknowledgement to the requesting switch. For example, if a slave switch wants to become the master, it enters the pre-master state, notifies the neighbor switch, and forces the neighbor to acknowledge the change. The neighbor then sends an acknowledgement back to the slave switch. While the requesting switch waits for the acknowledgements, future updates are suppressed to make sure the neighbor does not act on incorrect data.

- **Stickiness**

  In standard mode, if an event causes the ESRP master switch to fail over to the slave, it becomes the new master. If another event occurs, the new master switch returns to the slave and you have experienced two network interruptions.

  To prevent this, extended mode supports the sticky election metric. The default election algorithm uses the sticky metric. For example, if an event causes the ESRP master switch to fail over to the slave, it becomes the new master and has a higher sticky value. If another event occurs, for example adding active ports to the slave, the new master does not fail back to the original master even if the slave has more active ports. After sticky is set on the master, regardless of changes to its neighbor’s election algorithm, the new master retains its position. Sticky algorithms provide for fewer network interruptions than non-sticky algorithms. Sticky is set only on the master switch.

- **Port weight**

  In standard mode, the port count calculation does not take into account the available bandwidth of the ports. For example, a switch with a one Gigabit Ethernet uplink may be unable to become master because another switch has a load-shared group of four fast Ethernet links. The active port count calculation considers only the number of active ports, not the bandwidth of those ports.

  In extended mode, the active port count calculation considers the number of active ports and the port weight configuration considers the bandwidth of those ports. You enable port weight only on the load-shared master port.

- **Domain ID**

  In standard mode, ESRP packets do not contain domain information; therefore, the only information about the packet comes from the receiving port.

  The concept of domain ID is applicable only to extended mode. A domain ID in the packet clearly classifies the packet, associates a received ESRP PDU to a specific ESRP domain, and tells the receiving port where the packet came from. In extended mode, you must have a domain ID for each ESRP domain. Each switch participating in ESRP for a particular domain must have the same domain ID configured.

  The ESRP domain ID is determined from one of the following user-configured parameters:

  - **ESRP domain number created with the command:**

    ```bash
    configure esrp esrpDomain domain-id number
    ```
• **802.1Q tag (VLANid) of the tagged master VLAN**

Hello messages

In standard mode, both the master switch and slave switch send periodic ESRP hello messages. This causes an increase in packet processing by both the master and slave.

In extended mode, the master switch sends periodic ESRP hello messages. This reduces the amount of packet processing, increases the amount of available link bandwidth, and does not impact communicating state changes between switches.

• **ESRP Automatic Toggle Feature**

ESRP includes an automatic toggle feature, which toggles to the same mode of operation as an ESRP neighbor. This action causes the switch to enter the neutral state and re-elect the ESRP master.

**Note**

The automatic toggle feature toggles the ESRP operational mode, not the configured mode. If the switch is configured for ESRP extended mode and the switch toggles to standard mode, the switch enters extended mode the next time the switch boots.

### Linking ESRP Switches

When considering system design using ESRP, we recommend using a direct link.

Direct links between ESRP switches are useful under the following conditions:

• A direct link can provide a more direct routed path, if the ESRP switches are routing and supporting multiple VLANs where the master/slave configuration is split such that one switch is master for some VLANs and a second switch is master for other VLANs. The direct link can contain a unique router-to-router VLAN/subnet, so that the most direct routed path between two VLANs with different master switches uses a direct link, instead of forwarding traffic through another set of connected routers.

• A direct link can be used as a highly reliable method to exchange ESRP hello messages, so that the possibility of having multiple masters for the same VLAN is lessened if all downstream Layer 2 switches fail.

• A direct link is necessary for the ESRP host attach option. The direct link is used to provide Layer 2 forwarding services through an ESRP slave switch.

Direct links may contain a router-to-router VLAN, along with other VLANs participating in an ESRP domain. If multiple VLANs are used on the direct links, use 802.1Q tagging. The direct links may be aggregated into a load-shared group, if desired. If multiple ESRP domains share a host port, each VLAN must be in a different ESRP group.

### ESRP-Aware Switches

Extreme Networks switches that are not actively participating in ESRP but are connected on a network that has other Extreme Networks switches running ESRP are ESRP-aware. When ESRP-aware switches...
are attached to ESRP-enabled switches, the ESRP-aware switches reliably perform failover and failback scenarios in the prescribed recovery times.

If Extreme Networks switches running ESRP are connected to Layer 2 switches that are manufactured by third-party vendors, the failover times for traffic local to that segment may appear longer, depending on the application involved and the FDB (forwarding database) timer used by the other vendor’s Layer 2 switch. ESRP can be used with Layer 2 switches from other vendors, but the recovery times vary.

The VLANs associated with the ports connecting an ESRP-aware switch to an ESRP-enabled switch must be configured using an 802.1Q tag on the connecting port; or, if only a single VLAN is involved, as untagged using the protocol filter ‘any.’ ESRP does not function correctly if the ESRP-aware switch interconnection port is configured for a protocol-sensitive VLAN using untagged traffic. You can also use port restart in this scenario. For more information, see ESRP Port Restart on page 1195.

The following sections provide information on managing ESRP-aware switches:

- Configuring ESRP-Aware Switches on page 1188
- ESRP Configuration Examples on page 1198

## Configuring ESRP

### Guidelines

To participate in ESRP, the following must be true:

- A VLAN can belong to only one ESRP domain.
- The IP address for the VLANs participating in an ESRP domain must be identical.
- For operation over IPv6, both an IPv6 and an IPv4 address must be present on the master VLAN for every participating router.
- All switches in the ESRP network must use the same election algorithm, otherwise loss of connectivity, broadcast storms, or other unpredictable behavior may occur.
- If you have an untagged master VLAN, you must specify an ESRP domain ID. The domain ID must be identical on all switches participating in ESRP for that particular domain.
- If you have a tagged master VLAN, ESRP uses the 802.1Q tag (VLANid) of the master VLAN for the ESRP domain ID. If you do not use the VLANid as the domain ID, you must specify a different domain ID. As previously described, the domain ID must be identical on all switches participating in ESRP for that particular domain.

**Note**

If you configure the OSPF routing protocol and ESRP, you must manually configure an OSPF router identifier. Be sure that you configure a unique OSPF router ID on each switch running ESRP. For more information, see OSPF.

We recommend that all switches participating in ESRP run the same version of ExtremeXOS software.

## ESRP Configuration Overview

The following procedure can be used to configure a simple ESRP topology:
1 Create and configure a VLAN that will become the master VLAN. (See VLANs on page 503.)
2 As needed, create and configure the VLANs that will become the member VLANs. (See VLANs on page 503.)
3 Create the ESRP domain as described in Creating and Deleting an ESRP Domain on page 1186.
4 If your configuration requires an ESRP domain ID, configure it as described .
5 Add the master VLAN to the ESRP domain as described in Adding and Deleting a Master VLAN on page 1187.
6 If your configuration requires member VLANs, add the member VLANs to the ESRP domain as described in Adding and Deleting a Member VLAN on page 1187.
7 Enable ESRP for the specified ESRP domain as described in Enabling and Disabling an ESRP Domain on page 1187.

You can also configure other ESRP domain parameters, including ESRP:

- Timers as described in the ExtremeXOS 22.6 Command Reference Guide.
- Election algorithms as described in ESRP Election Algorithms on page 1179.
- Tracking as described in ESRP Tracking on page 1192.
- Port restart as described in ESRP Port Restart on page 1195.
- Host attach as described in ESRP Host Attach on page 1195.
- Groups as described in ESRP Groups on page 1182.

For more detailed information about all of the commands used to create, configure, enable, and disable an ESRP domain, refer to the ExtremeXOS 22.6 Command Reference Guide.

Creating and Deleting an ESRP Domain

You can specify a unique ESRP domain name to identify each ESRP domain in your network.

- To create an ESRP domain, use the following command:

  create esrp esrp_domain {type [vpls-redundancy | standard]}

  The esrpDomain parameter is a character string of up to 32 characters that identifies the ESRP domain to be created.

- To delete an ESRP domain, use the following command:

  delete esrp esrpDomain

Configuring the ESRP Domain ID

If you choose not use the 802.1Q tag (VLANid) of the master VLAN, or you have an untagged master VLAN, you must create a domain ID before you can enable the ESRP domain. For more information about ESRP domains and the ESRP domain ID, see ESRP Domains on page 1181.
To configure an ESRP domain ID, use the following command:

```
configure esrp esrpDomain domain-id number
```

The `number` parameter specifies the number of the domain ID. The user-configured ID range is 4096 through 65,535.

Adding and Deleting a Master VLAN

The master VLAN is the VLAN on the ESRP domain that exchanges ESRP PDUs and data between a pair of ESRP-enabled devices. You must configure one master VLAN for each ESRP domain, and a master VLAN can belong to only one ESRP domain.

- To add a master VLAN to an ESRP domain, use the following command:

```
configure esrp esrpDomain add master vlan_name
```

The `esrpDomain` parameter specifies the name of the ESRP domain, and the `vlan_name` parameter specifies the name of the master VLAN.

- To delete a master VLAN, you must first disable the ESRP domain before removing the master VLAN using the `disable esrp {esrpDomain}` command.

- To delete a master VLAN from an ESRP domain, use the following command:

```
configure esrp esrpDomain delete master vlan_name
```

Adding and Deleting a Member VLAN

The member VLAN can belong to only one ESRP domain, and you configure zero or more member VLANs for each ESRP domain. The state of the ESRP device determines whether the member VLAN is in the forwarding or blocking state.

- To add a member VLAN to an ESRP domain, use the following command:

```
configure esrp esrpDomain add member vlan_name
```

The `esrpDomain` parameter specifies the name of the ESRP domain, and the `vlan_name` parameter specifies the name of the member VLAN.

- To delete a member VLAN from an ESRP domain, use the following command:

```
configure esrp esrpDomain delete member vlan_name
```

Enabling and Disabling an ESRP Domain

- To enable a specific ESRP domain, use the following command:

```
enable esrp esrpDomain
```

- To disable a specific ESRP domain, use the following command:

```
disable esrp {esrpDomain}
```
Configuring ESRP-Aware Switches

For an Extreme Networks switch to be ESRP-aware, you must create an ESRP domain on the aware switch, add a master VLAN to that ESRP domain, add a member VLAN to that ESRP domain if configured, and configure a domain ID if necessary.

To participate as an ESRP-aware switch, the following must be true:

- The ESRP domain name must identical on all switches (ESRP-enabled and ESRP-aware) participating in ESRP for that particular domain.
- The master VLAN name and IP address must be identical on all switches (ESRP-enabled and ESRP-aware) participating in ESRP for that particular domain.
- If configured, the member VLAN name and IP address must be identical on all switches (ESRP-enabled and ESRP-aware) participating in ESRP for that particular domain.
- The domain ID must be identical on all switches (ESRP-enabled or ESRP-aware) participating in ESRP for that particular domain.
- If you have an untagged master VLAN, you must specify an ESRP domain ID.
- If you have a tagged master VLAN, ESRP uses the 802.1Q tag (VLANid) of the master VLAN for the ESRP domain ID. If you do not use the VLANid as the domain ID, you must specify a different domain ID.

**Note**
Before you begin, make a note of the ESRP domain parameters on the ESRP-enabled switch. That way you can easily refer to your notes while creating the ESRP domain on the ESRP-aware switch.

To configure an ESRP-aware switch:

1. Create an ESRP domain using the command:
   ```
   create esrp esrp_domain {type [vpls-redundancy | standard]}
   ```
   For complete information about software licensing for this feature, see the *ExtremeXOS 22.6 Feature License Requirements* document.
2. Add a master VLAN to your ESRP domain using the command:
   ```
   configure esrp esrpDomain add master vlan_name
   ```
3. If configured, add the member VLANs to your ESRP domain using the command:
   ```
   configure esrp esrpDomain add member vlan_name
   ```
4. If necessary, configure a domain ID for the ESRP domain using the command:
   ```
   configure esrp esrpDomain domain-id number
   ```

**Operation with Other ExtremeXOS Features**

**ESRP and IP Multinetting**

When configuring *ESRP* and IP multinetting on the same switch, the same set of IP addresses must be configured for all involved VLANs.
ESRP and STP

A switch running ESRP should not simultaneously participate in STP (Spanning Tree Protocol) for the same VLAN(s). Other switches in the VLAN being protected by ESRP may run STP; the switch running ESRP forwards, but does not filter, STP BPDUs. Therefore, you can combine ESRP and STP on a network and a VLAN, but you must do so on separate devices. You should be careful to maintain ESRP connectivity between ESRP master and slave switches when you design a network that uses ESRP and STP.

ESRP and VRRP

Do not configure ESRP and VRRP on the same VLAN or port. This configuration is not allowed or supported.

ESRP Groups and Host Attach

ESRP domains that share ESRP HA ports must be members of different ESRP groups.

Port Configurations and ESRP

The following ports cannot be part of a VLAN that participates in an ESRP domain:

- A mirroring target port
- A software-controlled redundant port
- A Netlogin port

In addition, the following ESRP ports cannot be a mirroring, software-controlled redundant port, or Netlogin port:

- Host Attach port
- Don’t-count port (This port has a port weight of 0.)
- Restart port

Using ELRP with ESRP

Extreme Loop Recovery Protocol (ELRP) is a feature of ExtremeXOS software that allows you to prevent, detect, and recover from Layer 2 loops in the network.

You can use ELRP with other protocols, including ESRP.

Note

When used on a VPLS service VLAN, ELRP does not detect loops involving the VPLS pseudowires.

For more information about standalone ELRP, see Using ELRP to Perform Loop Tests on page 1647.

With ELRP, each switch, except for the sender, treats the ELRP protocol data unit (PDU) as a Layer 2 multicast packet. The sender uses the source and destination MAC addresses to identify the packet it sends and receives. When the sender receives its original packet back, that triggers loop detection and
prevention. After a loop is detected, the loop recovery agent is notified of the event and takes the necessary actions to recover from the loop. ELRP operates only on the sending switch; therefore, ELRP operates transparently across the network.

How a loop recovers is dependent upon the protocol that uses the loop detection services provided by ELRP.

If you are using ELRP in an ESRP environment, ESRP may recover by transitioning the ESRP domain from master to slave. The following sections describe how ESRP uses ELRP to recover from a loop and the switch behavior:

• Using ELRP with ESRP to Recover Loops on page 1190
• Configuring ELRP on page 1190
• Displaying ELRP Information on page 1192

Using ELRP with ESRP to Recover Loops
ELRP sends loop-detect packets to notify ESRP about loops in the network.

In an ESRP environment, when the current master goes down, one of the slaves becomes the master and continues to forward Layer 2 and Layer 3 traffic for the ESRP domain. If a situation occurs when a slave incorrectly concludes that the master is down, the slave incorrectly assumes the role of master. This introduces more than one master on the ESRP domain which causes temporary loops and disruption in the network.

ELRP on an ESRP Pre-Master Switch
A pre-master switch is an ESRP switch that is ready to transition to master but is going through possible loop detection.

A pre-master periodically sends out ELRP loop-detect packets (ELRP PDUs) for a specified number of times and waits to make sure that none of the sent ELRP PDUs are received. Transition to master occurs only after this additional check is completed. If any of the ELRP PDUs are received, the switch transitions from pre-master to slave state. You configure pre-master ELRP loop detection on a per ESRP domain basis.

ELRP on an ESRP Master Switch
A master switch is an ESRP switch that sends ELRP PDUs on its ESRP domain ports.

If the master switch receives an ELRP PDU that it sent, the master transitions to the slave. While in the slave state, the switch transitions to the pre-master rate and periodically checks for loops before transitioning to the master. The pre-master process is described in ELRP on an ESRP Pre-Master Switch on page 1190. You configure the master ELRP loop detection on a per ESRP domain basis.

Configuring ELRP
By default, ELRP is disabled. The following sections describe the commands used to configure ELRP for use with ESRP:

• Configuring Pre-Master Polling on page 1191
• Configuring Master Polling on page 1191
Configuring Ports on page 1191

Note
When used on a virtual private LAN service (VPLS) VLAN, ELRP does not detect loops involving the VPLS pseudowires.

Configuring Pre-Master Polling

If you enable the use of ELRP by ESRP in the pre-master state, ESRP requests ELRP packets sent to ensure that there is no loop in the network before changing to the master state. If no packets are received, there is no loop in the network. By default, the use of ELRP by ESRP in the pre-master state is disabled.

• To enable the use of ELRP by ESRP in the pre-master state on a per-ESRP domain basis, and to configure how often and how many ELRP PDUs are sent in the pre-master state, use the following command:

  configure esrp esrpDomain elrp-premaster-poll enable {count count | interval interval}

• To disable the use of ELRP by ESRP in the pre-master state, use the following command:

  configure esrp esrpDomain elrp-premaster-poll disable

Configuring Master Polling

If you enable the use of ELRP by ESRP in the master state, ESRP requests that ELRP packets are periodically sent to ensure that there is no loop in the network while ESRP is in the master state. By default, the use of ELRP by ESRP in the master state is disabled.

• To enable the use of ELRP by ESRP in the master state on a per-ESRP domain basis, and to configure how often the master checks for loops in the network, use the following command:

  configure esrp esrpDomain elrp-master-poll enable {interval interval}

• To disable the use of ELRP by ESRP in the master state, use the following command:

  configure esrp esrpDomain elrp-master-poll disable

Configuring Ports

You can configure one or more ports of an ESRP domain where ELRP packet transmission is requested by ESRP. This allows the ports in your network that might experience loops, such as ports that connect to the master, slave, or ESRP-aware switches, to receive ELRP packets. You do not need to send ELRP packets to host ports.

By default, all ports of the ESRP domain have ELRP transmission enabled on the ports.

If you change your network configuration, and a port no longer connects to a master, slave, or ESRP-aware switch, you can disable ELRP transmission on that port.

• To disable ELRP transmission, use the following command:

  configure esrp esrpDomain delete elrp-poll ports [ports | all]

• To enable ELRP transmission on a port, use the following command:

  configure esrp esrpDomain add elrp-poll ports [ports | all]
Displaying ELRP Information

To display summary ELRP information, use the following command:

`show elrp`

In addition to displaying the enabled/disabled state of ELRP, the command displays the total number of:

- Clients registered with ELRP
- ELRP packets transmitted
- ELRP packets received

For more information about the output associated with the `show elrp` command, see the *ExtremeXOS 22.6 Command Reference Guide*.

Advanced ESRP Features

ESRP Tracking

Tracking information is used to track various forms of connectivity from the ESRP switch to the outside world.

ESRP Environment Tracking

You can configure ESRP to track hardware status. If a power supply fails, if the switch is overheating, or if a non-fully loaded power supply is detected, the priority for the ESRP domain will change to the failover settings.

**Note**

ExtremeXOS software determines the maximum available power required for the switch by calculating the number of power supplies and the power required by the installed modules. Enabling environmental tracking on the switch without enough power budget causes tracking to fail. In this case, the tracking failure occurs by design.

To configure the failover priority for an ESRP domain:

1. Set the failover priority using the following command:
   ```
   configure esrp esrpDomain add track-environment failover priority
   ```
2. Assign the priority flag precedence over the active ports count using the following command:
   ```
   configure esrp esrpDomain election-policy [ports > track > priority | ports > track > priority > mac | priority > mac | priority > ports > track > mac | priority > track > ports > mac | sticky > ports > track > priority > mac | sticky > ports > track > priority > mac | sticky > track > ports > priority | sticky > track > ports > priority | sticky > track > ports > priority > mac]
   ```
Because the priority of both ESRP domains are set to the same value, ESRP will use the active ports count to determine the master ESRP domain.

**ESRP VLAN Tracking**

You can configure an ESRP domain to track port connectivity to a specified VLAN as criteria for ESRP failover. The number of VLAN active ports are tracked. If the switch is no longer connected to the specified VLAN, the switch automatically relinquishes master status and remains in slave mode. You can track a maximum of one VLAN.

- To add a tracked VLAN, use the following command:

  ```
  configure esrp esrpDomain add track-vlan vlan_name
  ```

- To delete a tracked VLAN, use the following command:

  ```
  configure esrp esrpDomain delete track-vlan vlan_name
  ```

**ESRP Unicast Route Table Tracking**

You can configure ESRP to track specified IPv4 routes in the route table as criteria for ESRP failover. If all of the configured routes are not available within the route table, the switch automatically relinquishes master status and remains in slave mode. You can track a maximum of eight routes per route table.

- To add a tracked route, use the following command:

  ```
  configure esrp esrpDomain add track-iproute ipaddress / masklength
  ```

- To delete a tracked route, use the following command:

  ```
  configure esrp esrpDomain delete track-iproute ipaddress / masklength
  ```

**ESRP Ping Tracking**

You can configure ESRP to track connectivity using a simple ping to any IPv4 device. This may represent the default route of the switch, or any device meaningful to network connectivity of the master ESRP switch. The switch automatically relinquishes master status and remains in slave mode if a ping keepalive fails. You can configure a maximum of eight ping tracks.

- To configure ping tracking, use the following command:

  ```
  configure esrp esrpDomain add track-ping ipaddress {frequency seconds} {miss misses} {success successes}
  ```

  The **frequency** option specifies the number of seconds between ping requests.
The **miss** option specifies the number of consecutive ping failures that initiate failover to an ESRP slave.

The **success** option specifies the number consecutive ping successes required for tracking success.

- To disable ping tracking, use the following command:

  ```
  configure esrp esrpDomain delete track-ping ipaddress
  ```

**Displaying ESRP Tracking Information**

You can view the status of **ESRP** tracking on a per domain basis. The information displayed includes the type of tracking used by the ESRP domain and how you configured the tracking option.

To view the status of tracked devices, use the following command:

```
show esrp name
```

**ESRP Tracking Example**

**Figure 175** is an example of **ESRP** tracking.

**Figure 175: ESRP Tracking**

- To configure **VLAN** tracking, use the following command:

  ```
  configure esrp esrp1 add track-vlan vlan1
  ```

  Using the tracking mechanism, if VLAN1 fails, the ESRP master realizes that there is no path to the upstream router via the master switch and implements an ESRP failover to the slave switch.

- To configure route table tracking, use the following command:

  ```
  configure esrp esrp1 add track-iproute 10.10.10.0/24
  ```

  The IPv4 route specified in this command must exist in the IP routing table. When the route is no longer available, the switch implements an ESRP failover to the slave switch.
To configure ping tracking, use the following command:

```
configure esrp esrp1 add track-ping 10.10.10.121 frequency 2 miss 2
```

The specified IPv4 address is tracked. If the fail rate is exceeded, the switch implements an ESRP failover to the slave switch.

**ESRP Port Restart**

You can configure ESRP to restart ports in the ESRP master domain when the downstream switch is from a third-party vendor. This action takes down and restarts the port link to clear and refresh the downstream ARP table.

- To configure port restart, use the following command:
  ```
  configure esrp ports ports restart
  ```
- To disable port restart, use the following command:
  ```
  configure esrp ports ports no-restart
  ```

If a switch becomes a slave, ESRP takes down (disconnects) the physical links of member ports that have port restart enabled. The disconnection of these ports causes downstream devices to remove the ports from their **FDB** tables. This feature allows you to use ESRP in networks that include equipment from other vendors. After 2 seconds, the ports re-establish connection with the ESRP switch.

- To remove a port from the restart configuration, delete the port from the **VLAN** and re-add it.

**ESRP Host Attach**

**ESRP** host attach (HA) is an optional ESRP configuration that allows you to connect active hosts directly to an ESRP master or slave switch.

Normally, the Layer 2 redundancy and loop prevention capabilities of ESRP do not allow packet forwarding from the slave ESRP switch. ESRP HA allows configured ports that do not represent loops to the network to continue Layer 2 operation independent of their ESRP status.

ESRP HA is designed for redundancy for dual-homed server connections. HA allows the network to continue Layer 2 forwarding regardless of the ESRP status. Do not use ESRP HA to interconnect devices on the slave ESRP switch instead of connecting directly to the ESRP master switch.

The ESRP HA option is useful if you are using dual-homed network interface cards (NICs) for server farms, as shown in the following figure. The ESRP HA option is also useful where an unblocked Layer 2 environment is necessary to allow high-availability security.
If you use load sharing with the ESRP HA feature, configure the load-sharing group first and then enable HA on the group.

Other applications allow lower-cost redundant routing configurations because hosts can be directly attached to the switch involved with ESRP. HA also requires at least one link between the master and the slave ESRP switch for carrying traffic and to exchange ESRP hello packets.

Note
Do not use the ESRP HA feature with the following protocols: STP or VRRP. A broadcast storm may occur.

To configure a port to be a host port, use the following command: `configure esrp ports ports mode [host | normal]`

**ESRP Port Weight and Don’t Count**

In an ESRP domain, the switch automatically calculates the port weight based on the bandwidth of the port. ESRP uses the port weight to determine the master ESRP switch.

For load-shared ports, configure the master port in the load-share group with the port weight. A load-shared port has an aggregate weight of all of its member ports. If you add or delete a load-shared port (or trunk), the master load-shared port weight is updated.

If you do not want to count host ports and normal ports as active, configure the ESRP port weight on those ports. Their weight becomes 0 and that allows the port to be part of the VLAN, but if a link failure occurs, it will not trigger a reconvergence. With this configuration, ESRP experiences fewer state changes due to frequent client activities like rebooting and unplugging laptops. This port is known as a don’t-count port.
To configure the port weight on either a host attach port or a normal port, use the following command:

`configure esrp ports weight [auto | port-weight]`

Selective Forwarding

An ESRP-aware switch floods ESRP PDUs from all ports in an ESRP-aware VLAN. This flooding creates unnecessary network traffic because some ports forward ESRP PDUs to switches that are not running the same ESRP groups. You can select the ports that are appropriate for forwarding ESRP PDUs by configuring selective forwarding on an ESRP-aware VLAN and thus reduce this excess traffic. Configuring selective forwarding creates a port list of only those ports that forward to the ESRP groups that are associated with an ESRP-aware VLAN. This ESRP-aware port list is then used for forwarding ESRP PDUs.

Note

We recommend keeping the default settings unless you have considerable knowledge and experience with ESRP.

To configure selective forwarding, use the following command:

`configure esrp domain aware add selective-forward-ports portlist {group group number}`

When an ESRP-aware switch receives an ESRP PDU on a domain, the software looks up the group to which the PDU belongs. If the group is found, the ESRP-aware switch processes the PDU then and forwards it according to the group’s specified aware selective forwarding port list. If no selective forwarding port list is configured, the switch forwards the PDU from all of the ports of the domain’s master VLAN. If the group is not found, the PDU is forwarded on all ports.

When a user adds one or more ports to the ESRP-aware port list (for example, 5:1 and 6:2) that are not part of the master VLAN, the following message appears:

Warning: Port 5:1, 6:2 not currently a member of master vlan

The ports will still be added to the ESRP-aware port list; however, PDUs will not be forwarded out of those ports until they are added to the master VLAN.

To disable selective forwarding, use the following command:

`configure esrp domain aware delete selective-forward-ports all|portlist {group group number}`

Display Selective Forwarding Information

To display all selective forwarding information for a given domain, use the following command:

`show esrp domain aware {selective-forward-ports | statistics}`
Display ESRP Information

- To view ESRP information, use the command `show esrp`.
  Output from this command includes:
  - The operational state of an ESRP domain and the state of its neighbor.
  - ESRP port configurations.
- To view more detailed information about an ESRP domain on an ESRP enabled switch or an ESRP aware switch, use the following command and specify the domain name:
  ```
  show esrp { {name} | {type [vpls-redundancy | standard]} }
  ```
- To view ESRP counter information for a specific domain, use the following command:
  ```
  show esrp {name} counters
  ```
- To view ESRP-aware information for a specific domain (including the group number, MAC address for the master, and the age of information), use the following command:
  ```
  show esrp domain aware {selective-forward-ports | statistics}
  ```

ESRP Configuration Examples

Single Domain Using Layer 2 and Layer 3 Redundancy

The example shown in Figure 177 uses four Extreme Networks devices as edge switches that perform Layer 2 switching for VLAN Sales.

The edge switches are dual-homed two switches that are configured to support ESRP domain esrp1. The ESRP switches perform Layer 2 switching and Layer 3 routing between the edge switches and the outside world. Each ESRP switch has the VLAN Sales configured using the identical IP address. The ESRP switches then connect to the routed enterprise normally, using the desired routing protocol (for example, RIP or OSPF).
In this example, the ESRP master performs both Layer 2 switching and Layer 3 routing services for VLAN Sales. To prevent bridging loops in the VLAN, the ESRP slave performs no switching or routing for VLAN Sales while the ESRP master is operating.

There are four paths between each ESRP switch and the edge switches for VLAN Sales. All the paths are used to send ESRP packets, allowing for four redundant paths for communication. The edge switches, being ESRP-aware, allow traffic within the VLAN to failover quickly because these edge switches sense when a master/slave transition occurs and flush FDB entries associated with the uplinks to the ESRP-enabled switches.

This example assumes the following:

- ESRP election algorithm used is the default for standard mode (ports > track > priority > mac).
- The inter-router backbone is running OSPF, with other routed VLANs already properly configured. Similar commands would be used to configure a switch on a network running RIP.
- Ports added to the VLAN have already been removed from VLAN default.
- The same IP address is specified for all VLANs participating in ESRP.
- The master is determined by the programmed MAC address of the switch because the number of active links for the VLAN and the priority are identical for both switches.

Figure 177: Single ESRP Domain Using Layer 2 and Layer 3 Redundancy
The following commands are used to configure both ESRP switches:

```
create vlan sales
configure vlan sales add ports 1:1-1:4
configure vlan sales ipaddress 10.1.2.3/24
enable ipforwarding
create esrp esrp1
configure esrp esrp1 domain-id 4096
configure esrp esrp1 add master sales
enable esrp esrp1
configure ospf add vlan sales area 0.0.0.0 passive
configure ospf routerid 5.5.5.5
enable ospf
```

Multiple Domains Using Layer 2 and Layer 3 Redundancy

The example shown in Figure 178 illustrates an ESRP configuration that has multiple domains using Layer 2 and Layer 3 redundancy.

![Diagram: Multiple ESRP Domains Using Layer 2 and Layer 3 Redundancy](image)

**Figure 178: Multiple ESRP Domains Using Layer 2 and Layer 3 Redundancy**

This example builds on the previous example. It has the following features:

- An additional VLAN, Engineering, is added that uses Layer 2 redundancy.
- VLAN Sales uses three active links to each ESRP switch.
- VLAN Engineering has two active links to each ESRP switch.
- One of the edge devices carries traffic for both VLANs.
• The link between the third edge device and the first ESRP switch uses 802.1Q tagging to carry traffic from both VLANs on one link. The ESRP switch counts the link active for each VLAN.

• The second ESRP switch has a separate physical port for each VLAN connected to the third edge switch.

In this example, the ESRP switches are configured such that VLAN Sales normally uses the first ESRP switch and VLAN Engineering normally uses the second ESRP switch. This is accomplished by manipulating the ESRP priority setting for each VLAN for the particular ESRP switch.

Configuration commands for the first ESRP switch are as follows:

```
create vlan sales
configure vlan sales tag 10
configure vlan sales add ports 1:1-1:2
configure vlan sales add ports 1:3, 1:5 tagged
configure vlan sales ipaddress 10.1.2.3/24
create vlan engineering
configure vlan engineering tag 20
configure vlan engineering add ports 1:4
configure vlan engineering add ports 1:3, 1:5 tagged
configure vlan engineering ipaddress 10.4.5.6/24
create esrp esrp1
configure esrp esrp1 domain-id 4096
configure esrp esrp1 add master sales
configure esrp esrp1 priority 5
enable esrp esrp1
create esrp esrp2
configure esrp esrp2 domain-id 4097
configure esrp esrp2 add master engineering
enable esrp esrp2
```

Configuration commands for the second ESRP switch are as follows:

```
create vlan sales
configure vlan sales tag 10
configure vlan sales add ports 1:1-1:3
configure vlan sales ipaddress 10.1.2.3/24
configure vlan sales add ports 1:5 tagged
create vlan engineering
configure vlan engineering tag 20
configure vlan engineering add ports 1:4, 2:1
configure vlan engineering ipaddress 10.4.5.6/24
configure vlan engineering add ports 1:5 tagged
create esrp esrp1
configure esrp esrp1 domain-id 4096
configure esrp 1 add master sales
enable esrp esrp1
create esrp esrp2
configure esrp esrp2 domain-id 4097
configure esrp esrp2 add master engineering
configure esrp esrp2 priority 5
enable esrp esrp2
```
ESRP Over IPv6 Configuration Example

The example shown in the following figure illustrates an ESRP configuration that can operate over IPv6.

Note

To support operation over IPv6, the master VLANs configured in this example require both an IPv4 and an IPv6 address. ESRP route tracking and ESRP ping tracking are not supported for IPv6 addresses.

Configuration commands for the first ESRP switch are as follows:

```plaintext
create vlan sales
configure vlan sales tag 10
configure vlan sales add ports 1:1-1:2
configure vlan sales add ports 1:3, 1:5 tagged
configure vlan sales ipaddress 10.1.2.3/24
configure vlan sales ipaddress 2001:db8:36::1/48
create vlan engineering
configure vlan engineering tag 20
configure vlan engineering add ports 1:4
configure vlan engineering add ports 1:3, 1:5 tagged
configure vlan engineering ipaddress 10.4.5.6/24
configure vlan engineering ipaddress 2001:db8:36::2/48
create esrp esrp1
configure esrp esrp1 domain-id 4096
configure esrp esrp1 add master sales
enable esrp esrp1
create esrp esrp2
configure esrp esrp2 domain-id 4097
configure esrp esrp2 add master engineering
enable esrp esrp2
```

Configuration commands for the second ESRP switch are as follows:

```plaintext
create vlan sales
configure vlan sales tag 10
configure vlan sales add ports 1:1-1:3
configure vlan sales ipaddress 10.1.2.3/24
configure vlan sales ipaddress 2001:db8:36::1/48
configure vlan sales add ports 1:5 tagged
create vlan engineering
configure vlan engineering tag 20
configure vlan engineering add ports 1:4, 2:1
configure vlan engineering ipaddress 10.4.5.6/24
configure vlan engineering ipaddress 2001:db8:36::2/48
create esrp esrp1
configure esrp esrp1 domain-id 4096
configure esrp 1 add master sales
enable esrp esrp1
create esrp esrp2
configure esrp esrp2 domain-id 4097
configure esrp esrp2 add master engineering
configure esrp esrp2 priority 5
enable esrp esrp2
```
This chapter assumes that you are already familiar with the Virtual Router Redundancy Protocol (VRRP). If not, refer to the following publications for additional information:

- RFC 2338—Virtual Router Redundancy Protocol (VRRP)
- RFC 2787—Definitions of Managed Objects for the Virtual Router Redundancy Protocol

**VRRP Overview**

VRRP (Virtual Router Redundancy Protocol), like the ESRP (Extreme Standby Router Protocol), allows multiple switches to provide redundant routing services to users.

VRRP is used to eliminate the single point of failure associated with manually configuring a default gateway address on each host in a network. Without using VRRP, if the configured default gateway fails, you must reconfigure each host on the network to use a different router as the default gateway. VRRP provides a redundant path for the hosts. Using VRRP, if the default gateway fails, the backup router assumes forwarding responsibilities. An example VRRP topology is shown in Figure 179.

**Figure 179: Simple VRRP Network**
Switches A and B are both configured with the same VRRP router ID on the same VLAN (Virtual LAN), which establishes a VRRP relationship between the two routers. Because a single switch can support multiple VRRP relationships, each relationship is referred to as a VRRP router instance. Within a VRRP router instance, any VRRP router can become the master, but only one VRRP router can be master at a time. The master processes all client communications, and the other VRRP routers in the VRRP routing instance stand by, ready to take over if the master is no longer available.

Each switch in a VRRP topology has its own unique IP and MAC addresses, which are required for basic IP connectivity. For each VRRP router instance, there are shared VRRP IP and MAC addresses, which are used for network client communications. The VRRP router IP address is configured on all VRRP routers in a VRRP routing instance, and it is configured as the default gateway address on network clients. If the master VRRP router becomes unavailable, the backup VRRP router takes over using the same VRRP router IP address.

If the VRRP router IP address matches the actual VLAN IP address of the IP address owner has the highest priority value (255) and will always become the master when VRRP is enabled and operating correctly. If the switch or the VRRP process on the switch stops responding, a backup switch (Switch B in Figure 180) takes over the master role and serves as the default gateway for network clients.

VRRP supports multiple backup routers. If the master VRRP router stops working, one of the backup routers takes over as described in ESRP Master Election on page 1177.

VRRP also supports multiple VRRP router instances, which can be used to enable load sharing. The following figure shows a VRRP load-sharing configuration.

![Figure 180: VRRP Load-sharing Configuration](image)

Switches A and B in the above figure are each configured with two VRRP router instances. Switch A is the IP address owner and default master for VRRP instance 1, and Switch B is the IP address owner and default master for VRRP instance 2. Half the network clients are configured to use VRRP instance 1 as the primary gateway and VRRP instance 2 as the backup gateway. The other half of the network clients are configured to use VRRP instance 2 as the primary gateway and VRRP instance 1 as the backup gateway. When both switches are operating with VRRP, each switch supports half the clients in a load-
sharing topology. If either switch fails, or if VRRP is disabled on a switch, the remaining switch supports all network clients.

**Note**
We recommend that you do not enable VRRP on aggregated VLANs, which are also known as super VLANs.

**VRRP Guidelines**

The following guidelines apply to using VRRP:

- VRRP packets are encapsulated IP packets.
- The VRRP IPv4 multicast address is 224.0.0.18.
- The VRRP IPv6 multicast address is ff02::12.
- The maximum number of supported VRIDs per interface is 255 for V3-v2 version mode, and 255 for v2 or v# version mode.
- An interconnect link between VRRP routers should not be used, except when VRRP routers have hosts directly attached.
- VRRP instance scale is dependent on platform and license. Please refer to the ExtremeXOS release notes for details.
- Up to 255 unique VRIDs can be configured on the router.
- VRRP and other L2 redundancy protocols can be simultaneously enabled on the same switch.
- When VRRP and BOOTP/DHCP (Dynamic Host Configuration Protocol) relay are both enabled on the switch, the relayed BOOTP agent IP address is the actual switch IP address, not the virtual IP address.
- We do not recommend simultaneously enabling VRRP and ESRP on the same switch.
- VRRP and ESRP cannot be configured on the same VLAN or port. This configuration is not allowed.
- RFC 5798 describes a situation where a master VRRP router takes on a duplicate IP address due to interaction with the duplicate address detection (DAD) feature. To prevent such duplicate addresses, the DAD feature is disabled whenever a VRRP router is configured for IPv6 or IPv4.
- A VRRP router instance can be configured with multiple IP addresses on the same subnet or on different subnets, provided that all virtual IP addresses match the subnet address of a VLAN on the switch. For example, if a host switch has VLAN IP addresses in the 1.1.1.x and 2.2.2.x subnets, then that VRRP router instance can contain virtual IP addresses in both those subnets as well.
- If a VRRP router instance is assigned priority 255, then the host router must own all the IP addresses assigned to the VRRP router instance. That is, each virtual IP address must match an IP address configured for a VLAN on the router.
- When a VRRPv2 instance spans routers using ExtremeXOS version 12.6 and earlier and routers using ExtremeXOS version 12.7 and later, routers using ExtremeXOS version 12.6 and earlier log packet-size warning messages.
- VRRP scaling numbers differs based on the license and hardware used; please refer the release notes for individual scaling limits.

**Note**
A maximum of 511 VRRP instances are allowed without One-To-Many Mirroring. If using OTM Mirroring, only 507 VRRP instances are allowed. You can increase VRRP scaling limit by using VRRP grouping (see VRRP Grouping to Increase VR Scaling on page 1218).
VRRP Master Election

When a VRRP configured network starts, VRRP uses an election algorithm to dynamically assign master responsibility to one of the VRRP routers on the network.

The VRRP master is determined by the following factors:

- **VRRP priority**—Possible values are 0 through 255. Value 255 is reserved for the VRRP router IP address owner, and value 0 is reserved for the master router, to indicate it is releasing master responsibility. Values 1–254 can be configured on backup routers to influence which backup router becomes the master when the master VRRP router is no longer available. The higher number has higher priority. The default value for backup routers is 100.

- **Higher IP address**—If multiple backup routers have the same configured priority, the router with the highest IP address becomes the master.

If the master router becomes unavailable, the election process begins and the backup router that wins the election assumes the role of master.

**Note**

In VRRP IPv6, master election happens based on the interface link local address when the priorities are the same. The highest link local address switch is selected as the VRRP master.

A new master is elected when one of the following things happen:

- VRRP is disabled on the master router.
- Loss of communication occurs between master and backup router(s).

If VRRP is disabled on the master interface, the master router sends an advertisement with the priority set to 0 to all backup routers. This signals the backup routers that they do not need to wait for the master down interval to expire, and the master election process can begin immediately.

The master down interval is set using the following formula: 3 x advertisement interval + skew time.

The advertisement interval is a user-configurable option, and the skew time is (256-priority/256).

**Note**

The formula for VRRPv2; ((256 - priority) / 256). The VRRPv3 Skew time calculation will be different. Please refer to RFC 5798 (http://tools.ietf.org/html/rfc5798), Skew time. (((256 - priority) x Master_Adver_Interval) / 256)

**Note**

An extremely busy CPU can create a short dual master situation. To avoid this, increase the advertisement interval.

VRRP Master Preemption

VRRP master preemption is a feature that allows a VRRP backup router with a higher VRRP priority to take control from a lower priority backup that is acting as the master.
VRRP election occurs as described in ESRP Master Election on page 1177. VRRP preemption occurs when a VRRP backup router is added to the network or recovers, and that backup router has a higher priority than the current backup VRRP that is operating as the master.

**Note**
The VRRP router IP address owner always preempts, independent of the VRRP preemption setting.

When a VRRP backup router preempts the master, it does so in one of the following ways:

- If the preempt delay timer is configured for between 1 and 3600 seconds and the lower-priority master is still operating, the router preempts the master when the timer expires.
- If the preempt delay timer is configured for 0, the router preempts the master after three times length of the hello interval.
- If the higher priority router stops receiving advertisements from the current master for three times the length of the hello interval, it takes over mastership immediately.

The preempt delay timer provides time for a recovering router to complete start up before preemtting a lower-priority router. If the preempt delay timer is configured too low, traffic is lost between the time the preempting router takes control and the time when it has completed startup.

### VRRP Tracking

Tracking information is used to track various forms of connectivity from the VRRP router to the outside world.

#### VRRP Tracking Mode

When a VRRP tracked entity fails, the VRRP router behavior is controlled by the tracking mode. The mode can be all, or any. The default mode is all.

When the mode is all, the master role is relinquished when one of the following events occur:

- All of the tracked VLANS fail.
- All of the tracked routes fail.
- All of the tracked pings fail.

**Note**
Mastership is relinquished and the switch goes to INIT state.

When the mode is any, the master role is relinquished when any of the tracked VLANS, routes, or pings fail.

#### VRRP VLAN Tracking

You can configure VRRP to track active VLANS (active ports in a VLAN or Loopback) of up to eight specified VLANS as criteria for failover.

If no active ports remain on the specified VLANS, the router automatically relinquishes master status based on the tracking mode.
When a tracking condition is in a failed state, VRRP behaves as though it is locally disabled; so it is neither master nor backup (which are both active states).

**VRRP Route Table Tracking**

You can configure VRRP to track specified routes in the route table as criteria for VRRP failover.

If any of the configured routes are not available within the route table, the router automatically relinquishes master status based on the tracking mode.

**Note**

**MPLS (Multiprotocol Label Switching) LSPs are not considered to be part of VRRP route tracking.**

**VRRP Ping Tracking**

You can configure VRRP to track connectivity using a simple ping to any outside responder.

The responder may represent the default route of the router, or any device meaningful to network connectivity of the master VRRP router. If pinging the responder consecutively fails the specified number of times, the router automatically relinquishes master status based on the tracking mode.

**VRRP Address Support for IPv4**

For IPv4 traffic, a primary IPv4 address is selected from the set of real interface addresses. VRRP advertisements are always sent using the primary IPv4 address as the source of the IPv4 packet.

The VRRP MAC address for an IPv4 VRRP router instance is an IEEE 802 MAC address in the following hexadecimal format (in Internet-standard bit-order):

00-00-5E-00-01-<vrid>

The first three octets are derived from the IANA Organizational Unique Identifier (OUI). The next two octets (00-01) indicate the address block assigned to the VRRP router for the IPv4 protocol, and VRID is the VRRP instance identifier. This mapping provides for up to 255 IPv4 VRRP routers on a network.

When a VRRP router instance becomes active, the master router issues a gratuitous ARP response that contains the VRRP router MAC address for each VRRP router IP address.

The master also always responds to ARP requests for VRRP router IP addresses with an ARP response containing the VRRP MAC address. Hosts on the network use the VRRP router MAC address when they send traffic to the default gateway.

**VRRP Address Support for IPv6**

IPv6 VRRP router advertisements are always sent using the VRRP virtual link-local address as the source address.

Hosts on the LAN can use this link-local address as their default route gateway. If no VRRP link-local address is configured, a default value is derived as follows:
FE80::5E00:02{VRID}

VRID is the VRRP instance identifier.

**Note**
The host portion of this address corresponds to the virtual MAC address associated with the VRRP router.

When a backup VRRP router assumes the role of master, it must use the same link-local address in router advertisements as the previous master. Therefore, when configuring a backup VRRP router, you must either configure a virtual link local address that matches the link local address on the IP address owner or allow the virtual link local address to default to the derived value in the same manner as on the master.

Router advertisement prefixes are configured based on the VRRP IP addresses. The mask used for the prefix will be the smallest mask used by all VRRP IP addresses on a VLAN interface. The ExtremeXOS software supports multiple IPv6 addresses on an interface that can overlap. For example, you can add both 200d::1/48 and 200d::2/96 to a VLAN. IPv6 VRRP routers advertise the smallest mask that applies to all VRRP IP addresses. In this example, if VRRP IP address 200d::100 is added, the mask is 48.

The VRRP MAC address for an IPv6 VRRP router instance is an IEEE 802 MAC address in the following hexadecimal format (in Internet-standard bit-order):

```
00-00-5E-00-02-_<vrid>
```

The first three octets are derived from the IANA OUI. The next two octets (00-02) indicate the address block assigned to the VRRP router for IPv6 protocol, and VRID is the VRRP instance identifier. This mapping provides for up to 255 IPv6 VRRP routers on a network.

When a VRRP router assumes the role of master, it issues an unsolicited neighbor discovery (ND) neighbor advertisement message for each of the VRRP router IP addresses.

The master also always responds to ND neighbor solicitations with ND neighbor advertisements using the VRRP MAC address.

**NTP VRRP Virtual IP support**

This feature allows switches to configure the VRRP virtual IP as an NTP server address. The NTP server, when configured on the VRRP master, listens on the actual IP and virtual IP address for NTP clients.

On the VRRP backup node, only one socket is opened and bound to the physical IP address alone. Once a node transitions to the VRRP master, the ExtremeXOS software re-triggers a listen on the interface to ntpd for it to open a socket and bind to the VRRP VIP.

A flag configuration is added for the IPv4 cases, and these are propagated to VLAN Manager clients. NTP uses this to trigger a listen on the interface. For the master node to process non-ping packets destined to the VIP, the software already has a configuration command in VRRP (accept-mode on/off).

**Note**
If you want to configure VRRP VIP as the server address on NTP clients, enable accept mode.
Limitations

The following limitations exist for NTP VRRP Virtual IP support:

- Summit switches configured as NTP clients need to have the bootrom version: 2.0.1.7
- We do not recommend FHRP Virtual IPs for NTP configuration because they can cause undesirable behavior when the NTP servers are not in sync, or if the delay is asymmetric. Ensure that both servers derive their clock information from the same source.

This problem can be more acute if a node connected to VRRP peers using MLAG (Multi-switch Link Aggregation Group) and VRRP is in active-active mode. In this case, it is possible that every other packet could be sent to a different switch due to LAG (Link Aggregation Group) hashing at the remote node.

VRRPv3 Interoperation with VRRPv2

RFC 5798 states that VRRPv2 and VRRPv3 interoperation is optional, and that mixing these two versions should only be done when transitioning from VRRPv2 to VRRPv3.

VRRPv2 and VRRPv3 interoperation should not be implemented as a permanent solution.

This release supports configuration for the following modes of operation: VRRPv2, VRRPv3, and VRRPv2 and VRRPv3 interoperation.

VRRP Active-Active

VRRP Active-Active mode allows you to have two active VRRP masters in conjunction with MLAG by applying an ACL (Access Control List) on the ISC links in order to block VRRP updates.

When you configure VRRP with MLAG, you have the option to make VRRP operate in active-active mode. For MLAG peers to operate in VRRP active-active mode, configure the following ACL on both ends of the ISC link.

```
entry vrrp-act {
  if match all {
    destination-address 224.0.0.18/32 ;
  } then {
    deny ;
  }
}
```

There are two caveats that you need to be aware of that are illustrated in Figure 181:

- An ARP request from 10.0.0.4 results in duplicate ARP replies (one from each MLAG switch).
- For this to work correctly, you have to configure the virtual IP address to be a different address from either of the MLAG peer interface addresses. When an MLAG switch generates an ARP request it uses the vMAC instead of its own switch MAC, and the response (if the reverse path hashing chooses the other MLAG switch) is consumed by the peer MLAG switch.
VRRP Fabric Routing

Prior to ExtremeXOS 21.1, VRRP had one master router which would do L3 routing and one or more backup routers which would do L2 forwarding of packets to the master router. This caused loss of bandwidth in the links that connect the master and backup routers. This issue is present in any topology wherein host traffic is flowing via backup router. In case of multiple backup routers, traffic from hosts attached to some backup routers would have to traverse multiple links to reach the master router. This caused loss of bandwidth in multiple links towards the master.

The VRRP fabric routing feature introduced in ExtremeXOS 21.1 allows the backup router to take part in L3 routing for the packets it receives with DA=VMAC. A backup router enabled with this feature is called a Fabric Routing Enabled Backup (FREB) router. This feature allows load sharing of traffic between VRRP routers and saves the bandwidth of links connecting the master and backup. This bandwidth saved can be used to provide better connectivity between the segments of the network wherein each segment is connected to only one VRRP router directly. This solution is applicable for all topologies such as MLAG, EAPS (Extreme Automatic Protection Switching), or STP (Spanning Tree Protocol).

The VRRP FREB router receives and processes VRRP advertisements from the master, but does not generate advertisements. Broadcast ARP requests and multicast neighbor solicitations to resolve the virtual IP are responded to by the master router. The Fabric Routing Enabled Backup router behaves as mentioned in RFC 5798 with the following exceptions:

- The backup router performs forwarding functionality, similar to the master.
- The backup router responds to unicast ARP/Neighbor Solicitation requests it receives.

**Configuring VRRP Fabric Routing**

To configure the fabric routing feature, enter the following command:
configure vrrp vlan vlan_name vrid vridval fabric-routing [on | off]

This configuration can be present on all VRRP routers, regardless of VRRP state of the router. Fabric routing will be enabled only when the VRRP router is in backup state.

Fabric Routing Functionality

The VRRP backup router enabled with fabric routing mode is called a VRRP FREB router (Fabric Routing Enabled Backup router). The VRRP FREB router is responsible for the following:

- Performing routing for the packets destined for subnets other than the received interface's subnet. These packets should also have a destination MAC matching Virtual MAC. These packets will be routed by hardware.
- Forwarding the packets having a Destination IP matching Virtual IP, towards VRRP Master. These packets will have Destination MAC matching Virtual MAC. These packets will be forwarded by hardware.
- Responding for unicast ARP requests with target IP matching Virtual IP.
- Responding for unicast Neighbor Solicitation requests with target IP matching Virtual IP.
- Does not respond to broadcast ARP / multicast Neighbor solicitations targeted for Virtual IP.
- Does not respond for ICMP (Internet Control Message Protocol) requests destined for Virtual IP.
- Does not generate gratuitous ARP/ Neighbor Advertisements.
- Does not advertise Router Advertisement Prefixes in this state.

VRRP Router Accepts Packets Destined to Virtual IP

Only the master serves as protocol servers like NTP, telnet, SSH, etc and accepts connections destined to the virtual IP. By doing so, hosts always connect to the same virtual router (VR) by using the virtual IP, at any given point of time. This ensures that the host is getting a consistent response from the protocol server. This arrangement allows the host to reach the NTP server using the same IP i.e. virtual IP, even if VRRP mastership moves to a different router. A network monitoring tool is another example, which can use virtual IP to collect data about VRRP domain, by connecting to current VRRP Master. It is not recommended to change the configurations of the switch, when a management session is connected using virtual IP. When VRRP FREB router sits in between the host and VRRP Master router, FREB router does hardware forwarding of these packets from host towards VRRP Master, at Layer 3.
Note
A caveat is that TTL/hop count is decremented for the packets destined for virtual IP, when forwarded by FREB. This may be a problem to run any protocol that expects TTL not to be decremented, between host and Master.

Hosts can generate unicast ARP to validate a ARP cache entry. Similarly, unicast Neighbor Solicitation is generated to perform Neighbor Unreachability Detection for a neighbor. These requests are periodic. The unicast ARP/NS requests will be responded by FREB, if it receives the request. A downside of allowing VRRP Master to respond these requests is that it may take considerable CPU cycles when large numbers of hosts are present in VRRP domain.

Enabling Fabric Routing Mode

A VRRP router configured with fabric routing mode will be in backup state. There is some difference in behavior based on enabling sequence which is described below.

When enabling VRRP VR after configuring fabric routing mode, assume that fabric routing mode has already been configured for VRRP VR and VR is administratively enabled now. Initially the VRRP state machine will start from INIT state. It will move to backup state and wait for Master_Down_Interval duration to receive an advertisement from current master. Based on VRRP Master election (as described earlier in the sections), VRRP router will either become master or will assume forwarding responsibility.
while in backup state (i.e., FREB). Waiting in backup state avoids a burst of messages exchanged in software during the transition. This is useful in scaled setups.

**Note**

For the duration it waits in backup state, traffic will be forwarded to the VRRP master where it gets routed. This behavior is same as existing behavior without fabric routing.

When configuring fabric route mode when the VR is already in backup state, if the VR has received advertisements within the last advertisement interval, the router will take forwarding responsibility immediately.

The hold off timer will be applied before FREB starts IP forwarding. In case of reboot or process restart, the VR will wait for 60 seconds before taking forwarding responsibility. This will allow the routing protocols in the restarting system to converge.

To enable fabric routing, use the following command:

```bash
configure vrrp vlan [vlan_name | vlan_list] [vridval | all] {group group_name} fabric-routing [on | off]
```

To configure a specific VRRP instance as FREB:

```bash
configure vrrp vlan v1 vrid 1 fabric-routing on
```

To configure all the VRRP instances as FREB:

```bash
configure vrrp all fabric-routing on
```

Configured fabric routing can be seen in the show command output of the `show vrrp detail` or `show vrrp vlan` CLI command:

```bash
# sh vrrp detail
VLAN:  v1   VRID:  1   VRRP:  Disabled State:  Backup
Virtual Router:  VR-Default
Priority:  100(backup) Advertisement Interval:  1 sec
Version: v2   Preempt:  Yes   Preempt Delay: 0 sec
Virtual IP Addresses:
Accept mode:  Off
Host-Mobility:  Off
Host-Mobility Exclude-Ports:
Tracking mode:  ALL
Tracked Pings:  -
Tracked IP Routes:  -
Tracked VLANs:  -
Fabric Routing:  On

* indicates a tracking condition has failed
```

**Fabric Routing Limitations**

The following are limitation of VRRP fabric routing:

- VRRP fabric routing is not supported for the configuration of virtual IP address being same as interface IP address (i.e., IP owner case).
- VRRP fabric routing is not supported for PVLAN and VLAN aggregation topologies.
VRRP and Hitless Failover

Note
This section applies to SummitStack only.

The primary node executes the switch’s management functions, and the backup acts in a standby role. Hitless failover transfers switch management control from the primary to the backup and maintains the state of VRRP. While VRRP supports hitless failover, you do not explicitly configure hitless failover support; rather, if you have two nodes installed, hitless failover is available.

To support hitless failover, the primary node replicates VRRP protocol data units (PDUs) to the backup, which allows the nodes to run VRRP in parallel. Although both nodes receive VRRP PDUs, only the primary transmits VRRP PDUs to neighboring switches and participates in VRRP.

To initiate hitless failover on a network that uses VRRP:

1. Confirm that the primary and backup nodes are synchronized and have identical software and switch configurations using the `show switch {detail}` command.
   The output displays the status of the nodes, with the primary node showing MASTER and the backup node showing BACKUP (InSync).
   a. If the primary and backup nodes are not synchronized and both nodes are running a version of ExtremeXOS that supports synchronization, proceed to step 2 in STP and Hitless Failover—SummitStack Only on page 1131.
   b. If the primary and backup nodes are synchronized, proceed to step 3 in STP and Hitless Failover—SummitStack Only on page 1131.

2. If the primary and backup nodes are not synchronized, use the `synchronize` command to replicate all saved images and configurations from the primary to the backup.
   After you confirm the primary and backup nodes are synchronized, proceed to step 3 in STP and Hitless Failover—SummitStack Only on page 1131.

3. If the primary and backup nodes are synchronized, use the `run failover` (formerly `run msm-failover`) command to initiate failover.

For more detailed information about verifying the status of the nodes and system redundancy, see Understanding System Redundancy on page 67. For more information about hitless failover, see Understanding Hitless Failover Support on page 71.

Note
For complete information about software licensing, including how to obtain and upgrade your license and what licenses are appropriate for these features, in the ExtremeXOS 22.6 Feature License Requirements document.

VRRP Host Mobility

VRRP host mobility solves the asymmetric routing problem associated with VRRP where the path to return to an end host may be different and longer than necessary. This feature uses host routes to indicate where in the network an end host resides. Using other routing protocols such as OSPF (Open Shortest Path First), other routers will then pick the shortest path back to the end host when multiple paths are available via ECMP (Equal Cost Multi Paths) route entries.
Asymmetric Routing and VRRP

The optimum flow path for frames sourced by clients is that they are forwarded by the first encountered router in the path. The optimum flow path for return frames for these flows is through the same router that forwarded the initial frames of the flow. This is referred to as a symmetric routing path. Unfortunately, standard VRRP elects one of a group of routers to forward frames from a client, but the return path may be through any of the routers in the VRRP group. This condition is known as asymmetric routing. In the following figure there are three devices that are routers in a VRRP group servicing the 192.168.1.0/24 network with the VRRP virtual gateway 192.168.1.1. Router R2 has been elected VRRP master and this is the only router that will route frames from the clients to the core, even though the clients are not locally connected to the master. The other devices bridge frames from the clients to the master; therefore, the frames from User55 and User77 must traverse two devices when routing the frame to the core.

**Figure 183: Asymmetric Routing and VRRP (1)**

R1, R2, and R3 all advertise 192.168.1.0/24 to the core. This means that return traffic to the users will be sent from the core to any of these routers. A non-optimal path for the flows in either direction may result. Flows from User 55 to Core would traverse R1, R2. The return path could traverse R3, R2, and R1.
Figure 184: Asymmetric Routing and VRRP (2)

Fabric Routing solves part of this path problem by allowing the backup routers to forward frames for the clients without having to send the frame to the master router for the group. Now frames from User 55 will be routed by the first router that receives the frame (R1). Unfortunately, the return path to User 55 from the core is still via Equal Cost Multipath (ECMP) to any of the routers. Again, the frame may have to still traverse R3, R2, and finally R1 to reach User 55 from the core.

Host Mobility Solving Asymmetric Routing

The host mobility feature uses ARP/ND to learn each user connected to the IP Network on the router that is closest to the end host. It then uses routing protocols such as OSPF to advertise the hosts IP/IPv6 address. These “Host Routes” will be advertised to other routers making them the preferred route to the end host’s IP address. As the host route propagates through the network the most efficient path to the end host will be revealed as every other path will have an additional cost. With host mobility, User 55’s complete route will be advertised to R2, R3 and the core. The core will then receive a route to User 55’s address from all three routers. The most direct route will have less hops and a lower cost than the routes reported by R2 and R3. When traffic destined to User 55 enters the core the most direct path (R1) is selected.

VRRP Host Mobility Feature Detail

The ExtremeXOS Host-Mobility feature is implemented using the user space application VRRP, which listens for ARP/ND updates from the kernel using the FDB (forwarding database). When ARP/ND entries are inserted into the kernel, the FDB notifies the host-mobility application. If the new ARP/ND entry exists on an interface that has VRRP, host-mobility is configured on the VRRP & VRID pair, and the port is not being excluded, the host-mobility application will create a host route in the route table.

The host routes in the route table will be propagated via existing routing protocols such as OSPF.

As ARP/ND entries are removed from the kernel, the host-mobility portion of the VRRP application is notified. Normally if the interface is still up when entries are removed, the host-mobility application sends an ARP/ND packet to the IP address of the host associated with the ARP/ND entry to resolve the address again. The FDB attempts to resolve ARP addresses when near the age period. Due to the FDB keeping ARPs up to date, host-mobility does not need to try to resolve aging entries when aging. When the entry is removed by a clear CLI command, FDB does not send an ARP. When the entry is removed, Host-Mobility requests an ARP. After 5 seconds, if no route has been added, the host routes are removed from the route table.
Ports are designated as host or router ports; by default the ports are host ports. ARP/ND entries learned on router ports do not generate host route entries. Only ARP/ND entries learned on host ports generate route entries. Host route entries are removed if the ARP/ND entry is learned or changes to a router port.

When a host moves from one switch to another on the same layer 2 network, a new host route is created from the new location. In this case there may be two host routes throughout the network advertising for the same host. While not optimal, this situation does not cause any network delivery problems. Eventually the original host route is removed when the ARP/ND entry is removed from the switch or moves from a host port to a router port.

A redistribution command is required for OSPF or other routing protocols to distribute the new host routes. The command to redistribute is “enable ospf export host-mobility cost 0 type ase-type-2”. A new routing “Origin” type is added to route table for host-mobility routes.

Since OSPF will redistribute host-mobility routes, it is possible that a route could be learned for a host that the local device can reach at a lesser cost. Host-mobility monitors routes added by OSPF. If OSPF adds a route that is part of a subnet that the device is a member of, then host-mobility triggers ARP/ND to be performed. By performing ARP/ND, the lower cost route to host is added as an ARP/ND entry in the proper table and is used while routing traffic. If no response is received, then the OSPF route will continue to be used instead.

**VRRP Grouping to Increase VR Scaling**

To achieve scaling of VRRP VR instances above 511 to as high as 2,048, selected VRRP VRs must be grouped as instructed by the user. Groups involving the same set of VRRP VRs are configured in all VRRP routers. A single chosen VR out of the group (primary VR) transmits/receives VRRP advertisements at the configured interval. Other VRs (secondary VRs) in the group transmit/receive at a much slower rate. This requires a much fewer number of VRRP advertisements exchanged, and reduces CPU resource usage, increasing scaling. All VRs in a group assume same VRRP state in a given router.

VRRP Fabric Routing needs to be enabled on all member VRs of a group in participating VRRP routers. This does not have any effect when a VR (or group of VRs) is master; but, when a higher priority master becomes available, this VR transitions to Fabric Routing-enabled backup, instead of regular backup. Since the Fabric Routing feature enables VRRP backup routers to load share by Layer 3 forwarding, and conforms to RFC 5798, this mode is preferred over using a regular backup router. However, if you want the regular master-backup configuration, you can use a separate VRID that is not used by VRs in any group.

**VRRP Grouping Limitations**

- All VRRP VLANs participating in same group should have same topology in a given router.
- VRRP groups and individual VRs can not be mixed when VRs use the same VRID and are configured to operate in regular master-backup mode.
- Fabric Routing must be enabled for the group of VRs if the same VRID is repeated in multiple groups.
- When the number of VRs configured on a router exceeds 511, you must switch to high-scale mode (use VRRP grouping) to obtain scaling to 2,048 VR instances.
- The same group does not support combinations of some IPv4 VRs and some IPv6 VRs. Separate groups must be used for each type.
VRRP Grouping Description

Figure 185: Example VRRP Group Configuration

Figure 185 shows an example configuration of two different groups in simple MLAG topology. Group A is configured with 10 VRRP VRs, each VR on a separate VLAN, and using separate VRRP IDs. The same set of VRRP VLANs are grouped together on both routers. All the VRRP VLANs on Group A have the same topology with respect to Router 1 and Router 2. If a VLAN on Router 1 goes down due to link faults or I/O slot failure, other VLANs also go down (that is, all VLANs in the group share the same fate).

This is a typical topology for which this scaling is well suited. If the VLAN going down event triggers VRRP state change in one VLAN, a VRRP state change occurs on other VLANs also. This example has four hosts on different VLANs belonging to group A; traffic from hosts may get hashed to either of the MLAG links and reach either the VRRP master (RTR1) or the Fabric Routing-enabled backup router (RTR2). Both routers perform routing for host traffic. Group B has a different set of 10 VRRP VRs that were configured on a different set of VLANs and with a different set of VRIDs from that of Group A.
Routers are configured for regular master-backup states (unlike Group A which has master-FREB states).

**Note**
If you want a regular master-backup operation on a particular group for some reason, do not reuse the VRIDs configured in other groups or other individual VRs.

**Enabling Fabric Routing on VRs**

Enabling Fabric Routing is only required if a VRID is reused in more than one group. Only these groups of VRs need to be enabled for Fabric Routing in all participating VRRP routers.

**Grouping Reusing VRIDs in Different Groups (Fabric Routing Mode)**

Table 119 shows an example configuration that reuses VRIDs in multiple groups. All three groups are configured on each VRRP router. Notice that Groups A and C have the same set of VLANs, but VRID is interchanged between the VLANs. Since all three groups are sharing the same VRIDs, Fabric Routing needs to be enabled on VRs in all three groups.

**Table 119: VRRP Grouping Example #1**

</tbody>
</table>

**Grouping with Unique VRIDs**

All VRs in Group I use VRID 1 in Table 120. All VRs in Group J use VRID 2. In this configuration, all VR groups do not need to be enabled for Fabric Routing. Group I can operate in master-FREB mode, and Group J can choose to operate in master-backup mode. In this case, only VRs in Group I need to be enabled for Fabric Routing.

**Table 120: VRRP Grouping Example #2**

**Grouping with Multiple VRIDs per Group with VRIDs Not Repeated**

It is possible to have an individual VR when there are some groups already in the same router. This may be useful when this router has two VRRP peer routers and it has to operate in group mode with one peer, but has to operate in individual VR mode with another peer at the same time. In that case, an individual VR must be configured with a unique VRID that is not used in any of the groups or other
individual VRs. This unique VRID is required only if either a group or individual VR is operating in master-backup mode. However, if all groups and individual VRs are operating in master-FREB mode, then VRIDs used within a group can be assigned to individual VRs.

Characteristics of VRs in a Group

When VRs are grouped together you need to choose a VR from the group and configure it as the primary VR using the CLI. Other VRs belonging to the group need to be added as secondary VRs. When a group is operational, the following approach maintains the same state across all VRs:

- The primary VR sends VRRP advertisements at the configured interval.
- All the VRs in the group have the same VRRP state in a given router.
- Only the primary VR registers for tracking objects (iproute tracking, ping tracking, VLAN tracking) and processes tracked events. If any tracking configuration is present on secondary VRs, they are not effective when the VR is part of a group.
- Secondary VRs inherit the priority of the primary VR. This is useful because when you want to change the priority of a group, you only need to change priority of the single primary VR.
- The pre-empt configuration of the primary VR is applied for the group. If these configurations (pre-empt allowed, pre-empt delay) are present in secondary VRs, they are not effective.
- The advertisement interval configuration on a secondary VR is also not effective.

Other per VR configurations/properties should continue to work as-is, such as accept-mode and host-mobility. All secondary VRs send advertisements at 40 seconds intervals. Sending advertisements help Layer 2 switches in the network to learn VMACs on a secondary VR’s VLAN. Sending at a slower rate reduces processing load at control plane, on VRRP peers.

The other properties of individual VRs present in a group are not altered from their current behavior.

Switching Between Individual VR Mode and High-Scale Mode (Group)

It may be preferable to run in individual VR mode until VR count exceeds its maximum limit (511 instances), as it gives more flexibility with respect to topology choices and ‘per-VLAN routing control for the same VRID’. It will allow the VRs configured in different VLANs configured with same VRID to be in different routing states (for example, one VR can be master and that VLAN can do routing, but the other VR can be backup and that VLAN can do Layer 2 forwarding towards the master).

When you try to configure and enable a VR beyond 511 VRs, you are notified to configure VRRP groups and add VRs to appropriate groups. VRs configured on VLANs following the same topology can be grouped together. There can be multiple groups for the same topology for administrative reasons, or for running with different VRRP configurations (like advertisement interval, etc.), or with different Fabric Routing mode.
Alternatively, groups can be configured beforehand and kept for future use. Similarly, VRs can be added to the group beforehand. The groups can be kept in a disabled state (\texttt{disable vrrp group group_name (configuration | members)}) until you are notified to configure VRRP groups (VR count exceeds 511). When groups are in the disabled state, the VRs present in the group configuration run in individual VR mode.

During switchover, it is recommended to execute the commands:

\begin{verbatim}
disable vrrp
disable vrrp group group_name members
\end{verbatim}

After adding VRs to group, and enabling group configuration, execute the commands:

\begin{verbatim}
enable vrrp
enable vrrp group group_name members
\end{verbatim}

Keeping VRs in disabled state during transition, and then enabling afterwards, ensures that the bulk transfer of VR information across the system occurs more easily.

You can switch to individual VR mode from high-scale mode by disabling all VRRP groups. Since the limit of VRs in individual mode is 511, ensure that greater than 511 VRs are not enabled before disabling the group configuration.

When a group is already operational (the group is enabled, and also its member VRs are enabled), additional VR can be added to the group. It is recommended to disable the VR before adding it to a group that is currently running and forwarding traffic. Enable the VR after it is added to group in all participating routers. This avoids traffic loss during the transition to group mode.

You can have few individual VRs outside of groups. If you are transitioning to high-scale mode when an individual VR is present, disable all VRs (\texttt{disable vrrp}) before the transition and enable all VRs (\texttt{enable vrrp}) after the transition.

For a list of all VRRP group commands, see \textit{Configuring VRRP Groups} on page 1226.

\section*{Note}

If a large number of VRs are added under the same group, the advertisement interval of the primary VR of the group should be increased to multiples of seconds. This reduces the processing load on the VRRP backup router and avoids protocol flaps. For a large IPv6 group, chose an advertisement interval of a greater value than the value of a similarly sized IPv4 group.

\section*{Configuring VRRP}

The following procedure can be used to configure a simple VRRP topology:

1. Configure the VRRP IP address owner router as follows:
   a. Create a VLAN to serve as the VRRP router VLAN.
   b. Add an IP address to the VRRP VLAN.
c Enable IP forwarding on VRRP VLAN.
d Add the VRRP version for the VRRP instance (see Configuring VRRP Version Support on page 1225).
e Create the VRRP router instance for the intended VRRP master (see Creating and Deleting VRRP Router Instances on page 1223).
f Add the IP address defined in Step 1b as a VRRP router IP address (see Adding and Deleting VRRP Router IP Addresses on page 1223).
g Enable VRRP on the switch (see Enabling and Disabling VRRP and VRRP Router Instances on page 1227).

2 Configure each backup VRRP router as follows:

a Create a VLAN to serve as the VRRP router VLAN. This name must match the name used for the appropriate VRRP IP address owner.
b Add an IP address to the VRRP VLAN. This address must be different from the IP address assigned to the intended VRRP master, but it must use the same subnet.
c Enable IP forwarding on VRRP VLAN.
d Create the VRRP router instance that will serve as the backup instance (see Creating and Deleting VRRP Router Instances on page 1223).
e Configure the priority for the backup VRRP router to a value in the range of 1–254 (see Configuring VRRP Router Priority on page 1224).
f Add the same VRRP router IP address that was added to the intended VRRP master instance (see Adding and Deleting VRRP Router IP Addresses on page 1223).
g Enable VRRP on the switch (see Enabling and Disabling VRRP and VRRP Router Instances on page 1227).

3 Configure network workstations to use the VRRP router IP address as the default gateway address.

Creating and Deleting VRRP Router Instances

- To create a VRRP router instance, use the following command:
  `create vrrp vlan vlan_name vrid vridval`
- To delete a VRRP router instance, use the following command:
  `delete vrrp vlan vlan_name vrid vridval`

Adding and Deleting VRRP Router IP Addresses

- To add a VRRP router IP address to a switch, use the following command:
  `configure vrrp vlan vlan_name vrid vridval add ipaddress`

  **Note**
  A VRRP routing instance can support IPv4 or IPv6 addresses, but it cannot support both.

- To delete a VRRP router IP address from a switch, use the following command:
  `configure vrrp vlan vlan_name vrid vridval delete ipaddress`
Adding an IPv6 Link Local Address to a VRRP Router

To add an IPv6 link local address to a VRRP router, enter the following command:

```
configure vrrp vlan vlan_name vrid vridval add virtual-link-local vll_addr
```

Configuring the VRRP Router Advertisement Interval

To configure the VRRP router advertisement interval, use the following command:

```
configure vrrp vlan vlan_name vrid vridval advertisement-interval interval [seconds | centiseconds]
```

**Note**
We recommend that you configure the same router advertisement interval in all VRRP routers. VRRPv3 supports a 40 second maximum advertisement interval.

**Note**
If the advertisement interval is different on the master and backup switches, the master switch's advertisement interval is used by the backup as well.

Configuring Master Preemption

- To enable VRRP master preemption and configure the preempt delay timer, use the following command:
  ```
  configure vrrp vlan vlan_name vrid vridval preempt {delay seconds}
  ```
- To disable VRRP master preemption, use the following command:
  ```
  configure vrrp vlan vlan_name vrid vridval dont-preempt
  ```

Configuring VRRP Router Priority

To configure the priority for a VRRP router, use the following command:

```
configure vrrp vlan vlan_name vrid vridval priority priorityval
```

**Note**
If VRRPv3 and VRRPv2 routers participate in VRRP instance, the VRRPv3 routers should be configured with a higher priority to ensure that they win master elections over VRRPv2 routers.

Configuring the Accept Mode

To configure the accept mode, enter the following command:

```
configure vrrp vlan vlan_name vrid vridval accept-mode [on | off]
```
Configuring NTP VRRP Virtual IP support

To configure the VRRP virtual IP as NTP server address, enter the following command:

```
configure vrrp vlan vlan_name vrid vridval accept mode [on|off]
```

Enabling the `accept` mode allows the switch to process non-ping packets that have a destination IP set to the virtual IP address.

Configuring VRRP Version Support

To configure VRRP version support, use the following command:

```
configure vrrp vlan vlan_name vrid vridval version [v3-v2 | v3 | v2]
```

Configuring VRRP Tracking

Configuring the Tracking Mode

To configure the tracking mode, enter the following command:

```
configure vrrp vlan vlan_name vrid vridval track-mode [all | any]
```

Adding and Deleting Tracked Routes

- To add a tracked route, enter the following command:
  ```
  configure vrrp vlan vlan_name vrid vridval add track-iproute ipaddress/masklength
  ```
- To delete a tracked route, enter the following command:
  ```
  configure vrrp vlan vlan_name vrid vridval delete track-iproute ipaddress/masklength
  ```

Adding and Deleting Tracked VLANs

- To add a tracked VLAN, enter the following command:
  ```
  configure vrrp vlan vlan_name vrid vridval add track-vlan target_vlan_name
  ```
- To delete a tracked VLAN, enter the following command:
  ```
  configure vrrp vlan vlan_name vrid vridval delete track-vlan target_vlan_name
  ```

Adding and Deleting Tracked Pings

- To add a tracked ping, enter the following command:
  ```
  configure vrrp vlan vlan_name vrid vridval add track-ping ipaddress frequency seconds miss misses {success successes}
  ```
- To delete a tracked ping, enter the following command:
  ```
  configure vrrp vlan vlan_name vrid vridval delete track-ping ipaddress
  ```
Configuring VRRP Fabric Routing

To configure the fabric routing feature, enter the following command:

```
configure vrrp vlan[ vlan_name | vlan_list] [vridval | all] {group group_name}fabric-routing [on | off]
```

Configuring Host Mobility

To configure host-mobility, enter the following command:

```
```

In general, the port that is not connected to host is added in `exclude-ports` to avoid unnecessary host route.

Configuring VRRP Groups

To create VRRP groups:

```
create vrrp group group_name
```

To delete VRRP groups:

```
delete vrrp group group_name
```

To add/delete primary VRs or secondary VRs:

```
configure vrrp group group_name add [primary-vr | secondary-vr] [[vlan] vlan_name vrid vridval | vlan vlan_list {vrid vrid_list}]
```

```
configure vrrp group group_name delete [primary-vr | secondary-vr] [[vlan] vlan_name vrid vridval | vlan vlan_list {vrid vrid_list} | all] ]
```

To enable VRRP groups:

```
enable vrrp group group_name {configuration | members}
```

To disable VRRP groups:

```
disable vrrp group group_name {configuration | members}
```

To show VRRP group information:

```
show vrrp group group_name
```

For an example VRRP group configuration, see VRRP Groups Configuration Example on page 1229.
Managing VRRP

Enabling and Disabling VRRP and VRRP Router Instances

• To enable VRRP or a VRRP router instance, enter the following command:
  
```
  enable vrrp {vlan vlan_name vrid vridval}
```

• To disable VRRP or a VRRP router instance, enter the following command:
  
```
  disable vrrp {vlan vlan_name vrid vridval}
```

Clearing VRRP Counters

To clear the VRRP counters, enter the following command:

```
  clear counters vrrp {{vlan vlan_name} {vrid vridval}}
```

Displaying VRRP Information

Displaying VRRP Router Information

To display VRRP router information for one or all VRs, enter the following command:

```
  show vrrp {virtual-router {vr_name}} {detail}
```

Displaying VRRP Router Information and Statistics for VLANs

To display VRRP information or statistics for a VLAN, enter the following command:

```
  show vrrp vlan vlan_name | vlan_list {stats}
```

Displaying VRRP Tracking Information

To view the status of tracked devices, enter the following command:

```
  show vrrp {virtual-router {vr_name}} {detail}
```

VRRP Configuration Examples

Simple VRRP Network Examples

The topology for a simple VRRP network example is shown in Figure 179 on page 1203.

Switch A is the IP address owner, and Switch B is configured as the backup.
The configuration commands for switch A are as follows:

```plaintext
configure vlan vlan1 ipaddress 192.168.1.3/24
enable ipforwarding vlan vlan1
create vrrp vlan vlan1 vrid 1
configure vrrp vlan vlan1 vrid 1 priority 255
configure vrrp vlan vlan1 vrid 1 add 192.168.1.3
enable vrrp
```

The configuration commands for switch B are as follows:

```plaintext
configure vlan vlan1 ipaddress 192.168.1.5/24
enable ipforwarding vlan vlan1
create vrrp vlan vlan1 vrid 1
configure vrrp vlan vlan1 vrid 1 add 192.168.1.3
create vrrp vlan vlan1 vrid 2
configure vrrp vlan vlan1 vrid 2 add 192.168.1.5
enable vrrp
```

**VRRP Load Sharing Example**

You can use two or more VRRP-enabled switches to provide a fully redundant VRRP configuration that supports load sharing on your network.

The topology for a load sharing example is shown in Figure 180 on page 1204. Switch A is the IP address owner for VRRP router instance 1 and the backup for VRRP instance 2. Switch B is the IP address owner for VRRP router instance 2 and the backup for VRRP instance 1.

The configuration commands for switch A are as follows:

```plaintext
configure vlan vlan1 ipaddress 192.168.1.3/24
enable ipforwarding vlan vlan1
create vrrp vlan vlan1 vrid 1
configure vrrp vlan vlan1 vrid 1 priority 255
configure vrrp vlan vlan1 vrid 1 add 192.168.1.3
create vrrp vlan vlan1 vrid 2
configure vrrp vlan vlan1 vrid 2 add 192.168.1.5
enable vrrp
```

The configuration commands for switch B are as follows:

```plaintext
configure vlan vlan1 ipaddress 192.168.1.5/24
enable ipforwarding vlan vlan1
create vrrp vlan vlan1 vrid 2
configure vrrp vlan vlan1 vrid 2 priority 255
configure vrrp vlan vlan1 vrid 2 add 192.168.1.5
create vrrp vlan vlan1 vrid 1
configure vrrp vlan vlan1 vrid 1 add 192.168.1.3
enable vrrp
```

**VRRP Tracking**

VRRP Tracking on page 1228 is an example of VRRP tracking.
Figure 186: VRRP Tracking

- Configure VLAN tracking, as shown in Adding and Deleting Tracked VLANs on page 1225.

  ```
  configure vrrp vlan vrrp1 vrid 2 add track-vlan vlan1
  ```

  Using the tracking mechanism, if VLAN1 fails, the VRRP master realizes that there is no path to the upstream router through the master switch and implements a VRRP failover to the backup.

- Configure route table tracking, as shown in Adding and Deleting Tracked Routes on page 1225.

  ```
  configure vrrp vlan vrrp1 vrid 2 add track-iproute 10.10.10.0/24
  ```

  The route specified in this command must exist in the IP routing table. When the route is no longer available, the switch implements a VRRP failover to the backup.

- Configure ping tracking, as shown in Adding and Deleting Tracked Pings on page 1225.

  ```
  configure vrrp vlan vrrp1 vrid 2 add track-ping 10.10.10.121 frequency 2 miss 2
  ```

  The specified IP address is tracked. If the fail rate is exceeded, the switch implements a VRRP failover to the backup. A VRRP node with a priority of 255 may not recover from a ping-tracking failure if there is a Layer 2 switch between it and another VRRP node. In cases where a Layer 2 switch is used to connect VRRP nodes, we recommend that those nodes have priorities of less than 255.

VRRP Groups Configuration Example

**Note**

This configuration example assumes that VRs are already created and configured with regular VRRP parameters, but not yet enabled (enable vrrp {vlan [vlan_name | vlan_list] vrid [vridval | vrid_list]} command is not yet executed). If VRs are already enabled, disable all the VRs (disable vrrp {vlan [vlan_name | vlan_list] vrid [vridval | vrid_list]}).
1. Create VRRP group “groupA”:
   ```
   create vrrp group “groupA”
   ```

2. Add primary VR before adding any secondary VRs to the group:
   ```
   configure vrrp group “groupA” add primary-vr vlan “vlan1” vrid 1
   ```

3. Add secondary VRs one at a time:
   ```
   configure vrrp group “groupA” add secondary-vr vlan “vlan2” vrid 2
   configure vrrp group “groupA” add secondary-vr vlan “vlan3” vrid 3
   configure vrrp group “groupA” add secondary-vr vlan “vlan4” vrid 4
   configure vrrp group “groupA” add secondary-vr vlan “vlan5” vrid 5
   ```

   Or alternatively, VLAN tag range and VRID range can be specified. In this case, vlan1 has vlan-id 101, vlan2 has vlan-id 102, etc.:
   ```
   configure vrrp group “groupA” add secondary-vr vlan 102-105 vrid 2-5
   ```

4. Configure fabric routing on all the member VRs in the given group:
   ```
   configure vrrp group “groupA” fabric-routing on
   ```

5. Apply group configuration on member VRs. Before enabling the group, member VRs are operating in individual VR mode:
   ```
   enable vrrp group groupA
   ```

6. Enable all VRs using the global command, if there is only one group:
   ```
   enable vrrp
   ```
   or enable only member VRs of this group:
   ```
   enable vrrp group groupA members
   ```

After configuring VRRP groups, the following appears for the below show commands:

```
# show vrrp group
Members
Group Name  Priority  State Count  TP/TR/TV/P/T /FR
  groupA(En)   100     MSTR   6    0 0 0 Y 1 Y

En-Enabled, Ds-Disabled, Pri-Priority, T-Advert Timer, P-Preempt
TP-Tracked Pings, TR-Tracked Routes, TV-Tracked VLANs, FR-Fabric Routing,
MX-Mixed values
```

```
# show vrrp vlan1
VLAN:  vlan1  VRID:  1  VRRP: Enabled State: MASTER
Virtual Router: VR-Default
Priority: 100 (backup) Advertisement Interval: 1 sec
Version: v3-v2 Preempt: Yes Preempt Delay: 0 sec
Virtual IP Addresses:
Accept mode: Off   Group : groupA (Enabled)
Host-Mobility: Off
Host-Mobility Exclude-Ports:
Checksum: Include pseudo-header
Tracking mode: ALL
Tracked Pings: -
Tracked IP Routes: -
Tracked VLANs: -
Fabric Routing: On

* indicates a tracking condition has failed
```
Multiprotocol Label Switching (MPLS) is a connection-oriented technology that allows routers to make protocol-independent forwarding decisions based on fixed-length labels. This chapter provides an overview and discusses how to configure, monitor and troubleshoot the MPLS feature. The chapter provides specific configuration examples.

**MPLS Overview**

MPLS (Multiprotocol Label Switching) provides advanced IP services for switches that contain advanced ASICs that support MPLS.

To configure MPLS, L2 VPNs, and/or L3 VPNs on your switch, you need the MPLS enabled feature pack license.

**Note**

MPLS and MPLS subfeatures are supported on the platforms listed for specific features in the ExtremeXOS 22.6 Feature License Requirements document.

**Note**

ExtremeXOS MPLS does not support Graceful Restart. Any restart of the MPLS process or failover to a backup node requires re-signaling of all MPLS-related connections and entities.

**How MPLS Works**

MPLS is a connection-oriented technology that allows routers to make protocol-independent forwarding decisions based on fixed-length labels.

The use of MPLS labels enables routers to avoid the processing overhead of delving deeply into each packet and performing complex route lookup operations based upon destination IP addresses.
MPLS protocols are designed primarily for routed IP networks and work together to establish multiple, unidirectional Label Switched Path (LSP) connections through an MPLS network. Once established, an LSP can be used to carry IP traffic or to tunnel other types of traffic, such as bridged MAC frames. The tunnel aspects of LSPs, which are important in supporting virtual private networks (VPNs), result from the fact that forwarding is based solely on labels and not on any other information carried within the packet.

The MPLS protocols operate on Label Switch Routers (LSRs). The router where an LSP originates is called the ingress LSR, while the router where an LSP terminates is called the egress LSR. Ingress and egress LSRs are also referred to as Label Edge Routers (LERs). For any particular LSP, a router is either an ingress LER, an intermediate LSR, or an egress LER. However, a router may function as an LER for one LSP, while simultaneously functioning as an intermediate LSR for another LSP.

Figure 187 illustrates an MPLS network.

![Figure 187: MPLS Network](image)

In an MPLS environment, incoming packets are initially assigned labels by the ingress LER. The labels allow more efficient packet handling by MPLS-capable routers at each point along the forwarding path.

An MPLS label essentially consists of a short fixed-length value carried within each packet header that identifies a Forwarding Equivalence Class (FEC). The FEC tells the router how to handle the packet. An FEC is defined to be a group of packets that are forwarded in the same manner. Examples of FECs include an IP prefix, a host address, or a VLAN (Virtual LAN) ID.

**Note**
The label concept in MPLS is analogous to other connection identifiers, such as an ATM VPI/VCI or a Frame Relay DLCI.

By mapping to a specific FEC, the MPLS label efficiently provides the router with all of the local link information needed for immediate forwarding to the next hop. MPLS creates an LSP along which each LSR can make forwarding decisions based solely upon the content of the labels. At each hop, the LSR simply strips off the Incoming label and applies a new Outgoing label that tells the next LSR how to forward the packet. This allows packets to be tunneled through an IP network.
MPLS Protocol Preference

When LSPs from different protocols exist to the same destination/FEC, LSPs from only one protocol are used at a time for that destination/FEC. The preference, or precedence, for each LSP user is defined as follows.

For both IP/L3VPN and L2VPN the order of preference is:

- RSVP-TE
- LDP
- static

MPLS Terms and Acronyms

Table 122 defines common MPLS terms and acronyms.

Table 122: MPLS Terms and Acronyms

<table>
<thead>
<tr>
<th>Term or Acronym</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSPF</td>
<td>Constrained Shortest Path First. Route selection determined by an algorithm based on available link bandwidth and path cost.</td>
</tr>
<tr>
<td>DoD</td>
<td>Downstream-on-Demand. Distribution of labels as a result of explicit upstream label requests.</td>
</tr>
<tr>
<td>DU</td>
<td>Downstream Unsolicited. Distribution of labels downstream without an explicit label request.</td>
</tr>
<tr>
<td>EXP bits</td>
<td>A three-bit experimental field in an MPLS shim header.</td>
</tr>
<tr>
<td>FEC</td>
<td>Forward Equivalence Class. A group of packets that are forwarded in the same manner (for example, over the same Label Switched Path).</td>
</tr>
<tr>
<td>Label</td>
<td>A short, fixed-length identifier used to forward packets from a given link.</td>
</tr>
<tr>
<td>Label stack</td>
<td>A set of one or more MPLS labels used by MPLS to forward packets to the appropriate destination.</td>
</tr>
<tr>
<td>Label swapping</td>
<td>Lookup and replacement of an incoming label with the appropriate outgoing label.</td>
</tr>
<tr>
<td>LDP</td>
<td>Label Distribution Protocol. A protocol defined by the IETF used to establish an MPLS Label Switched Path (LSP).</td>
</tr>
<tr>
<td>LER</td>
<td>Label Edge Router. A Label Switch Router that is at the beginning (ingress) or end (egress) of an LSP.</td>
</tr>
<tr>
<td>LSP</td>
<td>Label Switched Path. The unidirectional MPLS connection between two routers over which packets are sent. LSPs are established using LDP or RSVP-TE.</td>
</tr>
<tr>
<td>LSR</td>
<td>Label Switch Router. A router that receives and transmits packets on an MPLS network.</td>
</tr>
<tr>
<td>MPLS</td>
<td>MultiProtocol Label Switching. A set of protocols defined by the IETF used to transmit information based on a label-switching forwarding algorithm.</td>
</tr>
<tr>
<td>NHLFE</td>
<td>Next Hop Label Forwarding Entry. The NHLFE represents the MPLS router next hop along the LSP.</td>
</tr>
<tr>
<td>PHP</td>
<td>Penultimate Hop Popping. A label stack optimization used for conserving the number of allocated labels.</td>
</tr>
<tr>
<td>PW</td>
<td>Pseudowire. A logical point-to-point connection.</td>

LDP Support

The Label Distribution Protocol (LDP) is a protocol defined by the IETF for the purpose of establishing MPLS LSPs. Using LDP, peer LSRs exchange label binding information to create LSPs. The LDP features supported in this release include:

- Downstream unsolicited label advertisement.
- Liberal label retention.
- Ordered control mode.
- Advertisement of labels for direct interfaces, RIP (Routing Information Protocol) routes, and static routes.
- Ability to use multiple IGP routing protocols (for example IS-IS, OSPF (Open Shortest Path First), and BGP (Border Gateway Protocol)).
- LDP loop detection.
- Configurable LDP timers.

**Note**

To use BGP as an IGP routing protocol, issue the `enable mpls ldp bgp-routes` command.

LDP Neighbor Discovery

LDP includes a neighbor discovery protocol that runs over UDP.
Using the basic discovery mechanism, each LSR periodically multicasts a hello message to a well-known UDP port to which all LSRs listen. These hello messages are transmitted to the all routers on this subnet multicast group. When a neighbor is discovered, a hello-adjacency is formed and the LSR with the numerically greater IP address is denoted as the active LSR.

Hello messages must continue to be received periodically for the hello-adjacency to be maintained. The hold time that specifies the duration for which a hello message remains valid can be negotiated by the peer LSRs as part of the HELLO exchange. During the HELLO exchange, each LSR proposes a value and the lower of the two is used as the hold time.

Targeted LDP hello-adjacencies between potentially non-directly connected LSRs are supported using an extended discovery mechanism. In this case, targeted hello messages are periodically sent to a specific IP address.

After the hello-adjacency is formed, the active LSR initiates establishment of a TCP connection to the peer LSR. At this point, an LDP session is initiated over the TCP connection. The LDP session consists of an exchange of LDP messages that are used to set up, maintain, and release the session.

**Advertising Labels**

You can control whether label mappings are advertised for:

- Direct routes
- RIP routes
- Static routes

In these cases, the switch is acting as the egress LER for these LSPs.

**Propagating Labels**

LDP propagates label mappings for FECs that exactly match a routing table entry.

In the case of label mappings received from an LDP peer, LDP checks for an exactly matching entry with a next hop IP address that is associated with the LDP peer from which a label mapping was received.

**Label Advertisement Modes**

LDP provides two modes for advertising labels:

- Downstream-on-demand (DoD)
- Downstream unsolicited (DU)

Using DoD mode, label bindings are only distributed in response to explicit requests. A typical LSP establishment flow begins when the ingress LER originates a label request message to request a label binding for a particular FEC (for a particular IP address prefix or IP host address). The label request message follows the normal routed path to the FEC. The egress LER responds with a label mapping message that includes a label binding for the FEC. The label mapping message then follows the routed path back to the ingress LSR, and a label binding is provided by each LSR along the path. LSP establishment is complete when the ingress LER receives the label mapping message.

Conversely, using DU mode, an LSR may distribute label bindings to LSRs that have not specifically requested them. These bindings are distributed using the label mapping message, as in downstream-
on-demand mode. From an LDP message perspective, the primary difference using DU mode is the lack of a preceding label request message.

Architecturally, the difference is more significant, because the DU mode is often associated with a topology-driven strategy, where labels are routinely assigned to entries as they are inserted into the routing database. In either case, an LSR only uses a label binding to switch traffic if the binding was received from the current next hop for the associated FEC.

Both label advertisement modes can be concurrently deployed in the same network. However, for a given adjacency, the two LSRs must agree on the discipline. Negotiation procedures specify that DU mode be used when a conflict exists when using Ethernet links. Label request messages can still be used when MPLS is operating in unsolicited mode.

The Extreme LDP implementation supports DU mode only.

**Label Retention Modes**

LDP provides two modes for label retention:
- Conservative
- Liberal

Using conservative label retention mode, an LSR retains only the label-to-FEC mappings that it currently needs (mappings received from the current next hop for the FEC).

Using liberal retention mode, LSRs keep all the mappings that have been advertised to them. The trade-off is memory resources saved by conservative mode versus the potential of quicker response to routing changes made possible by liberal retention (for example, when the label binding for a new next hop is already resident in memory).

The Extreme MPLS implementation supports liberal label retention only.

**LSP Control Modes**

LDP provides two LSP control modes:
- Independent
- Ordered

Using independent LSP control, each LSR makes independent decisions to bind labels to FECs. By contrast, using ordered LSP control, the initial label for an LSP is always assigned by the egress LSR for the associated FEC (either in response to a label request message or by virtue of sending an unsolicited label mapping message).

More specifically, using ordered LSP control, an LSR only binds a label to a particular FEC if it is the egress LSR for the FEC, or if it has already received a label binding for the FEC from its next hop for the FEC. True to its name, the mode provides a more controlled environment that yields benefits such as preventing loops and ensuring use of consistent FECs throughout the network.

The Extreme MPLS implementation supports ordered LSP control only.
MPLS Routing

This section describes how **MPLS** and IP routing work together to forward information on your network.

MPLS provides a great deal of flexibility for routing packets. Received IP unicast frames can be routed normally or tunneled through LSPs. If a matching FEC exists for a received packet, the packet may be transmitted using an LSP that is associated with the FEC. The packet is encapsulated using an MPLS shim header before being transmitted.

Received MPLS packets can be label switched or routed normally toward the destination. Packets that are in the middle of an LSP are label switched. The incoming label is swapped for a new outgoing label and the packet is transmitted to the next LSR. For packets that have arrived at the end of an LSP (the egress end of the LSP), the label is popped. If this label is the bottom of the stack, the shim header is stripped and the packets are routed to the destination as normal IP packets.

**Note**

Multicast routing and **ECMP (Equal Cost Multi Paths)** on MPLS are not supported.

An MPLS domain is generally defined to be an **OSPF** or IS-IS autonomous system (AS). You can use MPLS to reach destinations inside one of these AS types. You can also use MPLS to tunnel through all or part of an AS in order to reach destinations outside of the AS.

### MPLS Layer Details

**MPLS** can be thought of as a shim-layer between Layer 2 and Layer 3 of the protocol stack. MPLS provides connection services to Layer 3 functions while making use of link-layer services from Layer 2. To achieve this, MPLS defines a shim header that is inserted between the link layer header and the network layer header of transmitted frames. The format of a 32-bit MPLS shim header is illustrated in the following figure.

<table>
<thead>
<tr>
<th>Label (20 bits)</th>
<th>EXP (3 bits)</th>
<th>bottom-of-stack (1 bit)</th>
<th>TTL (8 bits)</th>
</tr>
</thead>
</table>

**Figure 188: MPLS Shim Header**

**MPLS Shim Header**

The **MPLS** shim header contains the following fields:

- 20-bit label
- 3-bit experimental (EXP) field

The EXP field can be used to identify different traffic classes to support the DiffServ **QoS (Quality of Service)** model.

- 1-bit bottom-of-stack flag

The bottom-of-stack bit is set to 1 to indicate the last stack entry.

- 8-bit Time-To-Live (TTL) field

The TTL field is used for loop mitigation, similar to the TTL field carried in IP headers.
MPLS Label Stack

The format of an MPLS label stack containing two MPLS shim header entries is shown in Figure 189.

<table>
<thead>
<tr>
<th>Label 1</th>
<th>EXP</th>
<th>bottom-of-stack = 0</th>
<th>TTL</th>
<th>Label 2</th>
<th>EXP</th>
<th>bottom-of-stack = 1</th>
<th>TTL</th>
</tr>
</thead>
</table>

Figure 189: MPLS Label Stack

Figure 190 illustrates the format of a unicast MPLS frame on an Ethernet link. The MAC addresses are those of the adjacent MPLS router interfaces. The x8847 Ethertype value indicates that the frame contains an MPLS unicast packet. A different Ethertype value (x8848) is used to identify MPLS multicast packets.

<table>
<thead>
<tr>
<th>MAC DA</th>
<th>MAC SA</th>
<th>Ethertype x8847</th>
<th>MPLS label stack</th>
<th>remainder of frame</th>
</tr>
</thead>
</table>

Figure 190: MPLS Unicast Frame on Ethernet

Figure 191 shows the format of a unicast MPLS frame that contains an 802.1Q VLAN tag. In both cases, the Ethertype values no longer identify the network layer protocol type. This implies that, generally, the protocol type must be inferable from the MPLS label value(s). For example, when only one type of protocol is carried on a given LSP.

<table>
<thead>
<tr>
<th>MAC DA</th>

Note
For more detailed information on MPLS encapsulations, see RFC 3032, MPLS Label Stack Encoding.

Penultimate Hop Popping

Penultimate hop popping (PHP) is an LSR label stack processing optimization feature. When enabled, the LSR can pop (or discard) the remaining label stack and forward the packet to the last router along the LSP as a normal Ethernet packet.

By popping the label stack one hop prior to the LSP egress router, the egress router is spared having to do two lookups. After the label stack has been popped by the penultimate hop LSR, the LSP egress router must only perform an address lookup to forward the packet to the destination.

PHP label advertisements using implicit NULL labels can be optionally enabled. Support for receiving implicit NULL label advertisements by neighbor LSRs is always enabled. For example, if an LSR advertises implicit NULL labels for IP prefixes, the neighbor LSRs must support PHP.

Note
PHP should not be enabled on egress LER when there is a ExtremeSwitching and Summit X670-G2 or X770 in a network acting as a PHP LSR.
**Label Binding**

Label binding is the process of, and the rules used to, associate labels with FECs.

LSRs construct label mappings and forwarding tables that comprise two types of labels: labels that are locally assigned and labels that are remotely assigned.

Locally assigned labels are labels that are chosen and assigned locally by the LSR. For example, when the LSR assigns a label for an advertised direct interface. This binding information is communicated to neighboring LSRs. Neighbor LSRs view this binding information as remotely assigned.

Remotely assigned labels are labels that are assigned based on binding information received from another LSR.

**Label Space Partitioning**

The Extreme implementation partitions its label space as described in the following illustration.
Platforms that support MPLS divide the incoming (MPLS egress) label space into static, L3VPN, and dynamic label ranges. The static label range starts immediately after the reserved labels at 16 (0x10), and spans up through the configured maximum number of static labels. In ExtremeXOS 15.4, the `configure mpls label max-static` command is added to allow the static partition range to be changed. Any changes made to the static range affect subsequent ranges.

VRFs used for L3VPNs are allocated from a label range that immediately follows the static range. The remaining label space is called the dynamic label space, and is used by LDP and RSVP-TE. The `show mpls label usage` command displays the label ranges on a given system. The outgoing (MPLS ingress) label space spans the full 20-bit label range, and is used for all outgoing labels for both LSPs and PWs, static and signaled.

No hard limits are imposed on the maximum size of the label stack, other than the constraint of not exceeding the maximum frame size supported by the physical links comprising the LSP.

### Figure 192: MPLS Label Space Partitions

<table>
<thead>
<tr>
<th>Reserved</th>

<td>(Platform dependent)</td>
</tr>
<tr>
<td>Internal</td>
<td>(256 labels on E4G, 200, 400)</td>
</tr>
</tbody>
</table>
Jumbo frames should be enabled on all ports, and the jumbo frame size should be set to accommodate the addition of a maximally-sized label stack. For example, a jumbo frame size of at least 1530 bytes is needed to support a two-level label stack on a tagged Ethernet port, and a jumbo frame size of at least 1548 bytes is needed to support a VPLS encapsulated MPLS frame.

Routing Using Matching and Calculated LSP Next Hops

Normally, a route table prefix is associated with a gateway or next hop IP address.

Using MPLS, a route table prefix can also be associated with an LSP that can be used as the next hop. There are two types of LSP next hops that can be used to route a packet to its destination:

- Matching LSP next hop

An LSP is considered matching with respect to an FEC if it has been associated with that FEC via LDP or RSVP-TE. An example of this is an IPv4 prefix for which a matching label mapping has been received by LDP. Matching LSPs are supported for all route origin types.

- Calculated LSP next hop

An LSP is considered calculated with respect to an FEC if it has been associated with that FEC through a routing protocol. Both OSPF and BGP can perform the calculations necessary to associate a route table prefix with an LSP next hop.

Figure 193 illustrates the concept of matching and calculated LSPs.

Figure 193: Matching and Calculated LSP Next Hops

Table 123 describes the label bindings in the MPLS forwarding table for LSR A that are maintained for FECs reachable via LSR A to LSR C, shown in Figure 193.

<td>34</td>
<td>31</td>
</tr>
</tbody>
</table>
Matching LSP Next Hops

A matching LSP next hop is always preferred over a calculated LSP next hop.

Matching LSP next hop entries are added to the route table when an LSP becomes operational. They are deleted when an LSP is no longer operational.

OSPF Calculated LSP Next Hops

Managing calculated LSP next hop entries is more involved.

The OSPF Shortest Path First (SPF) algorithm checks the availability of LSPs to remote OSPF routers during a calculation. The intra-area SPF algorithm begins with the calculating router as the root of a graph. The graph is expanded by examining the networks connected to the root and then examining the routers connected to those networks. Continuing in this manner, the graph is built as a series of parent and child nodes. A check is made for a matching LSP next hop as each entry is added. A check is also made for an LSP next hop that can be inherited from the parent node. These inherited LSP next hops are referred to as calculated LSP next hops. Thus, for each route table entry, the modified SPF algorithm determines whether a matching LSP next hop is available and whether a calculated LSP next hop is available for use whenever a matching LSP next hop is not present.

The modification to the SPF algorithm described above is important, because it enables the capabilities provided by LDP or RVSP-TE LSPs to be fully utilized, while minimizing the resources devoted to label management.

For example, in a network where all the LERs/LSRs implement this feature (such as an all-Extreme MPLS network), labels only need to be advertised for the router IDs of the LERs/LSRs. Yet, LSPs can still be used to route traffic destined for any OSPF route.

More specifically, LSPs can be used for all routes advertised by OSPF, with the possible exception of LDP LSPs to routes summarized by OSPF area border routers (ABRs). The problem with using routes summarized by OSPF ABRs is that route summarization can prevent label mappings from being propagated for the links internal to the area being summarized, since an LSR only propagates LDP labels for FECs that exactly match a routing table entry.

BGP Calculated LSP Next Hops

BGP can also calculate how to use LSPs to reach BGP next hops.

For example, an IBGP session is established across the OSPF/MPLS backbone, and the communicating routers run both OSPF and IBGP. When an IBGP route is installed, BGP determines whether a matching LSP next hop exists to the destination. If not, it checks for an LSP to the BGP next hop. If an LSP exists to the BGP next hop, that LSP is used as an LSP next hop for the IBGP route.

The recalculation requirements for BGP are similar to those for OSPF; when an LSP to a BGP next hop router changes state, the BGP routing table entries must be checked to ensure their LSP next hop information is still valid.

LSP Precedence and Interaction

A longest prefix match (LPM) is determined for all packets.
If an LSP next hop is available, routed IP traffic may be forwarded over an LSP using the LSP next hop. With respect to a given prefix, LSP next hops can be either matching or calculated, and can be based on LDP, RSVP-TE, or static LSPs. Matching LSP next hops are preferred over calculated LSP next hops. RSVP-TE LSPs are preferred over LDP LSPs, and LDP LSPs are preferred over static LSPs. Also, RSVP-TE LSPs and static LSPs can be individually configured to enable or disable their use as LSP next hops.

Therefore, if a more preferred LSP is established, routed IP traffic may begin to use a new LSP next hop. Likewise, if a preferred LSP is torn down, routed traffic may begin to use the next best LSP next hop. These changes can take place when there is an OSPF routing topology change, an LDP label advertisement event, or a RSVP-TE signaling action.

**Multivendor Support for Calculated LSPs**

Unfortunately, some MPLS implementations do not support the ability to forward packets received on an egress LSP to their OSPF router ID and/or BGP next hop address.

If your MPLS network includes equipment that does not support this type of IP forwarding, you can use configuration commands to explicitly control the use of calculated LSP next hops.

The following commands enable and disable all use of LSP next hops. No IP traffic is routed over an LSP when mpls-next-hop IP routing capability is disabled.

- `enable iproute mpls-next-hop`
- `disable iproute mpls-next-hop`

**Note**

You can enable the use of LSP next hops, or you can enable DHCP (Dynamic Host Configuration Protocol)/BOOTP relay. The software does not support both features at the same time.

These commands enable and disable the calculation of LSP next hops by OSPF:

- `enable ospf mpls-next-hop {vr vrf_name}`
- `disable ospf mpls-next-hop {vr vrf_name}`

These commands enable and disable the calculation of LSP next hops by BGP:

- `enable bgp mpls-next-hop`
- `disable bgp mpls-next-hop`

**Layer 2 VPN over MPLS Overview (VPLS and VPWS)**

Layer 2 virtual private networking (VPN) services over MPLS include Virtual Private LAN Services (VPLS) and Virtual Private Wire Services (VPWS).

These services enable Layer 2 VPN service offerings in a simple manner that is easy to deploy and operate. Layer-2 VPN services, based on a combination of Ethernet and MPLS/IP technologies, are designed to enable service providers to offer Business Ethernet private line services. These services use a simple Layer 2 interface at the customer edge and benefit from the resilience and scalability of an MPLS/IP core.
VPLS provides a virtual LAN between multiple locations. VPWS provides a virtual dedicated line between only two locations.

Layer 2 VPN Support

The LDP Layer 2 VPN implementation includes support for:

- LDP signaling support for pseudowire ID (PWid) FEC for pseudowire (PW) establishment.
- Use of LDP, RSVP-TE, or Static to establish transport LSPs.
- Tunnel endpoints, identified via configured IP addresses.
- Different VLAN IDs at each end of a PW, with the VLAN ID set by the egress switch to match that of the locally configured VLAN.
- Operations as VPLS, H-VPLS, or VPWS node.
- VLAN, VMAN, and port edge services (no port-qualified VLAN service).
- Flooding of Layer 2 packets to multiple PWs when operating as a VPLS or H-VPLS node.

**Note**
The implementation does not include support for pseudowire participation in running the Spanning Tree Protocol.

Layer 2 VPN Service Delimiters

Service delimiters are used to define how the customer is identified to the Layer 2 VPN service.

There are multiple types of service delimiters. The ExtremeXOS software currently supports three types. The first is a VLAN service. This service transparently interconnects two or more VLAN segments together over an MPLS network. The configured VLAN IDs for the customer switch interfaces are not required to match, as long as the egress LSR overwrites the VLAN tag with the locally defined VLAN ID.

The second service is a VMAN service, which interconnects two or more VMAN segments. The service operates like the VLAN service but uses the VMAN tag instead of the VLAN tag to identify the service. As with the VLAN service, the interconnected VMAN segments do not need to have matching VMAN IDs.

The third service is a port service, which transparently interconnects two or more ports together over an MPLS network. Traffic is transported unmodified between ports.

The VLAN and VMAN services are configured by adding the service VLAN or a VMAN to a VPLS or VPWS. The port service is not explicitly configured but is emulated using a combination of Layer 2 VPN capabilities. First a VMAN must be configured and the port added untagged to the VMAN. The service VMAN is then added to the VPLS or VPWS. At this point all traffic received on the port is VMAN encapsulated for transmission across the Layer 2 VPN. To transmit the traffic across the Layer 2 VPN as it was received on the port, the VPLS or VPWS is configured to exclude the service tag. By excluding the service tag, the VMAN tag is stripped prior to being transmitted from the switch. This configuration provides port mode service and allows one or multiple ports to be associated with a Layer 2 VPN.

MPLS Pseudowires

MPLS pseudowire (PW) tunnels are logical connections between two LERs over an LSP.
LDP Pseudowires are signaled based on the configured PW identifier (pwid). The signaled PW label is used to create a two-label-stack shim header on PW encapsulated packets. The outer label is the transport LSP label obtained from LDP or RSVP-TE and the inner label is the signaled PW label. LERs also signal the PW type when attempting to establish a PW. The ExtremeXOS software supports only the PWWid type FEC. The Generalized ID FEC type is currently not supported.

Note
MPLS PWs can also be configured with statically assigned labels.

Transporting 802.1Q Tagged Frames

When an 802.1Q Ethernet frame is encapsulated for transport over a VC tunnel, the entire frame is included, except for the preamble and FCS.

There is a configuration option that determines whether the 4-byte VLAN tag field is included in the transmitted packet. By default, the tag field is not included. If the tag field is not included, the egress LER may add one. If it is included, the tag service identifier may be overwritten by the egress LER. The ability to add a tag field or to overwrite the service identifier at the egress node allows two (possibly independently administered) VLAN segments with different VLAN IDs to be treated as a single VLAN.

The following command can be used to include the VLAN tag field:

```bash
configure 12vpn [vpls vpls_name | vpws vpws_name] {dot1q [ethertype hex_number | tag [include | exclude]]} {mtu number}
```

This command can also be used to control the overwriting of the 802.1Q ethertype when the VLAN tag field is included. In this case, the ingress node prior to transmitting the encapsulated packet overwrites the ethertype. This allows devices with a configurable VLAN tag ethertype to interoperate.

Establishing LDP LSPs to PW Endpoints

Establishing a PW requires both an LSP and a targeted LDP session between the two endpoints.

The local PW endpoint is the MPLS LSR ID. The remote PW endpoint is identified using an IP address configuration parameter.

When using LDP to establish the LSPs, each endpoint needs to advertise a label mapping for an LSP to its local endpoint address. To ensure that its LDP peers use the label mapping, a corresponding IGP route should also be advertised for the address. The IGP route can come from any of the supported routing protocols, such as OSPF, or IS-IS. For example, when using OSPF, an OSPF route with prefix length 32 should be advertised for the configured IP address.

We recommend that you configure a loopback VLAN using the IP address of the local endpoint (the MPLS LSR ID). Use prefix length 32 for the IP address configured for the loopback VLAN. When you configure a loopback VLAN, the IP address used to identify the endpoint remains active, even when one or more of the LSR VLAN interfaces go down. Should a remote peer normally use one of the down interfaces, the normal IGP and LDP recovery procedures allow the PW to use one of the remaining up interfaces to minimize the network outage.

You should also configure the loopback VLAN for MPLS using the `configure mpls add vlan vlan_name` command. The addition of the loopback VLAN to MPLS causes LDP to include the IP
address in LDP address messages. Some implementations (including the ExtremeXOS software) require this information to determine the correct LDP session over which to advertise label mappings for VC FECs (see Using LDP to Signal PW Label Mappings on page 1246).

**Note**
Neither MPLS nor LDP have to be enabled on the loopback VLAN.

There are two options to initiate the LDP advertisement of an LSP to the local MPLS LSR ID when a loopback VLAN has been configured for that IP address:

- Configure MPLS LDP to advertise a direct interface whose IP address matches the LSR ID and has prefix length 32. Use the `configure mpls ldp advertise direct lsr-id` command to do this.
- Configure MPLS LDP to advertise direct interfaces using the `configure mpls ldp advertise direct all` command.

**Note**
This causes LDP to advertise label mappings for all VLANs that have an IP address configured and have IP forwarding enabled.

While both of the above methods initiate the advertisement of a label mapping for an LSP to the local endpoint, the first method is the preferred method.

**Using LDP to Signal PW Label Mappings**

Just as LDP advertises label mappings for LSPs, it can also advertise label mappings for Layer 2 VPNs.

In this case, the signaled FEC information describes a particular Layer 2 VPN. This FEC is often called a Virtual Circuit FEC, or VC FEC. The VC FEC information includes a PWid that is a 32-bit numeric field. Unlike LSP label advertisements that are usually sent to all possible upstream peers, the VC FEC information is sent only to the configured remote endpoint.

When the first Layer 2 VPN is configured to a remote peer, MPLS automatically creates a targeted hello adjacency entity for establishing an LDP session. Once the session is established, LDP passes the VC FEC label mapping associated with the Layer 2 VPN. Once VC FECs for the same PW ID have been exchanged in each direction, MPLS is ready to associate the PW with an LSP to the remote endpoint as described in Message Types on page 1271.

To determine the correct LDP session over which to send a VC FEC, MPLS checks the IP addresses learned from its LDP peers via LDP address messages. The ExtremeXOS software MPLS expects to find the IP address of a remote PW peer among the addresses received over the LDP session to that peer.

To ensure that the local endpoint IP address is included in LDP address messages, it is highly recommended to configure MPLS on a loopback VLAN as described in Establishing LDP LSPs to PW Endpoints on page 1245.

Use the command `configure mpls add vlan vlan_name` to configure MPLS on the loopback VLAN. It is not required that LDP or MPLS be enabled on the VLAN for the associated IP address to be advertised in LDP address messages.
Statically Configured Pseudo-Wires

Static MPLS PWs are configurable point-to-point emulated circuits that have statically configured MPLS PW labels. Static PWs do not use targeted Label Distribution Protocol (LDP) to negotiate setup and exchange peer status. They can use any type of MPLS tunnel Label Switch Path (LSP). When used in conjunction with static routes and static LSPs, no routing protocol (such as OSPF or ISIS), and no label distribution protocol (such as LDP or RSVP-TE) are needed to provision and manage static PWs. Managing this kind of network can provide a disruptive architectural solution for building large backhaul networks that are easy to provision, operate, and incrementally expand. Because protocols are no longer required to set up emulated circuits over MPLS, you now have the capability to proactively, or on-demand, verify end-to-end PW connectivity, to provide remote endpoint status, and offer options to configure redundant PWs to maintain network high availability.

Statically configured PWs provide greater administrative and management control over the network. It also allows MPLS PWs to be configured across a network when no label distribution protocol is running. This can simplify operational management and reduce equipment interoperability issues that can arise when deploying routing packet networks.

You can use the `configure mpls label max-static` command to configure the max number of static labels (labels reserved for static configuration). The maximum number of static labels depends on the underlying hardware platform, and at least 100 labels are reserved for dynamic or signaled labels, such as those used by LDP and RSVP-TE. Use the `show mpls label usage` command to display the current label ranges and usage.

ExtremeXOS supports TDM PWs for CES and Ethernet PWs, for L2VPN VPLS/VPWS, and both types of PWs can be statically configured. The PWs in a VPLS can be a mix of signaled and statically configured, but the corresponding peer PW must be of the same type.

Static PWs are created by adding a peer with configured labels. If the configured labels are not in the allowable range, or are already in use by some other statically configured entity such as static LSPs, then the command is rejected. Once a static PW is created, the labels for that PW can be changed without deleting and re-adding the peer. The CES or L2VPN can remain operational during the change; however, the PW will go down and come back up. If the configured PW labels are accepted, but have not yet replaced the "in-use" labels in hardware, the `show 12vpn detail` and `show ces detail` commands will output an additional line showing the "pending" rx and tx labels. This line will only be shown if necessary, and generally, would not be shown since this is only a transient condition with a small window for its occurrence.

Since static PWs are not signaled, the remote parameters, such as remote Virtual Circuit (VC) status and remote I/F MTU, are not "none" for Ethernet PWs. The local VC status is still calculated and displayed, but is not sent to the peer. Additionally, since the “standby” VC status bit cannot be signaled, PW redundancy cannot be configured for L2VPNs that have static PWs, and Hierarchical Virtual Private LAN Services (H-VPLS) is not supported. TDM PWs already use an associated channel through the “control word”, so the remote VC status is available for those types of PWs. For TDM PWs, the normal TDM signaled parameters, such as payload size and bit-rate, are not sent to the peer and are displayed as a “N/A” in the `show ces detail` command output. There is no OAM support for static PWs, and VCCV is not supported.

Use the `show ces` and `show 12vpn` commands to display PWs that are statically configured. Since static PWs are not signaled, a static PW in a state similar to an LDP PW in signal state, will display in a down state.
Configuring Static Pseudowires

- To configure TDM Circuit Emulation Service over MPLS Static PW, use the following commands:

```plaintext
configure ces ces_name add peer ipaddress ipaddress fec-id-type pseudo-wire pw_id {static-pw transmit-label outgoing_pw_label receive-label incoming_pw_label} {lsp lsp_name}
```

Use this command to statically configure a new MPLS TDM PW for the specified CES. Both the outgoing (MPLS ingress) and incoming (MPLS egress) PW labels must be specified. The peer must be similarly configured with a static PW that has the reverse PW label mappings. Locally, the `incoming_pw_label` must be unique and is allocated out of the static label space. The `outgoing_pw_label` must match the peer’s configured incoming PW label.

Optionally, you can configure the PW to use any type of tunnel LSP: LDP, RSVP-TE, or Static. In the case of RSVP-TE and LDP, those protocols must be configured and enabled, and an LSP must be established before traffic can be transmitted over the static PW.

For Static LSPs, only the MPLS ingress LSP (or outgoing LSP) is specified. Unlike signaled PWs, there is no end-to-end PW communication that is used to verify that the PW endpoint is operational, and in the case of static LSPs, that the data path to the PW endpoint is viable.

In the event of a network fault, if a secondary RSVP-TE LSP is configured or the routing topology changes such that there is an alternate LDP LSP, the static PW will automatically switch LSPs in order to maintain connectivity with the PW endpoint. Static LSPs can be protected proactively by configuring BFD to verify the static LSPs IP next hop connectivity.

Optionally, the underlying LSP for the PW can be explicitly specified using a named LSP. When a named LSP is explicitly specified, only the specified named LSP is used to carry the PW. In the event that a specified named LSP is withdrawn, the CES remains operationally down until the named LSP is restored.

- To configure L2PN VPLS/VPWS Service over MPLS Static PW, use the following commands:

```plaintext
configure {l2vpn} vpls vpls_name add peer ipaddress ipaddress {core} {full-mesh} {static-pw transmit-label outgoing_pw_label receive-label incoming_pw_label}
```

Use these commands to statically configure a new MPLS Ethernet PW for the specified VPLS or VPWS. Both the outgoing (MPLS ingress) and incoming (MPLS egress) PW labels must be specified. You must similarly configure the peer with a static PW that has the reverse PW label mappings. Locally, the `incoming_pw_label` must be unique and is allocated out of the static label space. The `outgoing_pw_label` must match the peer’s configured incoming PW label.

Just like a signaled PW, a static PW can optionally be configured to use any type of tunnel LSP: LDP, RSVP-TE, or Static. In the case of RSVP-TE and LDP, those protocols must be configured and enabled and an LSP must be established before traffic can be transmitted over the static PW. For Static LSPs, only the MPLS ingress LSP (or outgoing LSP) is specified. Unlike signaled PWs, there is no end-to-end PW communication that is used to verify that the PW endpoint is operational, and in the case of static LSPs, that the data path to the PW endpoint is viable.
In the event of a network fault, if a secondary RSVP-TE LSP is configured or the routing topology changes such that there is an alternate LDP LSP, the static PW will automatically switch LSPs in order to maintain connectivity with the PW endpoint. Static LSPs can be protected proactively by configuring BFD to verify the static LSPs IP next hop connectivity. Optionally, the underlying LSP for the PW can be explicitly specified using a named LSP. When a named LSP is explicitly specified, only the specified named LSP is used to carry the PW.

In the event that a specified named LSP is withdrawn, the VPLS/VPWS remains operationally down until the named LSP is restored.

Since VC Status signaling is not supported, the VC Status “standby” bit cannot be used to allow support for PW redundancy and H-VPLS. Consequently, only “core full-mesh” PWs are allowed to have statically configured labels.

- To modify the current configuration of a PW for the specified `ces_mpls_name`, use the following command:

```plaintext
configure ces ces_name peer ipaddress ipaddress static-pw [{transmit-label outgoing_pw_label} {receive-label incoming_pw_label}]
```

Network administrators can use this command to modify the current configuration of a PW for the specified `ces_mpls_name`. The `incoming_pw_label` must be locally unique and is allocated out of the static label space. The `outgoing_pw_label` can be any value and must match the peer’s configured incoming PW label.

- To change labels for L2PN VPLS/VPWS service over MPLS Static PW, use the following commands:

```plaintext
configure 12vpn vpls vpls_name peer ipaddress static-pw [{transmit-label outgoing_pw_label} {receive-label incoming_pw_label}]
configure 12vpn vpws vpws_name peer static-pw [{transmit-label outgoing_pw_label} {receive-label incoming_pw_label}]
```

Use these commands to change the labels of a statically configured Ethernet PW for a VPLS or VPWS that already exists. You can specify either, or both the outgoing (MPLS ingress) and incoming (MPLS egress) PW labels. The peer must be similarly configured with a static PW that has the reverse PW label mappings. Locally, the `incoming_pw_label` must be unique and is allocated out of the static label space. The `outgoing_pw_label` must match the peer’s configured incoming PW label. The CES or L2VPN can remain operational during the change; however, the PW will go down and come back up.

- To display TDM Circuit Emulation Service, use the following command:

```plaintext
show ces {ces_name} {detail}
```

For CES services created for use with MPLS, the “Type: Static/Signaled” line in the CES section of the output will show “N/A” until a PW is configured, since this the PW type is not known until the peer is added to the CES. The PW section of the output includes a “PW Signaling” line that will display “LDP” or “None (Static)”, depending on the PW configuration.

Since the configured labels can be changed while the current labels are in-use, there is a small window where the configured labels and in-use labels are different. If you issue the `show ces detail` command during this window, an extra line is output to indicate the extra information.

- To display L2PN VPLS/VPWS service, use the following command:

```plaintext
show [{12vpn} vpls {vpls_name} | 12vpn vpws {vpws_name} | 12vpn ] {{peer ipaddress} {detail} | summary}
```
The non-detail version of this command includes a peer flag that indicates the signaling protocol, if any, for a PW/peer. An “L” indicates LDP is used to signal the PW. A “T” indicates that no signaling is done, and therefore, this is a static PW.

The detail version of this command now displays a “PW Signaling” line that displays “LDP” or “None (Static)”, depending on the PW configuration. The “Local PW Status” shows “--” instead of “Not Signaled”, since the PW status is not currently signaled. For informational purposes, any local faults are still shown.

The “Remote PW Status” and “Remote I/F MTU” always show “--”. Since the configured labels can be changed while the current labels are in-use, there is a small window where the configured labels and in-use labels are different. If you issue the `show 12vpn detail` command during this window, an extra line is output to indicate this extra information.

- To display the MPLS label ranges and usage statistics, use the following command:
  `show mpls label usage`

  This command displays the label ranges on the current running system, including configurable and non-configurable ranges. The output also includes hardware resource usage to provide a better picture about the MPLS hardware utilization and capacity.

**LSP Selection**

A PW can be configured to use any available LSP to the peer endpoint IP address, or the PW can be configured to use one or more specific named LSPs.

In either case, the LSP has to egress (terminate) at the remote endpoint. In the case of an LDP LSP, the LSP’s FEC has to be a /32 prefix length to the endpoint IP address. In the case of an RSVP-TE LSP or static LSP, the destination address has to be that of the remote endpoint. When configured to use any available LSP, MPLS gives preference to RSVP-TE LSPs, then to LDP LSPs, and lastly, to static LSPs. As a single LSP is chosen to carry the PW traffic, if multiple LSPs of the chosen type exist, the decision of which LSP of this type to use is non-deterministic.

The `configure 12vpn [vpls vpls_name | vpws vpws_name] peer ipaddress [add | delete] mpls lsp lsp_name` command forces the PW to use the specified named LSP. If multiple named LSPs are configured, only one is used to carry the PW. The decision of which of the multiple configured LSPs to use is non-deterministic.

RSVP-TE can be configured to allow specific types of traffic on an LSP. By default, LSPs are used to transport all traffic. Optionally, named LSPs can be configured to allow only IP traffic or only VPN traffic. This can be used to control the LSP selection for specific types of packets. For example, if both LDP and RSVP-TE LSPs exist and the RSVP-TE LSPs are configured to transport only VPN traffic, all IP traffic is forwarded using LDP LSPs. Since RSVP-TE LSPs are preferred over LDP LSPs, VPN traffic flows over the RSVP-TE LSPs. The following command configures this behavior for the specified RSVP-TE LSP:

```
configure mpls rsvp-te lsp lsp_name transport ip-traffic deny
```

For more information see Pseudowire Label Switch Path Load Sharing on page 1250.

**Pseudowire Label Switch Path Load Sharing**

Pseudowire (PW) Label Switch Path (LSP) Load Sharing provides the ability for L2VPN PWs to use up to 16 or 64 Transport LSPs, depending on the platform, for carrying tunneled data across the MPLS.
network. Previously, Ethernet PWs could only use one tunnel LSP. This feature is related to traffic distribution over Link Aggregation Groups (LAGs).

The current HW hashing algorithm on MPLS Transit Nodes uses MPLS labels to derive a hash value. In previous implementations where an L2VPN PW used only one Transport LSP, there were only two MPLS labels to hash on (the outer transport label, and inner VC label) for a given PW. In an eight-port LAG (Link Aggregation Group) that L2VPN tunneled traffic would only be distributed to one or two links in the LAG. When a PW uses multiple Tunnel LSPs, there are more labels for the HW to use for hashing, and this allows improved distribution over LAG in MPLS Transit Nodes.

**Limitations**

This feature has the following limitations:

- Support only for RSVP TE and Static LSPs (Named LSPs).
- Named LSPs must be configured for each PW.
- LSP-Sharing must be enabled in order to be able to configure more than one Transport LSP for a given PW.
- Multiple PWs can use the same LSP, or set of LSPs (same as today).
- A maximum of 16 or 64 LSPs per PW can be configured, depending on the platform.
- If LSP-sharing is disabled when more than 1 LSP is programmed into ExtremeXOS, all LSPs used by the PW, except one, will be removed from ExtremeXOS (HAL). The configuration will not be modified.
- A single default load sharing hashing algorithm is used. When multiple Transport LSPs are configured for a PW, the PW will be UP as long as one Transport LSP is available.
- HW counters are only supported for PW packet counts (VC LSP), not Transport LSP (outer label).
- No support for VPWS.
- ECMP is not supported in slow-path forwarding.
- ECMP is not supported for flood traffic (unknown unicast, multicast, broadcast). These packets will only go over one LSP.
- When multiple LSPs are configured for use by a PW, the HW counts packets for the PW only, and not individual LSPs associated with the PW. So, if there are six LSPs in use for a given PW, you will not be able to display packet counts for each individual Transport LSP.

**Platforms Supported**

This feature is supported on the following platforms:

- Summit X460-G2 (16 LSPs)
- Summit X670-G2 (16 LSPs)
- Summit X770 (16 LSPs per PW)
- ExtremeSwitching X870 (16 LSPs per PW)
- ExtremeSwitching X690 (16 LSPs per PW)

**Configuring Pseudowire LSP Sharing**

- To enable or disable LSP sharing for L2VPNs, use the following commands:
  
  `[enable|disable] 12vpn sharing`
When LSP sharing is disabled, only one named LSP is used for a PW. When LSP sharing is enabled, up to 16 or 64 Named LSPs, depending on the platform, are used for a PW.

If LSP Sharing is disabled, and more than one Transport LSP is programmed into HW, all but one Transport LSP are removed from HW, and the configuration is preserved.

If LSP Sharing is enabled, and more than one Transport LSP was previously configured, the remaining LSPs are programmed into HW as they become available for use.

- To configure LSP sharing parameters for PW LSP sharing, use the following command:
  ```
  ```

- To display if PW LSP sharing is enabled, use the following command:
  ```
  show 12vpn sharing
  ```

- To display the status of the L2VPN Sharing configuration, use the following command:
  ```
  show vpls detail
  ```

If L2VPN Sharing is enabled, and more than one Transport LSP is configured, the output will display the status of each Transport LSP.

- To display an informational message when multiple transport LSPs are configured for a VPLS PW, and when LSP sharing is not enabled, use the following command:
  ```
  configure vpls vpls1 peer 20.20.20.83 add mpls lsp lsp2
  ```

**Note:** To share LSPs in HW, use the command: enable l2vpn sharing.

Layer 2 VPN Domains

Layer 2 VPN domains are created by adding PWs to each peer LSR to build a fully-meshed interconnected VPLS.

For each peer added, a PW is signaled that is used to carry traffic from the local LSR to the remote peer LSR. Flood traffic from the local service (broadcast, multicast, and unknown unicast packets) is replicated and forwarded across all PWs in the VPLS. Each peer receives one copy of the packet for delivery to its locally attached service. As MAC learning occurs on PWs, unicast packets to a known destination MAC address are forwarded to the peer over the PW from which the MAC address was learned.

MAC Learning

Learned MAC addresses are associated with the PWs from which the packets are received.

The learned MAC address is always inserted into the FDB (forwarding database) as though it was learned on the local service VLAN (and not the VLAN identified in the dot1q tag in the received PW packet). MAC addresses learned from PWs use a different FDB aging timer than those MAC addresses learned on Ethernet interfaces. Different FDB aging timers are maintained for Ethernet and pseudowire Layer 2 VPN FDB entries. By default, both aging timers are set to 300 seconds. However, the aging timers for each type of FDB entry can be configured to different values. Note that PW FDB entries are
not refreshed; they age out based on the configured aging timer setting, unless you have disabled the aging timer. Ethernet FDB entries automatically refresh with use, and do not age out unless they are not used for the length of time configured for the aging timer. Any MAC address associated with a PW is automatically cleared from the FDB when the PW label is withdrawn.

**Note**
MAC learning is disabled for VPWS.

**Spanning Tree Protocols**

There is some debate as to the benefit of supporting *STP* (Spanning Tree Protocol) within a Layer 2 VPN.

The idea is that STP protocols can be used to provide redundant VPN data paths that can be unblocked if the STP detects a spanning tree topology failure. In general, it is believed that introducing STP to VPLS increases network complexity with very little real benefit.

*MPLS* already provides a significant level of redundancy for the LSP over which a PW is carried. For example, if a PW is using an LDP established LSP, provided there are parallel routed paths to the PW endpoint, the PW automatically shifts from a withdrawn or failed LSP to the next best available LSP. For transport LSPs established using RSVP-TE, secondary LSPs can be configured that can be hot-swapped in the event of a primary LSP failure. Fast-reroute detour LSPs can also be used to protect RSVP-TE LSPs. Thus, even though the underlying transport LSP might have changed, the Layer 2 VPN data plane remains unaffected.

For these reasons, VPLS and STP are not normally enabled on the same *VLAN*. The exception is for local customer network redundancy such as shown in VPLS STP Redundancy Overview on page 1263.

When STP is not enabled on a VPLS VLAN, the BPDU functional address is not inserted into the *FDB* for this VLAN and all received BPDU packets are flooded across the Layer 2 VPN. In this scenario, a single large spanning tree topology spanning all interconnected Layer 2 VPN service sites is constructed. Note that this is not a recommended configuration for a Layer 2 VPN service. Depending on the packet latency within the backbone network, STP timers might need to be tuned to build and maintain reliable topologies.

Currently, most ExtremeXOS software Layer 2 protocols cannot be configured on MPLS Layer 2 VPN domains. Likewise, the following protocols cannot be enabled on a Layer 2 VPN service VLAN:

- **VRRP** (Virtual Router Redundancy Protocol)
- **ESRP** (Extreme Standby Router Protocol)
- **EAPS** (Extreme Automatic Protection Switching) control VLAN

**IP Protocol Considerations**

The ExtremeXOS software allows an IP address to be configured for a Layer 2 VPN service *VLAN*. This is permitted to allow the switch to use the IP ping and traceroute functions to and from other nodes on the VLAN. It is envisioned that any such IP address is configured temporarily to assist in network verification.

As such, the ExtremeXOS software does not allow IP forwarding to be enabled on a Layer 2 VPN service VLAN for either IPv4 or IPv6. Therefore, any higher-level protocol that requires IP forwarding to be
enabled cannot be enabled on a Layer 2 VPN service VLAN. For example, OSPF cannot be enabled on a VPLS service VLAN at the PE router. However, OSPF routers can be attached to the service vlan transparently at the customer interfaces. In addition, IGMP (Internet Group Management Protocol) snooping cannot be enabled on a VPLS service VLAN.

**MPLS Layer 2 VPN Characteristics**

Characteristics of a Layer 2 VPN include:

- Use of LDP or RSVP-TE to establish the underlying pseudowire transport LSPs.
- Pseudowire endpoints are identified through configured VPLS/VPWS peer IP addresses.
- Configuration of a Layer 2 VPN pseudowire ID doubles as VPN ID.
- Customer packet VLAN tags may be overwritten on egress from the pseudowire allowing local service VLANs or VMANs interconnected over the same Layer 2 VPN to have different IDs.
- Customer packet VLAN tags can be included or excluded from packets transmitted on the pseudowire.
- Customer packet VLAN tag ethertype value can be modified before packet is transmitted on the pseudowire, allowing local service VLANs or VMANs interconnected over the same VPLS to have different 802.1Q tag ethertype values.
- Support for full-mesh VPN architectures.
- Support for VLAN, VMAN, and port Layer 2 VPN services.
- Support for enabling and disabling VPLS and/or the VPLS service.
- Support for enabling and disabling VPWS and/or the VPWS service.

**Layer 3 VPN over MPLS Overview**

Layer 3 VPN services over MPLS are supported using BGP. For more information, see Layer 3 VPN Configuration Overview on page 625.

**H-VPLS Overview**

VPLS requires a full mesh of pseudowires between all Provider Edge (PE) peers.

As MPLS is pushed to the edge of the network, this requirement presents a number of problems. One problem is the increased number of pseudowires required to service a large set of VPLS peers. In a full-mesh VPLS, pseudowires must be established between all VPLS peers across the core. Full-mesh networks do not scale well due to the number of pseudowires that are required, which is $p(p-1)$, where $p$ is the number of peer devices in the network. Hierarchical VPLS (H-VPLS) networks can dramatically increase network scalability by eliminating the $p^2$ scaling problem.

In a hierarchical VPLS network, a spoke node (often a Multi-Tenant Unit—MTU) is only required to establish a pseudowire to a single core PE. Thus the number of pseudowires required in the provider’s network is $c(c-1) + s$, where $c$ is the number of core PE nodes and $s$ is the number of spoke MTU edge devices. This is a significant reduction in the number of pseudowires that need to be established and maintained. For example, a 10-core PE network with 50 MTU devices per core PE requires almost 260,000 pseudowires using a full-mesh VPLS design. A hierarchical VPLS design requires only 590 pseudowires.

An example H-VPLS network is shown in Figure 194.
H-VPLS spokes allow VPLS domains to be constructed hierarchically in a partial-mesh or hub-and-spoke configuration. This is useful for increasing the scaling of VPLS domains that can be supported. Within the context of H-VPLS, a spoke is a VPLS connection between two VPLS peers. Typically, one spoke node provides connectivity to the customer VLAN or customer service while its peer, a core node, provides repeater connectivity to other VPLS peers.

The pseudowire hierarchy must be known because the forwarding rules for spoke and core pseudowires are different. Flood traffic received on a core pseudowire from another full-mesh core PE must not be transmitted over other core pseudowires to other PEs. However, flood traffic received on a core pseudowire is transmitted on all spoke pseudowires in the VPLS. Unlike core pseudowires in a full-mesh VPLS, flood traffic received on a spoke pseudowire must be transmitted on all other pseudowires in the VPLS, including pseudowires to other core PEs.

H-VPLS introduces the definition of a pseudowire type. In previous ExtremeXOS releases, only core peers were supported in an interconnected full-mesh configuration. Therefore, all pseudowires were considered to be of the type core. A new spoke pseudowire type is introduced and is highlighted in Figure 195 on page 1257. A VPLS core node that has multiple spoke pseudowires but no configured core pseudowires is informally referred to as a hub.

**Eliminating Packet Replication by the MTU**

A scaling problem inherent in a full-mesh VPLS network is packet replication.

In a full-mesh configuration, until a node learns over which pseudowire a MAC address is reachable, unknown unicast frames must be flooded on all pseudowires within the VPLS. Packet replication is always true for broadcast and multicast traffic. As the number of VPLS peers increase, the packet replication burden on a node increases. MTU devices attached to a full-mesh core most likely cannot maintain wire-speed forwarding as the number of VPLS peers increase. Hierarchical VPLS eliminates
this MTU burden by requiring only a single pseudowire connection between a spoke and its core PE peer. Packet replication is pushed to the PEs, where it is more suitably handled.

**Simplifying Customer Service Provisioning**

Bandwidth provisioning between an MTU and a PE is extremely difficult with a full-mesh VPLS design. Since each VPLS instance can require multiple tunnel LSPs, the bandwidth requirements for each tunnel LSP must be separately accepted and individually enforced by every PE a tunnel LSP traverses. Because the provider requirement is to manage the provisioned bandwidth for the VPLS and not each tunnel LSP, the MTU has the added responsibility of rate limiting the aggregate egress traffic across multiple tunnel LSPs on the uplink. Due to packet replication issues described previously, this is not practical.

Hierarchical VPLS designs simplify bandwidth provisioning and management. Because tunnel LSPs from the MTU are terminated at the PE, tunnel LSP resources are easily shared and managed between customers. Thus, traffic for multiple VPLS instances can be transported across a single tunnel LSP. In some cases only a single best-effort tunnel LSP is required between the MTU and the PE. Traffic for each customer is carried over a different pseudowire on the same tunnel LSP. This allows the tunnel LSP to be signaled once, with the desired bandwidth and priority parameters sufficient for providing best-effort service for customers connected to the spoke peer. If a customer upgrades their service or a new customer is connected that requires guaranteed bandwidth, a second tunnel LSP could be signaled with the SLA bandwidth parameters. Once established, the second tunnel LSP can carry traffic for a single customer as a premium service.

**Redundant Spoke Pseudowire Connections**

Redundant spoke pseudowires to PE peers can be configured from an MTU to provide backup connectivity into a VPLS core.

The addition of a redundant spoke pseudowire is optional. By default, when the MPLS Feature Pack license has been applied to the switch, the spoke pseudowire to the primary peer is used to forward packets. In the event of a network failure over the primary pseudowire, the spoke pseudowire to the secondary peer is used to provide redundant VPLS connectivity. An example network is shown in Figure 195.
When both the primary and secondary pseudowires are established, the MTU is responsible for blocking the secondary pseudowire. Any packets received on the secondary pseudowire while the primary pseudowire is active are discarded. This behavior prevents packet-forwarding loops within the L2 VPN.

Since the MTU is responsible for choosing which pseudowire to the VPLS is active, the MTU is uniquely responsible for preventing network loops. The MTU uses only one spoke pseudowire per VPLS and only the label stack associated with the active pseudowire is programmed into the hardware. If the active pseudowire fails, then the label stack for the active pseudowire is removed from hardware. The secondary pseudowire label stack is then installed in the hardware in order to use the redundant VPLS link from the MTU into the VPLS core. Customer connectivity through the MTU should experience minimal disruption.

IETF RFC 6870 defines the “Preferential Forwarding” status bit to designate which pseudowire is active and can be used to forward user packets. The MTU sets this bit to indicate that a pseudowire is standby (not active) and should not be used to forward user packets.

When a failover occurs from a primary pseudowire to a secondary pseudowire, the MTU clears its FDB database of MAC addresses learned over the primary pseudowire. It then begins learning MAC addresses over the new active pseudowire. To inform other nodes to clear their learned MAC database, the MTU can send a MAC address-withdraw message (if this feature is enabled) to the peer PE node of the secondary pseudowire. This PE node can subsequently send its own MAC address-withdraw message to the other VPLS full-mesh core nodes. Upon receipt of the MAC address withdrawal message, each core node clears its database. In this manner, other core nodes re-learn MAC addresses from the correct pseudowire or port.

Packets can be received out-of-order by the VPLS destination device during certain pseudowire failover events. In the redundant VPLS spoke configuration, when the primary pseudowire fails, traffic is immediately switched to the secondary pseudowire. For a very short period of time, there may be
packets that are in route via both pseudowires. No attempt to prevent mis-ordered packets from being received is made.

The command to configure the VPLS peer from an MTU to a PE and from a PE to an MTU is fundamentally the same. However, the optional primary and secondary pseudowire keywords are only applicable on the MTU since the MTU is responsible for preventing loops within the VPLS. A switch cannot be configured with a primary and a secondary pseudowire to the same peer within a VPLS. This is an invalid configuration since it provides no redundant protection for a failed PE node.

**MAC Address Withdrawal TLV Support**

MAC address withdrawal is a feature that is used to inform other nodes that certain FDB MAC address entries should be immediately unlearned, rather than waiting for them to age out. Traffic destined to these unlearned MAC addresses is then flooded until the MAC addresses are learned again. MAC address withdrawal is enabled by default when the MPLS Feature Pack License has been applied to the switch, but can be disabled. When this feature is disabled, traffic destined to MAC addresses previously learned over a now unusable pseudowire (PW) is not flooded until the FDB entries eventually age out. However, it can take the VPLS network longer to adjust than when MAC address withdrawal is enabled. This section describes how this feature operates when it is enabled.

After certain network recovery events, MAC addresses should be unlearned. For example, if the MTU’s last usable transport LSP for the primary spoke pseudowire goes down, the MTU decides to activate and switch to the secondary pseudowire and send the primary and secondary core PE nodes an LDP notification message containing the appropriate PW status codes. The core PE node of the primary pseudowire flushes its FDB of any MAC addresses learned from the MTU, but does not send any MAC address-withdraw messages. It is the responsibility of the MTU to initiate the sending of MAC address-withdraw messages. If MAC address withdrawal is enabled, the MTU sends a MAC address-withdraw message to the core PE node of the secondary pseudowire. This node, in turn, sends its own MAC address-withdraw message to all the other core PE nodes in the VPLS causing each of these other core PE nodes to flush their FDB of any matching learned MAC addresses specified in the address-withdraw message. By withdrawing MAC addresses immediately, the other core PE nodes are forced to flood traffic destined to the MAC addresses specified in the address-withdraw message. If an alternate VPLS path exists, the new path can be quickly learned without having to wait for the FDB MAC entry to age out.

When a node needs to withdraw a MAC address, it can signal the MAC withdrawal for a VPLS using an address-withdraw message in one of two ways: the MAC address is explicitly specified in a MAC TLV; or an empty MAC TLV is sent indicating that all MAC addresses not learned from that node should be unlearned. Because this information may be propagated to multiple VPLS nodes, a control plane processing trade-off exists. To reduce the processing load, ExtremeXOS sends an empty MAC TLV. Additionally, ExtremeXOS supports the processing of multiple withdraw messages per VPLS, since other vendors may choose not to send an empty MAC TLV.

**Event Log Messages**

The H-VPLS feature has full EMS logging capabilities to capture error and debug information. Messages are logged with the **MPLS** component identifier.

**SNMP Support**

No **SNMP (Simple Network Management Protocol)** support is provided for H-VPLS.
Protected VPLS and H-VPLS with ESRP Redundancy Overview

Protected VPLS Access enables redundant nodes at the entry to a VPLS or H-VPLS network.

This feature provides fault tolerant connectivity from the customer VLAN to the backbone VPLS. This could be implemented by running Layer 2 protocols across the VPLS to block switch ports, but this can lead to sub optimal spanning tree topologies across the VPLS backbone and relatively long outages while the STP converges. Instead, the ExtremeXOS software has been enhanced to provide the ability to configure redundant VPLS switches using a dual-homed design that provides fast failover for protected access points.

The first figure below shows fault-tolerant access in a full mesh core VPLS network while the second figure shows fault-tolerant access in a hierarchical VPLS network.

**Figure 196: Example Protected Access VPLS Network**

In the above figure, fault tolerance is provided at the customer site by MTU-A and MTU-B. A failure of either MTU-A or MTU-B does not result in any loss of customer connectivity beyond the failover time from one MTU to the other.

**Figure 197: Example Protected Access H-VPLS Network**
**ESRP** is employed to ensure that only one VPLS switch is active at any instant in time for a protected customer access point. Only the ESRP master switch forwards packets between the access network and the backbone VPLS network. This active primary switch retains this status based on a set of predefined tracking criteria. If the configured criteria can be better satisfied by the inactive secondary VPLS switch, the primary VPLS switch relinquishes control and the secondary switch assumes the active role. The secondary switch can also autonomously assume the active role if it detects that the primary switch has failed. This use of ESRP helps to prevent duplicate packet delivery and to prevent broadcast loops when the customer network is a loop topology.

**Fault Tolerant Access Points Assumptions and Limitations**

The following assumptions and limitations are associated with a fault tolerant access point network:

- This feature supports a maximum of two redundant VPLS switches per protected **VLAN** access point.
- This feature operates only with **ESRP** extended mode.
- For ESRP to communicate between neighbor switches, you must configure a separate control VLAN with the same network layout as the set of protected customer VLANs. For example, consider two customer VLANs, VLAN-X and VLAN-Y. Both require protected VPLS access. If both VLAN-X and VLAN-Y have the same network layout (for example, both are part of a single **EAPS** domain), you must create an ESRP control VLAN that has the same layout as VLAN-X and VLAN-Y. Conversely, if VLAN-X and VLAN-Y do not have the same layout, you must create two separate ESRP domains with each control VLAN following the layout of the associated service VLAN(s).
- All VPLS switches in the control VLAN need to have the same ESRP domain configured. VPLS switches that provide protected access to the VPLS network need to have ESRP enabled while other nodes in the control VLAN need to be ESRP aware.
- The software does not validate the configuration between switches to determine if all VPLS switches for a protected VLAN are configured to be part of the same ESRP.

**H-VPLS Redundant Edge Network**

In Figure 198, PE-C still represents a single point of failure. To remove this exposure, the fault tolerant access points can be combined with the redundant spoke pseudowires to produce a redundant edge configuration, as shown below.
Figure 198: Example Redundant Edge H-VPLS Network

In the network shown in the above figure, only one of the pseudowires between the MTUs and their attaching PEs is active at any instant in time. This network provides fault tolerance for a failure at either MTU or at either of the attaching PEs, as well as for the active pseudowire in use between the MTUs and PEs.

Fault Tolerant VPLS Operation

To provide the fault tolerance shown in the following figure through the following figure, the redundant network nodes communicate with each other to determine the active primary and inactive secondary status and elect an active master node.

For a VPLS domain type, ESRP considers election factors in the following order: standby, active ports, tracking information, stickiness, ESRP priority, and MAC. For more information on the ESRP election priority, see ESRP on page 1175.

For fault tolerant VPLS to function correctly, the ExtremeXOS software imposes restrictions on the configuration options on the VPLS redundancy type ESRP domain. Table 124 lists the configuration restrictions on the control VLAN.

</table>

The MTU nodes in the following figure signal the PE nodes about active/inactive state using the Status TLV defined in RFC 4447, Pseudowire Setup and Maintenance Using the Label Distribution Protocol (LDP). This operation is described in Redundant Spoke Pseudowire Connections on page 1256.

Performance of Fault Tolerant VPLS Access Points

Switching times for a VPLS type ESRP domain are the same as that for regular domains. Actual time depends on the configured hello timer values and is expected to be in the order of seconds.

Deployment and Application Considerations

The following configuration guidelines should be observed when deploying fault tolerant access points:

- When this feature is deployed with EAPS access rings, it is strongly recommended that the EAPS health check time is configured to a value that is less than or equal to the ESRP hello time. Current defaults are one second and two seconds for EAPS health check and ESRP hello, respectively.
- All nodes in the control VLAN other than the two VPLS enabled nodes are configured as ESRP-Aware.

Event Log Messages

MPLS has full EMS logging capabilities to capture error as well as debug information. Messages are logged with the MPLS component identifier.
SNMP Support

No SNMP support is provided for protected VPLS access.

VPLS STP Redundancy Overview

Figure 199 shows an example network that uses STP to support redundant links to an H-VPLS network.

This topology uses redundant VPLS spoke nodes (S1 and S2) and an STP customer network to protect customer access. The redundant VPLS nodes provide protection from the loss of a VPLS node, and STP provides protection from the loss of a node or link in the customer access network. Within the VPLS nodes, VPLS and STP work together to react to topology changes in the customer access VLAN.

This topology uses the restricted role feature on access switch ports to control path redundancy. In Figure 199, the VPLS nodes S1 and S2 are the lowest priority STP bridges (STP prefers lower priority for root bridge election and shortest path calculation). The S1 ports connected to the R links are configured for STP restricted role mode. To prevent network loops, the restricted role mode in S1 blocks an STP enabled port when STP BPDUs with better information are received from the access network. As shown, the customer traffic uses S2 to access the VPLS network. Should one of the two restricted ports on S1 become unblocked due to a topology change, customer traffic could use both S1 and S2 to access the VPLS network.

The selection of primary and secondary PWs for this configuration is arbitrary. Therefore data paths traversing the spoke nodes S1 or S2 could use either or both core nodes C1 and C2.

In the network shown in Figure 199, traffic destined to R1 from the VPLS core traverses C2, S2, and R1.

Failure Recovery Scenario without VPLS STP Redundancy

If VPLS STP redundancy is not configured on the network shown in the following figure and the S2-R1 link fails, S1 unblocks S1-R1 and S2 flushes its FDB on the S2-R1 port.
The VPLS core nodes C3 and C4 are unaware of this change and continue to forward any traffic destined for R1 to C2. C2 continues to forward traffic towards S2. This results in data loss because S2 is not able to reach R1 over the customer network.

This data loss continues until one of the following events occurs:

- The FDB entry for R1 ages out in the VPLS core nodes
- R1 sends traffic into the VPLS core allowing its MAC address to be relearned by the VPLS core nodes

Depending on the type of data traffic from R1, the latter scenario might not occur quickly.

**Failure Recovery Scenario with VPLS STP Redundancy**

If VPLS **STP** redundancy is configured on switches S1 and S2 in the following figure and the S2-R1 link fails, S1 unblocks S1-R1 and S2 flushes its **FDB** on the S2-R1 port.

When S2 flushes its FDB, it also sends a flush message to its core peer C2. Upon receipt of this flush message, C2 flushes its FDB entries learned over the PW to S2. C2 also sends flush messages to its core peers C1, C3, and C4. These core nodes then flush their FDB entries learned over their PWs to C2. Any traffic from the VPLS core destined for R1 is flooded until such time as traffic from R1 is forwarded into the VPLS core.

**Note**

In the example shown in Figure 199 on page 1263, the core nodes are unaware that STP redundancy is configured on S1 and S2. There is no STP redundancy configuration on C1 and C2.

The following figure shows an H-VPLS configuration where the STP network directly connects to redundant spoke nodes. A similar configuration is possible where the STP network directly connects to redundant VPLS core nodes. In this case, the core nodes participating in STP are configured for STP redundancy and originate flush messages to their core peers whenever STP causes a flush on an STP port.

**Requirements and Limitations**

The configuration in the following figure has the following requirements and limitations:

- The VPLS nodes with **STP** redundancy (Switches S1 and S2) must always be the lowest priority STP bridges to ensure that STP port blocking is done by one of the VPLS nodes. For example, the following priorities for the nodes in the following figure will work correctly: S1, priority 8192; S2, priority 4096; R1, priority 32768; and R2, priority 32768.
- For VPLS STP redundancy to work properly, the VPLS nodes must be directly connected to the STP nodes. For example, if a node R3 is added between S2 and R2, node S2 cannot directly detect a failure of the link between R3 and R2.

**Enabling and Disabling VPLS STP Redundancy**

To enable or disable VPLS **STP** redundancy, use the following commands:

```
configure {l2vpn} vpls vpls_name redundancy [esrp esrpDomain | eaps | stp]
unconfigure {l2vpn} vpls vpls_name redundancy [eaps | esrp | stp]
```
VPLS EAPS Redundancy Overview

To protect your customer access network from link and node failures, you can use the VPLS with Redundant EAPS configuration shown in Figure 200.

Figure 200: VPLS with Redundant EAPS Configuration Example

This topology uses redundant VPLS core nodes and an EAPS ring to protect customer access. The redundant VPLS nodes provide protection from the loss of a VPLS node, and the EAPS ring provides protection from the loss of a node or link on the EAPS ring. Within the VPLS nodes, VPLS and EAPS work together to control the use of PWs so that no loops are created.

During normal operation, the Dist2 node is the EAPS ring master, and it blocks the port leading to the link at point 2. The protected VLANs on the EAPS ring do not include the EAPS common link at point 3. The protected VLANs on the EAPS ring use VPLS PWs between the redundant VPLS nodes to connect the two ring segments. This difference in normal EAPS operation is established during configuration by configuring an EAPS-protected VLAN on the core node with only one port on the ring.

To see the commands used to create the configuration shown above, see VPLS with Redundant EAPS Configuration Example on page 1312.

Requirements and Limitations

The solution shown in VPLS EAPS Redundancy Overview on page 1265 has the following requirements and limitations:

- The redundant VPLS nodes must be core nodes.
- An EAPS common link is required between the redundant VPLS nodes.
- The redundant VPLS nodes (Core 1 and Core 2) use PWs to connect to each other and the other core nodes (Core 3 and Core 4).
- The redundant VPLS nodes use PWs to support the EAPS-protected VLANs, not the EAPS common link.
 Works only with EAPS customer attachment ring.
• The EAPS master should not be on a VPLS node.
• EAPS state used by VPLS to control state of PWs (Active/Ready).
• EAPS monitors common link state and ring state.
• VPLS on controller node uses EAPS state to set Active/Ready PWs.
• EAPS blocks customer-facing ports as normal.

Failure Recovery Scenario 1

Suppose that a failure occurs at point 1 in the following figure.

The EAPS master detects the topology change (either through a failure notification from a node on the ring or through a hello timeout), and it unblocks the port on the protected VLAN at point 2. The Dist 2 node now connects to the VPLS through Core 2 instead of through Core 1.

When the topology changes either on an access ring or the shared port link, the path used to reach customer devices can change. For example, in the following figure, the path that Dist 2 takes to reach other parts of the VPLS network changes following the failure on the access ring at point 1. Prior to the failure, Dist 2 used Core 1 to reach the VPLS network. Following the failure, Dist 2 accesses the VPLS network using Core 2.

When the EAPS master detects a topology change, it sends a flush FDB message to its transit nodes. The transit nodes re-learn all the MAC addresses on the ring. However, this flush FDB message is not propagated over the VPLS network. As a result, Core 3 in the following figure still expects to find Dist 2 through the PW between Core 3 and Core 1. Any traffic destined for Dist 2 that is sent to Core 1 will not reach its destination.

To correct this problem, EAPS informs VPLS about any received EAPS flush FDB messages on both the controller and the partner nodes, and VPLS performs a local flush of any MAC addresses learned from the originating nodes. In this example, the EAPS processes in both Core 1 and Core 2 notify VPLS because neither node knows where the access ring is broken. The VPLS services in Core 1 and Core 2 send flush messages to the other VPLS nodes.

Failure Recovery Scenario 2

The recovery scenario is more complicated when the common link fails between Core 1 and Core 2.

The common link is configured to be an EAPS common link, and this configuration requires that one node be designated as the EAPS controller node and the other node be designated as the EAPS partner node. As described below, the selection of which node is assigned which role must consider the overall customer topology.

If the shared port link fails, the EAPS master node unblocks its port, and VPLS on the EAPS controller node takes the additional action to remove the PWs (point 4 in the following figure) associated with the VPLS from hardware.

In this recovery mode, all traffic to and from the access ring and the rest of the VPLS instance passes through Core 2. When the EAPS controller node detects that the common link is repaired, it enters the preforwarding state as normal. When the controller node exits the preforwarding state, EAPS informs VPLS so that VPLS can reestablish the PWs.
Failure Recovery Scenario 3

Now suppose there is a failure on the shared port link (point 3) and on the access ring at point 1.

The recovery actions for this double-failure need to be somewhat different. In this case, even though the core link has failed, both core nodes do not receive a copy of the ring traffic. For example, the only path to the VPLS network for Dist 1 is through the controller core node. In this case, the controller node does not take down its PWs.

It is possible that the customer access network could have parallel EAPS rings that attach to Core 1 and Core 2 as shown in Figure 201. In this example, the network connections are broken at each point X and as long as any of the parallel EAPS rings are complete, there is a path to both core VPLS nodes. Thus, the controller node must take down its PWs as long as any of the parallel EAPS rings is complete.

Figure 201: VPLS with Parallel Redundant EAPS Rings Configuration Example

PW Management for Network Failures

Table 125 shows how the controller node responds to multiple failures in a network with parallel EAPS rings.

Selective VLAN Mapping to VPLS

ExtremeXOS currently supports filtering a set of CVIDs received on a VMAN port by classifying the port as a CEP. Since a VPLS can already be configured to carry VMAN traffic, ExtremeXOS 15.4 release extends support for mapping a CEP to a VPLS.

VMAN is the VLAN stacking feature in EXOS. It has two types of ports: access and network. The access port can be both aware or unaware of VLAN. The customer edge port is the VLAN aware port of VMAN. The CEP allows several configurable options:

- An Ethernet port can be associated with multiple VMANs based on the CVIDs.
- Multiple CVIDs on multiple Ethernet ports can be associated with a VMAN.
- A range of CVIDs can be specified instead of individually configured.
- CVID translations and egress filtering.

VMAN with CEP ports can work as a way to achieve some of the requirements. However, you cannot currently assign it to a VPLS.

When implemented, a VMAN with CNP, or CEP, or both can be assigned as a service to a VPLS. This feature does not add any other capability beyond associating a VMAN with CEP port to a VPLS. Existing VMAN features such as CVID translation and egress filtering do not change. The existing VPLS feature to include or exclude SVLAN also does not change.

Supported Platforms

VLAN mapping to VPLS is supported on the following platforms:

- Summit X460-G2 (supported from ExtremeXOS 15.6)
- Summit X670-G2 (supported from ExtremeXOS 15.6)
- Summit X770
- ExtremeSwitching X870 (supported from ExtremeXOS 22.2)
- ExtremeSwitching X690 (supported from ExtremeXOS 22.3)

Limitations

The Selective VLAN Mapping to VPLS feature has the following limitations:

- You cannot assign multiple VMANs to a VPLS.
- You cannot use SNMP and XML to assign a VMAN with CEP port to VPLS.

Configuring Selective VLAN Mapping to VPLS

The CEP port is configured as normal. The existing command to associate VMAN to VPLS also does not change. The following example illustrates the three-step process:

1. Create VMAN with CEP ports.
2. Create VPLS.
3. Associate the VMAN to the VPLS.

```
# create vman vml
configure vman vml add ports 3 cep cvid 2 - 3
create vpls vsi1 fec-id-type pseudo-wire 35
configure vpls vsi1 add peer 192.168.0.2 core
configure vpls vsi1 add service vman vml
```
Additionally, the display does not change. To show the mapping, you need to configure the following two-step process:

1. Show the VPLS.
2. Show the VMAN.

Here is an example:

```bash
# show vpls vsi1

<table>

ExtremeXOS® User Guide for version 22.6
RSVP-TE Overview

RSVP is a protocol that defines procedures for signaling QoS requirements and reserving the necessary resources for a router to provide a requested service to all nodes along a data path. This release supports inter-area RSVP tunnels.

Note
Partial path computation for FRR over multiple OSPF areas is not supported.

RSVP is not a routing protocol. It works in conjunction with unicast and multicast routing protocols. An RSVP process consults a local routing database to obtain routing information. Routing protocols determine where packets get forwarded; RSVP is concerned with the QoS of those packets that are forwarded in accordance with the routing protocol.

Reservation requests for a flow follow the same path through the network as the data comprising the flow. RSVP reservations are unidirectional in nature, and the source initiates the reservation procedure by transmitting a path message containing a traffic specification (Tspec) object. The Tspec describes the source traffic characteristics in terms of peak data rate, average data rate, burst size, and minimum/maximum packet sizes.

RSVP-TE is a set of traffic engineering extensions to RSVP. RSVP-TE extensions enable RSVP use for traffic engineering in MPLS environments. The primary extensions add support for assigning MPLS labels and specifying explicit paths as a sequence of loose and strict routes. These extensions are supported by including label request and explicit route objects in the path message. A destination responds to a label request by including a label object in its reserve message. Labels are then subsequently assigned at each node the reserve message traverses. Thus, RSVP-TE operates in downstream-on-demand label advertisement mode with ordered LSP control.

The ExtremeXOS software implementation of RSVP-TE complies with RFC 3209 and includes support for:
- Configuration on a per VLAN interface.
- Operation as either edge or core MPLS router.
• Support for specifying explicitly routed paths.
• Support for both loose and strict route objects.
• Recording the route of an established path.
• Bandwidth reservation and policy per LSP.
• Signaling QoS along the RSVP path using the Tspec and Adspec objects.
• Fixed Filter (FF) and Shared Explicit (SE) reservation styles.
• Specifying RSVP-TE session attributes.
• Scaling enhancements using Refresh Overhead Reduction extensions.
• Improved link failure detection using the RSVP-TE Hello Message.
• Ability to reroute traffic over pre-configured backup LSPs.

**RSVP Elements**

**Message Types**

RSVP messages are passed between RSVP-capable routers to establish, remove, and confirm resource reservations along specified paths.

RSVP messages are sent as raw IP datagrams with protocol number 46. Each LSR along the path must process RSVP control messages so that it can maintain RSVP session state information. Therefore, most RSVP messages are transmitted with the IP Router Alert Option. Including the IP Router Alert provides a convenient mechanism allowing the IP routing hardware to intercept IP packets destined to a different IP address and deliver them to the RSVP control plane for processing. This is needed to set up and refresh RSVP-TE LSPs that follow an explicitly specified network path and thus may not use the normal routed next hop IP address. RSVP has two basic message types, path message and reserve message, as shown in the following figure.

**Figure 202: RSVP Messages**

RSVP has the following message types:

• Path message
• Reserve message
• Path tear message
• Reserve tear message
- Path error message
- Reserve error message
- Reserve confirm message

**Path Message:** The RSVP path message is used to store state information about each node in the path. Each RSVP sender transmits path messages downstream along routed paths to set up and maintain RSVP sessions. Path messages follow the exact same path as the data flow, creating path states in each LSR along the path. The IP source address of the path message must be an address of the sender it describes and the IP destination address must be the endpoint address for the session. The path message is transmitted with the IP Router Alert option since each router along the path must process the path message. Each LSR is responsible for refreshing its path status by periodically transmitting a path message to the downstream LSR.

In addition to the previous hop address, the path message contains the sender Tspec and Adspec. The reservation message carries the flowspec.

**Reserve Message:** Each receiver host transmits an RSVP reservation request to its upstream neighbor. Reserve messages carry reservation requests hop-by-hop along the reverse path. The IP destination address of a reserve message is the unicast address of the previous-hop LSR, obtained from the session’s path state. The IP source address is the address of the node that originated the message. The reserve message creates and maintains a reserve state in each node on the path. Each LSR is responsible for refreshing its reserve status by periodically transmitting a reserve message to the upstream LSR.

Reserve messages are eventually delivered to the sender, so that the sender can configure appropriate traffic control parameters for the first hop node.

**Path Tear Message:** Path tear messages delete path state information reserved along the path. The message is initiated by the path sender or by any LSR in which a path state time-out occurs or an LSP is preempted (due to bandwidth reservations), and is sent downstream to the session’s path endpoint. Path tear messages are transmitted with the IP Router Alert option and are routed exactly the same as path messages. The IP destination address must be the path endpoint and the source IP address must be the sender address obtained from the session’s path state for the path that is being torn down.

When a path state is deleted as the result of the path tear message, the related reservation state must also be adjusted to maintain consistency in the node. The adjustment depends on the reservation style.

**Reserve Tear Message:** Reserve tear messages delete reservation state information. The message is initiated by the path endpoint or any node along the path in which a reservation state has timed out or an LSP is preempted (due to bandwidth reservations), and is sent upstream to the session’s path sender. Reserve tear messages are routed exactly the same as reserve messages. The IP destination address of a reserve message is the unicast address of the previous-hop node, obtained from the session’s reservation state. The IP source address is the address of the node that originated the message.

If no reservation state matches the reserve tear message, the message is discarded. The reserve tear message can delete any subset of the filter specification in FF-style or SE-style reservation state. Reservation styles are described in the following table.

---

11 The routed path may be the best routed path or an explicitly specified routed path using EROs.
12 IP Router Alert option is described in RFC 2113.
Path Error Message: Path error messages are used to report processing errors for path messages. These messages are sent upstream to the sender that issued the path message. The message is routed hop-by-hop using the path state information maintained in each node. Path error messages are informational and do not modify the path state within any node.

Reserve Error Message: Reserve error messages are used to report processing errors for reserve messages. In addition, reserve error messages are used to report the spontaneous disruption of a reservation. Reserve error messages travel downstream to the endpoint of the session. The message is forwarded hop-by-hop using the reservation state information maintained in each node. Reserve error messages are informational and do not modify the reservation state within any node.

Reserve Confirm Message: Reserve confirm messages are optionally transmitted to acknowledge a reservation request. These messages are transmitted from the sender to the endpoint. The destination IP address is the IP address of the endpoint and the source IP address is the address of the sender. Since none of the intermediate path nodes need to process a reserve confirm message, the message is transmitted without the IP Router Alert option.

Reservation Styles

A reservation style is a set of options that is included in the reservation request.

One reservation style concerns how reservations requested by different senders within the same session are handled. This type of reservation style is handled in one of two ways: either create a distinct reservation for each sender in the session, or use a single reservation that is shared among all packets of the selected senders.

Another reservation style concerns how senders are selected. Again, there are two choices: an explicit list of all selected senders, or a wildcard that implies all senders in the session.

Table 126 describes the relationship between reservation attributes and styles.

Table 126: Reservation Attributes and Styles

<table>
<thead>
<tr>
<th>Sender Selection</th>
<th>Distinct Reservation Style</th>
<th>Shared Reservation Style</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explicit</td>
<td>Fixed filter (FF)</td>
<td>Shared explicit (SE)</td>
</tr>
<tr>
<td>Wildcard</td>
<td>Not defined</td>
<td>Wildcard filter (WF)</td>
</tr>
</tbody>
</table>

Fixed Filter: The fixed filter (FF) reservation style uses a distinct reservation and an explicit sender selection. This means that each resource reservation is for a specific sender. The session resources are not shared with other senders’ packets. Because each reservation is identified with a single sender, a unique label is assigned by the endpoint to each sender (i.e., point-to-point LSP reservation).

Shared Explicit: The shared explicit (SE) reservation style uses a shared reservation and an explicit sender selection. This means that a single resource reservation is created that is shared by multiple senders. The endpoint may specify which senders are to be included for the reservation. Because different senders are explicitly listed in the RESV message, different labels may be assigned to each sender. Thus, multiple shared-resource LSPs to the same endpoint can be created (i.e., multipoint-to-point LSP reservation). The Extreme MPLS implementation requests SE reservation style when signaling RSVP-TE LSPs.
**Wildcard**: The wildcard (WF) reservation style uses the shared reservation and wildcard sender options. A wildcard reservation creates a single reservation that is shared by data flows from all upstream senders.

The Extreme MPLS implementation does not support WF reservation style.

**RSVP Traffic Engineering**

MPLS Traffic Engineering (TE) extends RSVP to support several unique capabilities.

By coupling RSVP and MPLS, LSPs can be signaled along explicit paths with specific resource reservations. Additional RSVP objects have been defined to provide TE extensions. These objects include the Label Request, Label, Explicit Route, Record Route, and Session Attribute. Extreme’s RSVP-TE implementation supports all of these TE objects.

**RSVP Tunneling**

An RSVP tunnel sends traffic from an ingress node through an LSP. The traffic that flows through the LSP is opaque (or tunneled) to the intermediate nodes along the path. Traffic flowing through the tunnel to an intermediate node along the path is identified by the previous hop and is forwarded, based on the label value(s), to the downstream node.

RSVP-TE can:
- Establish tunnels with or without QoS requirements.
- Dynamically reroute an established tunnel.
- Observe the actual route traversed by a tunnel.
- Identify and diagnose tunnels.
- Use administrative policy control to preempt an established tunnel.
- Perform downstream-on-demand label allocation, distribution, and binding.

Some LSRs require their neighboring LSRs to include their Router ID in the Extended Tunnel ID field when sending RSVP-TE messages. The Extended Tunnel ID is a globally unique identifier present in the RSVP common header Session object (see RFC 3209). To provide maximum compatibility with other vendors' implementations, the ExtremeXOS MPLS implementation accepts RSVP-TE messages regardless of the Extended Tunnel ID value and always inserts the local Router ID into the Extended Tunnel ID field prior to transmission of an RSVP-TE message.

**RSVP Objects**

This section describes the RSVP objects that are used to establish RSVP-TE LSPs:
- Label
- Label request
- Explicit
- Record route
- Session attribute

**Label**: The label object is carried in the reserve message and is used to communicate a next hop label for the requested tunnel endpoint IP address upstream towards the sender.
**Label Request:** To create an RSVP-TE LSP, the sender on the MPLS path creates an RSVP path message and inserts the label request object into the path message.

A label request object specifies that a label binding for the tunneled path is requested. It also provides information about the network layer protocol that is carried by the tunnel. The network layer protocol sent through a tunnel is not assumed to be IP and cannot be deduced from the Layer 2 protocol header, which simply identifies the higher layer protocol as MPLS. Therefore, the Layer 3 Protocol ID (PID) value must be set in the Label Request Object, so that the egress node can properly handle the tunneled data.

**Note**
The ExtremeXOS RSVP-TE implementation supports only Label Request objects with no Label Range. Label Ranges are used to signal ATM VPI/VCI or Frame Relay DLCI information for the LSP. These types of Label Requests are not supported. In the ExtremeXOS RSVP-TE implementation, the L3 PID value, which identifies the Layer 3 protocol of the encapsulated traffic, is always set to 0x0800 (IP).

**Explicit Route:** The explicit route object specifies the route of the traffic as a sequence of nodes. Nodes may be loosely or strictly specified.

The explicit route object is used by the MPLS sender if the sender knows about a route that:

- Has a high likelihood of meeting the QoS requirements of the tunnel.
- Uses the network resources efficiently.
- Satisfies policy criteria.

If any of the above criteria are met, the sender can decide to use the explicit route for some or all of its sessions. To do this, the sender node adds an explicit route object to the path message.

After the session has been established, the sender node can dynamically reroute the session (if, for example, if discovers a better route) by changing the explicit route object.

**Record Route:** The record route object is used by the sender to receive information about the actual route traversed by the RSVP-TE LSP. It is also used by the sender to request notification if there are changes to the routing path. Intermediate or transit nodes can optionally use the RRO to provide loop detection.

To use the object, the sender adds the record route object to the path message.

**Session Attribute:** The session attribute object can also be added to the path message. It is used for identifying and diagnosing the session. The session attribute includes the following information:

- Setup and hold priorities
- Resource affinities
- Local protection

**ERO Exclude Option**

In order to allow more flexibility when traffic engineering redundant paths for RSVP-TE LSPs, this feature adds the “exclude” option to the “configure mpls rsvp-te path <path> add ero” command. An “include” option is also available, but is optional. If neither option is used, “include” will be used for backward compatibility.
A hop that is excluded is avoided when CSPF does path calculations. By adding an “exclude” hop to a path, LSPs can be set up to avoid certain links. An example of this is to configure a secondary RSVP-TE LSP to avoid the hops that a primary LSP has been configured to traverse. This can allow the secondary LSP more freedom to route through other parts of the network. Often, without the “exclude” option, the secondary LSP must be configured more tightly than desired to ensure that its path never overlaps with the primary LSP’s path.

Establishing RSVP-TE LSPs

Establishing LSPs requires every LSR along the path to support RSVP and the TE extensions defined in RFC 3209.

The LSP endpoints attempt to detect non-RSVP capable LSRs by comparing the time-to-live (TTL) value maintained in the RSVP common header with that of the IP TTL. If these values are different, it is assumed that a non-RSVP capable LSR exists along the path. By including the Label Request object in the path message, RSVP capable routers that do not support the TE extensions can be detected. RSVP routers that do not support TE extensions reply with the Unknown object class error.

RSVP-TE LSPs are referred to as named LSPs. These LSPs have configurable names that are used to identify the LSP within the CLI. The command create mpls rsvp-te lsp lsp_name destination ipaddress allocates the internal resources for the LSP. The newly created LSP is not signaled until the LSP has been configured. The LSP can be configured to take a specific path through the network or the administrator can let the switch choose the best path by specifying the path any. Up to three paths may be configured for an LSP to provide redundancy. The command configure mpls rsvp-te lsp lsp_name add path configures an LSP. Optionally, RSVP-TE profiles may be applied to an LSP to change its properties. An RSVP-TE profile is a specific CLI container used to hold configuration parameters associated with timers, bandwidth reservation, limits, and other miscellaneous properties.

Once the RSVP-TE LSP is configured, the LSP is immediately signaled. If signaled successfully, the LSP becomes active. The commands disable mpls rsvp-te lsp lsp_name and enable mpls rsvp-te lsp lsp_name are used to tear down and re-signal the LSP. Disabling the LSP causes the LER to send a path tear message to the destination, forcing the LSP down and all resources along the path to be freed. Enabling the LSP instructs the LER to send a path message to the destination re-establishing the LSP. The configuration of the LSP is not modified by the enable or disable LSP commands.

RSVP-TE Implementation

Explicit Route Path LSPs

An explicit route is a specified path through a routed network topology.

The path can be strictly or loosely specified. If strictly specified, each node or group of nodes along the path must be configured. Thus, no deviation from the specified path is allowed.

Loosely specified paths allow for local flexibility in fulfilling the requested path to the destination. This feature allows for significant leeway by the LSR in choosing the next hop when incomplete information about the details of the path is generated by the LER. Each node along the path may use other metrics to pick the next hop along the path, such as bandwidth available, class of service, or link cost. The
command configure mpls rsvp-te path \textit{path\_name} add ero is used to add an Explicit Route Object to a path container.

An explicit routed path is encoded using the explicit route object (ERO) and is transmitted in the path message. The ERO consists of a list of subobjects, each of which describes an abstract node. By definition, an abstract node can be an IP prefix or an autonomous system (AS) number. The ExtremeXOS RSVP-TE implementation supports only IPv4 abstract nodes. The ExtremeXOS RSVP-TE implementation supports both strict and loose IPv4 abstract nodes. Received path messages with EROs that contain any other subobject type result in the transmittal of an Unknown object class error message. All LSRs along the specified path must support the inclusion of the ERO in the path message for an explicitly routed path to be successfully set up.

An LSR receiving a path message containing an ERO must determine the next hop for this path.

The steps for selection of the next hop are as follows:

1. The receiving LSR evaluates the first subobject. If the subobject type is not supported or there is no subobject, a Bad ERO error is returned. The abstract node is evaluated to ensure that this LSR was the valid next hop for the path message. If the subobject is a strict abstract node, the abstract node definition must match the local interface address. If it does, then this LSR is considered to be a member of the abstract node. Additionally, if the /32 address matches a local interface address, the path message must have been received on the direct interface corresponding to the /32 address. If the abstract node is an IP prefix, the subnet configured for the interface from which the path message was received must match the abstract node definition. In the event that this LSR is not part of the strict abstract node definition, a Bad initial subobject error is returned. If the subobject is a loose abstract node, the LSR determines if the abstract node definition corresponds to this LSR. If it doesn't, the path message is transmitted along the best-routed or constrained optimized path to the endpoint and the ERO is not modified. If it is, then processing of the ERO continues.

2. If there is no second subobject, the ERO is removed from the path message. If this LSR is not the end of the path, the next hop is determined by the constrained optimized path (through Constrained Shortest Path First—CSPF) to the path message endpoint.

3. If there is a second subobject, a check is made to determine if this LSR is a member of the abstract node. If it is, the first subobject is deleted and the second subobject becomes the first subobject. This process is repeated until either there is only one subobject or this LSR is not a member of the abstract node as defined by the second subobject. Processing of the ERO is then repeated with step 2. By repeating steps 2 and 3, any redundant subobjects that are part of this LSRs abstract node can be removed from the ERO. If this operation were not performed, the next hop LSR might reject the path message.

4. The LSR uses its CSPF to determine the next hop to the second subobject. If the first object is a /32 address, the first subobject is removed, since it would not be part of the next hop's abstract node. The path message is then sent along the explicit path to the path message endpoint. No determination is made to verify that the abstract node defined in the subobject is topologically adjacent to this LSR. The next hop should verify this as part of its processing as defined in step 1.

If CSPF determines that a specific path needs to be taken through the network, additional EROs are inserted into the path message.

\textbf{Route Recording}

The route a path takes can be recorded.
Recording the path allows the ingress LER to know, on a hop-by-hop basis, which LSRs the path traverses. Knowing the actual path of an LSP can be especially useful for diagnosing various network issues.

Network path recording is configurable per LSP. This feature is configured by enabling route recording for a specific RSVP-TE profile using the command `configure mpls rsvp-te lsp profile lsp_profile_name record enabled` and associating the profile to an LSP. The ExtremeXOS software sets the label recording desired flag in the path message if route recording has been enabled for the LSP.

If route recording is enabled, the record route object (RRO) is inserted into the path message using a single RRO subobject, representing the ingress LER. When a path message that contains an RRO is received by an Extreme LSR, an RRO IPv4 subobject representing the /32 address of the outgoing interface of the path message is pushed onto the top of the first RRO. The updated RRO is returned in the reserve message.

The label recording flag is supported by the ExtremeXOS software and is set automatically when route recording is enabled. The `route-only` option can be used when enabling route recording in the profile to prevent the label recording flag from being set. If an Extreme LSR receives a path message with the label recording flag set in the RRO, the LSR encodes the LSP label into a label subobject and pushes it onto the RRO.

If a path message is received that contains an RRO, the Extreme LSR uses the RRO to perform loop detection. The RRO is scanned to verify that the path message has not already traversed this LSR. If the RRO contains an IPv4 subobject that represents a local LSR interface, the path message is dropped and a Routing Problem error message is sent to the originating LER with an error value of Loop detected.

### LSP Session Attributes

Session attributes are signaled for configured RSVP-TE LSPs using the session attribute object without resource affinities (that is, LSP_TUNNEL Type).

The ExtremeXOS software uses the setup and hold priority values to preempt established LSPs in order to satisfy bandwidth requests. Lower hold priority LSPs are preempted in order to satisfy the bandwidth request in a path message with a higher setup priority. LSP attributes are configured by setting the priorities for a specific RSVP-TE profile using the command `configure mpls rsvp-te lsp profile lsp_profile_name setup-priority priority hold-priority priority` and associating the profile to the configured LSP.

### Bandwidth Reservation

As mentioned previously, RSVP reservations are unidirectional in nature.

The source initiates the reservation procedure by transmitting a path message containing a sender Tspec object. The Tspec describes the source traffic characteristics in terms of peak data rate, average data rate, burst size, and minimum/maximum packet sizes. The path message can also contain an optional AdSpec object that is updated by network elements along the path to indicate information such as the availability of particular QoS services, the maximum bandwidth available along the path, the minimum path latency, and the path maximum transmission unit (MTU).

---

13 RRO is organized as a LIFO stack.
The ExtremeXOS software supports LSR bandwidth reservation requests per LSP. Only the Int-Serv Controlled-Load service request is supported. Bandwidth is always reserved on the physical ports that the LSP traverses. Depending on the platform, the bandwidth reservation may also be policed. The network administrator can verify that the requested bandwidth was actually reserved. In those cases when the bandwidth reserved is less than the requested bandwidth, the LSP can be manually torn down, re-signaled using a different path, or accepted. The LSR automatically attempts to find a path that best satisfies the bandwidth request. Constrained path selections are supported using OSPF-TE. Best effort LSPs are provisioned by specifying a reserved bandwidth as best-effort. The reserved LSP bandwidth is configured by setting the bps rate for a specific RSVP-TE profile, using the `configure mpls rsvp-te lsp profile lsp_profile_name bandwidth` command and associating the profile to an LSP.

Accounting of bandwidth reserved through an Extreme LSR RSVP-TE enabled VLAN is supported. The maximum available bandwidth per physical port or trunk group is enforced. Thus, the available bandwidth specified in the Adspec object is not modified as the path message is forwarded to the LSP endpoint. As reserve messages are processed, the reserved bandwidth specified in the Flowspec is added to the total reserved bandwidth allocated for the physical ports.

Because LSP bandwidth is dynamically allocated, a configuration command is provided to reserve port bandwidth for use by MPLS. The command `configure mpls rsvp-te bandwidth committed-rate` pre-reserves bandwidth from the specified MPLS enabled VLAN for RSVP-TE traffic only. This pre-allocation of bandwidth is useful since other applications may compete with MPLS for available bandwidth. By pre-reserving a portion of the MPLS interface's bandwidth capacity, MPLS is guaranteed to have that amount of the MPLS interface's bandwidth to meet RSVP-TE LSP reservation requests.

CIR bandwidth for the receive direction is not tracked by TE IGPs, such as OSPF-TE, and configuring it is not required. Configuring CIR bandwidth for the receive direction does not prevent an LSP from going operational due to lack of receive bandwidth; however, it can be useful for tracking and informational purposes. An Info level log (MPLS.RSVPTE.IfRxBwdthExcd) is generated if the setup of a TE LSP requires receive bandwidth greater than that which is currently available for the receive direction on a particular interface. This generally happens only when TE LSPs with different previous hops ingress the switch on the same interface (for example, from a multi-access link) and egress the switch on different interfaces.

### Bandwidth Management for RSVP-TE LSPs

If an RSVP-TE LSP is signaled through a switch with bandwidth parameters, the LSP bandwidth request is granted or rejected based on the availability of bandwidth resources on the physical ports that the LSP traverses.

Data traffic through these switches is not policed and there are no guarantees that the packets using the LSP are not dropped.

**Note**

Per LSP rate limiting is not supported in this release.

The available bandwidth for each OSPF interface is continually updated within the OSPF area. As RSVP-TE LSPs are established and torn down, the reserved bandwidth associated with these LSPs is used to update the total bandwidth available through each OSPF interface. RSVP-TE and CSPF can use the
bandwidth information to determine the appropriate path that each LSP should take through the network based on the LSP's profile parameters. LSP parameters that can affect the CSPF TE path calculation include the LSP setup priority and bandwidth configuration.

Available bandwidth is calculated for eight CoS (Class of Service) levels. Each CoS uniquely maps to an LSP hold priority. Thus, when an LSP is set up through the switch, the reserved bandwidth consumed is associated with a CoS based on the signaled LSP hold priority. The available bandwidth is recalculated and advertised to its OSPF neighbors. Advertised bandwidth is calculated using graduated bandwidth reporting methodology. Using this scheme, higher CoS levels advertise available bandwidth that includes allocated bandwidth for lower CoS levels. The reasoning for doing this is that higher priority LSPs can preempt lower priority LSP. Thus, even though the bandwidth has been allocated to a lower priority LSP, it is still available for use by higher priority LSPs.

In the following example, an interface is configured to reserve 250 Mbps for MPLS traffic.

The following LSPs are established through this interface. Remember, hold priority value of 0 is the highest priority and 7 is the lowest.

• LSP A, hold priority = 7, reserved = 50 Mbps
• LSP B, hold priority = 5, reserved = 100 Mbps
• LSP C, hold priority = 2, reserved = 25 Mbps
• LSP D, hold priority = 1, reserved = 25 Mbps

OSPF advertises the following available bandwidth for each CoS.

CoS 0 is the highest and CoS 7 is the lowest:
• CoS 0 (hold = 0): 250 Mbps (No LSPs; all bandwidth available)
• CoS 1 (hold = 1): 225 Mbps (LSP D)
• CoS 2 (hold = 2): 200 Mbps (LSP C & D)
• CoS 3 (hold = 3): 200 Mbps (LSP C & D)
• CoS 4 (hold = 4): 200 Mbps (LSP C & D)
• CoS 5 (hold = 5): 100 Mbps (LSP B, C & D)
• CoS 6 (hold = 6): 100 Mbps (LSP B, C & D)
• CoS 7 (hold = 7): 50 Mbps (LSP A, B, C & D)

CSPF calculations only use the available bandwidth for the desired CoS, as specified by the LSP hold priority. Thus in this example, if LSP E, with a configured setup priority of 6, requires 150 Mbps, CSPF calculates a path to the destination that does not go through the above interface, since only 100 Mbps worth of bandwidth is available.

Redundant LSPs

There are three methods for provisioning redundant RSVP-TE LSPs at the ingress LER, also referred to as head-end LSP protection:

• Configured secondary (or backup) LSPs
• Fast reroute (detour) LSPs
• Multipath LSPs

Secondary RSVP-TE LSPs can be configured to provide backup LSPs in the event that the primary LSP fails. You can create up to two secondary LSPs for each primary LSP. The secondary LSPs are fully
provisioned, pre-established RSVP-TE LSPs that are maintained as inactive until needed. If the primary LSP is torn down, the associated LSP next hop is removed from the route table, and a new LSP next hop representing one of the secondary LSPs is installed as the preferred LSP. If there are multiple secondary LSPs available, the secondary LSP is randomly selected. If the primary LSP is re-established, the primary LSP next hop information is re-installed and the secondary LSP returns to inactive state.

If both the primary and secondary paths for an LSP fail, and there are no other RSVP-TE LSPs active to the destination, an LDP LSP can be used if available.

Operation with L2 VPNs is similar. If a primary path fails, and a secondary LSP is available, VPLS uses the secondary LSP. When the primary LSP is re-established, VPLS again uses the primary LSP.

Specifying redundant LSPs is accomplished by assigning secondary paths to an LSP. The `configure mpls rsvp-te lsp lsp_name add path path_name secondary` command can configure the specified path as a backup LSP. A path different from the primary path must be specified. It is recommended that defined paths be configured using EROs to specify different paths through the network. Relying on the routing topology, by configuring the path to any, can create two LSPs that take the same path. It is important to understand that the configured LSP signals multiple LSPs, up to three (one primary and two secondary), but only one LSP can be used to forward traffic at any one time.

Fast Reroute LSPs are based on the IETF RFC 4090, Fast Reroute Extensions to RSVP-TE for LSP Tunnels, which defines RSVP-TE extensions to establish backup LSP tunnels for local repair of LSP tunnels. To respond to failures, these mechanisms enable the re-direction of traffic onto backup LSP tunnels in tens of milliseconds, and this meets the needs of real-time applications such as voice over IP (VoIP). This timing requirement is satisfied by computing and signaling backup LSP tunnels in advance of a failure and by re-directing traffic as close to the failure point as possible. In this way the time for redirection includes no path computation and no signaling delays, which include delays to propagate failure notification between label-switched routers (LSRs). Speed of repair is the primary advantage of using fast-reroute backup methods.

There are two backup methods; the detour LSP method (which is also called the one-to-one backup method) and the facility backup method (which is also called the by-pass tunnel method). The software supports only the detour LSP method.

Based on the RFC-4090 there are two different methods to uniquely identify a backup path:

1. Path-specific method
2. Sender template-specific method

The software supports only the path-specific method, which uses a new object, the DETOUR object, to distinguish between PATH messages for a backup path and the protected LSP.

Figure 203 illustrates the terminology used to describe fast-reroute configuration and operation.
The primary LSP in Figure 203 is established between MPLS routers A and D. Router A is the ingress LER, and Router D is the egress LER. When used with fast-reroute protection, the primary LSP is also called the protected LSP, as it is protected by the detour LSP created by the fast-reroute feature. The detour LSP provides a route around a protected component. The link between Router B and Router C has failed. The detour LSP, which is indicated by the dashed line, provides a path around the failure.

Routers B and C are transit LSRs for the primary LSP. With respect to a specific LSP, any router that is not the ingress or egress LER is a transit LSR. Routers F and G are transit LSRs for the detour LSP.

The origin of the detour LSP is called the Point of Local Repair (PLR), and the termination of the detour LSP is called the Merge Point. A protected LSP is an explicitly-routed LSP that is provided with protection. A detour LSP is also an explicitly-routed LSP. If you configure a series of one or more hops (EROs), then based on the currently set DYNAMIC_FULL option in the Constrained-based Shorted Path First (CSPF) routing component, the CSPF will calculate and try to fill in the gaps to build a complete list of EROs.

You can configure up to two secondary LSPs for each standard TE (non-FRR) LSP or for each protected FRR LSP. If a standard TE LSP fails, then one of the secondary LSPs becomes active. If that secondary LSP fails, the other secondary LSP becomes active. If a protected FRR LSP fails, its detour LSP becomes active. If the detour LSP fails, then one of the secondary LSPs becomes active, and if that secondary LSP fails, the other secondary LSP becomes active. If all configured backup and secondary paths for an LSP fail, a different active RSVP-TE LSP to the destination can be used. Otherwise, an LDP LSP can be used if available.

The primary advantage of detour LSPs is the repair speed. The cost of detour LSPs is resources. Each backup LSP reserves resources that cannot be used by other LSPs. Another cost is that currently there is no automatic way to redirect traffic from a detour LSP back to a primary LSP when the protected LSP recovers. Redirecting traffic from the detour LSP to the primary LSP requires a series of CLI commands.

Fast reroute protection is configured primarily on the ingress LER, however, it must be enabled on all transit LSRs and the egress LER also. After configuration is complete and fast-reroute protection is enabled on the primary LSP, the primary and detour LSPs are signalled. Provided that the resources are available, detour LSPs are set up at each transit LSP along the primary LSP.
Multiple RSVP-TE LSPs can exist or be configured to the same destination. The paths do not need to be equal cost; all that is required is that all the LSPs to the same destination must have IP transport enabled. In this scenario, LSP next hop information is communicated to the route table for up to eight different named RSVP-TE LSPs. Locally originated traffic is distributed across each LSP based on standard IP address hash algorithms. If one of the LSPs fails, the traffic is redistributed across the remaining active named LSPs. Unlike the backup LSP mechanism, all of the redundant multipath LSPs are unique named LSPs and in general have primary configured paths.

**Improving LSP Scaling**

RSVP maintains path and reserve state by periodically sending refresh messages.

Refresh messages allow each LSR along the path to properly maintain reservation state information and to recover from network failures. Because refresh messages are periodically sent for each path reservation, scaling the number of RSVP-TE LSPs is an issue. Additionally, network requirements for faster failure detection and improved LSP recovery times further exacerbate the scaling issue.

Several techniques are described in RFC 2961 RSVP Refresh Overhead Reduction to improve the scalability of RSVP. These techniques include the bundle message, message ID extension, and summary refresh extension. Support for these extensions is signaled between RSVP peers via the refresh-reduction-capable bit in the flags field of the common RSVP header. Additionally, the hello extension, described in RFC 3209, provides a fourth scaling mechanism for RSVP. The hello extension is designed so that either peer can use the mechanism regardless of how the other peer is configured. Therefore, support for the hello extension is not signaled between RSVP peers. The ExtremeXOS software supports and is compliant with the RSVP-TE scaling features described in RFC 2961.

These features include the following:

- Bundle message
- Summary refresh extension
- Message ID extension
- Hello extension

**Bundle Message:** RSVP bundle messages aggregate multiple RSVP messages within a single PDU. The messages are addressed directly to peer LSRs. Therefore, bundle messages are not sent with the IP Router Alert option. Bundling multiple RSVP messages into a single PDU reduces the per packet overhead associated with local delivery and local origination. Each bundle message must contain at least one RSVP message. Transmission of RSVP messages may be delayed up to the number of seconds configured for bundle time. The size of the bundle message is limited to the RSVP-TE interface MTU size. Bundle messaging is enabled using the enable mpls rsvp-te bundle-message command.

**Summary Refresh Extension:** A summary refresh message is used to refresh RSVP states along an LSP without having to explicitly send path and reserve refresh messages. This can substantially reduce the RSVP control bandwidth overhead. Summary refresh messages contain a list of message_ID objects. Each message_ID object identifies a path and reserve state to be refreshed. When summary refresh support is enabled, path and reserve refresh messages are suppressed. If the message identifier value indicates that the RSVP state has changed, the receiving LSR notifies the sender by transmitting a message_ID_NACK message. The summary refresh rate is enabled using the enable mpls rsvp-te summary-refresh command.

**Message ID Extension:** The message ID extension provides reliable delivery of RSVP messages. It also provides a simple mechanism for identifying refresh messages, which can greatly reduce refresh
message processing on the receiving LSR. The message ID extension defines three new objects: message_ID, message_ID_ACK, and message_ID_NACK. The message_ID object contains a unique message identifier based on the sender's IP address. Only one message_ID object is inserted into an RSVP message. The receiving LSR can use the message_ID object to quickly refresh path and reserve states. If the message identifier value in the message_ID object is greater than the locally saved message identifier value, then the RSVP message represents a new or modified state. The receiving LSR must acknowledge an RSVP message using the message_ID_ACK object if the sender set the ACK_desired flag in the message_ID object, otherwise the message_ID acknowledgement is optional. The message_ID_ACK object may be included in any unrelated RSVP message or in an RSVP ACK message. Message ID extension is required for both bundle message and summary refresh, so this capability is automatically enabled if either of the other capabilities is enabled.

Hello Extension: The RSVP hello message provides a quick and simple mechanism for detecting the loss of a peer RSVP-TE LSR. The hello protocol is implemented using the RSVP soft-state model. RSVP hello messages may be enabled independently of each LSR peer. The hello protocol consists of two new objects: hello_request and hello_ACK. If configured, an LSR sends a hello_request every hello interval. If a hello_ACK is not received within a specified amount of time, the sending LSR assumes that its peer LSR is no longer active. Once a peer LSR is deemed inactive, all reservation states associated with LSPs established to or through the peer LSR must be freed and the LSPs torn down. The hello interval is configurable using the command configure mpls rsvp-te timers session hello-time.

You can improve LSP scaling by configuring the following RSVP-TE parameters:
- Refresh time
- Summary refresh time
- Bundle time

Refresh Time: The refresh time specifies the interval for sending refresh path messages. RSVP refresh messages provide soft state link-level keep-alive information for previously established paths and enable the switch to detect when an LSP is no longer active. RSVP sessions are torn down if an RSVP refresh message is not received from a neighbor within [(keep-multiplier + 0.5) * 1.5 * refresh-time] seconds. The valid refresh time may be set to any value between 1 and 360000 seconds. The default setting is 30 seconds. Configuring a longer refresh time reduces both switch and network overhead.

Summary Refresh Time: The summary refresh time, specified in tenths of a second, indicates the time interval for sending summary refresh RSVP messages. The summary refresh time must be less than the configured refresh time. The default summary refresh time is zero, indicating that no summary refresh RSVP messages are sent. The summary refresh time value may be set to any value between zero to 100 (or 10 seconds). If configured, the bundled and summary refresh RSVP messages are only sent to RSVP-TE peers supporting RSVP refresh reduction.

Bundle Time: The bundle time, specified in tenths of a second, indicates the maximum amount of time a transmit buffer is held so that multiple RSVP messages can be bundled into a single PDU. The default bundle time is zero, indicating that RSVP message bundling is not enabled. The bundle time value can be set to any value between zero and 30 (or 3 seconds).

Supporting Quality of Service Features

QoS LSP support is an important attribute of MPLS.
MPLS supports the Differentiated Services (DiffServ) model of QoS. The DiffServ QoS model is supported by mapping different traffic classes to different LSPs, or by using the EXP bits in the MPLS shim header to identify traffic classes with particular forwarding requirements.

**Propagation of IP TTL**

There are two modes of operation for routed IP packets: pipe TTL mode and uniform TTL mode.

Currently, switches that run Extreme OS support only the pipe TTL mode. In pipe TTL mode, the LSP is viewed as a point-to-point link between the ingress LSR and the egress LSR; intermediate LSRs in the MPLS network are not viewed as router hops from an IP TTL perspective. Thus, the IP TTL is decremented once by the ingress LSR, and once by the egress LSR.

In this mode, the MPLS TTL is independent of the IP TTL. The MPLS TTL is set to 255 on all packets originated by the switch and on all packets that enter a pseudowire.

**IXP MPLS Enhancements**

ExtremeXOS Release 15.4 adds the following IXP MPLS feature enhancements:

- EMS logs reflect the operation status changes of LSPs, PWs, and Interfaces.
- Show command displays details for transit and egress RSVP-TE LSPs.
- Metaswitch fixpack enhances logging of PATH failures.
- RSVP-TE description field now displays LSP Name/Path.
- MPLS commands are added to “show tech-support” functionality.
- Add support for the Metaswitch dmptrace facility.

**EMS Logging of MPLS Protocols, LSPs, PWs, and Interfaces**

The following EMS logs allow you to track MPLS protocols, some LSPs, and PW and MPLS I/F operational states. These logs are added at the "Info" level, and are not generated in the default log output (the default level for MPLS is “Warning”).

**LSPs**

- MPLS.ChgStaticIngrLSPState
- MPLS.ChgStaticTrnstLSPState
- MPLS.ChgStaticEgrLSPState
- MPLS.RSVPTE.ChgIngrLSPState

**PWs**

- MPLS.L2VPN.ChgPWState

**MPLS Protocol Interfaces**

- MPLS.ChgIfState
- MPLS.ChgProtoState
• MPLS.LDP.ChgProtoState
• MPLS.RSVPTE.ChgProtoState

Note
CES.TDM.PWUp and CES.TDM.PWDown EMS logs already exist.

Enhanced Show Details for Transit and Egress RSVP-TE LSPs

The following fields are added to the `show mpls rsvp-te lsp` command output on transit and egress nodes:
• Administrative & Operational Statuses
• Setup & Hold Priorities

Enhance Usability and Ability to Debug MPLS

• Apply fixpack to provide better debugging for RSVP-TE Path message handling
• Use RSVP-TE “Tunnel Description” field in MPLS TE MIB to indicate LSP and Path

Because primary and secondary RSVP-TE LSPs use the same LSP name, and the idea of Redundant LSPs is an EXOS feature, determining which path is associated with an LSP could only be done through the CLI. To eliminate this problem, the RSVP-TE “Tunnel Description” MIB field (RFC 3812: `mplsTunnelDescr`) now returns the “LSPName (PathName) on the Ingress node.

Note
The tunnel description is not signaled as part of RSVP messaging, so this information is not available at transit and egress nodes.

• Add MPLS (including RSVP-TE) debug information to `show tech-support mpls` command.
• Add support for the Metaswitch dmptrace facility

Configuring MPLS

`MPLS` has the following configuration constraints:
• IP flow redirection—IP flow redirection commands and MPLS are mutually exclusive functions. Both functions cannot be enabled simultaneously.
• IGMP snooping—OSPF and LDP session establishment require the switch to receive and process IP multicast frames. Therefore, IGMP snooping must be enabled to support MPLS.
• VPLS—VPLS requires that IGMP snooping be disabled on customer-facing VLANs.

Configuration Overview

1. If you want to use `MPLS` in a different VR (the default is `VR-Default`), move MPLS to the appropriate VR as described in Moving MPLS From VR to VR on page 1287.
2. Create and configure the VLANs that will use MPLS.
3. Configure an MPLS LSR ID for each switch that serves as an LSR in the network. (See Configuring the MPLS LSR ID on page 1287.)
4. Add MPLS support to the appropriate VLANs. (See Adding MPLS Support to VLANs on page 1288.)
5 Enable MPLS on each switch that serves as an LSR. (See Enabling and Disabling MPLS on an LSR on page 1288.)
6 Enable MPLS on the appropriate VLANs. (See Enabling and Disabling MPLS on a VLAN on page 1288.)
7 Enable LDP on each switch that serves as an LSR. (See Enabling LDP on the Switch on page 1288.)
8 Enable LDP on the appropriate VLANs. (See Enabling and Disabling LDP on a VLAN on page 1289.)
9 Configure an IGP, such as OSPF or IS-IS, for the appropriate switches and VLANs.

Moving MPLS From VR to VR

By default, MPLS is enabled on the VR-Default virtual router (VR). You can operate MPLS in VR-Default or in any user VR, but MPLS only operates in one VR. If you want to use MPLS in a user VR, you must delete it from VR-Default first.

• To delete MPLS from a VR, do the following:
  a Disable MPLS on the LSR as described in Enabling and Disabling MPLS on an LSR on page 1288.
  b Disable MPLS on all VLANs and reset the MPLS configuration as described in Resetting MPLS Configuration Parameter Values on page 1295.
  c Remove MPLS from the VR by entering the following command:

     ```
     configure vr vr-name delete protocol protocol-name
     ```

     **Note**
     When you enter the command to delete MPLS from a VR, the software displays a prompt to remind you that the MPLS configuration is lost when MPLS is deleted.

• To add MPLS to VR, do the following:
  a Use the following command:

     ```
     configure vr name add protocol mpls
     ```
  b Add any other protocols that you want to use with MPLS.

After you add MPLS to a VR, you must configure and enable MPLS. MPLS commands operate only in the VR to which MPLS is added. An error message appears if you enter an MPLS command in a VR that does not support MPLS.

Configuring the MPLS LSR ID

The MPLS LSR ID must be configured before MPLS can be used. The address chosen must be a routable IP address on the switch. It is suggested that this be set to the same IP address as a routing protocol ID (for example, the OSPF Router ID).

• To configure the MPLS LSR ID, use the following command:

     ```
     configure mpls lsr-id ipaddress
     ```

     **Note**
     The MPLS LSR ID must be configured before MPLS can be enabled. The LSR ID should be configured on a loopback VLAN.
Adding MPLS Support to VLANs

To use MPLS on a VLAN, MPLS must first be configured on that VLAN.

- To configure a specific VLAN or all VLANs, use the following command:
  
  ```plaintext
  configure mpls add {vlan} vlan_name
  ```

MPLS must be configured on a VLAN before it can be used to transmit or receive MPLS-encapsulated frames. By default, MPLS is not configured on a newly created VLAN.

If you have enabled MPLS on an OSPF interface that is used to reach a particular destination, make sure that you enable MPLS on all additional OSPF interfaces that can reach that same destination (for example, enable MPLS on all VLANs that are connected to the backbone network).

Enabling and Disabling MPLS on an LSR

- To enable MPLS on an LSR, use the following command:
  
  ```plaintext
  enable mpls
  ```

  **Note**

  For SummitStacks, see the ExtremeXOS 22.6 Command Reference Guide description for the `enable mpls` command for special requirements for SummitStacks.

  By default, MPLS is disabled on the switch. This command starts the MPLS process, allowing MPLS protocols to run and MPLS packets to be forwarded.

- To disable MPLS on an LSR, use the following command:
  
  ```plaintext
  disable mpls
  ```

  When you disable MPLS, LDP and RSVP-TE are effectively disabled. The MPLS configuration remains intact.

Enabling and Disabling MPLS on a VLAN

After MPLS is enabled globally, MPLS must be enabled on the MPLS configured VLANs. Configuring a VLAN for MPLS does not enable MPLS on the VLAN. The VLAN must be specifically MPLS enabled in order to send and receive MPLS packets over an interface.

- To enable MPLS on specific VLANs, use the following command:
  
  ```plaintext
  enable mpls [{vlan} vlan_name | vlan all]
  ```

- To disable MPLS on specific VLANs, use the following command:
  
  ```plaintext
  disable mpls [{vlan} vlan_name | vlan all]
  ```

  MPLS must be enabled on all VLANs that transmit or receive MPLS-encapsulated frames. By default, MPLS and MPLS label distribution protocols are disabled when MPLS is first configured on a VLAN.

Enabling LDP on the Switch

- To enable LDP on the switch, use the following command:
  
  ```plaintext
  enable mpls protocol ldp
  ```
By default, LDP is disabled on the switch. This command enables MPLS to process LDP control packets and to advertise and receive LDP labels.

Note
Globally enabling the LDP protocol does not enable LDP on MPLS configured VLANs. See the next section for instructions on enabling LDP on a VLAN.

Enabling and Disabling LDP on a VLAN

Each VLAN must be specifically LDP-enabled in order to set up LDP adjacencies over the interface. Before LDP can be enabled on a VLAN, the VLAN must be configured to support MPLS as described in Adding MPLS Support to VLANs on page 1288.

• To enable LDP on a VLAN, use the following command:

   `enable mpls ldp [{vlan} vlan_name | vlan all]`

   This command enables LDP on one or all VLANs for which MPLS has been configured.

   Note
   If you have enabled LDP and MPLS on an IGP interface that is used to reach a particular destination, make sure that you enable LDP and MPLS on all additional IGP interfaces that can reach that same destination (for example, enable LDP and MPLS on all OSPF VLANs that are connected to the backbone network).

• To disable LDP on a VLAN, use the following command:

   `disable mpls ldp [{vlan} vlan_name | vlan all]`

   This command disables LDP on one or all VLANs for which MPLS has been configured. This command terminates all LDP hello adjacencies and all established LDP LSPs that use the specified interface(s).

Creating Static LSPs

Static LSPs are label switched paths that are manually configured at each LSR in the prospective path. Static LSPs are too labor intensive for building complex network topologies, but they can be useful for defining simple one-hop LSPs to MTUs that might not have the CPU power necessary to support routing and label distribution protocols.

Figure 204 shows two static LSPs configured between VLAN A and VLAN B. The dashed line shows the static LSP for unidirectional communications from VLAN A to VLAN B. The solid line shows the static LSP for communications in the reverse direction.

Figure 204: Static LSP Example
The path that an LSP takes and the labels the LSP uses at every hop do not change when the network topology changes due to links and nodes going up or down. Once enabled, a static LSP remains administratively up until it is manually disabled.

Static LSP configuration is different for ingress, transit, and egress LSRs. At the ingress LER, only an egress label is defined. At transit LSRs, both ingress and egress labels must be defined, and at the egress LER, only the ingress label is defined. During configuration, you must ensure that the egress label number for each LSR matches the ingress label number for the downstream LSR.

When creating static LSPs, consider the following guidelines:

- It is your responsibility to ensure that the egress label of an LSR matches the ingress label of the downstream LSR. The software does not detect or report label mismatches. Mismatches result in dropped or mis-routed packets.
- The operational state of the LSP is set to down at the head-end on local failures. However, there is no mechanism to detect the LSP going down when a failure occurs on a downstream node. When a failure occurs at a downstream node, traffic may be black-holed for the duration of the failure.
- The traffic profile for static LSPs is not configurable in this release. All static LSPs are given best effort treatment.
- The maximum number of static LSPs configurable on any given node is 1024. The maximum number of ingress static LSPs that are used to forward traffic to a single destination is 16 (as limited by ECMP).
- When multiple LSPs exist for the same destination, unless forced otherwise, signaled LSPs are preferred to static LSPs. When choosing an LSP for a FEC, the software prefers RSVP-TE LSPs first, LDP next, and finally static LSPs.
- Since the software has no knowledge of the cost or hop-count associated with each static LSP, all static LSPs to the same destination are equally preferred by IP routing.
- We recommend that the same LSP name be used on every LSR along the path of the static LSP. The software does not check for naming consistency across LSRs. However the switch does report an error when the configured name is not unique to the LSP on that LSR.

To configure a static LSP, use the following procedure at each node on the path:

1. Create a namespace for the LSP using the following command:
   ```
   create mpls static lsp lsp_name destination ipaddress
   ```
2. Configure the appropriate labels for the LSP using the following command:
   ```
   configure mpls static lsp lsp_name [{egress [egress_label | implicit-null] egress-vlan evlan_name next-hop ipaddress] {ingress ingress_label [ingress-vlan ivlan_name]}]
   ```
3. Configure optional traffic restrictions for IP or VPN traffic as needed using the following command:
   ```
   configure mpls static lsp lsp_name transport [ip-traffic [allow | deny] | vpn-traffic [allow {all | assigned-only} | deny]]
   ```
4. Enable the static LSP for operation using the following command:
   ```
   enable mpls static lsp {lsp_name | all }
   ```
5. When the configuration is complete, you can view the static LSP configuration with the following command:
   ```
   show mpls static lsp {summary | {lsp_name} {detail}}
   ```
6. Clear the counters for the static LSP using the command:
   ```
   clear counters mpls static lsp {lsp_name | all }
   ```
7 Once the static LSP is created on all path nodes, you can configure a default route, an IP route, or a VPN route to use the LSP. To configure a default or IP route to use the LSP, use the following command:

```plaintext
configure iproute add default [{gateway {metric} {vr vr_name} (unicast-only | multicast-only)} | {lsp lsp_name {metric}}]
```

8 To configure a VPN route to use the LSP, use the following command:

```plaintext
configure l2vpn [vpls vpls_name | vpws vpws_name] peer ipaddress [add | delete] mpls lsp lsp_name
```

9 To disable a static LSP, use the following command:

```plaintext
disable mpls static lsp {lsp_name | all }
```

10 To delete a static LSP, use the following command:

```plaintext
delete mpls static lsp {lsp_name | all}
```

Configuring Penultimate Hop Popping

- To enable or disable PHP, use the following command:

```plaintext
enable mpls php [{vlan} vlan_name | vlan all]
```

This command enables or disables whether PHP is requested by the egress LER. If vlan all is selected, PHP is enabled on all VLANs on which MPLS has been configured. By default, PHP is disabled.

When PHP is enabled, PHP is requested on all LSPs for which the switch is the egress LER.

PHP is requested by assigning the Implicit Null Label in an advertised mapping. PHP is always performed when requested by a peer (for example, when acting as an intermediate LSR).

Configuring QoS Mappings

The ExtremeXOS software provides examination and replacement services for the EXP field.

These services behave like the dot1p QoS commands. When EXP examination is enabled, the EXP value from the received frame is used to assign the packet to a QoS profile. Once a packet is assigned to a QoS profile, the EXP value may be overwritten in hardware before being transmitted. By default, the QoS profile EXP value is equivalent to the QoS profile number one (QP1). To enable QoS for MPLS LSPs, use the following command: enable mpls exp examination

This command enables EXP examination for MPLS received packets. When EXP examination is enabled, the EXP field in the outer or top label of the label stack is used to assign the received packet to an internal switch qosprofile. If enabled, all MPLS packets are mapped to a qosprofile based on the configured EXP bit value. That is, a packet with an EXP value of 0 is mapped to qosprofile QP1, a packet with an EXP value of 1 is mapped to qosprofile QP2, and so on. By default, EXP examination is disabled and all received MPLS packets are sent to QP1.

Each EXP value can be assigned a qosprofile. Multiple EXP values can be assigned to the same qosprofile. The following command is used to configure the switch to route packets with a received EXP value to a specific qosprofile:
configure mpls exp examination \{value\} value \{qosprofile\} qosprofile

The switch can overwrite the EXP value in the outer label of an MPLS packet.

The following command is used to enable the switch to replace the EXP value:

```
enable mpls exp replacement
```

This command enables EXP replacement for MPLS transmitted packets. When EXP replacement is enabled, the EXP field in the outer or top label of the label stack is replaced with the EXP value configured for the QoS profile for which the packet was assigned. By default, EXP replacement is disabled and packets are propagated without modifying the EXP field value.

Each qosprofile can be assigned an EXP value used to overwrite the EXP bit field in the outer label of the transmitted packet.

All qosprofiles can be configured to overwrite the EXP bit field using the same EXP value. The following command is used to configure the switch to overwrite MPLS packets transmitted from a specific qosprofile with a new EXP value:

```
configure mpls exp replacement \{qosprofile\} qosprofile \{value\} value
```

Note
On the X670-G2 and X770, when exp examination is enabled, the dot1p value of VPLS/VPWS terminated frames are set from the internal priority. The enable/disable dot1p replacement commands do not have any effect in this situation. A future release will eliminate this restriction.

Mapping Dot1p to EXP Bits

The priority of Ethernet tagged packets can be mapped into the MPLS network and vice versa using the switch fabric qosprofile.

Ethernet packets are assigned to a qosprofile by enabling dot1p examination. MPLS packets are assigned to a qosprofile by enabling exp examination. When the packets egress the switch, the dot1p and exp bit fields can be overwritten.

Enabling EXP replacement instructs the switch to overwrite both the dot1p field and the exp field in the outer most label.
By default, when dot1p examination and exp replacement are not enabled, all received packets are routed through qosprofile q1 and the packets are transmitted with the dot1p and exp value of zero. As shown in Figure 205, the switch can be configured to route packets to a specific qosprofile based on the dot1p value in the 802.1p bit field. In this example dot1p examination is enabled. By default, when dot1p examination is enabled, packets are sent to the qosprofile that corresponds dot1p type to qosprofile mapping.

This mapping can be viewed using `show dot1p type`. By default, MPLS exp replacement is disabled. By enabling MPLS exp replacement, MPLS packets are transmitted with the configured qosprofile dot1p and exp value. By default, these values correspond to the qosprofile. Qosprofile 1 overwrites the dot1p and exp fields with 0, qosprofile 2 overwrites the dot1p and exp fields with 1, and so on.

To configure the reverse packet flow, mpls exp examination and dot1p replacement must be configured. Enabling MPLS exp examination instructs the switch to route received MPLS packets to a qosprofile based on the EXP value. Enabling dot1p replacement instructs the switch to write the dot1p value in the transmitted packet.

**Enabling and Disabling LDP Loop Detection**

There are two types of LDP loop detection. By default both are disabled. Enabling loop detection allows the switch to detect if a label advertisement loop exists within the network. Both hop count and path vector loop detection methods are used if loop detection is enabled.

- To enable LDP loop detection, use the following command:
  ```
  enable mpls ldp loop-detection
  ```
- To disable LDP loop detection, use the following command:
  ```
  disable mpls ldp loop-detection
  ```

These commands affect the LDP loop detection behavior for all LDP enabled VLANs.
Configuring an LDP Label Advertisement Filter

- To configure an LDP label advertisement filter, use the following command:
  ```bash
  configure mpls ldp advertise [{{direct [all | lsr-id | none]} | {rip [all | none] | {static [all | none]}}
  ```

  This command configures a filter to be used by LDP when originating unsolicited label mapping advertisements to LDP neighbors.

  You can configure how the direct advertisement filter is applied, as follows:
  - direct—The advertisement filter is applied to the FECs associated with direct routes.
  - rip—The advertisement filter is applied to the FECs associated with RIP routes.
  - static—The advertisement filter is applied to the FECs associated with static routes.

  You can configure the advertisement filter, as follows:
  - all—Unsolicited label mappings are originated for all routes of the specified type (direct, RIP, or static).
  - lsr-id—An unsolicited label mapping is originated if a /32 direct route exists that matches the MPLS LSR ID. This filter is the default setting for direct routes and is only available for direct routes.
  - none—No unsolicited label mappings are originated for all routes of the specified type. This is the default setting for RIP and static routes.

  You can control the number of labels advertised using the `configure mpls ldp advertise` command. Advertising labels for a large number of routes can increase the required number of labels that must be allocated by LSRs. Care should be used to ensure that the number of labels advertised by LERs does not overwhelm the label capacity of the LSRs.

Configuring LDP Session Timers

- To configure LDP session timers, use the following command:
  ```bash
  configure mpls ldp timers [targeted | link] [{hello-time hello_hold_seconds} {keep-alive-time keep_alive_hold_seconds}]
  ```

  This command configures the LDP peer session timers for the switch. The LDP peer session timers are separately configurable for link and targeted LDP hello adjacencies.

  The `hello-time hello_hold_seconds` parameter specifies the amount of time (in seconds) that a hello message received from a neighboring LSR remains valid. The rate at which hello messages are sent is one third the configured hello-time. If a hello message is not received from a particular neighboring LSR within the specified hello-time `hello_hold_seconds` then the hello-adjacency is not maintained with that neighboring LSR. Should two peers have different configured hello-time values, they negotiate to use the lower value.

  The `session keep-alive time keep_alive_hold_seconds` parameter specifies the time (in seconds) during which an LDP message must be received for the LDP session to be maintained. The rate at which keep alive messages are sent, provided there are no LDP messages transmitted, is one sixth the configured keep-alive-time. If an LDP PDU is not received within the specified `session keep-alive time keep_alive_hold_seconds` interval, the corresponding LDP
session is torn down. Should two peers have different configured keep-alive-time values, they negotiate to use the lower value.

In the event that two peers have both a link and a targeted hello adjacency, the hello-time values for the two hello adjacencies are negotiated separately. The keep-alive-time value is established based on negotiations occurring when the LDP session is established following the first hello adjacency to be established.

The minimum and maximum values for both the **hello-time** `hello_hold_seconds` and **keep-alive time** `keep_alive_hold_seconds` are 6 and 65,534, respectively. Changes to targeted timers only affect newly created targeted peers. Disabling and then enabling all VPLS instances causes all current targeted peers to be re-created.

The default values are as follows:

- link ldp hello-time `hello_hold_seconds` - 15
- targeted-ldp hello-time `hello_hold_seconds` - 45
- link ldp hello-time `interval_time` - auto set to 1/3 the configured hello-time
- targeted-ldp hello-time `interval_time` - auto set to 1/3 the configured hello-time
- link ldp keep-alive `keep_alive_hold_seconds` - 40
- targeted-ldp keep-alive `keep_alive_hold_seconds` - 60
- link ldp keep-alive `interval_time` - auto set to 1/6 the configured keep-alive time
- targeted-ldp keep-alive `interval_time` - auto set to 1/6 the configured keep-alive time

### Restoring LDP Session Timers

- To restore the default values for LDP session timers, use the following command:
  
  ```
  unconfigure mpls
  ```

  This command can only be executed when **MPLS** is disabled, and it restores all MPLS configuration settings.

### Clearing LDP Protocol Counters

- To clear the LDP control protocol error counters, use the following command:

  ```
  clear counters mpls ldp {{vlan vlan_name} | lsp all}
  ```

  Omitting the optional `vlan` parameter clears counters for all LDP enabled interfaces.

### Resetting MPLS Configuration Parameter Values

- To reset **MPLS** configuration parameters to their default values, disable MPLS (see Enabling and Disabling MPLS on an LSR on page 1288) and then use the following command:
  
  ```
  unconfigure mpls
  ```

  This command affects the following configuration parameters:
• All VLANs are removed from MPLS.
• All EXP (examination and replacement) QOS mappings are reset.
• LSR-ID is reset.
• LDP and RSVP-TE are globally disabled.
• MPLS Traps are disabled.
• LDP and RSVP-TE timers are reset.
• LDP Advertisement settings are reset.
• LDP Loop Detection settings are reset.
• All RSVP-TE LSPs are deleted.
• All RSVP-TE Paths are deleted.
• All RSVP-TE Profiles are deleted.
• The default RSVP-TE Profile is reset.

Managing the MPLS BFD Client

Bidirectional Forwarding Detection (BFD) is introduced in Bidirectional Forwarding Detection (BFD) on page 432.

The MPLS BFD client enables rapid detection of failures between MPLS neighbors on specific VLANs. BFD detects forwarding path failures at a uniform rate, which makes the re-convergence time consistent and predictable and makes network profiling and planning easier for network administrators.

When BFD detects a communication failure, it informs MPLS, which treats the indication as an interface (VLAN) failure. This allows the MPLS protocols to quickly begin using alternate paths to affected neighbors (the methodology for selecting alternate paths is dependent upon the MPLS protocol in use and how it reacts to interface failure conditions). As MPLS connections (LSPs) are removed from the interface, BFD sessions are removed as well, and the interface returns to a state without BFD protection. The MPLS protocol might continue to attempt to reestablish LSP connections across the interface, and if successful, also attempt to establish a BFD session with the corresponding neighbor. MPLS does not process BFD state changes until the BFD session is fully active in the UP state, at which point state changes are processed and the state for LSPs which cross the interface becomes BFD protected.

Note
BFD sessions are established only when both peers select the same LSP route. We recommend that BFD operate only on interfaces that have one peer.

• To enable the MPLS BFD client, use the following command:
  enable mpls bfd [{vlan} vlan_name | vlan all]

Note
BFD must be enabled on the interface before sessions can be established. To enable BFD, use the command: [enable | disable] bfd vlan vlan_name.

• To disable the MPLS BFD client, use the following command:
  disable mpls bfd [vlan all | {vlan} vlan_name] {delete-sessions}

• To display the MPLS BFD client information, use the following commands:
  show mpls interface {{vlan} vlan_name} {detail}
  show mpls bfd [{vlan} vlan_name | ip_addr]
Displaying MPLS Configuration Information

Displaying MPLS Basic Configuration Information

- To display basic MPLS configuration information, use the following command:
  ```show mpls```

  This command displays the general configuration of all the MPLS components and system wide configuration.

  The output, shown below, displays the switch MPLS, RSVP-TE, and LDP configuration status. It also shows the configuration status of SNMP trap, EXP examination, and EXP replacement settings. The configured LSR ID are also shown.

```
# show mpls
Virtual Router Name : VR-Default
MPLS Admin Status   : Enabled
MPLS Oper Status    : Enabled
RSVP-TE Admin Status: Enabled
RSVP-TE Oper Status : Enabled
LDP Admin Status    : Enabled
LDP Oper Status     : Enabled
MPLS SNMP Traps     : Disabled
L2VPN SNMP Traps    : Disabled
EXP Examination     : Enabled
EXP Replacement     : Disabled
LSR ID              : 192.99.1.5
```

Displaying LDP Basic Configuration Information

- To display basic LDP configuration information, use the following command:
  ```show mpls ldp```

  This command displays the general configuration of LDP.

  Some settings are not configurable. These fields are identified with an asterisk (*). The remaining fields can be modified using LDP configuration commands to change the behavior of LDP. A list of VLANs that have LDP enabled is shown at the bottom of the display output.

```
# show mpls ldp
LDP Status               : Enabled
Protocol Version         : v1*
Label Retention Mode     : Liberal*
Label Distribution Method: Downstream Unsolicited*
LDP Targeted Timers      :
  Hello Hold : 45 seconds
  Keep Alive Hold : 60 seconds
LDP Link Timers          :
  Hello Hold : 15 seconds
  Keep Alive Hold : 40 seconds
Label Advertisement
```
Displaying MPLS Interface Information

- To display the MPLS interface information, use the following command:
  
  ```
  show mpls interface {{vlan} vlan_name} {detail}
  ```

  When the optional parameters are omitted, this command displays information for all the configured MPLS VLAN interfaces.

  The summary MPLS interface information displayed includes the configured IP address, approximate time RSVP-TE and LDP have been up, number of neighbors or adjacencies, and a set of status flags.

  When the `vlan_name` parameter is specified, this command displays the current MPLS interface summary configuration and status for only the specified VLAN. If the optional detail keyword is specified, the summary information is displayed in the detail format.

Displaying LDP Interface Information

- To display LDP interface information, use the following command:
  
  ```
  show mpls ldp interface {{vlan} vlan_name} {detail | counters}
  ```

  This command displays the operational LDP interface information.

  All the VLANs that have LDP enabled are listed. The negotiated LDP hello hold time is displayed. This is not the configured LDP hello hold time but represents the value that is negotiated between the local switch and the connected LDP peer. Hello messages are transmitted every 1/3 the negotiated hello hold time. In the following example, that would be every 5 seconds. The hello timer status information is displayed in milliseconds. The approximate LDP uptime and status flags are also shown.

  ```
  # show mpls ldp interface
  VLAN Name      #Adj  NegHHldTm  NxtHello  UpTm  Flags
  ---------------- ---- --------- -------- ---- -----
  loopback       0    15000     2230    16h   MLU
  blowingrock    1    15000     2200    14h   MLU
  boone          1    15000     2210    16h   MLU
  asheville      1    15000     2210    16h   MLU
  Flags: (M) MPLS Enabled, (L) LDP Enabled, (U) LDP Operational
  ```
Displaying MPLS Label Information

To display MPLS label information, use the following commands:

```
show mpls {rsvp-te | static} label {summary | label_num | [advertised | received] {label_num} | received implicit-null}
show mpls label 13vpn {summary | label_num | [advertised | received] {label_num}}
show mpls {ldp} label {lsp} {summary | label_num | [advertised | received] {label_num} | received implicit-null}
show mpls ldp label {lsp} advertised implicit-null {ipNetmask}
show mpls {ldp} label 12vpn {summary | label_num | [advertised | received] {label_num}}
show mpls ldp label 12vpn retained {ipaddress}
show mpls ldp label lsp retained {ipNetmask}
show mpls ldp label retained [12vpn {ipaddress} | lsp {ipNetmask}]
```

Displaying MPLS Label Mapping Information

To display MPLS label mapping information, use the following command:

```
show mpls ldp lsp {prefix ipNetmask} {ingress | egress | transit} {detail}
show mpls rsvp-te lsp [egress | transit] [fast-reroute] {[destination | origin] ipaddress} {detail} | summary
```

This command displays information about how to forward packets that arrive labeled as MPLS packets. As such, it shows how labels advertised to upstream peers are mapped to labels received from downstream peers. This mapping is sometimes referred to as the Incoming Label Map (ILM).

When the label_number parameter is omitted, summary information is displayed for all incoming label assignments that have been made by the switch. When the label_number is specified, summary information is displayed for the specified label.

As can be seen below, the output display differs for label mappings signaled by LDP and RSVP-TE. Please see the respective sections for additional information.

```
# show mpls ldp lsp
Prefix            Adv Label Peer Label Next Hop        VLAN
192.168.0.4/32    0x80402   --         --              lpbk
192.168.0.2/32    0x00039   0x80400    11.0.2.2        vlan2

ExtremeXOS® User Guide for version 22.6

1299
Displaying MPLS QoS Mapping Information

- To display *MPLS QoS* mapping information, use the following command:

  ```
  * BD-10K.10 # show mpls exp examination
  EXP --> QoS Profile mapping:
  00 --> QP1
  01 --> QP2
  02 --> QP3
  03 --> QP4
  04 --> QP5
  05 --> QP6
  06 --> QP7
  07 --> QP8
  EXP Examination is disabled
  * BD-10K.11 # show mpls exp replacement
  QoS Profile --> EXP mapping:
  QP1 --> 00
  QP2 --> 01
  QP3 --> 02
  QP4 --> 03
  QP5 --> 04
  QP6 --> 05
  QP7 --> 06
  QP8 --> 07
  EXP Replacement is disabled
  * BD-10K.12 #
  ```

  Configured mappings for both dot1p-to-exp and exp-to-dot1p are displayed.

Displaying LDP Peer Session Information

- To display *MPLS* LDP peer session information, use the following command:

  ```
  show mpls ldp peer {ipaddress} {detail}
  ```

  This command displays information about the status of LDP peer sessions. Summary information is displayed for all known LDP peers and LDP peer sessions. If you specify the `ipaddress` of an LDP peer, information for the single LDP peer is displayed. If you specify the `detail` keyword, additional information is displayed in a comprehensive detailed format.

  By default the information displayed includes:
  - Peer sessions
  - Peer state
  - Uptime
  - Number of hello adjacencies

  If you specify the `detail` keyword, the following additional information is displayed:
Displaying LDP Protocol Counters

LDP control protocol packet error counters are maintained per interface.

- To view these counters, use the following command:

  \[\text{show mpls ldp interface \{vlan} \text{ vlan_name} \{\text{detail} | \text{counters}\}\]

  These counters may be useful in determining LDP issues between peers.

Error counters that continually increment should be investigated.

<table>

</tbody>
</table>

Omitting the optional `vlan` parameter displays counters for all LDP enabled interfaces.

Displaying LDP LSP Forwarding Database

- To display information about LDP LSPs, use the following command:

  \[\text{show mpls ldp lsp \{prefix ipNetmask\} \{egress | ingress | transit\} \{detail\}\]

  This command displays the LDP LSPs established to, from, and through this switch. By default, ingress, egress, and transit LSPs are all displayed. By optionally specifying the LSP type, the output display is filtered to show only the type of LSPs specified.

  When all LSP types are being displayed, LSPs that show only an advertised label represent egress LSPs from the network perspective or incoming LSPs from the switch perspective. LSPs that show only a received label represent ingress LSPs from the network perspective or outgoing LSPs from the switch perspective. LSPs that show both an incoming and an outgoing label represent transit LSPs. As Extreme switches are merge-capable, all LDP transit LSPs can also be used as ingress LSPs.
The significance of the VLAN information shown depends on the LSP type. For ingress and transit LSPs, the indicated VLAN is the MPLS interface used to reach the next hop peer. For egress LSPs, there is no associated MPLS next hop interface. When the prefix being advertised is associated with a local (direct) VLAN, that VLAN name is displayed. When the advertised prefix is associated with a static or an RIP route, the VLAN field is empty.

Advertised labels have switch-wide significance and are generally advertised out multiple interfaces.

```
* BD=10K.15 # show mpls ldp lsp
Prefix          Adv Label Peer Label Next Hop        VLAN
192.99.1.5/32   0x80402   --         --              loopback
192.80.40.0/24  0x80403   --         --              asheville
192.100.40.0/24 0x80404   --         --              boone
192.60.40.0/24  0x8040b   --         --              blowingrock
192.24.100.0/24 0x00015  0x80401    192.100.40.3    boone
192.99.1.3/32   0x00016   0x80403    192.100.40.3    boone
192.10.50.0/24  0x00018   0x80405    192.100.40.3    boone
10.20.30.0/24   0x0001c   0x00013    192.100.40.3    boone
11.136.96.0/24  0x0001d   0x00014    192.100.40.3    boone
```

Specifying the optional detail keyword displays each LSP in detail format.

Additionally, received packets and bytes are maintained for transit and egress (or incoming) LSPs. Specifying the keyword prefix and a matching ipNetmask restricts the display to a single entry.

```
**BD=X8.17 # show mpls ldp lsp prefix 11.108.96.0/24 detail
FEC IP/Prefix: 11.108.96.0/24:
Advertised Label: 0 (0)
Received Label  : 0x18 (24)
Next Hop IP     : 192.100.40.3
VLAN Name       : boone
Packets received :        489
Bytes received   :      46944
```

### Displaying RSVP-TE LSP Configuration Information

- To display RSVP-TE LSP configuration information, use the following command:
  ```
  show mpls rsvp-te
  ```

  This command displays summary configuration and status information for RSVP-TE. Global status of RSVP-TE and the configured standard and rapid-retry LSP timer values are included in the display output.

### Displaying the RSVP-TE Paths

- To display RSVP-TE paths, use the following command:
  ```
  show mpls rsvp-te path {path_name} {detail}
  ```

  This command displays the configuration and status information for MPLS RSVP-TE paths. Information is listed in tabular format and includes the path name, number of configured ERO objects, number of LSPs configured to use this path, the list of EROs and their type. Optionally specifying the `detail` keyword displays the path information in verbose format, including all LSPs that are configured to use the path.
Displaying the RSVP-TE Path Profile

- To display RSVP-TE path profiles, use the following command:

  `show mpls rsvp-te profile {profile_name} {detail}`

By default, this command displays all configured profile parameters for the specified profile. If the profile name is omitted, the profile parameter values for all configured LSP profiles are displayed. Optionally specifying the keyword `detail` displays the profile information in verbose format. When the `detail` keyword is specified, all LSPs that are configured to use this profile are also displayed.

Displaying the RSVP-TE LSP

- To display the RSVP-TE LSP, use the following command:

  `show mpls rsvp-te lsp {{[destination | origin] ipaddress} {fast-reroute} {detail} | summary}`

This command displays the LSP information associated with RSVP-TE that is used to forward packets within the MPLS network. If no options are specified, summary information for all RSVP-TE LSPs is displayed. This information includes the LSP name, LSP direction relative to the MPLS network (i.e., ingress, egress, or transit), incoming and or outgoing interface, configured destination, and uptime. If the optional LSP name parameter is specified, only the LSP information for the specified ingress LSP name is displayed. Optionally, the LSPs displayed can be further qualified by the keywords `ingress`, `egress`, and `transit`. These keywords qualify the LSPs displayed from the perspective of the switch.

Ingress LSPs identify LSPs that originate from the switch into the MPLS network. Egress LSPs identify LSPs that terminate at the switch from the MPLS network. Transit LSPs represent LSPs that traverse the switch.

The optional `destination` keyword limits the display to only those LSPs that terminate at the specified IP address. The optional `origin` keyword limits the display to only those LSPs that originate at the specified IP address. Optionally specifying the `detail` keyword displays the LSP information in verbose format. Additional information displayed includes the configured path and profile, transmit and/or receive labels, failure and retry counts, packet and byte counters, and recorded routes.

**MPLS Configuration Example**

The network configuration, shown in Figure 206, illustrates how to configure a BlackDiamond switch to support a routed MPLS network.
Figure 206: MPLS Configuration Example

The four switches, labeled LSR 1, LSR 2, LSR 3, and LSR 4, have the same physical hardware configuration. Each switch contains two 8900-G48T-xl and an 8900-MSM128 module. The switches are all interconnected via Gigabit Ethernet to form the OSPF backbone area and the MPLS domain. In this example, two directly connected OSPF-disabled VLANs are shown: unc and duke. Traffic between unc and duke follows routed paths over calculated LSPs established between LSR 1 and LSR 4.

The commands used to configure LSR 1 are described below. The remaining LSRs are configured similarly.

The following commands configure the module types for specific slots:

```
configure slot 2 module 8900-G48T-xl
configure slot 2 module 8900-G48T-xl
```

The following command sets the maximum jumbo frame size for the switch chassis to 1600:

```
configure jumbo-frame-size size 1600
enable jumbo-frame ports all
```

The following commands create the VLANs:

```
create vlan lpbk
create vlan vlan1
create vlan vlan2
create vlan unc
```

The following commands configure the VLAN IP address and assign ports participating in each VLAN:

```
configure vlan lpbk ipaddress 192.168.0.1/32
enable ipforwarding lpbk
enable loopback-mode lpbk
configure vlan default delete ports all
configure vlan vlan1 ipaddress 11.0.1.1/24
configure vlan vlan1 add port 3:2 untagged
```
The following commands enable IP forwarding on the configured VLANs.

The MTU size is increased on the MPLS VLANs to accommodate the MPLS shim header:

```
enable ipforwarding vlan vlan1
configure ip-mtu 1550 vlan vlan1
enable ipforwarding vlan vlan2
configure ip-mtu 1550 vlan vlan2
enable ipforwarding vlan unc
```

The following command configures the MPLS LSR ID:

```
configure mpls lsr-id 192.168.0.1
```

The following commands add MPLS support to VLANs lpbk, vlan1, and vlan2:

```
configure mpls add vlan lpbk
configure mpls add vlan vlan1
configure mpls add vlan vlan2
```

The following commands enable MPLS on VLANs lpbk, vlan1, and vlan2 and LDP on VLANs vlan1 and vlan2:

```
enable mpls lpbk
enable mpls vlan1
enable mpls vlan2
enable mpls ldp vlan1
enable mpls ldp vlan2
```

The following command allows LDP to advertise a label mapping for the LSR ID:

```
configure mpls ldp advertise direct lsr-id
```

The following commands globally enable LDP and MPLS on the switch:

```
enable mpls protocol ldp
enable mpls
```

The following commands add lpbk, vlan1, and vlan2 to the backbone area.

The 0.0.0.0 (backbone) area does not need to be created because it exists by default:

```
configure ospf add vlan lpbk area 0.0.0.0
configure ospf add vlan vlan2 area 0.0.0.0
configure ospf add vlan vlan1 area 0.0.0.0
```

The following command enables distribution of local (direct) interfaces into the OSPF area:

```
enable ospf export direct cost 10 type ase-type-1
```

The following command configures the OSPF router ID on the switch and enables the distribution of a route for the OSPF router ID in the router LSA.
Originating the router ID as a host route allows other routers in the same OSPF area to establish calculated LSPs for external routes to this router:

```
configure ospf routerid 192.168.0.1
```

It also allows this router to be a peer in a L2 VPN.

The following command enables OSPF:

```
enable ospf
```

## Configuring MPLS Layer-2 VPNs (VPLS and VPWS)

**Note**

ELRP should not be used to protect VPLS service VLANs because ELRP is not aware of VPLS pseudowires.

### Configuring MPLS for Establishing Layer 2 VPN Instances

As described in Using LDP to Signal PW Label Mappings on page 1246, **MPLS** and LDP must be properly configured in order to establish the PWs that make up a Layer 2 VPN.

MPLS should be enabled using the `enable mpls` command and LDP should be enabled using the `enable mpls protocol ldp` command.

Since the MPLS LSR ID is used as the local endpoint for PWs, it is highly desirable to create a loopback VLAN whose associated IP address is that of the MPLS LSR ID. The configured prefix length should be 32. As described in Establishing LDP LSPs to PW Endpoints on page 1245, configuring this loopback VLAN for MPLS causes the address to be included in LDP address messages. Use the `configure mpls add vlan vlan_name` command for this. It is not required that LDP or MPLS be enabled on the VLAN for the address to be advertised by LDP. Use the `configure mpls ldp advertise direct lsr-id` command to initiate an LDP label mapping for an LDP LSP to the local endpoint.

### Creating or Deleting a Layer 2 VPN Domain

- To create a Layer 2 VPN, use the following command:

  ```
  create 12vpn [vpls vpls_name | vpws vpws_name] fec-id-type pseudo-wire pwid
  ```

  This command creates a named Layer 2 VPN instance. Multiple domains can be created, each representing a different L2 VPN. The pwid is a number that is used to signal and identify which Layer 2 VPN is associated with each pseudowire. All of the pseudowires carrying traffic for a specific Layer 2 VPN are signaled with the same pwid. No Layer 2 VPN traffic is forwarded over the Layer 2 VPN until at least one peer is added to the Layer 2 VPN and a service is associated with the Layer 2 VPN. The configured pwid also doubles as the Layer 2 VPN ID.

- To delete a Layer 2 VPN, use the following command:

  ```
  delete 12vpn [vpls [vpls_name | all] | vpws [vpws_name | all]]
  ```
This command deletes the named Layer 2 VPN instance or all Layer 2 VPN instances, depending on the keyword. All Layer 2 VPN peers and services associated with the deleted Layer 2 VPN instance(s) are also deleted.

Enabling or Disabling a Layer 2 VPN Domain

- To enable a Layer 2 VPN, use the following command:
  ```bash
  enable 12vpn [vpls [vpls_name | all] | vpws [vpws_name | all]]
  ```

  This command enables a named Layer 2 VPN instance. By default, a newly created Layer 2 VPN is enabled.

- To disable a Layer 2 VPN, use the following command:
  ```bash
  disable 12vpn [vpls [vpls_name | all] | vpws [vpws_name | all]]
  ```

  This command disables the named Layer 2 VPN instance. When a Layer 2 VPN is disabled, no traffic flows across the Layer 2 VPN. The pseudowires connecting this peer to all other configured peers are also terminated, so the remote peers no longer see this LSR as an active peer.

Adding or Deleting a Layer 2 VPN Peer

- To add a peer to the Layer 2 VPN, use the following command:
  ```bash
  configure 12vpn [vpls vpls_name | vpws vpws_name] add peer ipaddress
  {{core {full-mesh | primary | secondary} | spoke}
  ```

  For each new peer added, a pseudowire is signaled to carry traffic for this Layer 2 VPN. Up to 64 peers can be added to a VPLS; and only one peer can be added to a VPWS. For each peer added, that remote peer must also configure this local LSR as a peer for the Layer 2 VPN. For VPLS configurations, this insures that the VPLS core is configured as a full mesh of VPLS peers.

  The Layer 2 VPN names on each peer do not have to match since the pseudowire ID is used to define the Layer 2 VPN to which each pseudowire is associated.

- Delete a peer from the Layer 2 VPN, use the following command:
  ```bash
  configure 12vpn [vpls vpls_name | vpws vpws_name] delete peer
  [ipaddress | all]
  ```

  Once the peer is deleted, that specified peer is no longer a member of the Layer 2 VPN. For VPLS configurations, the peer must also be removed from all other VPLS peers to insure a proper full mesh and to prevent connectivity issues.

Add or Delete a Layer 2 VPN Service

- To add a service to a Layer 2 VPN, use the following command:
  ```bash
  configure 12vpn [vpls vpls_name | vpws vpws_name] add service [{vlan}
  vlan_name | {vman} vman_name]
  ```

  Only one service can be added to each Layer 2 VPN. Traffic associated with the service is transported over the Layer 2 VPN. Three basic types of services are supported: VLAN, VMAN, and port. Both the VLAN and VMAN services are specified by adding the VLAN or VMAN name to the
Layer 2 VPN. The port service is configured by adding a VMAN name to the Layer 2 VPN, configuring the Layer 2 VPN to strip the VMAN tag, and adding the port as untagged to the VMAN. This allows incoming service traffic to be transported across the Layer 2 VPN exactly as it was received. See Managing Layer 2 VPN Packet Forwarding Options on page 1308 for information about configuring a Layer 2 VPN to strip the VMAN tag.

• To delete a service from a Layer 2 VPN, use the following command:

```bash
configure l2vpn [vpls vpls_name | vpws vpws_name] delete service [{vlan} vlan_name | {vman} vman_name]
```

Since there is no local service that needs to be connected to the Layer 2 VPN, the pseudowires to each of the configured peers for this Layer 2 VPN are terminated.

**Note**
Ports added to Layer 2 VPN service VPLS/VMAN should not be part of PVLAN or VLAN aggregation or VLAN translation.

### Enabling or Disabling a Layer 2 VPN Service

• To enable a Layer 2 VPN service, use the following command:

```bash
enable l2vpn [vpls [vpls_name | all] | vpws [vpws_name | all]] service
```

By default, any configured Layer 2 VPN service is enabled.

• To disable a service from the Layer 2 VPN, use the following command:

```bash
disable l2vpn [vpls [vpls_name | all] | vpws [vpws_name | all]] service
```

When the service is disabled, the service is disconnected from the Layer 2 VPN and disabled such that no packets are sent to or received from the service. The pseudowires to each of the configured peers for this Layer 2 VPN are terminated.

### Managing Layer 2 VPN Packet Forwarding Options

• To configure Layer 2 VPN packet forwarding options, use the following command:

```bash
configure l2vpn [vpls vpls_name | vpws vpws_name] {dot1q [ethertype hex_number | tag [include | exclude]]} {mtu number}
```

The options should be configured the same for every LSR for this Layer 2 VPN in order to prevent connectivity issues. Specifying the dot1q ethertype forces the switch to overwrite the dot1q ethertype value in the service packet. This can be used to interconnect two customer segments over the Layer 2 VPN that are using different configured ethertype values. By default, the dot1q tag in the service packet is not included. The switch can be configured to strip or exclude the dot1q tag. This can be used to emulate port services or for interoperability with equipment that may require tags.

• To unconfigure Layer 2 VPN packet forwarding options, use the following command:

```bash
unconfigure l2vpn [vpls vpls_name | vpws vpws_name] dot1q ethertype
```

This command resets the dot1q ethertype for the specified Layer 2 VPN to the default ethertype configured for the switch.
Configuring the Layer 2 VPN MTU

The Maximum Transmission Unit (MTU) is the maximum packet size (excluding the data link header) that an interface can transmit. The Layer 2 VPN MTU defines the MTU for the customer facing interface. By default, the MTU size is set to 1500 bytes, which is the MTU size for standard Ethernet frames.

The frame size of the customer packet also includes the data link header and FCS field. The Ethernet data link header includes a minimum of a destination MAC address (six bytes), a source MAC address (six bytes), and an ethertype field (two bytes). The FCS field is four bytes. For a 1500-byte customer payload, the minimum customer frame size is 1518 bytes.

The Layer 2 frame, minus the FCS field, is encapsulated to form an MPLS packet to be transmitted to a Layer 2 VPN peer. This encapsulation adds another Ethernet header, an MPLS shim header, and a FCS field. The MPLS shim header usually includes two four-byte MPLS labels. Therefore, this encapsulation adds a minimum of 26 bytes.

The total frame size includes the customer payload, the Ethernet header on the customer facing interface (minimum 14 bytes), and the MPLS encapsulation (minimum 26 bytes). For a 1500-byte customer payload, the minimum Layer 2 VPN frame size is 1540 bytes.

The total frame size is restricted by the jumbo frame size. The maximum jumbo frame size that can be configured is 9216 bytes. If the customer payload in the above example is increased to 9176 bytes, the resulting Layer 2 VPN encapsulated frame size is 9216 bytes. Therefore, the maximum practical value of the Layer 2 VPN MTU is 9176 bytes.

There are additional considerations that can lower the maximum practical value of the Layer 2 VPN MTU setting. If the Layer 2 VPN is configured to include the VLAN tag of the customer interface, this increases the total frame size by four bytes. If the MPLS interface used to transmit the encapsulated Layer 2 VPN packet is a tagged VLAN, this also increases the total frame size by four bytes. If either of these configuration options is present, the maximum practical Layer 2 VPN MTU size is reduced accordingly.

- To configure the Layer 2 VPN MTU size, use the `mtu` option in the following command:

  ```
  configure l2vpn [vpls vpls_name | vpws vpws_name] {dot1q [ethertype hex_number | tag [include | exclude]]} {mtu number}
  ```

  The Layer 2 VPN MTU value is signaled to peers as part of the VC FEC information during PW setup. The local value must match the value received from the PW peer. If the two values do not match, the PW is not established.

Managing VPLS Redundancy Options

- To configure VPLS redundancy options, use the following command:

  ```
  configure {l2vpn} vpls vpls_name redundancy [esrp esrpDomain | eaps | stp]
  ```

- To unconfigure VPLS redundancy options, use the following command:

  ```
  unconfigure {l2vpn} vpls vpls_name redundancy [eaps | esrp | stp]
  ```

- To display the configured VPLS redundancy option, use the following command:

  ```
  show l2vpn vpls {vpls_name} {peer ipaddress} detail
  ```
Displaying Layer 2 VPN Status

- To display the status of all Layer 2 VPNs, a configured Layer 2 VPN, or a specific peer within a specific Layer 2 VPN, use the following command:

  ```
  show [ {l2vpn} vpls {vpls_name} | l2vpn vpws {vpws_name} | l2vpn ]
  (peer ipaddress) (detail) | summary
  ```

Displaying Layer 2 VPN Statistics

- To display statistics for Layer 2 VPNs, use the following command:

  ```
  show mpls statistics l2vpn {vpls_name | vpws_name} {detail}
  ```

Managing Layer 2 VPN SNMP Traps

- To enable or disable Layer 2 VPN SNMP traps, use the following commands:

  ```
  enable snmp traps l2vpn
  disable snmp traps l2vpn
  ```

- To configure or remove a text-string identification for traps from a Layer 2 VPN, use the following command:

  ```
  configure vpls vpls_name snmp-vpn-identifier identifier
  unconfigure vpls vpls_name snmp-vpn-identifier
  ```

- To view the configured state for Layer 2 VPN SNMP traps, use the following command:

  ```
  show mpls
  ```

VPLS VPN Configuration Examples

Basic Point-to-Point VPLS Configuration Example

This MPLS VPLS network configuration shown Figure 207, builds upon the routed MPLS network configuration example shown in MPLS Configuration Example on page 1303.
Figure 207: MPLS VPLS Configuration Example

Assuming that the routed MPLS network has already been configured as in the previous example, the commands used to create the VPLS on LSR1 and LSR4 follow. The nc-university-vpn is a point-to-point VPLS, since only two peers are participating.

The following command creates the VPLS with VPN ID 35. This command must be issued on both LSR1 and LSR4:

```
create l2vpn vpls nc-university-vpn fec-id-type pseudo-wire 35
```

The following command enables the VPLS instance specified by the vpls_name:

```
enable l2vpn [vpls [ vpls_name | all ]]
```

On LSR1, configure the local VLAN service and the VPLS peer:

```
configure l2vpn vpls nc-university-vpn add service vlan unc-charlotte
configure l2vpn vpls nc-university-vpn add peer 192.168.0.4
```

On LSR4, configure the local VLAN service and the VPLS peer:

```
configure l2vpn vpls nc-university-vpn add service vlan unc-wilmington
configure l2vpn vpls nc-university-vpn add peer 192.168.0.1
```

### Multipoint Full Mesh VPLS Configuration Example

The example shown in Figure 208 configures a four node full-mesh MPLS VPLS configuration by adding two additional peers to the previous example.
VPLS with Redundant EAPS Configuration Example

The following sections provide examples of how to configure switches to support the configuration described in VPLS EAPS Redundancy Overview on page 1265:
Core 1 Router Configuration

The following example shows the EAPS and VPLS configuration for the Core 1 router.

```bash
//create the EAPS protected VLAN and the VPLS service vlan
create vlan v1
configure v1 add ports 2:3 // port 2:3 is the port connected to dist 1
create eaps eaps2
configure eaps eaps2 mode transit
configure eaps eaps2 primary port 2:1 // port going to core 2
configure eaps eaps2 secondary port 2:3
configure eaps eaps2 add control vlan ctrl2 // eaps control vlan
configure eaps eaps2 add protected vlan v1
create eaps shared-port 2:1
configure eaps shared-port 2:1 mode controller
configure eaps shared-port 2:1 link-id 888
enable eaps2
create vpls vpls1 fec-id-type pseudo-wire 2
configure vpls vpls1 add service vlan v1
configure vpls vpls1 redundancy eaps
configure vpls vpls1 add peer <core2>
configure vpls vpls1 add peer <core3>
configure vpls vpls1 add peer <core4>
```

Core 2 Router Configuration

The following example shows the EAPS and VPLS configuration for the Core 2 router.

```bash
//create the EAPS protected VLAN and the VPLS service vlan
create vlan v1
configure v1 add ports 2:9 // port 2:9 is the port connected to dist 5
create eaps eaps2
configure eaps eaps2 mode transit
configure eaps eaps2 primary port 2:1 // port going to core 1
configure eaps eaps2 secondary port 2:9
configure eaps eaps2 add control vlan ctrl2
configure eaps eaps2 add protected vlan v1
create eaps shared-port 2:1
configure eaps shared-port 2:1 mode partner
configure eaps shared-port 2:1 link-id 888
enable eaps2
create vpls vpls1 fec-id-type pseudo-wire 2
configure vpls vpls1 add service vlan v1
configure vpls vpls1 redundancy eaps
configure vpls vpls1 add peer <core1>
configure vpls vpls1 add peer <core3>
configure vpls vpls1 add peer <core4>
```

Configuring H-VPLS

H-VPLS is configured at the edge of the network. The core of the network supports H-VPLS and is configured as described in Configuring MPLS Layer-2 VPNs (VPLS and VPWS) on page 1306. To configure H-VPLS, you need to configure the H-VPLS spoke nodes and the PE core nodes that peer with the spoke nodes.
Configuring H-VPLS Spoke Nodes

• To configure an MTU as an H-VPLS spoke node, use the following command:

```
configure l2vpn [vpls vpls_name | vpws vpws_name] add peer ipaddress
{{core {full-mesh | primary | secondary} | spoke}
```

Use the `core primary` and `core secondary` command options as needed. The `core primary` option specifies that the spoke node peer is a core node and that the link between the peers is the primary spoke. The `core secondary` option specifies that the spoke node peer is a core node and that the link between the peers is the secondary spoke.

• To delete an H-VPLS spoke node, use the following command:

```
configure l2vpn [vpls vpls_name | vpws vpws_name] delete peer
[ipaddress | all]
```

Configuring H-VPLS Core Nodes

• To configure a VPLS core node as an H-VPLS core node, use the following command:

```
configure l2vpn [vpls vpls_name | vpws vpws_name] add peer ipaddress
{{core {full-mesh | primary | secondary} | spoke}
```

Use the `spoke` command option to specify that the peer is an H-VPLS spoke node. When the H-VPLS spoke and core peers are configured, VPLS communications can be established between them.

Note
To enable communications from the H-VPLS spoke across the VPLS network, the H-VPLS core node must also be configured to peer with the other VPLS nodes.

• To delete an H-VPLS core node, use the following command:

```
configure l2vpn [vpls vpls_name | vpws vpws_name] delete peer
[ipaddress | all]
```

Configuring the MAC Address Withdrawal Feature

The MAC address withdrawal feature is enabled by default.

• To disable this feature, use the following command:

```
disable l2vpn vpls peer [ipaddress | all] fdb send-mac-withdrawal
```

• To enable this feature after it has been disabled, use the following command:

```
enable l2vpn vpls peer [ipaddress | all] fdb send-mac-withdrawal
```

Displaying H-VPLS Configuration Information

• To display H-VPLS configuration information, use the following command:

```
show [{l2vpn} vpls {vpls_name} | l2vpn vpws {vpws_name} | l2vpn ]
{peer ipaddress} {detail} | summary }
```
Configuring Protected VPLS

- To configure a protected VPLS, use the following command:
  ```
  create esrp esrp_domain {type [vpls-redundancy | standard]}
  configure {l2vpn} vpls vpls_name redundancy [esrp esrpDomain | eaps | stp]
  ```
- To unconfigure a protected VPLS, use the following command:
  ```
  unconfigure {l2vpn} vpls vpls_name redundancy [eaps | esrp | stp]
  ```
- To display information about the protected VPLS, use the following command:
  ```
  show esrp { {name} | {type [vpls-redundancy | standard]}}
  ```

Configuring RSVP-TE

Enabling and Disabling RSVP-TE on the Switch

- To enable RSVP-TE on a switch, use the following command:
  ```
  enable mpls protocol rsvp-te
  ```
- To disable RSVP-TE on a switch, use the following command:
  ```
  disable mpls protocol rsvp-te
  ```

Note

MPLS must be globally enabled before RSVP-TE can become operational. For more information, see Enabling and Disabling MPLS on an LSR on page 1288.

Enabling and Disabling RSVP-TE on a VLAN

- To enable RSVP-TE on one or all VLANs, use the following command:
  ```
  enable mpls rsvp-te [{vlan} vlan_name | vlan all]
  ```
- To disable RSVP-TE on one or all VLANs, use the following command:
  ```
  disable mpls rsvp-te te [{vlan} vlan_name | vlan all]
  ```

Disabling RSVP-TE on a VLAN causes all TE LSPs using that interface to be released, and prevents TE LSPs from being established or accepted on the specified VLAN.

Configuring RSVP-TE Protocol Parameters

- To configure RSVP-TE protocol parameters, use the following command:
  ```
  configure mpls rsvp-te timers session[{bundle-message-time
  bundle_message_milliseconds} {hello-keep-multiplier hello_keep_number}
  {hello-time hello_interval_seconds} {refresh-keep-multiplier
  refresh_keep_number} {refresh-time refresh_seconds} {summary-refresh-
  time summary_refresh_milliseconds}] [{vlan} vlan_name | vlan all]
  ```
This command configures the RSVP-TE protocol parameters for the specified VLAN. The RSVP-TE keyword `all` indicates that the configuration changes apply to all RSVP-TE enabled VLANs.

The hello-interval time specifies the RSVP hello packet transmission interval. The RSVP hello packet is used by the switch to detect when an RSVP-TE peer is no longer reachable. If an RSVP hello packet is not received from a peer within \([\text{hello-interval} \times \text{keep-multiplier}]\) seconds, the peer is declared down and all RSVP sessions to and from that peer are torn down. The default hello-interval time is zero, indicating that RSVP hellos are not enabled. The hello-interval can be set to any value between zero and 60 seconds.

The `refresh-time` parameter specifies the interval for sending refresh path messages. RSVP refresh messages provide soft state link-level keep-alive information for previously established paths and enable the switch to detect when an LSP is no longer active. RSVP sessions are torn down if an RSVP refresh message is not received from a neighbor within \([(\text{keep-multiplier} + 0.5) \times 1.5 \times \text{refresh-time}]\) seconds. The default `refresh-time` is 30 seconds and the default keep-multiplier value is three. The minimum and maximum `refresh-time` values are one and 36,000 seconds (or ten hours), respectively. The minimum and maximum keep-multiplier values are one and 255, respectively.

The bundle-time, specified in tenths of a second, indicates the maximum amount of time a transmit buffer is held so that multiple RSVP messages can be bundled into a single PDU. The default bundle-time is zero, indicating that RSVP message bundling is not enabled. The bundle-time value can be set to any value between zero and 30 (or 3 seconds).

The summary-refresh-time, specified in tenths of a second, indicates the time interval for sending summary refresh RSVP messages. The summary-refresh-time must be less than the configured `refresh-time`. The default summary-refresh-time is zero, indicating that no summary refresh RSVP messages are sent. The summary-refresh-time value may be set to any value between zero to 100 (or 10 seconds).

If configured, the bundled and summary refresh RSVP messages are only sent to RSVP-TE peers supporting RSVP refresh reduction.

**Creating or Deleting an RSVP-TE LSP**

- To create an RSVP-TE LSP, use the following command:

  ```
  create mpls rsvp-te lsp lsp_name destination ipaddress
  ```

  The `lsp_name` parameter is a character string that identifies the LSP within the switch. The `lsp_name` string must begin with an alphabetic character and can contain up to 31 additional alphanumeric characters. The LSP is not signaled until at least one path is added. See Adding a Path to an RSVP-TE LSP on page 1320.

- To delete an RSVP-TE LSP, use the following command:

  ```
  delete mpls rsvp-te lsp [lsp_name | all]
  ```

  Deleting an LSP name disassociates all configured paths with this LSP and all configuration information for the LSP name is deleted. If the LSP has been specified for use by a static route or a VPLS, that configuration information is also deleted. If you specify the `all` keyword, all LSPs are deleted.
Creating an RSVP-TE Path

- To create an RSVP-TE routed path resource, use the following command:
  `create mpls rsvp-te path path_name`

  The `path_name` parameter is a character string that is used to identify the path within the switch. The `path_name` string must begin with an alphabetic character, and can contain up to 31 additional alphanumeric characters. The RSVP-TE LSP is not signaled along the path until an LSP adds the specified path name. The maximum number of configurable paths is 1000.

- To delete an RSVP-TE path, use the following command:
  `delete mpls rsvp-te path [path_name | all]`

  This command deletes a configured MPLS RSVP-TE routed path with the specified `path_name`. All associated configuration information for `path_name` is deleted. A path cannot be deleted as long as the `path_name` is associated with an LSP. If the `all` keyword is specified, all paths not associated with an LSP are deleted.

Configuring an Explicit Route

The routed path for an RSVP-TE LSP can be described by a configured sequence of the LSRs and/or subnets traversed by the path. Each defined LSR or subnet represents an ERO subobject. Up to 64 subobjects can be added to each path name. LSRs and/or subnets can be either included or excluded.

- To add an RSVP-TE explicit route, use the following commands:
  - To specify an LSR or subnet to be included in the path calculation:
    `configure mpls rsvp-te path path_name add ero {include} ipNetmask [strict|loose] {order number}`
  - To specify an LSR or subnet to be excluded from the path calculation:
    `configure mpls rsvp-te path path_name add ero exclude ipNetmask {order number}`

  These commands add an IP address to the explicit route object (ERO) for the specified path name. The include keyword is optional and the default behavior is to define an ERO that must be included in the path. The exclude keyword allows a path to be created that must avoid certain subnets. This can be useful when defining redundant LSPs or paths that must avoid the path of other LSPs or paths.

  The `ipaddress` keyword identifies an LSR using either a /32 address, which may represent an LSR router ID, loopback address, or direct router interface, or an IP prefix, which represents a directly connected subnet. Each IP address or prefix is included in the ERO as an IPv4 subobject.

  For EROs that are configured to be included in the path calculation, if the IP address is specified as strict, the strict subobject must be topologically adjacent to the previous subobject as listed in the ERO. If the IP address is specified as loose, the loose subobject is not required to be topologically adjacent to the previous subobject as listed in the ERO. If omitted, the default subobject attribute is loose.
For EROs that are configured to be excluded in the path calculation, a given subnet is avoided if any address on that subnet is specified.

If the subobject matches a direct router interface or a directly attached subnet, the switch verifies that the path message is received on the matching router interface. The LSR path order is optionally specified using the order keyword. The order number parameter is an integer value from 1 to 65535. IP prefixes with a lower order number are sequenced before IP prefixes with a higher number. You can specify multiple addresses and assign them an order number. The order number determines the path that the LSP follows. Thus, the LSP follows the configured path of the IP prefix with the order value from low to high. If the order keyword is not specified, the number value for the LSR defaults to a value 100 higher than the current highest number value. For excluded nodes, the order is not important. Any excluded ERO will be always be avoided no matter where it is in the list of ERO objects.

If the list of IP prefixes added to the path does not reflect an actual path through the network topology, the path message is returned with an error from a downstream LSR and the LSP is not established.

The order of a configured subobject can not be changed. The ERO subobject must be deleted and re-added using a different order. If a subobject is added to or deleted from the ERO while the associated LSP is established, the path is torn down and is resignaled using the new ERO. Duplicate ERO subobjects are not allowed. Defining an ERO for the path is optional. If you do not configure an ERO, the path is signaled along the best CSPF calculated path and the ERO is not included in the path message. When the last subobject in the ERO of the path message is reached and the egress IP node of the path has not been reached, the remaining path to the egress node is signaled along the best CSPF calculated path. Specification of an ERO could lead to undesirable routed paths, so care should be taken when terminating the ERO routed-path definition prior to the configured path egress node.

To delete an RSVP-TE explicit route, use the following command:

```
configure mpls rsvp-te path path_name delete ero [all | ipNetmask | order number]
```

This command deletes an LSR or subnet from the ERO for the specified path name. The LSR is specified using the `ipaddress` or `order` parameter. If an LSR is deleted from an ERO while the associated LSP is established, the path is torn down and is resignaled using a new ERO. Use the all keyword to delete the entire ERO from the path name. When there is no configured ERO, the path is no longer required to take an explicit routed path. The path is then signaled along the best CSPF calculated path and no ERO is included in the path message.

### Reserving Bandwidth for MPLS

In order to manage the bandwidth used by MPLS RSVP-TE LSPs, a configured amount of bandwidth must be reserved for MPLS. Bandwidth in the transmit direction must be reserved on all MPLS interfaces which will be used as egress interfaces for RSVP-TE LSPs requesting bandwidth. Bandwidth in the receive direction can be optionally reserved on all MPLS interfaces that will be used as ingress interfaces for RSVP-TE LSPs requesting bandwidth. Note that the receive bandwidth reservation can be exceeded, and is provided only for tracking and informational purposes.

- The following command is used to reserve bandwidth for MPLS:

```
configure mpls rsvp-te bandwidth committed-rate committed_bps [Kbps | Mbps | Gbps] [{vlan} vlan_name | vlan all] {receive | transmit | both}
```
The committed_rate_unit must be specified in Kbps, Mbps, or Gbps. Choosing the `vlan all` option reserves the specified amount of bandwidth on all MPLS interfaces.

The default reserved value is zero. Therefore, no LSPs requesting bandwidth can be established until the bandwidth has been configured.

Creating and Deleting an RSVP-TE Profile

- To create a traffic engineered LSP profile, use the following command:

  ```
  create mpls rsvp-te profile profile_name {standard}
  ```

  This command creates a configured RSVP-TE profile with the specified profile name. The default profile cannot be deleted. If a profile is associated with a configured LSP, the profile cannot be deleted.

- To delete a traffic engineered LSP profile, use the following command:

  ```
  delete mpls rsvp-te profile [profile_name | all]
  ```

Configuring an RSVP-TE Profile

- To configure an RSVP-TE profile, use the following command:

  ```
  configure mpls rsvp-te profile profile_name {bandwidth [best-effort | [(committed-rate committed_bps [Kbps | Mbps | Gbps]) {max-burst-size burst_size [Kb | Mb]} {peak-rate peak_bps [Kbps | Mbps | Gbps]}]} {hold-priority hold_priority} {mtu [number | use-local-interface]} {path-computation [full | partial]} {record [enabled | route-only] | disabled} | setup-priority setup_priority}
  ```

  A profile is a set of attributes that are applied to the LSP when the LSP is configured using the `create mpls rsvp-te lsp` command. A default profile is provided which cannot be deleted, but can be applied to any configured LSP. The profile name for the default profile is `default`. The default profile parameter values are initially set to their respective default values. The maximum number of configurable profiles is 1000 (one of which is reserved for the default profile).

  The `bandwidth` parameter specifies the desired reserved bandwidth for the LSP. Any positive integer value is valid. You must append the characters k for kilobits, m for megabits, or g for gigabits, to the bps value to specify the unit of measure. The default bandwidth bps value is zero, which indicates that the QoS for the LSP is best effort.

  The `max-burst-size` and `peak-rate` parameters are signaled in the sender Tspec object and add further definition of the expected traffic. The `mtu` parameter is also signaled in the sender Tspec object and defines the expected maximum packet size that is sent over the LSP.

  The `setup-priority` and `hold-priority` are optional parameters indicating the LSP priority. During path set up, if the requested bandwidth cannot be reserved through the LSR, the `setup-priority` parameter is compared to the `hold-priority` of existing LSPs to determine if any of the existing LSPs need to be preempted to allow a higher priority LSP to be established. Lower numerical values represent higher priorities. The `setup-priority` range is 0 to 7 and the default value is 7. The `hold-priority` range is also 0 to 7 and the default value is 0.
The **path-computation** keyword specifies computation strategy for calculating a path to the LSP destination. “full” requires the ingress node to fully calculate a path to the LSP destination. “partial” allows the ingress node to calculate only part of the path to the LSP destination.

**Note**
Inter area RSVP fast reroute (FRR) is not supported.

The **record** keyword is used to enable hop-by-hop path recording. The enabled keyword causes the record route object (RRO) to be inserted into the path message. The RRO is returned in the reserve message and contains a list of IPv4 subobjects that describe the RSVP-TE path. Path recording by default is disabled. When disabled, no RRO is inserted into the path message.

- To delete an RSVP-TE path profile, use the following command:
  ```
  delete mpls rsvp-te profile [profile_name | all]
  ```

  This command deletes a configured RSVP-TE profile with the specified profile name. The default profile cannot be deleted. If a profile is associated with a configured LSP, the profile cannot be deleted. If you specify the **all** keyword, all profiles not associated with an LSP are deleted (except for the default profile).

### Adding a Path to an RSVP-TE LSP

- To add a path to an RSVP-TE LSP, use the following command:
  ```
  configure mpls rsvp-te lsp lsp_name add path [path_name | any]
  {profile profile_name} {primary {frr_profile_name} | secondary}
  ```

  This command adds a configured path to the specified RSVP-TE LSP. The LSP name parameter is a character string that is to be used to identify the LSP within the switch and must have been created previously. The LSP is not signaled until a path is added to the LSP. Up to three paths can be defined for the LSP: one primary and two secondary. All paths are signaled, but only one path is used to forward traffic at any one time. The switch chooses the local **MPLS VLAN** interface from which to signal the LSP. To force an LSP to use a specific local MPLS interface, configure the peer’s interface IP address as the first ERO in the associated path. The profile name is optional. If omitted, the default profile is applied to the LSP. The path name can be specified or the LSP can be configured to take any path. For a given LSP, only one path can be configured to take any path through the MPLS network.

  The specified path defaults to primary when no primary path has been configured for the LSP and defaults to secondary if the primary path has been previously configured for the LSP.

  Each **path_name** added to an **lsp_name** must be unique, but a **path_name** can be associated with multiple LSP names.

  All configured primary and secondary paths for the **lsp_name** must have the same endpoint IP address. For example, three paths can be configured for the **lsp_name**, but all paths should represent different topological paths through the network to the same LSP endpoint.

  Adding a secondary **path_name** designates a path as a hot-standby redundant path, used in the event that the primary or the other secondary path cannot be established or fails. Provided the **path_name** has not already been established, all paths are signaled as soon as they are associated.
with an `lsp_name`. If the primary `path_name` fails, is not configured, or cannot be established after the specified LSP retry-timeout, one of the configured secondary paths becomes the active path for `lsp_name`. All of the secondary paths have equal preference; the first one available is chosen. If at any time the primary path is reestablished, `lsp_name` immediately switches to using the primary path. If a secondary path fails while in use, the remaining configured secondary path can become the active path for `lsp_name`.

- To delete a path from an RSVP-TE LSP, use the following command:
  ```bash
  configure mpls rsvp-te lsp lsp_name delete path [path_name | any | all]
  ```
  When you issue this command, the LSP associated with the path is immediately torn down. If the deleted path represents the in-use LSP for `lsp_name` and another secondary path is configured, the LSP immediately fails over to an alternate LSP. Because at least one path must be defined for each LSP, the last configured path cannot be deleted from the LSP.

### Setting up Fast-Reroute Protection for an LSP

To create a protected LSP, do the following:

1. Create the LSP as described in Creating or Deleting an RSVP-TE LSP on page 1316.
2. Enable the fast-reroute feature on the LSP using the following command:
   ```bash
   configure mpls rsvp-te lsp lsp_name fast-reroute [enable | disable]
   ```
3. Create a path for the LSP as described in Creating an RSVP-TE Path on page 1317.
4. Define the path route as described in .
5. If you want to use a custom profile instead of the default profile, create a profile for the protected LSP as described in Creating and Deleting an RSVP-TE Profile on page 1319.
6. If you want to configure the custom profile created in the previous step, configure the profile as described in Configuring an RSVP-TE Profile on page 1319.
7. If you want to use a custom fast-reroute profile instead of using the default fast-reroute profile, create the profile using the following command at the ingress LER:
   ```bash
   create mpls rsvp-te profile profile_name fast-reroute
   ```
8. If you want to configure the custom fast-reroute profile created in the previous step, use the following command at the ingress LER:
   ```bash
   configure mpls rsvp-te profile frr_profile_name
   {bandwidth|bandwidth_rate_bps|bandwidth_rate_unit} {detour {hop-limit|hop_limit_value} {bandwidth-protection [enabled | disabled | secondary] | secondary}
   {node-protection [enabled | disabled]} (hold-priority|hold_priority_value) {setup-priority|setup_priority_value}
   ```
9. Add the path to the protected LSP and select the standard and fast-reroute profiles using the following command:
   ```bash
   configure mpls rsvp-te lsp lsp_name addpath [path_name | any]
   {profile|profile_name} {primary | [frr_profile_name | secondary]}
   ```

### RSVP-TE Configuration Example

RSVP-TE LSPs comprise profiles, paths, and the actual LSP. This section describes how to configure an RSVP-TE LSP.
Configuring RSVP LSPs is a multi-step process with some optional steps, depending on the specific requirements of the LSP. Conceptually, a number of mandatory elements must be configured to create an RSVP-TE LSP. In addition, you can also configure optional elements. In certain configurations, there are also order dependencies.

The profile contains constraints that you might wish to apply to the LSP. These constraints can affect the path selected across the MPLS domain in order to meet those constraints. Examples of profile parameters include bandwidth, setup, and hold priority relative to other configured LSPs.

The path can be used to specify the explicit path across the MPLS domain that the LSP should follow. This is done using EROs. An ERO is an object, sent as part of the LSP setup request (path message) that explicitly specifies the part of the path across the MPLS domain the setup request should follow. You can configure both loose and strict EROs in a path.

Certain elements of configuration are order dependent. For example if you specify a profile or path when creating an LSP, those path or profile definitions must already exist. Similarly a path must exist before an ERO is created, as the ERO is added explicitly to the path.

The typical steps used to configure and verify an RSVP-TE LSP are as follows:

1. Create and configure a path (optional).
2. Reserve bandwidth for the LSP (optional).
3. Create and configure a profile (optional).
4. Create an LSP (mandatory).
5. Add a primary/secondary path to the LSP (mandatory).
6. Add a secondary path to the LSP (optional).
7 Verify LSP status (recommended).

Figure 209: RSVP-TE Configuration Example

The configuration example, shown in Figure 209, creates primary and secondary LSPs between the node Glasgow and the node Birmingham. The steps specifically create an LSP between Glasgow and Birmingham based on an explicitly routed path via London with bandwidth, setup priority, and hold priority profile requirements. A secondary path is also created which, in the event of failure of a link or node on the primary path, activates the secondary LSP from Glasgow to Liverpool to Birmingham.

Note

Before configuring RSVP-TE LSPs, you need to enable the protocol on the switch, and an initial step of adding RSVP-TE to a VLAN must be carried out for all VLANs over which the user wishes RSVP-TE LSPs to be signaled. This is a one-time operation. A loopback VLAN with the LSR-ID should be added to MPLS to allow RSVP-TE LSPs to be established to the LSR-ID.

The following commands configure RSVP-TE for the switch and add RSVP signaling capabilities to the specified VLANs:

```bash
enable mpls
enable mpls protocol rsvp-te
configure mpls add vlan loopback
configure mpls add vlan gla-lon
enable mpls rsvp-te vlan gla-lon
enable mpls vlan gla-lon
configure mpls add vlan gla-liv
```
enable mpls rsvp-te vlan gla-liv
enable mpls vlan gla-liv

The following commands reserve bandwidth for RSVP-TE LSPs on these MPLS interfaces:

```
configure mpls rsvp-te bandwidth committed-rate 20 Mbps gla-lon
configure mpls rsvp-te bandwidth committed-rate 20 Mbps gla-liv
```

The following commands create and configure an LSP profile named Glasgow-Birmingham-pro.

LSPs that use the Glasgow-Birmingham-pro profile are signaled with a reserved bandwidth of 10 Mbps and an LSP setup and hold priority of 5.

```
create mpls rsvp-te profile Glasgow-Birmingham-pro
configure mpls rsvp-te profile Glasgow-Birmingham-pro bandwidth committed-rate 10 m
configure mpls rsvp-te profile Glasgow-Birmingham-pro setup-priority 5 hold-priority 5
```

The following commands define the primary and secondary paths between Glasgow and Birmingham:

```
create mpls rsvp-te path Glasgow-Birmingham-pri-path
create mpls rsvp-te path Glasgow-Birmingham-sec-path
```

The following commands pin each path to an LSR, such that each path takes a different route to the endpoint 4.0.0.0.

Path Glasgow-Birmingham-pri-path is routed through LSR 1.0.0.0 and path Glasgow-Birmingham-sec-path is routed through LSR 5.0.0.0.

```
configure mpls rsvp-te path Glasgow-Birmingham-pri-path add ero 1.0.0.0/32 loose
configure mpls rsvp-te path Glasgow-Birmingham-sec-path add ero 5.0.0.0/32 loose
```

The following commands create one RSVP-TE LSP with one primary and one secondary or backup path.

Each path uses the same profile.

```
create mpls rsvp-te lsp Glasgow-Birmingham-lsp destination 4.0.0.0
configure mpls rsvp lsp Glasgow-Birmingham-lsp add path Glasgow-Birmingham-pri-path profile Glasgow-Birmingham-pro primary
configure mpls rsvp lsp Glasgow-Birmingham-lsp add path Glasgow-Birmingham-sec-path profile Glasgow-Birmingham-pro secondary
```

**Note**
The secondary LSP is signaled, however it remains in a standby state unless the primary path becomes unavailable.

By default, a VPLS pseudowire flows over any available LSP.

However, a VPLS pseudowire can be specifically directed to use a configured RSVP-TE based LSP. Configuration is no different from configuring an LDP-based VPLS pseudowire, except that the RSVP-TE LSP is explicitly specified. The following command specifically directs a VPLS pseudowire to use a previously configured RSVP-TE LSP:

```
configure vpls Glasgow-Birmingham-cust1 peer 4.0.0.0 add mpls lsp Glasgow-Birmingham-lsp
```
Troubleshooting MPLS

The ExtremeXOS software includes multiple mechanisms for detecting and reporting problems.

Many failures generate an SNMP trap or log an error message. To find out more about a problem, you can enter show commands and review the flag states in the command output. The software also includes some MPLS troubleshooting tools, which are described in the following sections.

Using LSP Ping

To assist with problem determination in an MPLS network, LSP ping support is included as a CLI ping option in the ExtremeXOS software. The LSP ping support is based on draft-ietf-mpls-lsp-ping-13.txt. This draft includes support for both connectivity verification and fault isolation for transport LSPs. Connectivity verification is supported using a modified ping packet that is sent over the specified transport LSP.

LSP ping is designed to catch failures where a transport LSP appears to be operational but is actually not functioning correctly. LSP data plane corruption is far less likely to occur than an LSP control plane failure, but the LSP ping is also useful for detecting possible latency issues.

- To send MPLS ping packets over an LSP, enter the following command:

```plaintext
ping mpls lsp [lsp_name | any host | prefix ipNetmask] {reply-mode [ip | ip-router-alert]} {continuous | count count} {interval interval} {start-size start-size} {end-size end-size} [ttl ttl] {from from} {next-hop hopaddress}
```

MPLS pings are sent to the well-known UDP port number 3503 with an IP in the 127.0.0.0/8 IP subnet. The source IP address is set to the sender.

The time stamp field is supported for calculating round trip times and is accurate to 1/100 of a second. When replying to a ping, the LSP ping response (MPLS echo reply) sequence number and time-stamp fields are set to the LSP ping request (MPLS echo request) values. One MPLS echo response is sent for each MPLS echo request received. An MPLS echo reply is sent out-of-band as a natively IP routed IPv4 UDP packet. The normal IP routed path might or might not use an LSP.

To reduce the possibility of fragmentation problems on the return path, MPLS echo reply packets do not include any padding that was sent in the MPLS echo request. Because each LSP is unidirectional, the return path is not directly relevant for verification of the LSP's functionality. What is important is that the LSP ping results are returned to the source of the MPLS echo request.

Using LSP Trace

Transport LSP fault isolation is supported using the LSP trace feature. When the control plane detects a transport LSP failure, the LSR can switch to another LSP if one is available. When the failure is detected by LSP ping, you can use LSP trace to try to isolate the fault.

- To start an LSP trace, use the following command:

```plaintext
traceroute mpls lsp [lsp_name | any host | prefix ipNetmask] {reply-mode [ip | ip-router-alert]} {(from from) (ttl ttl) {next-hop hopaddress}}
```
Using the Health Check VCCV Feature

Health check Virtual Circuit Connectivity Verification (VCCV) can be used as a network diagnostic tool or as a network fault-alert tool, and can be configured on up to 16 VPLS domains. Connectivity between VPLS peers can be verified using the health check VCCV feature, which is defined in RFC 5085, Pseudowire Virtual Circuit Connectivity Verification (VCCV).

This implementation uses the following components defined in that RFC:

- VCCV Control Channel Type: MPLS Router Alert Label
- VCCV Control Verification Type: LSP Ping

Health check uses the LSP ping capability to verify connectivity. When the PW is set up, the two peers negotiate the VCCV capabilities, and if they establish a common set, health check becomes operational. If the VCCV capabilities do not match, health check cannot operate.

Health check operates in a single direction, so health checking should be enabled on the LSRs at both ends of the pseudowire in order to verify that traffic can flow bi-directionally between two VPLS peers. For multi-peer full-mesh or hierarchical VPLS networks, VCCV should be enabled on all VPLS peers to verify the entire VPLS network.

VCCV sends health check packets at regular intervals (the default interval is 5 seconds). If health check reaches the threshold for missed responses (the default fault-multiplier is 4), health check logs a message in EMS at the Warning level. Note that this log is not seen with the default log settings and no SNMP traps are sent. A health check failure does not change the state of the PW, which could remain operationally up and continue to support traffic, depending on the actual problem.

- To enable health check, use the following commands:
  ```
  enable l2vpn [vpls vpls_name | vpws vpws_name] health-check vccv
  ```
- To configure health check, use the following command:
  ```
  configure l2vpn [vpls [vpls_name | all] | vpws [vpws_name | all]]
  health-check vccv {interval interval_seconds} {fault-multiplier fault_multiplier_number}
  ```
- View VPLS configuration information, including the health check feature configuration.
  ```
  show [ {l2vpn} vpls {vpls_name} | l2vpn vpws {vpws_name} | l2vpn ]
  (peer ipaddress) {detail} | summary sharing }
  ```
- To disable health check, use the following command:
  ```
  disable l2vpn [vpls [vpls_name | all] | vpws [vpws_name | all]]
  health-check vccv
  ```
This chapter assumes that you are already familiar with IP unicast routing. If not, refer to the following publications for additional information:

- RFC 1256—ICMP (Internet Control Message Protocol) Router Discovery Messages
- RFC 1812—Requirements for IP Version 4 Routers

**Note**
For more information on interior gateway protocols, see:
- RIP on page 1412
- OSPF on page 1423
- IS-IS on page 1450

For information on exterior gateway protocols, see BGP on page 1472.
For more information on switch support for IPv6, IPv6 Unicast Routing on page 1377.

**IPv4 Unicast Overview**

The switch provides full Layer 3, IPv4 unicast routing to all switches that run the Edge, Advanced Edge, and Core licenses. (See the ExtremeXOS 22.6 Feature License Requirements document.) It exchanges routing information with other routers on the network using one of the following routing protocols:

- RIP (Routing Information Protocol)
- OSPF (Open Shortest Path First)
- BGP (Border Gateway Protocol)
- Intermediate System-Intermediate System (ISIS)
The switch dynamically builds and maintains a set of routing tables and determines the best path for each of its routes. Each host using the IP unicast routing functionality of the switch must have a unique IP address assigned. In addition, the default gateway assigned to the host must be the IP address of the router interface.

The ExtremeXOS software can provide both IPv4 and IPv6 routing at the same time. Separate routing tables are maintained for the two versions. Most commands that require you to specify an IP address can accept either an IPv4 or IPv6 address and act accordingly. Additionally, many of the IP configuration, enabling, and display commands have added tokens for IPv4 and IPv6 to clarify the version required. For simplicity, existing commands affect IPv4 by default and require you to specify IPv6, so configurations from an earlier release still correctly configure an IPv4 network.

**Router Interfaces**

The routing software and hardware routes IP traffic between router interfaces. A router interface is simply a virtual LAN (VLAN) that has an IP address assigned to it.

As you create VLANs with IP addresses belonging to different IP subnets, you can also choose to route between the VLANs. Both the VLAN switching and IP routing function occur within the switch.

---

**Note**

Each IP address and mask assigned to a VLAN must represent a unique IP subnet. You cannot configure the same IP address and subnet on different VLANs.

---

**Figure 210** shows an example switch configuration with two VLANs defined: Finance and Personnel. All ports on slots 1 and 3 are assigned to Finance, and all ports on slots 2 and 4 are assigned to Personnel. The figure shows the subnet address and interface address for each VLAN. Traffic within each VLAN is switched using the Ethernet MAC addresses. Traffic between the two VLANs is routed using the IP addresses.
ExtremeXOS 15.4 and above supports creating a GRE-based IPv4 tunnel, and routing IPv4 traffic over it. This feature is supported on all platforms that have GRE tunneling support (see ExtremeXOS 22.6 Feature License Requirements).

The switch administrator can configure a GRE tunnel by supplying the local source IPv4 address and the destination IPv4 address. Once configured, traffic can be redirected through the GRE tunnel. The TTL value of the outer IPv4 header will be set to 255 and the DSCP value is copied from the inner IPv4 header, the same as for the IPv6 tunnels. The encapsulated packets do not include the GRE checksum option, however if received with a checksum they are verified by the software, and then dropped if incorrect. The GRE module is capable of dealing with RFC 1701 neighbor options, with exception of the router option. Packets with this option set are dropped. However hardware does not support any options in the GRE header. If any of these options are set, the packet is either dropped, or sent to the CPU for processing. Since the key option of GRE tunnel is not configured, the GRE module only accepts GRE packets with a key value of 0, if present, and drops packets with other key values.

**Note**

GRE tunnels are IP tunnels which require L3 Function. L3 features are supported with EDGE license and above. All of the supported platforms' default license is EDGE or above, which include L3 features. In a stack all of the nodes must be GRE capable. For GRE in a stack, all stack nodes must be GRE hardware capable.

All nodes in a stack need to support GRE tunnels, or else the feature cannot be configured/enabled. When all nodes in the system are capable of running GRE, new GRE tunnels can be created. If a new node is added to a stack, it will be powered on, and a log message is logged that the node is not compatible with GRE, and should be removed. This is done to prevent the node from continuously...
rebooting. If a system boots up with both a GRE configuration, and an incapable blade/node in the system, all GRE tunnels we be put in system disabled state. The “show tunnels” command displays this.

**GRE Tunnel Example Configuration**

This example shows how the GRE tunnel feature could be configured.

```
configure default del port all
create vlan inet
configure vlan inet add port 24
configure vlan inet ipa 1.1.1.1/24
create vlan users
configure vlan users add port 1
configure vlan users ipa 100.0.0.1/24
create tunnel mytunnel gre destination 1.1.1.2 source 1.1.1.1
configure tunnel "mytunnel" ipaddress 2.0.0.1/24
configure iproute add 200.0.0.0/24 2.0.0.2
enable ipforwarding
```

**Populating the Routing Tables**

The switch maintains a set of IP routing tables for both network routes and host routes. Some routes are determined dynamically from routing protocols, and some routes are manually entered. When multiple routes are available to a destination, configurable options such as route priorities, route sharing, and compressed routes are considered when creating and updating the routing tables.

**Dynamic Routes**

Dynamic routes are typically learned by enabling the *RIP, OSPF, IS-IS* or *BGP* protocols, and are also learned from *ICMP* redirects exchanged with other routers. These routes are called dynamic routes because they are not a permanent part of the configuration. The routes are learned when the router starts up and are dynamically updated as the network changes. Older dynamic routes are aged out of the tables when an update for the network is not received for a period of time, as determined by the routing protocol.

Once a routing protocol is configured, dynamic routes require no configuration and are automatically updated as the network changes.
Static Routes

Static routes are routes that are manually entered into the routing tables and are not advertised through the routing protocols. Static routes can be used to reach networks that are not advertised by routing protocols and do not have dynamic route entries in the routing tables. Static routes can also be used for security reasons, to create routes that are not advertised by the router.

Static routes are configured in the ExtremeXOS software, remain part of the configuration when the switch is rebooted, and are immediately available when the switch completes startup. Static routes are never aged out of the routing table, however, the Bidirectional Forwarding Detection (BFD) feature, can be used to bring down static routes when the host link fails.

Without BFD, static routes always remain operationally active because there is no dynamic routing protocol to report network changes. This can lead to a black hole situation, where data is lost for an indefinite duration. Because upper layer protocols are unaware that a static link is not working, they cannot switch to alternate routes and continue to use system resources until the appropriate timers expire.

With BFD, a static route is marked operationally inactive if the BFD session goes down. Upper layer protocols can detect that the static route is down and take the appropriate action.

A default route is a type of static route that identifies the default router interface to which all packets are routed when the routing table does not contain a route to the packet destination. A default route is also called a default gateway.

ExtremeXOS Resiliency Enhancement for IPv4 Static Routes

The ExtremeXOS Resiliency Enhancement feature provides a resilient way to use ECMP (Equal Cost Multi Paths) to load balance IPv4 traffic among multiple servers or other specialized devices. ExtremeXOS automatically manages the set of active devices using ECMP static routes configured with ping protection to monitor the health of these routes. Such servers or specialized devices do not require special software to support Bidirectional Forwarding Detection (BFD), or IP routing protocols such as OSPF, or proprietary protocols to provide keepalive messages. ExtremeXOS uses industry-standard and required protocols ICMP/ARP for IPv4 to accomplish the following automatically:

- Initially verify devices and activate their static routes, without waiting for inbound user traffic, and without requiring configuration of device MAC addresses.
- Detect silent device outages and inactivate corresponding static routes.
- Reactivate static routes after device recovery, or hardware replacement with a new MAC address.

ExtremeXOS currently supports similar protection and resiliency using Bidirectional Forwarding Detection (BFD) on IPv4 static routes. However, BFD can only be used when the local and remote device both support BFD.

Multiple Routes

When there are multiple, conflicting choices of a route to a particular destination, the router picks the route with the longest matching network mask. If these are still equal, the router picks the route using the following default criteria (in the order specified):

- Directly attached network interfaces
- Static routes
- ICMP redirects
• Dynamic routes
• Directly attached network interfaces that are not active.

You can also configure blackhole routes—traffic to these destinations is silently dropped.

The criteria for choosing from multiple routes with the longest matching network mask is set by choosing the relative route priorities.

Relative Route Priorities

The following table lists the relative priorities assigned to routes depending on the learned source of the route.

Note
You can change the order of the relative priorities, but we recommend that you only make changes if you are aware of the possible consequences.

IP Route Sharing and ECMP

IP route sharing allows a switch to communicate with a destination through multiple equal-cost routes. In OSPF, BGP, and IS-IS, this capability is referred to as ECMP routing.

Without IP route sharing, each IP route entry in the routing tables lists a destination subnet and the next-hop gateway that provides the best path to that subnet. Every time a packet is forwarded to a particular destination, it uses the same next-hop gateway.

With IP route sharing, an additional ECMP table lists up to 2, 4, 8, 16, 32, or 64 next-hop gateways (depending on the platform and feature configuration) for each route in the routing tables. When multiple next-hop gateways lead to the same destination, the switch can use any of those gateways for packet forwarding. IP route sharing provides route redundancy and can provide better throughput when routes are overloaded.

The gateways in the ECMP table can be defined with static routes (up to 64 way), or they can be learned through the OSPF, BGP, or IS-IS protocols (64-way for OSPFv2, OSPFv3 (Open Shortest Path First version 3), and BGP; and 8-way for IS-IS). For more information on the ECMP table, see ECMP Hardware Table on page 1347.

Note
BGP does not use ECMP by default, so if you require that functionality you must explicitly issue the command configure bgp maximum-paths max-paths with a value greater than 1.

Equal-cost Multi-path Routing (ECMP) Hashing Alternatives for IPv4/IPv6

You can dynamically choose between the existing ECMP hash method ("default") and the "custom" hash method. Within each of these two hash methods, several hash algorithm options are available to vary traffic distribution among multiple equal-cost IP gateways.

Note
Custom hashing method is not supported on the X440-G2 and X620 series switches.

To configure the hash method, use the following command:

```
configure iproute sharing hash-method custom {hash-algorithm [xor | crc-16 | crc-32 [lower | upper]]}
```

Compressed Routes

Compressed routes allow you to reduce the number of routes that are installed in the hardware routing tables. The switch uses hardware routing tables to improve packet forwarding performance. The switch can use both hardware and software to forward packets, but packet forwarding without software processing is faster. The hardware routing tables have less storage space than the software, so compressed routes conserve resources and improve scaling.

The compressed route feature allows you to install less specific routes in the table, when overlapping routes with same next-hop exist. This route pruning technique is implemented as part of the Route Manager (RtMgr) process.
When a route is added, deleted or updated, the pruning algorithm is applied to see if the new route and/or its immediate children can be compressed or uncompressed as follows:

- If the parent node (immediate less specific route) of the newly added IP prefix has the same gateway as the new IP prefix, the newly added prefix is compressed.
- If the gateways of the newly added IP prefix and its immediate children are the same, the child nodes are compressed.
- If the gateways of the newly added IP prefix and its immediate children are not the same, and the child nodes had been previously compressed, the child nodes are uncompressed.

**Event Log Messages**

Event log messages are given in the following circumstances:

- When compression or uncompression start and end.
  
  ![Severity level: Debug -Summary]

- During each chunking start and end.
  
  ![Severity level: Debug -Verbose]

- When a route is compressed or uncompressed.
  
  ![Severity level: Debug -Verbose]

**Exceptional Scenarios**

This section explains instances of exceptional route compression behavior.

- When a node does not have any best route.

  Consider the routing table shown in Table 128. When a node does not have any best route, children are uncompressed, if they were already compressed. Also this node is uncompressed, if it had previously been compressed.

  **Table 128: Route Manager’s Table When There is No Best Route for a Node**

<table>

</tr>
</tbody>
</table>

- When a node contains only a multicast route.

  Route compression is applied to unicast routes only. If a node contains only a multicast route, the compression algorithm is not applied to the node. Therefore multicast nodes are considered as nodes with no best unicast routes as shown in Table 129.

  **Table 129: Route Manager’s Table When a Node Contains Only a Multicast Route**

ECMP Handling When IP Route Sharing Is Enabled

The nodes that have ECMP table entries are compressed only if the following conditions are met; otherwise, potential sub-optimal forwarding occurs:

- The number of ECMP gateways for a given node must match the number of ECMP gateways in its parent node.
- A given node’s set of gateways must match its parent’s set of gateways.

Table 130 shows how compression is applied for the nodes with ECMP table entries when IP route sharing is enabled. Sample routes with ECMP table entries are taken for illustration. The Reason field in the table provides information about why the compression is applied or not applied for the node.

IPv4 Unicast Routing

ExtremeXOS® User Guide for version 22.6
ECMP Handling When IP Route Sharing Is Disabled

If IP route sharing is disabled, the first best route is installed in the hardware table, if multiple best routes are available. Hence the compression algorithm considers the first best route for ECMP cases. As shown in the following table, when IP route sharing is disabled, all routes are compressed, except the first one in this case.

**Table 132: Route Manager’s Table When IP Route Sharing is Disabled**

## Hardware Routing Table Management

The switch hardware can route traffic based on information stored in hardware and software routing tables. Routing tasks are completed much faster when the routes are already stored in hardware routing tables. When packets are routed using the hardware routing tables, this is called fast-path routing, because the packets take the fast path through the switch.

The switch hardware provides the fast path, and the ExtremeXOS software provides the routing management capabilities, including management of the hardware routing tables. The software collects all routing information, manages the routes according to the switch configuration, and stores the appropriate routes in the hardware routing tables. When an IP unicast packet arrives and the destination IP address is not found in the hardware route tables, it is routed by software. The software processing takes more time than the fast path, so routing based on the software tables is called slow-path routing.

ExtremeXOS switches allow you to customize the software management of the hardware routing tables using the following hardware components:

- **Extended IPv4 Host Cache** on page 1339
Extended IPv4 Host Cache

The extended IPv4 host cache feature provides additional, configurable storage space on L3-capable switches to store additional IPv4 hosts in the hardware routing tables. This feature is supported on all switches.

All switches support slow-path routing (using software routing tables), so adding more entries in the hardware routing table is a performance feature, which allows more hosts to benefit from fast-path routing. To use the extended IPv4 host cache feature effectively, it helps to understand how the hardware tables operate on the switches that support this feature. The hardware forwarding tables controlled by this feature store entries for the following:

- IPv4 local and remote hosts
- IPv4 routes
- IPv6 local hosts
- IPv6 routes
- IPv4 and IPv6 multicast groups

The extended IPv4 host cache feature works by customizing the forwarding table space allotted to these components.

Introduction to Hardware Forwarding Tables

The extended IPv4 host cache feature relates to the four hardware forwarding tables shown in Figure 212.

![Figure 212: Hardware Forwarding Tables](image)

The Longest Prefix Match (LPM) and Layer 3 (L3) Hash tables store host and route information for fast-path forwarding. When the switch locates a route or host in one of these tables, it follows a table index to the Next Hop table, which contains MAC address and egress port information that is shared by the hosts and routes in the other tables. The hardware routing table capacity is partly determined by the capacity of the Next Hop table. The Next Hop table capacity is smaller than the combined capacity of the other tables because typically, multiple routes and hosts share each Next Hop table entry. When the other tables map to many different next hop entries, the Next Hop table can limit the total number of hosts and routes stored in hardware.

On most platforms, the L3 Hash table is smaller than the LPM tables. Because the L3 Hash table is the only table that can store IPv4 and IPv6 multicast entries and IPv6 local hosts, and because of the way the L3 Hash table is populated, forwarding table capacity and forwarding performance can be improved by allocating space for storing IPv4 local and remote host entries in the LPM tables.
The extended IPv4 host cache feature specifically allows you to define the number of entries that are reserved in the LPM tables for IPv4 and IPv6 routes. The unreserved entries are available for IPv4 local and remote hosts. IPv4 hosts can also occupy unused areas of the L3 Hash table, and when necessary, unused space in the reserved section of the LPM tables. The maximum number of hosts that can be stored in the hardware routing tables depends on the configuration and usage of the tables, but the number of local IPv4 hosts and gateways is ultimately limited to the size of the Next Hop table minus three reserved entries.

**LPM Table Management**

The internal LPM tables are provided on all platforms.

The ExtremeXOS software manages the content of the hardware tables based on the configuration specified by the following commands:

```
configure iproute reserved-entries [ num_routes_needed | maximum | default | slot [all | slot_num]
```

The `configure iproute reserved-entries` command configures the LPM tables.

```
configure forwarding internal-tables [ l2-and-l3 | more | l3-and-icmp | routes {ipv6-mask-length [64 | 128] } ]
```

The `configure forwarding internal-tables` command provides the ability to support additional L2 and L3 hosts, routes, or multicast table entries.

Starting with ExtremeXOS 22.5, the `ipv6-mask-length` option provides greater hardware route scale and IP route sharing (ECMP) support for IPv6 “long-mask routes”, meaning IPv6 subnets with mask lengths 65–128 bits. This provides additional scale and resilience for IPv6 host routes whose mask length is 128 bits. Increasing scale and providing ECMP for IPv6 mask 65–128 routes decreases IPv4 route scale. The default IPv6 mask length is 64.

IPv6 hardware and slowpath forwarding are supported on user-created Virtual Routers, and IPv6 tunnels are only supported on `VR-Default`.

The size of the internal LPM tables, and the size of the L3 Hash and Next Hop tables are fixed for some platforms. The following tables list the hardware capacity for each of the tables shown in Figure 212 on page 1339.

ExtremeSwitching and Summit X670-G2 and X770 series switches have hardware forwarding tables internal to the switch chips that can be partitioned in a flexible manner. The ExtremeSwitching and Summit X670-G2 and X770 switches have the following configurable internal tables.

Extended IPv4 Host Cache Management Guidelines

When configuring the extended IPv4 host cache feature, consider the following guidelines:

- The default option configures the switch to store entries for local and remote IPv4 hosts in the LPM tables.
• The **maximum** option reserves all space in the LPM tables for IPv4 and IPv6 routes. This option provides the maximum storage for IPv4 and IPv6 routes when you do not expect to store many IPv4 and IPv6 multicast and IPv6 hosts in the L3 Hash table.

**Note**

If no IPv4 route is found in the LPM table and IPv4 unicast packets are slow-path forwarded for a given remote host, an IPv4 entry is created for the remote host in either the L3 hash table or LPM table. The hardware does not cache entries for remote IPv6 hosts, so IPv6 routes take precedence over IPv4 routes.

**IPv4 Host Entry Population Sequence**

The ExtremeXOS software populates the hardware tables with IPv4 host entries by searching for available space in the following sequence:

1. Unreserved space in the LPM tables.
2. Available space in an L3 Hash table bucket.
3. Available space in the reserved section of the LPM table.
4. Space used by the oldest host entries in the LPM and L3 Hash tables.

The L3 Hash table is named for the hash function, which stores host and multicast entries based on an algorithm applied to the host IP address or multicast tuple (Source IP, Group IP, VLAN ID). The hash table stores entries in groups of 8 or 16 (depending on the hardware), and these groups are called buckets. When a bucket is full, any additional host or multicast addresses that map or hash to that bucket cannot be added. Another benefit of the extended IPv4 host cache feature is that you can reduce these conflicts (or “hash table collisions”), by making room for IPv4 hosts in the LPM table and reducing demand for the L3 Hash table.

A hardware-based aging mechanism is used to remove any remote IPv4 host entries that have not had IPv4 unicast packets forwarded to them in the previous hour. (Note that remote IPv4 hosts only need to be cached when all IPv4 routes do not fit within the number of routes reserved.) Aging helps to preserve resources for the hosts that are needed most. In a SummitStack, aging is performed independently for each stack node based on the ingress traffic for that node. Even with aging, it is still possible that the Next Hop table, LPM table, or L3 Hash bucket do not have space to accept a new host. In those cases, a least-recently used algorithm is used to remove the oldest host to make space for the new host in hardware.

Local IPv4 host entries are only subject to hardware-based aging if there has been a large amount of least-recently used replacement, indicating severe contention for HW table resources. Otherwise, local IPv4 host entries are retained just as in ExtremeXOS releases prior to 12.1, based on whether IP ARP refresh is enabled or disabled, and the value for the `configure iparp timeout` command.

**Note**

Gateway entries are entries that represent routers or tunnel endpoints used to reach remote hosts. Gateway entries are not aged and are not replaced by IPv6 hosts or multicast entries in the L3 Hash table or by any entries requiring space in the Next Hop table. The software can move gateway entries from the LPM table to the L3 Hash table to make room for new reserved routes.
Calculating the Number of Routes Needed

Guidelines for calculating the number of routes to reserve are provided in the ExtremeXOS Command Reference description for the following command:

```
configure iproute reserved-entries [num_routes_needed | maximum | default] slot [all | slot_num]
```

ECMP Hardware Table

IP route sharing and the ECMP hardware table are introduced in IP Route Sharing and ECMP on page 1333. The following sections provide guidelines for managing the ECMP hardware table:

- ECMP Table Configuration Guidelines
- Troubleshooting: ECMP Table-Full Messages on page 1348

ECMP Table Configuration Guidelines

The ECMP table contains gateway sets, and each gateway set defines the equal-cost gateways that lead to a destination subnet. When IP route sharing is enabled, subnet entries in the LPM table can be mapped to gateway set entries in the ECMP table, instead of to a single gateway within the LPM table.

For improved ECMP scaling, each LPM table entry points to a gateway set entry in the ECMP table. Each gateway set entry is unique and appears only once in the ECMP table.

Each gateway set entry for the platforms listed above is unique and appears only once in the ECMP table. Multiple LPM table entries can point to the same gateway set entry. This efficient use of the ECMP table creates more room in the ECMP table for additional gateway set entries. It also makes IP route sharing available to every entry in the LPM table.

The following command allows you to configure the maximum number of next-hop gateways for gateway sets in the ECMP table:

```
configure iproute sharing max-gateways max_gateways
```

Each gateway entry in a gateway set consumes ECMP table space. As the `max_gateways` value decreases, the ECMP table supports more gateway sets. If you configure the `max_gateways` value to 32, the switch supports route sharing through up to 32 gateways per subnet, but supports the smallest number of gateway sets. If you do not need to support up to 32 different gateways for any subnet, you can decrease the `max_gateways` value to support more gateway sets.

To determine which gateways might be added to the ECMP table, consider how many local gateways are connected to the switch and can be used for ECMP, and consider the `max_gateways` value.

For example, suppose that you have four ECMP gateway candidates connected to the switch (labeled A, B, C, and D for this example) and the `max_gateways` option is set to 4. For platforms that allow a gateway set entry to support multiple subnets, this configuration could result in up to 11 gateway sets in the ECMP table: ABCD, ABC, ABD, ACD, BCD, AB, AC, AD, BC, BD, and CD.

If there are 4 gateways and you set `max_gateways` to 4, you can use the choose mathematical function to calculate the total number of gateway set possibilities as follows:

\[
(4 \text{ choose } 4) + (4 \text{ choose } 3) + (4 \text{ choose } 2) = 11
\]
To calculate the number of gateway set possibilities for a given number of total gateways and a specific max-gateways value, use the choose function in the following formula:

\[
(TGW \text{ choose } MGW) + (TGW \text{ choose } MGW-1) + \ldots + (TGW \text{ choose } 2) = TGWsets
\]

In the formula above, TGW represents the total local gateways, MGW represents the max_gateways value, and TGWsets represents the total gateway sets needed to support all possible shared paths.

To see if your platform supports the total gateway sets needed, do the following:
- Calculate the total ECMP gateway sets possible as described above.
- Compare your result to the IP route sharing (total combinations of gateway sets) capacities listed in the ExtremeXOS Release Notes to verify that the switch can support the desired number of gateway sets.

Troubleshooting: ECMP Table-Full Messages

If the ECMP table is full, no new gateway sets can be added, and IP forwarding is still done in hardware through one of the following:
- For platforms that allow a gateway set entry to support multiple subnets, forwarding can be done using an existing gateway set that is a partial subset of the unavailable gateway set. If the unavailable gateway set consists of N gateways, the subset used could include a range of gateways from N-1 gateways down to a single gateway. For example, if the ECMP table does not have room for a new gateway set using gateways E, F, G, and H, a partial subset such as EFG, EF, or E will be used.
- For platforms that require one gateway set entry per subnet, forwarding is done through a single gateway.

On Summit family switches, an ECMP table-full condition produces the following message:

\[
\text{Noti:Card.IPv4FIB.ECMPTblFull Slot-1: IPv4 route can not use sharing on all its gateways. Hardware ECMP Table full. Packets are HW forwarded across a subset of gateways. (Logged at most once per hour.)}
\]

If the ECMP table-full message appears, consider the following remedies:
- Reduce the number of gateways adjacent to the switch used for IP route sharing.
- Monitor the switch to see if the condition is transient. For example, if the number of ECMP table entries temporarily increases due to a network event and then returns to within the supported range, a permanent change might not be required.
- Determine if IP route sharing to all gateways is required. Since traffic is still being forwarded in hardware using one or more gateways, the condition may be acceptable.

Configuring Unicast Routing

Configuring Basic Unicast Routing

To configure IP unicast routing on the switch:

1. Create and configure two or more VLANs.
2. For each VLAN that participates in IP routing, assign an IP address, use the following command:

```plaintext
configure {vlan} vlan_name ipaddress [ipaddress {ipNetmask} | ipv6-link-local] | [eui64] ipv6_address_mask
```

Ensure that each VLAN has a unique IP address.
3 Configure a default route using the following command:
   ```
   configure iproute add default gateway {metric} {multicast | multicast-only | unicast | unicast-only} {vr vrname}
   ```

   Default routes are used when the router has no other dynamic or static route to the requested destination.

4 Turn on IP routing for one or all VLANs using the following command:
   ```
   enable ipforwarding {ipv4 | broadcast | ignore-broadcast | fast-direct-broadcast} {vlan vlan_name}
   ```

5 Configure the routing protocol, if required. For a simple network using RIP, the default configuration may be acceptable.

6 Turn on RIP or OSPF using one of the following commands:
   ```
   enable rip
   enable ospf
   ```

**Adding a Default Route or Gateway**

A default route or gateway defines a default interface to which traffic is directed when no specific routes are available. To add a default route, use the command:

```
configure iproute add default gateway {metric} {multicast | multicast-only | unicast | unicast-only} {vr vrname}
```

**Note**

If you define a default route and subsequently delete the VLAN on the subnet associated with the default route, the invalid default route entry remains. You must manually delete the configured default route.

**Configuring Static Routes**

- To configure a static route, use the command:
  ```
  configure iproute add [ipNetmask | ip_addr mask] gateway {bfd} {metric} {multicast | multicast-only | unicast | unicast-only} {vlan egress_vlan} {vr vrname}
  ```

**Note**

Tracert might not always work if inter-VR routing is configured in one of the hops to the destination.

**Note**

When inter-vr routing is configured the gateway address should be different from VLAN IP of the switch and it should be reachable (ARP resolved) from the switch.

The gateway address cannot be loop back address or any local address. A static route's next-hop (gateway) must be associated with a valid IP subnet and cannot use the same IP address as a local VLAN. An IP subnet is associated with a single VLAN by its IP address and subnet mask. If the VLAN is subsequently deleted, the static route entries using that subnet must be deleted manually.
For Inter-VR routing, the egress VLAN name specified in the static route command may be a VLAN belonging to a VR different from the VR of the static route itself. When the VRs differ, Inter-VR routing of hardware and software forwarded packets is performed. This command can enable or disable BFD protection for one static route. However, this protection is not provided until the BFD client is enabled at each end of the route with the following command:

```
enable iproute bfd {gateway} ip_addr {vr vrname}
```

- To disable BFD protection for a static route, use the following command:
  ```
  disable iproute bfd {gateway} ip_addr {vr vrname}
  ```

### Configuring the Relative Route Priority

To change the relative route priority, use the following command:

```
configure iproute {ipv4} priority [blackhole | bootp | ebgp | host-mobility | ibgp | icmp | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external | mpls | ospf-as-external | ospf-external | ospf-external | ospf-inter | ospf-intra | rip | static] priority {vr vrname}
```

### Configuring Hardware Routing Table Usage

Allowing individual local and remote IPv4 unicast hosts to occupy the unused portion of the Longest Prefix Match (LPM) table helps reduce Layer 3 hardware hash table collisions, and reduces slowpath forwarding of IP unicast and multicast traffic. For more information, see “Hardware Routing Table Management” on page 1262.

- To configure the number of IP routes to reserve in the LPM hardware table, use the command:
  ```
  configure iproute reserved-entries [ num_routes_needed | maximum | default ] slot [all | slot_num]
  ```

- To display the current configuration for IP route reserved entries, use the command:
  ```
  show iproute reserved-entries {slot slot_num}
  ```

- To display the hardware table usage for IP routes, unicast and multicast, use the command:
  ```
  show iproute reserved-entries statistics {slot slot_num }
  ```

### Configuring IP Route Sharing

IP route sharing is introduced in IP Route Sharing and ECMP on page 1333. The following sections describe how to manage IP route sharing:

- Managing IP Route Sharing on page 1350
- Viewing the IP Route Sharing Configuration on page 1351

#### Managing IP Route Sharing

For SummitStack and Summit family switches that support Layer 3 routing, the ExtremeXOS software supports route sharing across up to 2, 4, 8, 16, 32, or 64 next-hop gateways.
• To configure the maximum number of ECMP gateways, use the following command:
  
  ```
  configure iproute sharing max-gateways max_gateways
  ```

  For guidelines on managing the number of gateways, see ECMP Hardware Table on page 1347.

• To enable route sharing, use the following command:

  ```
  enable iproute {ipv4} sharing {{vr}vrname
  ```

• To disable route sharing, use the following command:

  ```
  disable iproute {ipv4} sharing {{vr}vrname
  ```

**Viewing the IP Route Sharing Configuration**

To view the route sharing configuration, use the following command:

  ```
  show ipconfig {ipv4} {vlan vlan_name
  ```

**Configuring Route Compression**

• To enable route compression for IPv4 routes, use the following command:

  ```
  enable iproute compression {vr vrname
  ```

• To disable route compression for IPv4 routes, use the following command:

  ```
  disable iproute compression {vr vrname
  ```

When you enable or disable route compression, that process is performed in chunks, rather than as one single processing event. Because the ExtremeXOS Route Manager processes a limited number of IP prefixes per second, route compression should not have any significant impact on performance. Likewise, when IP route compression is enabled, incremental route addition or deletion should not have a significant impact on performance.

---

**Note**

You should disable iproute compression if MPLS (Multiprotocol Label Switching) next hop is enabled on the switch.

---

**Note**

IP route is enabled by default.

---

**Configuring Static Route Advertisement**

• To enable or disable advertisement of all static routes, use one of the following commands:

  ```
  enable rip export [bgp | direct | e-bgp | i-bgp | ospf | ospf-extern1 | ospf-extern2 | ospf-inter | ospf-intra | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external ] [cost number {tag number} | policy policy-name]
  ```

  or

  ```
  disable rip export [bgp | direct | e-bgp | i-bgp | ospf | ospf-extern1 | ospf-extern2 | ospf-inter | ospf-intra | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external ]
  ```
enable ospf export [bgp | direct | e-bgp | i-bgp | rip | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external | host-mobility] [cost cost type [ase-type-1 | ase-type-2] {tag number} | policy-map]

or

disable ospf export [bgp | direct | host-mobility | e-bgp | i-bgp | rip | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external]

Displaying the Routing Configuration and Statistics

Viewing IP Routes

Use the show iproute command to display the current configuration of IP unicast routing for the switch and for each VLAN. The show iproute command displays the currently configured routes and includes how each route was learned.

Viewing the IP ARP Table

To view the IP ARP table entries and configuration, use the show iparp command.

Viewing IP ARP Statistics

To view IP ARP table statistics, use the following commands:

show iparp distributed-mode statistics { slot [ slot | all ] }
show iparp stats [[ vr_name | vr {all | vr_name} ] {no-refresh} | {vr} summary]
show iparp stats [vlan {all {vr vr_name}} | {vlan} vlan_name] {no-refresh}
show iparp stats ports {all | port_list} {no-refresh}

Viewing the IP Configuration for a VLAN

To view the IP configuration for one or more VLANs, use the show ipconfig command.

Viewing Compressed Routes

- View a compressed route using the following command: show iproute.

Sample output:

<table>
<thead>
<tr>
<th>Ori Destination</th>
<th>Gateway</th>
<th>Mtr</th>
<th>Flags</th>
<th>VLAN</th>
<th>Duration</th>
</tr>
</thead>
</table>
# Module rtmgr configuration.

```
# disable iproute sharing
configure iproute priority mpls 20

disable icmp timestamp vlan "to62"
enable ip-option loose-source-route
enable iproute compression ipv4 vr "VR-Default"
```

## Routing Configuration Example

Figure 213 on page 1354 illustrates a switch with three VLANs defined as follows:
• Finance
  • All ports on slots 1 and 3 have been assigned.
  • IP address 192.207.35.1.
• Personnel
  • Protocol-sensitive VLAN using the IP protocol.
  • All ports on slots 2 and 4 have been assigned.
  • IP address 192.207.36.1.
• MyCompany
  • Port-based VLAN.
  • All ports on slots 1 through 4 have been assigned.

Figure 213: Unicast Routing Configuration Example

The stations connected to the system generate a combination of IP traffic and NetBIOS traffic. The IP traffic is filtered by the protocol-sensitive VLANs. All other traffic is directed to the VLAN MyCompany.

In this configuration, all IP traffic from stations connected to slots 1 and 3 have access to the router by way of the VLAN Finance. Ports on slots 2 and 4 reach the router by way of the VLAN Personnel. All other traffic (NetBIOS) is part of the VLAN MyCompany.

The example in the above figure is configured as follows:

```bash
create vlan Finance tag 10
create vlan Personnel tag 11
create vlan MyCompany

configure Finance protocol ip
configure Personnel protocol ip
```
Duplicate Address Detection

The Duplicate Address Detection (DAD) feature checks networks attached to a switch to see if IP addresses configured on the switch are already in use on an attached network.

DAD Overview

When enabled on a user VR or VR-Default, the DAD feature checks all IP addresses configured on the DAD-enabled VRs to determine if there are duplicate IP addresses on the networks connected to the switch. If a duplicate address is discovered, the switch does one of the following:

- Marks the IP address as valid
- Marks the IP address as duplicate and generates EMS events to advertise this

At the completion of the DAD check for each interface, the interface is marked valid or duplicate. A valid IP interface can be used by all switch processes for IP communications. There are no restrictions on a valid IP address. If no duplicate address is detected, the IP address is marked valid.

A duplicate IP address cannot be used for IP communications. If a duplicate IP address is detected, the marking depends on the action that initiated the test and can depend on a previous marking for the IP address. For some events, a duplicate IP address generates an EMS event, and for some other events, a duplicate IP address results in a disabled IP address and corresponding EMS events.

Prerequisites for a DAD Check

To successfully test an IP interface, at least one port in the host VLAN must be in the Up state. If all ports in the host VLAN are Down, the DAD check does not run.

The DAD check does not run on loopback VLANs; an IP address for a loopback VLAN is marked valid and the address is identified in the show ip dad command display with the L flag.

The DAD Check

The DAD feature checks IP addresses by sending an ARP request to each IP address it checks. The source IP address in the ARP request is 0, and the destination IP address is the IP address being checked. If another device replies to the ARP request, a duplicate IP address is detected.

The DAD check is repeated a configurable number of times for each IP interface. During the IPv4 DAD check, the status for an interface under test is tentative, and this status is shown with the T flag when the show ip dad command is entered. The DAD check is very fast, so it might be hard to view the tentative state for an address. If the address had previously been marked duplicate, the status remains...
duplicate while the DAD check runs. If no duplicate address is detected when the DAD check runs at interface startup, the interface IP address is declared valid.

If the DAD check feature is not enabled at startup, you can enable it after startup with a CLI command. Once enabled at the switch prompt, a DAD check runs on all IP interfaces when you enter the `run ip dad`, and it automatically runs on a single interface when an interface is initialized.

**Note**

When you enable the DAD feature at the CLI prompt, no DAD check is performed until you enter the `run ip dad` command or an interface is initialized.

An interface initialization can be triggered by enabling a disabled VLAN that has an IP configuration, or you can initialize an interface by adding an IP address to a VLAN and enabling IP forwarding. The DAD check runs only on the interface being initialized, and it does not run again until another interface is initialized.

When a duplicate IP address is detected, an EMS event is generated and the IP address is marked as follows:

- **Valid**—The interface remains valid if it was marked valid as a result of a previous DAD check. This treatment prevents the switch from disabling an interface that was working and now has an address conflict with another device.
- **Duplicate**—The duplicate IP address is disabled and cannot be used by switch processes. This treatment is appropriate for an interface that is just joining a network and should not conflict with pre-established services.

You can use the `show ip dad` command to display duplicate IP addresses, which are marked with the D flag.

**Switch Impact for DAD State Changes**

When an IP address is in a duplicate or tentative state, the normal behavior of the switch may change since that IP address isn’t usable, even though it does exist. The following are some examples of what can happen when an IP address is marked duplicate or tentative:

- Routes may be withdrawn or marked inactive
- Dynamic IP ARP entries may get flushed
- VRRP (Virtual Router Redundancy Protocol) virtual router (VR) instances may be disabled and put into init state causing the backup VRRP router to take over mastership.
- Ping and traceroute commands may fail.
- The DHCP (Dynamic Host Configuration Protocol) client will send a DHCP decline to the DHCP server if the IP address for a DHCP client on a VLAN is not Valid
- The DHCP scope IP address range configuration might fail when the DHCP enabled VLAN IP address becomes duplicate.
- SNMP (Simple Network Management Protocol) requests may fail
- SNMP traps will not be sent if the configured source IP address is not Valid
Fixing a Duplicate IP Address

If a DAD check declares an IP address duplicate, the address remains duplicate until a later DAD check declares the IP address valid, or until the affected VLAN is configured as a loopback VLAN. To make the interface IP address valid, do either of the following:

- Correct the duplicate address situation and enter the `run ip dad` command.
- Disable the host VLAN, correct the duplicate address situation, and bring up the interface.

Guidelines and Limitations

The following guidelines and limitations apply to the DAD check feature:

- IPv6 and GRE tunnels are not supported on IP addresses that are validated by a DAD check.
- The DAD check does not run on loopback VLANs; an IP address for a loopback VLAN is marked valid and the address is identified in the show ip dad command display with the L flag.
- The switch MAC address is installed for a VLAN if needed.
- DAD detects duplicate IPv4 address configured on a VLAN that spans MLAG (Multi-switch Link Aggregation Group) peer switches only when the solicitation attempts using `configure ip dad` attempts `max_solicitations` is more than 1.

Configuring DAD

To enable or disable the DAD feature and configure feature operation, use the following command:

```
configure ip dad [off | on | {on} attempts max_solicitations] {vr} vr_name | vr all
```

Running a DAD Check

To initiate a DAD check, use the following command:

```
run ip dad [{vlan} vlan_name | {vr} vr_name} ip_address]
```

Displaying DAD Configuration and Statistics

To display DAD configuration and statistics information, use the following command:

```
show ip dad [{vr} vr_name {ip_address} | vr all | {vlan} vlan_name]
```

Clearing the DAD Counters

To clear the DAD feature statistics counters, use the following command:

```
clear ip dad [{vr} vr_name {ip_address} | vr all | {vlan} vlan_name} {counters}
```
Proxy ARP

Proxy Address Resolution Protocol (ARP) was first invented so that ARP-capable devices could respond to ARP request packets on behalf of ARP-incapable devices. Proxy ARP can also be used to achieve router redundancy and to simplify IP client configuration. The switch supports proxy ARP for this type of network configuration.

ARP-Incapable Devices

- Configure the switch to respond to ARP requests on behalf of devices that are incapable of doing so. Configure the IP address and MAC address of the ARP-incapable device using the following command:

  configure iparp add proxy [ipNetmask | ip_addr {mask}] {vr vr_name} {mac | vrrp} {always}

After it is configured, the system responds to ARP requests on behalf of the device as long as the following conditions are satisfied:

- The valid IP ARP request is received on a router interface.
- The target IP address matches the IP address configured in the proxy ARP table.
- The proxy ARP table entry indicates that the system should answer this ARP request, based on the ingress VLAN and whether the `always` parameter is set. When the `always` option is set, the switch always responds to the ARP request even when the ARP requester is on the same subnet as the requested host. If the `always` option is not set, the switch only answers if the ARP request comes in from a VLAN that is not on the same subnet as the requested host.

When all the proxy ARP conditions are met, the switch formulates an ARP response using one of the following MAC addresses:

- A specific MAC address specified with the `mac` variable.
- The VRRP virtual MAC address when the `vrrp` option is specified and the request is received on a VLAN that is running VRRP.
- The switch MAC address when neither of the above options applies.

Proxy ARP Support for Reachable Routes in the Network

You can configure whether the switch replies to ARP (Address Resolution Protocol) requests on a specified VLAN by proxy ARP if the route to the IP address is reachable, or only if proxy ARP entries have been created.

If an ARP request is received by the switch, it checks the ExtremeXOS proxy ARP table (user adds the entries through the CLI). If it is present, an ARP reply is sent. If not present, it searches for the entry in the kernel route table. If this IP address is reachable, then the ARP reply is sent. The default behavior is for the switch to reply to ARP requests on the specified VLAN(s) by proxy ARP only if proxy ARP entries have been created.

The following table summarizes the this feature’s behavior:
Entry present in proxy ARP Table (static entry added through command `configure iparp add ip_addr {vr vr_name} mac`)

<table>
<thead>
<tr>
<th>reachable</th>
<th>entry-required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reply to ARP request</td>
<td>Reply to ARP request (or command not configured)</td>
</tr>
</tbody>
</table>

Static entry not present in proxy ARP table

<table>
<thead>
<tr>
<th>reachable</th>
<th>entry-required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reply to ARP request if route is reachable</td>
<td>No reply to ARP request</td>
</tr>
</tbody>
</table>

No static entry, but route reachable.

<table>
<thead>
<tr>
<th>reachable</th>
<th>entry-required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reply to ARP request</td>
<td></td>
</tr>
</tbody>
</table>

No static entry and route is not reachable

<table>
<thead>
<tr>
<th>reachable</th>
<th>entry-required</th>
</tr>
</thead>
<tbody>
<tr>
<td>No reply to ARP request</td>
<td></td>
</tr>
</tbody>
</table>

Static entry present and route is reachable

<table>
<thead>
<tr>
<th>reachable</th>
<th>entry-required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reply to ARP request</td>
<td></td>
</tr>
</tbody>
</table>

No static entry and route is not reachable

<table>
<thead>
<tr>
<th>reachable</th>
<th>entry-required</th>
</tr>
</thead>
<tbody>
<tr>
<td>No reply to ARP request</td>
<td></td>
</tr>
</tbody>
</table>

Route reachable

<table>
<thead>
<tr>
<th>reachable</th>
<th>entry-required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reply to ARP request</td>
<td></td>
</tr>
</tbody>
</table>

Route not reachable

<table>
<thead>
<tr>
<th>reachable</th>
<th>entry-required</th>
</tr>
</thead>
<tbody>
<tr>
<td>No reply to ARP request</td>
<td></td>
</tr>
</tbody>
</table>

Supported Platforms

ExtremeSwitching and Summit X450-G2, X460-G2, X670-G2, X770, X590, X620, X870 series switches.

Limitations

- No support of SNMP.
- For this feature the statistics of ARP send "Out Response" is incremented.

To configure proxy ARP support for reachable routes, use the command:

```
configure iparp proxy [vlan all | {vlan} vlan_name] [reachable | entry-required]
```

To view the status for proxy ARP reachable routes on a VLAN, use the command:

```
show vlan {virtual-router vr-name}
```

Proxy ARP Between Subnets

In some networks, it is desirable to configure the IP host with a wider subnet than the actual subnet mask of the segment. You can use proxy ARP so that the router answers ARP requests for devices outside of the subnet. As a result, the host communicates as if all devices are local. In reality, communication with devices outside of the subnet are proxied by the router.

For example, an IP host is configured with a class B address of 100.101.102.103 and a mask of 255.255.0.0. The switch is configured with the IP address 100.101.102.1 and a mask of 255.255.255.0. The switch is also configured with a proxy ARP entry of IP address 100.101.0.0 and mask 255.255.0.0, without the `always` parameter.

When the IP host tries to communicate with the host at address 100.101.45.67, the IP host communicates as if the two hosts are on the same subnet, and sends out an IP ARP request. The switch answers on behalf of the device at address 100.101.45.67, using its own MAC address. All subsequent
data packets from 100.101.102.103 are sent to the switch, and the switch routes the packets to 100.101.45.67.

**IPv4 Multinetting**

IP multinetting refers to having multiple IP networks on the same bridging domain (or VLAN). The hosts connected to the same physical segment can belong to any one of the networks, so multiple subnets can overlap onto the same physical segment. Any routing between the hosts in different networks is done through the router interface. Typically, different IP networks are on different physical segments, but IP multinetting does not require this.

Multinetting can be a critical element in a transition strategy, allowing a legacy assignment of IP addresses to coexist with newly configured hosts. However, because of the additional constraints introduced in troubleshooting and bandwidth, Extreme Networks recommends that you use multinetting as a transitional tactic only, and not as a long-term network design strategy.

Multinetting in ExtremeXOS does not require that you create a dummy multinetting protocol, and does not require that you create VLANs for each IP network. This implementation does not require you to explicitly enable IP multinetting. Multinetting is automatically enabled when a secondary IP address is assigned to a VLAN.

**Multinetting Topology**

For an IP multinetted interface, one of the IP networks on the interface acts as the transit network for the traffic that is routed by this interface. The transit network is the primary subnet for the interface. The remaining multinetted subnets, called the secondary subnets, must be stub networks. This restriction is required because it is not possible to associate the source of the incoming routed traffic to a particular network. IP routing happens between the different subnets of the same VLAN (one arm routing) and also between subnets of different VLANs.

![Figure 214: Multinetted Network Topology](Image)
Figure 210 shows a multinetted VLAN named multi. VLAN multi has three IP subnets so three IP addresses have been configured for the VLAN. One of the subnets is the primary subnet and can be connected to any transit network (for example, the Internet). The remaining two subnets are stub networks, and multiple hosts such as management stations (such as user PCs and file servers) can be connected to them. You should not put any additional routing or switching devices in the secondary subnets to avoid routing loops. In Figure 210 the subnets are on separate physical segments, however, multinetting can also support hosts from different IP subnets on the same physical segment.

When multinetting is configured on a VLAN, the switch can be reached using any of the subnet addresses (primary or secondary) assigned to VLAN. This means that you can perform operations like ping, Telnet, Trivial File Transfer Protocol (TFTP), Secure Shell 2 (SSH2), and others to the switch from a host residing in either the primary or the secondary subnet of the VLAN. Other host functions (such as traceroute) are also supported on the secondary interface of a VLAN.

### How Multinetting Affects Other Features

**ARP**

ARP operates on the interface and responds to every request coming from either the primary or secondary subnet. When multiple subnets are configured on a VLAN and an ARP request is generated by the switch over that VLAN, the source IP address of the ARP request must be a local IP address of the subnet to which the destination IP address (which is being ARPed) belongs.

For example, if a switch multinets the subnets 10.0.0.0/24 and 20.0.0.0/24 (with VLAN IP addresses of 10.0.0.1 and 20.0.0.1), and generates an ARP request for the IP address 10.0.0.2, then the source IP address in the ARP packet is set to 10.0.0.1 and not to 20.0.0.1.

**Route Manager**

The Route Manager installs a route corresponding to each of the secondary interfaces. The route origin is direct, is treated as a regular IP route, and can be used for IP data traffic forwarding.

These routes can also be redistributed into the various routing protocol domains if you configure route redistribution.

**IRDP**

Some functional changes are required in Internet Router Discovery Protocol (IRDP) to support IP multinetting. When IRDP is enabled on a Layer 3 VLAN, the ExtremeXOS software periodically sends ICMP router advertisement messages through each subnet (primary and secondary) and responds to ICMP router solicitation messages based on the source IP address of the soliciting host.

**Unicast Routing Protocols**

Unicast routing protocols treat each IP network as an interface. The interface corresponding to the primary subnet is the active interface, and the interfaces corresponding to the secondary subnet are passive subnets.

For example, in the case of OSPF, the system treats each network as an interface, and hello messages are not sent out or received over the non-primary interface. In this way, the router link state advertisement (LSA) includes information to advertise that the primary network is a transit network and...
the secondary networks are stub networks, thereby preventing any traffic from being routed from a source in the secondary network.

Interface-based routing protocols (for example, OSPF) can be configured on per VLAN basis. A routing protocol cannot be configured on an individual primary or secondary interface. Configuring a protocol parameter on a VLAN automatically configures the parameter on all its associated primary and secondary interfaces. The same logic applies to configuring IP forwarding, for example, on a VLAN.

Routing protocols in the multinetted environment advertise the secondary subnets to their peers in their protocol exchange process. For example, for OSPF the secondary subnets are advertised as stub networks in router LSAs. RIP also advertises secondary subnets to its peers residing on the primary subnet.

This section describes the behavior of OSPF in an IPv4 multinetting environment:

- Each network is treated as an interface, and hello messages are not sent out or received over the non-primary interface. In this way, the router LSA includes information to advertise that the primary network is a transit network and the secondary networks are stub networks, thereby preventing any traffic from being routed from a source in the secondary network.
- Any inbound OSPF control packets from secondary interfaces are dropped.
- Direct routes corresponding to secondary interfaces can be exported into the OSPF domain (by enabling export of direct routes), if OSPF is not enabled on the container VLAN.
- When you create an OSPF area address range for aggregation, you must consider the secondary subnet addresses for any conflicts. That is, any secondary interface with the exact subnet address as the range cannot be in another area.
- The automatic selection algorithm for the OSPF router ID considers the secondary interface addresses also. The numerically highest interface address is selected as the OSPF router-id.

This section describes the behavior of the Routing Information Protocol (RIP) in an IP multinetting environment:

- RIP does not send any routing information update on the secondary interfaces. However, RIP does advertise networks corresponding to secondary interfaces in its routing information packet to the primary interface.
- Any inbound RIP control packets from secondary interfaces are dropped.
- Direct routes corresponding to secondary interfaces can be exported into the RIP domain (by enabling export of direct routes), if RIP is not enabled on the container VLAN.

There are no behavioral changes in the BGP in an IP multinetting environment.

This section describes a set of recommendations for using BGP with IP multinetting:

- Be careful of creating a BGP neighbor session with a BGP speaker residing in secondary subnet. This situation can lead to routing loops.
- All secondary subnets are like stub networks, so you must configure BGP in such a way that the BGP next hop becomes reachable using the primary subnet of a VLAN.
- When setting the BGP next hop using an inbound or outbound policy, ensure that the next hop is reachable from the primary interface.
- A BGP static network’s reachability can also be resolved from the secondary subnet.
• Secondary interface addresses can be used as the source interface for a BGP neighbor.
• Direct routes corresponding to secondary interfaces can be exported into the BGP domain (by enabling export of direct routes).

This section describes the behavior of IS-IS in an IPv4 multinetting environment:
• IS-IS includes all the interface addresses in its reachability information. Adjacency is established only based on the primary interface address. If the adjacency-check option is disabled by the disable isis adjacency-check command, then IS-IS adjacency is established irrespective of the subnet address match.

**IGMP Snooping and IGMP**

IGMP (Internet Group Management Protocol) snooping and IGMP treat the VLAN as an interface. Only control packets with a source address belonging to the IP networks configured on that interface are accepted.

IGMP accepts membership information that originates from hosts in both the primary and secondary subnets. The following describes the changes in behavior of IGMP in an IP multinetting environment:
• A Layer 3 VLAN always uses the primary IP address as the source address to send out an IGMP query, and querier election is based on the primary IP address of interface. Because the RFC dictates that there is only one querier per physical segment, the querier may be attached to any of configured IP interfaces, including secondary interfaces, although this is not a recommended configuration.
• For a static IGMP group, the membership report is also sent out using the primary IP address.
• For local multicast groups such as 224.0.0.X, the membership report is sent out using the first IP address configured on the interface, which is the primary IP address in ExtremeXOS.
• The source IP address check is disabled for any IGMP control packets (such as IGMP query and IGMP membership report). Source IP address checking for IGMP control packet is disabled for all VLANs, not just the multinetted VLANs.

**Multicast Routing Protocols**

For Protocol-Independent Multicast (PIM), the following behavior changes should be noted in a multinetting environment:
• PIM does not peer with any other PIM router on a secondary subnet.
• PIM also processes data packets from the hosts secondary subnets.
• PIM also accepts membership information from hosts on secondary subnets.

**EAPS, ESRP, and STP**

Control protocols like EAPS (Extreme Automatic Protection Switching), ESRP (Extreme Standby Router Protocol), and the STP (Spanning Tree Protocol) treat the VLAN as an interface. If the protocol control packets are exchanged as Layer 3 packets, then the source address in the packet is validated against the IP networks configured on that interface.

**DHCP Server**

The DHCP server implementation in ExtremeXOS only supports address allocation on the primary IP interface of the configured VLAN. That is, all DHCP clients residing on a bridging domain have IP...
addresses belonging to the primary subnet. To add a host on secondary subnet, you must manually configure the IP address information on that host.

**DHCP Relay**

When the switch is configured as a **DHCP** relay agent, it forwards the DHCP request received from a client to the DHCP server. When doing so, the system sets the GIADDR field in the DHCP request packet to the primary IP address of the ingress **VLAN**. This means that the DHCP server that resides on a remote subnet allocates an IP address for the client in the primary subnet range.

**VRRP**

**Virtual Router Redundancy Protocol (VRRP)** protection can be provided for the primary as well as for the secondary IP addresses of a **VLAN**. For multinetting, the IP address assigned to an VRRP **VR** identifier (VRID) can be either the primary or the secondary IP addresses of the corresponding **VLAN**.

For example, assume a VLAN v1 with two IP addresses: a primary IP address of 10.0.0.1/24, and a secondary IP address of 20.0.0.1/24.

To provide VRRP protection to such a VLAN, you must configure one of the following:

- Configure VRRP in VLAN v1 with two VRRP VRIDs. One VRID should have the virtual IP address 10.0.0.1/24, and the other VRID should have the virtual IP address 20.0.0.1/24. The other VRRP router, the one configured to act as backup, should be configured similarly.

—OR—

- Configure VRRP in VLAN v1 with two VRRP VRIDs. One VRID should have the virtual IP address as 10.0.0.1/24, and the other VRID should have the virtual IP address as 20.0.0.1/24.

It is possible for a VRRP VR to have additional virtual IP addresses assigned to it.

In this case, the following conditions must be met:

- Multiple virtual IP addresses for the same VRID must be on the same subnet.
- Multiple virtual IP addresses must all not be owned by the switch.

Assuming a VLAN v1 that has IP addresses 1.1.1.1/24 and 2.2.2.2/24, here are some more examples of valid configurations:

- VRRP VR on v1 with VRID of 99 with virtual IP addresses of 1.1.1.2 and 1.1.1.3
- VRRP VR on v1 with VRID of 100 with virtual IP addresses of 2.2.2.3 and 2.2.2.4
- VRRP VR on v1 with VRID of 99 with virtual IP addresses of 1.1.1.98 and 1.1.1.99
- VRRP VR on v1 with VRID of 100 with virtual IP addresses of 2.2.2.98 and 2.2.2.99

Given the same VLAN v1 as above, here are some invalid configurations:

- VRRP VR on v1 with VRID of 99 with virtual IP addresses of 1.1.1.1 and 2.2.2.2 (the virtual IP addresses are not on the same subnet)
- VRRP VR on v1 with VRID of 100 with virtual IP addresses of 2.2.2.2 and 1.1.1.1 (the virtual IP addresses are not on the same subnet)
- VRRP VR on v1 with VRID of 99 with virtual IP addresses of 1.1.1.1 and 1.1.1.99 (one virtual IP address is owned by the switch and one is not)
- VRRP VR on v1 with VRID of 100 with virtual IP addresses of 2.2.2.2 and 2.2.2.99 (one virtual IP address is owned by the switch and one is not).
Configuring IPv4 Multinetting

You configure IP multinetting by adding a secondary IP address to a VLAN.

- Use the following command to add a secondary IP address:

  `configure vlan vlan_name add secondary-ipaddress [ip_address {netmask} | ipNetmask]

After you have added a secondary IP address, you cannot change the primary IP address of a VLAN until you first delete all the secondary IP addresses.

- To delete secondary IP addresses, use the following command:

  `configure vlan vlan_name delete secondary-ipaddress [ip_address | all]

IP Multinetting Examples

The following example configures a switch to have one multinetted segment (port 5:5) that contains three subnets (192.168.34.0/24, 192.168.35.0/24, and 192.168.37.0/24).

```
configure default delete port 5:5
create vlan multinet
configure multinet ipaddress 192.168.34.1/24
configure multinet add secondary-ipaddress 192.168.35.1/24
configure multinet add secondary-ipaddress 192.168.37.1/24
configure multinet add port 5:5
enable ipforwarding
```

The following example configures a switch to have one multinetted segment (port 5:5) that contains three subnets (192.168.34.0, 192.168.35.0, and 192.168.37.0). It also configures a second multinetted segment consisting of two subnets (192.168.36.0 and 172.16.45.0). The second multinetted segment spans three ports (1:8, 2:9, and 3:10). RIP is enabled on both multinetted segments.

```
configure default delete port 5:5
create vlan multinet
configure multinet ipaddress 192.168.34.1
configure multinet add secondary-ipaddress 192.168.35.1
configure multinet add secondary-ipaddress 192.168.37.1
configure multinet add port 5:5
configure default delete port 1:8, 2:9, 3:10
create vlan multinet_2
configure multinet_2 ipaddress 192.168.36.1
configure multinet_2 add secondary-ipaddress 172.16.45.1
configure multinet_2 add port 1:8, 2:9, 3:10
configure rip add vlan multinet
configure rip add vlan multinet_2
enable rip
enable ipforwarding
```

DHCP/BOOTP Relay

The following sections describe how to use the DHCP/BOOTP Relay feature:
Managing DHCP/BOOTP Relay on page 1366.
Configuring the DHCP Relay Agent Option (Option 82) at Layer 3 on page 1366.
Viewing the DHCP/BOOTP Relay Statistics and Configuration on page 1368.

Note
This section discusses DHCP/BOOTP relay operation at Layer 3. For information on DHCP/BOOTP relay operation at Layer 2, see DHCP Snooping and Trusted DHCP Server on page 927.

BOOTP Relay agent of DHCPv6 relays the DHCPv6 messages between the server/client across subnets of a larger IPv6 network.

The DHCPv6 server/BOOTP relay agent listens to UDP port 547.

A relay agent relays both messages from clients and Relay-forward messages from other relay agents. When a relay agent receives a valid message, it constructs a new Relay-forward message and option from the DHCP message received, then forwards it to the next hop/server. The server responds with the corresponding IP address or configuration through a Relay-Reply message to its peer, and thus to the client.

The ExtremeXOS implementation of DHCPv6 takes reference from ISC DHCPv6.

Managing DHCP/BOOTP Relay

After IP unicast routing has been configured, you can configure the switch to forward DHCP or BOOTP requests coming from clients on subnets being serviced by the switch and going to hosts on different subnets. This feature can be used in various applications, including DHCP services between Windows NT servers and clients running Windows 95.

Note
If DHCP/BOOTP Relay is enabled on a per VLAN basis, make sure it is enabled on both the client-side and server-side VLANs.

You can enable the use of LSP next hops, or you can enable DHCP/BOOTP relay. The software does not support both features at the same time.

You can enable BOOTP Relay over VRFs and VPN-VRFs in the same manner as with normal VRs. For more information about BOOTP Relay over L3VPN, see L3VPN BOOTP Relay on page 1538.

Note
BOOTP Relay show commands do not increment DHCP Release counters that are received from the client since DHCP release is hardware forwarded. Counters are incremented for other options in these commands.

Configuring the DHCP Relay Agent Option (Option 82) at Layer 3

After configuring and enabling the DHCP/BOOTP relay feature, you can enable the DHCP relay agent option feature. This feature inserts a piece of information, called option 82, into any DHCP request...
packet that is to be relayed by the switch. Similarly, if a DHCP reply received by the switch contains a valid relay agent option, the option is stripped from the packet before it is relayed to the client.

When DHCP option 82 is enabled, two types of packets need to be handled:

| DHCP Request | When the switch (relay agent) receives a DHCP request, option 82 is added at the end of the packet. If the option has already been enabled, then the action taken depends on the configured policy (drop packet, keep existing option 82 value, or replace the existing option). If the incoming DHCP request is tagged, then the VLAN ID is added to the circuit ID sub-option of option 82; otherwise, the default VLAN ID is added. |
| DHCP Reply | When the option 82 information check is enabled, the packets received from the DHCP server are checked for option 82 information. If the remote ID sub-option is the switch’s MAC address, the packet is sent to the client; if not, the packet is dropped. If the check is not enabled, the packets are forwarded as-is. |

The DHCP relay agent option consists of two pieces of data, called sub-options. The first is the agent circuit ID sub-option, and the second is the agent remote ID sub-option. When the DHCP relay agent option is enabled on switches running ExtremeXOS, the value of these sub-options is set as follows:

**Agent circuit ID sub-option**
The full circuit ID string uses the format `<vlan_info>-<port_info>`. You can use the default values for `vlan_info` and `port_info`, or you can configure these values as described later in this section.

**Agent remote ID sub-option** Always contains the Ethernet MAC address of the relaying switch. You can display the Ethernet MAC address of the switch by issuing the `show switch` command. You can configure string up to 32 characters as agent remote ID option.

---

**Note**
For more general information about the DHCP relay agent information option, refer to RFC 3046.

---

**Enabling and Disabling the DHCP Relay Agent Option**

- To enable the DHCP relay agent option, use the following command after configuring the DHCP/BOOTP relay function:
  ```
  configure bootprelay dhcp-agent information option
  ```
- To disable the DHCP relay agent option, use the following command:
  ```
  unconfigure bootprelay dhcp-agent information option
  ```

**Enabling and Disabling DHCP Packet Checking**

In some instances, a DHCP server may not properly handle a DHCP request packet containing a relay agent option.

- To prevent DHCP reply packets with invalid or missing relay agent options from being forwarded to the client, use this command:
  ```
  configure bootprelay dhcp-agent information check
  ```
- To disable checking of DHCP replies, use this command:
  ```
  unconfigure bootprelay dhcp-agent information check
  ```
Configuring the DHCP Packet Handling Policy

A DHCP relay agent may receive a client DHCP packet that has been forwarded from another relay agent. If this relayed packet already contains a relay agent option, then the switch handles this packet according to the configured DHCP relay agent option policy. The possible actions are to replace the option information, to keep the information, or to drop packets containing option 82 information.

- To configure this policy, use the following command:
  ```
  configure bootprelay dhcp-agent information policy [drop | keep | replace]
  ```
- The default relay policy is replace. Configure the policy to the default, use this command:
  ```
  unconfigure bootprelay dhcp-agent information policy
  ```

Configuring the DHCP Agent Circuit ID Suboption

- To configure the values used to create the agent circuit ID suboption, use the following commands:
  ```
  configure bootprelay dhcp-agent information circuit-id port-information port_info port
  ```
  ```
  configure bootprelay dhcp-agent information circuit-id vlan-information vlan_info {vlan} [vlan_name | all]
  ```

Note
When both ipsecurity DHCP option and bootprelay DHCP agent option are configured, the Bootprelay DHCP agent option takes higher precedence.

Viewing the DHCP/BOOTP Relay Statistics and Configuration

- To view the DHCP/BOOTP relay statistics and configuration, use the following command:
  ```
  show bootprelay
  ```
- To view the BOOTP relay enable/disable configuration, use the following command:
  ```
  show bootprelay configuration {{vlan} vlan_name | {vr} vr_name}
  ```
- To view the DHCP relay agent option (Option 82) configuration, use the following commands:
  ```
  show bootprelay dhcp-agent information circuit-id port-information ports all
  ```
  ```
  show bootprelay dhcp-agent information circuit-id vlan-information
  ```

DHCP Smart Relay

A DHCP Relay agent relays DHCP requests from the client to the DHCP server, and relays the DHCP replies from the server to the client. It acts as a proxy, and can reduce the number of DHCP servers required in the network. The DHCP relay agent inserts its own IP address in the giaddr field (gateway address) of the DHCP request. The DHCP server looks into this IP address, identifies the DHCP client’s subnet, and assigns an IP address accordingly.

The ExtremeXOS BOOTP Relay module is Extreme Networks’ DHCP Relay agent. It is now enhanced to optionally insert the secondary addresses of the interface.

DHCP clients can now be dynamically assigned both public and private addresses in an effort to reduce administrative overhead. ExtremeXOS can now configure the BOOTP Relay agent to insert both primary
and secondary address(es) of the client-facing interface as a gateway address in the DHCP packet. At any given point in time, the DHCP client can be assigned one IP address.

You can insert different addresses in the giaddr field (gateway address) in two different ways:

- **Parallel mode:** the switch simultaneously relays multiple DHCP Discover packets, each containing a different IP address as the gateway address. The relay agent receives a DHCP Discover request from the DHCP client. The relay agent makes multiple copies of this DHCP DISCOVER request, inserts each IP address of the client-facing interface in the giaddr field (gateway address) in each one of these copies, and relays all these DHCP DISCOVER packets simultaneously to the DHCP server.

  The DHCP server has the responsibility to assign the correct IP address in the correct subnet by choosing the DHCP DISCOVER packet to respond to. Similarly, the DHCP client is responsible for accepting the appropriate DHCP OFFER from the DHCP server.

  **Note**
  Only the DHCP DISCOVER request is sent in multiple copies, with different IP addresses as the gateway address in each. All other DHCP packets are relayed normally.

- **Sequential mode:** the switch relays a DHCP DISCOVER packet for each IP address sequentially.

  The relay agent receives a DHCP DISCOVER request and inserts the primary address of the client-facing interface as the gateway address, and relays this packet to the server. The switch counts the number of times a DHCP client sends out a DHCP request without receiving a DHCP OFFER message. After three retries, the relay agents sets the secondary address as the gateway address in the next DHCP Discover request that gets relayed. If the DHCP server still does not respond after three retries, the next secondary address is used as the gateway address, and so on cyclically.

**Configuring DHCP Smart Relay**

Issue the following commands to configure the DHCP Smart Relay feature:

- To configure DHCP smart relay mode to include the secondary IP address as giaddr at VR level:
  ```
  configure bootprelay {ipv4 | ipv6} include-secondary {sequential | parallel | off} {vr vr_name}
  ```

- To configure DHCP smart relay mode to include the secondary IP address as giaddr at VLAN level:
  ```
  configure bootprelay {ipv4 | ipv6} {vlan} vlan_name include-secondary {sequential | parallel | off}
  ```

- To unconfigure any smart relay configuration that was specified at the VLAN level:
  ```
  unconfigure bootprelay {ipv4 | ipv6} {vlan} vlan_name include-secondary
  ```

- To display various DHCP BOOTP Relay statistics:
  ```
  show bootprelay
  show bootprelay ipv6
  show bootprelay configuration ipv4
  show bootprelay configuration ipv6
  ```

**Supported Platforms**

This feature is supported on all platforms.
Broadcast UDP Packet Forwarding

UDP Forwarding is a flexible and generalized routing utility for handling the directed forwarding of broadcast UDP packets. UDP Forwarding enables you to configure your switch so that inbound broadcast UDP packets on a VLAN are forwarded to a particular destination IP address or VLAN. UDP Forwarding allows applications, such as multiple DHCP relay services from differing sets of VLANs, to be directed to different DHCP servers.

The following rules apply to UDP broadcast packets handled by this feature:

- If the UDP profile includes BOOTP or DHCP, it is handled according to guidelines specified in RFC 1542.
- If the UDP profile includes other types of traffic, these packets have the IP destination address modified as configured, and changes are made to the IP and UDP checksums and TTL field (decrements), as appropriate.

If UDP Forwarding is used for BOOTP or DHCP forwarding purposes, do not configure or use the existing bootprelay function. However, if the previous bootprelay functions are adequate, you may continue to use them.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>When using udp-profile to forward dhcp request, the behavior will be different from bootprelay. Where bootprelay will forward the dhcp packet with the client vlan IP as source IP, udp-profile will forward the dhcp packet with the source IP of the egress vlan towards the destination server.</td>
</tr>
</tbody>
</table>

UDP Forwarding only works across a Layer 3 boundary and currently, UDP Forwarding can be applied to IPv4 packets only, not to IPv6 packets.

Configuring UDP Forwarding

- To configure UDP Forwarding, create a policy file for your UDP profile, and then associate the profile with a VLAN using the following command:

  ```
  configure vlan vlan_name udp-profile [profilename | none]
  ```

  You can apply a UDP Forwarding policy only to an L3 VLAN (a VLAN having at least one IP address configured on it). If no IP address is configured on the VLAN, the command is rejected.

  UDP profiles are similar to ACL (Access Control List) policy files. UDP profiles use a subset of the match conditions allowed for ACLs. Unrecognized attributes are ignored. A UDP forwarding policy must contain only the following attributes:

  - Match attributes
    - Destination UDP port number (destination-port)
    - Source IP address (source-ipaddress)
  - Action modified (set) attributes
    - Destination IP address (destination-ipaddress)
    - VLAN name (vlan)
Policy files used for UDP forwarding are processed differently from standard policy files. Instead of terminating when an entry’s match clause becomes true, each entry in the policy file is processed and the corresponding action is taken for each true match clause.

For example, if the following policy file is used as a UDP forwarding profile, any packets destined for UDP port 67 are sent to IP address 20.0.0.5 and flooded to VLAN to7:

```plaintext
entry one {
    if match all {
        destination-port 67 ;
    } then {
        destination-ipaddress 20.0.0.5 ;
    }
}
entry two {
    if match all {
        destination-port 67 ;
    } then {
        vlan "to7" ;
    }
}
```

If you include more than one VLAN set attribute or more than one destination-ipaddress set attribute in one policy entry, the last one is accepted and the rest are ignored.

**Note**

Although the XOS policy manager allows you to set a range for the destination-port, you should not specify the range for the destination-port attribute in the match clause of the policy statement for the UDP profile. If a destination-port range is configured, the last port in the range is accepted and the rest are ignored.

You can have two valid set statements in each entry of a UDP forwarding policy; one a destination-ipaddress and one a VLAN. The ExtremeXOS software currently allows a maximum of eight entries in a UDP forwarding policy, so you can define a maximum of 16 destinations for one inbound broadcast UDP packet: eight IP addresses and eight VLANs.

**Note**

It is strongly advised to have no more than eight entries in a UDP forwarding profile. The UDP forwarding module processes those entries even if the entries do not contain any attributes for UDP forwarding. Having more than eight entries drastically reduces the performance of the system. If the inbound UDP traffic rate is very high, having more than eight entries could cause the system to freeze or become locked.

If you rename a VLAN referred to in your UDP forwarding profile, you must manually edit the policy to reflect the new name, and refresh the policy.

You can also validate whether the UDP profile has been successfully associated with the VLAN by using the show policy command. UDP Forwarding is implemented as part of the netTools process, so the command does display netTools as a user of the policy.

- To remove a policy, use the **none** form of the following command:
  ```plaintext
  configure vlan vlan_name udp-profile [profilename | none]
  ```

  or use the following command:
  ```plaintext
  unconfigure vlan vlan_name udp-profile
  ```
For more information about creating and editing policy files, see Chapter 17, “Policy Manager.” For more information about ACL policy files, see Chapter 18, “ACLs.”

Configuring UDP Echo Server Support

You can use UDP echo packets to measure the transit time for data between the transmitting and receiving ends.

- To enable UDP echo server support, use the following command:
  ```
  enable udp-echo-server {vr vrid} {udp-port port}
  ```
- To disable UDP echo server support, use the following command:
  ```
  disable udp-echo-server {vr vrid}
  ```

IP Broadcast Handling

The ExtremeXOS software supports IP subnet directed broadcast forwarding. In the ExtremeXOS software, IP subnet directed broadcast forwarding is done in the software by default; if you want to perform forwarding in the hardware, see the command reference pages on IP forwarding in the ExtremeXOS 22.6 Command Reference Guide.

IP Broadcast Handling Overview

To understand how IP broadcast handling functions in the ExtremeXOS software, consider the following two examples.

For the first example, a system sends an IP packet (such as the IP packet generated by the ping command) to an IP subnet directed broadcast address which is directly connected to that system. In this case, the IP packet goes out as a Layer 2 broadcast with the destination media access control (DMAC) addresses all set to FF, while the source media access control (SMAC) is set to the system MAC. This packet is sent out of all the ports of the VLAN.

In the second example, a system sends a packet (such as the IP packet generated by the ping command) to an IP subnet directed broadcast address which is remotely connected through a gateway. In this case, the IP packet goes out as a Layer 2 unicast packet with the DMAC equal to the gateway’s MAC address, while the SMAC is set to the system MAC. At the gateway router, the existing IP packet forwarding mechanism is sufficient to send the packet out of the correct interface if the router is not the final hop router.

When the packet reaches the final hop router, which is directly connected to the target IP subnet, IP directed broadcast forwarding needs to be turned on.

The IP broadcast handling feature is applicable only at the final hop router directly attached to the target subnet. At the final hop router, when IP subnet directed broadcast forwarding is enabled on an IP VLAN via the command line, the following happens:

- Some basic validity checks are performed (for example, a check to see if the VLAN has IP enabled)
- A subnet broadcast route entry for the subnet is installed. For example, consider a system with the following configuration:
  ```
  VLAN-A = 10.1.1.0/24, ports 1:1, 1:2, 1:3, 1:4
  ```
VLAN-B = 20.1.1.0/24, ports 1:5, 1:6, 1:7, 1:8
VLAN-C = 30.1.1.0/24, ports 1:9, 1:10, 1:11

If you enable IP directed broadcast forwarding on VLAN-A, you should install a route entry for 10.1.1.255 on this system.

- A packet arriving on port 1:5 VLAN-B with destination IP (DIP) set to 10.1.1.255, the source IP (SIP) set to 20.1.1.3, the DMAC set to the router MAC, and the SMAC set to the originating system MAC, arrives at the installed route entry and is sent out on all the ports of VLAN-A, with DMAC set to be all FF and the SMAC set to the router’s system MAC.
- An IP packet arriving on port 1:1 VLAN-A with the DIP set to 10.1.1.255, the SIP set to 10.1.1.3, the DMAC set to all FF, and the SMAC set to the originator’s MAC, causes Layer 2 flooding on all ports of VLAN-A.

When IP subnet directed broadcast is disabled on an IP VLAN, it is disabled on all VLAN ports and all IP subnet directed broadcast entries are deleted.

Note
IP subnet directed broadcast uses fast-path forwarding.

## VLAN Aggregation

VLAN aggregation is a feature aimed primarily at service providers.

Note
This feature is supported only on the platforms listed for this feature in the license tables in the *ExtremeXOS 22.6 Feature License Requirements* document.

The purpose of VLAN aggregation is to increase the efficiency of IP address space usage. It does this by allowing clients within the same IP subnet to use different broadcast domains while still using the same default router.

Using VLAN aggregation, a superVLAN is defined with the desired IP address. The subVLANs use the IP address of the superVLAN as the default router address. Groups of clients are then assigned to subVLANs that have no IP address, but are members of the superVLAN. In addition, clients can be informally allocated any valid IP addresses within the subnet. Optionally, you can prevent communication between subVLANs for isolation purposes. As a result, subVLANs can be quite small, but allow for growth without re-defining subnet boundaries.

Without using VLAN aggregation, each VLAN has a default router address, and you need to use large subnet masks. The result of this is more unused IP address space.

Multiple secondary IP addresses can be assigned to the superVLAN.

*Figure 215* illustrates VLAN aggregation.
Figure 215: VLAN Aggregation

In this example, all stations are configured to use the address 10.3.2.1 for the default router.

VLAN Aggregation Properties

VLAN aggregation is a very specific application, and the following properties apply to its operation:

- All broadcast and unknown traffic remains local to the subVLAN and does not cross the subVLAN boundary. All traffic within the subVLAN is switched by the subVLAN, allowing traffic separation between subVLANs (while using the same default router address among the subVLANs).
- Hosts can be located on the superVLAN or on subVLANs. Each host can assume any IP address within the address range of the superVLAN router interface. Hosts on the subVLAN are expected to have the same network mask as the superVLAN and have their default router set to the IP address of the superVLAN.
- All IP unicast traffic between subVLANs is routed through the superVLAN. For example, no ICMP redirects are generated for traffic between subVLANs, because the superVLAN is responsible for subVLAN routing. Unicast IP traffic across the subVLANs is facilitated by the automatic addition of an ARP entry (similar to a proxy ARP entry) when a subVLAN is added to a superVLAN. This feature can be disabled for security purposes.

VLAN Aggregation Limitations

The following limitations apply to VLAN aggregation:

- No additional routers may be located in a subVLAN. This feature is only applicable for “leaves” of a network.
- A subVLAN cannot be a superVLAN, and vice-versa.
- SubVLANs are not assigned an IP address.
• A subVLAN should belong to only one superVLAN.
• A subVLAN or superVLAN should not be added to a private VLAN.
• Before you can delete a superVLAN, you must delete all subVLANs in that superVLAN.
• When configuring a subVLAN address range, all addresses in the range must belong to the superVLAN subnet.

SubVLAN Address Range Checking
You can configure subVLAN address ranges on each subVLAN to prohibit the entry of IP addresses from hosts outside of the configured range.

• To configure a subVLAN range, use the following command:
  `configure vlan vlan_name subvlan-address-range ip address1 - ip address2`
• To remove a subVLAN address range, use the following command:
  `unconfigure vlan vlan_name subvlan-address-range`
• To view the subVLAN address range, use the following command:
  `show dhcp-server {vlan vlan_name}`

**Note**
Also, for super VLANs/SubVLAN, to assign an IP address, any trunk port added to a super VLAN needs to be enabled for DHCP server.

Isolation Option for Communication Between SubVLANs
To facilitate communication between subVLANs, by default, an entry is made in the IP ARP table of the superVLAN that performs a proxy ARP function. This allows clients on one subVLAN to communicate with clients on another subVLAN. In certain circumstances, intra-subVLAN communication may not be desired for isolation reasons.

• To prevent normal communication between subVLANs, disable the automatic addition of the IP ARP entries on the superVLAN using the following command:
  `disable subvlan-proxy-arp vlan [vlan-name | all]`

**Note**
The isolation option works for normal, dynamic, ARP-based client communication.

VLAN Aggregation Example
The follow example illustrates how to configure VLAN aggregation. The VLAN vsuper is created as a superVLAN, and subVLANs, vsub1, vsub2, and vsub3 are added to it.

1. Create and assign an IP address to a VLAN designated as the superVLAN. Be sure to enable IP forwarding and any desired routing protocol on the switch.

```bash
create vlan vsuper
configure vsuper ipaddress 192.201.3.1/24
enable ipforwarding
```
<p>| | |</p>
<table>
<thead>
<tr>

</tr>
<tr>
<td><strong>4 Optionally, disable communication among subVLANs.</strong></td>
<td></td>
</tr>
<tr>
<td><strong>disable subvlan-proxy-arp vlan all</strong></td>
<td></td>
</tr>
</tbody>
</table>

**Note**
The above command has no impact on Layer 3 traffic.

**Verify the VLAN Aggregation Configuration**

The following commands can be used to verify proper VLAN aggregation configuration:

- **show vlan**—Indicates the membership of subVLANs in a superVLAN.
- **show iparp**—Indicates an ARP entry that contains subVLAN information. Communication with a client on a subVLAN must have occurred in order for an entry to be made in the ARP table.
This chapter assumes that you are already familiar with IPv6 unicast routing. If not, refer to the following publications for additional information:

- RFC 2460—Internet Protocol, Version 6 (IPv6) Specification
- RFC 4291—IP Version 6 Addressing Architecture

Note
For more information on interior gateway protocols, see RIPng or IPv6 Unicast Routing.

IPv6 Unicast Overview

The switch provides full Layer 3, IPv6 unicast routing. It exchanges routing information with other routers on the network using the IPv6 versions of the following protocols:

- RIPng (Routing Information Protocol Next Generation)
- OSPFv3 (Open Shortest Path First version 3)
- Intermediate System-Intermediate System (IS-IS)
- BGP (Border Gateway Protocol)

The switch dynamically builds and maintains a routing table and determines the best path for each of its routes.

The ExtremeXOS software can provide both IPv4 and IPv6 routing at the same time. Separate routing tables are maintained for the two protocols. Most commands that require you to specify an IP address can now accept either an IPv4 or IPv6 address and act accordingly. Additionally, many of the IP configurations, enabling, and display commands have added tokens for IPv4 and IPv6 to clarify the version for which the command applies. For simplicity, existing commands affect IPv4 by default and...
require you to specify IPv6, so configurations from an earlier release will still correctly configure an IPv4 network.

ACLs and routing policies also support IPv6. Use of an IPv6 address in a rule entry will automatically use IPv6.

**Router Interfaces**

The routing software and hardware routes IPv6 traffic between router interfaces. A router interface is either a virtual LAN (VLAN (Virtual LAN)) that has an IP address assigned to it, or a Layer 3 tunnel.

As you create VLANs and tunnels with IP addresses, you can also choose to route (forward traffic) between them. Both the VLAN switching and IP routing function occur within the switch.

IPv4 and IPv6 interfaces can coexist on the same VLAN, allowing both IPv4 and IPv6 networks to coexist on the same Layer 2 broadcast domain.

---

**Note**

Each IP address and mask assigned to a VLAN must represent a unique IP subnet. You cannot configure the same IP address and subnet on different VLANs within the same **virtual router** (VR).

---

**Tunnels**

The ExtremeXOS software supports Layer 3 tunnels, which serve as a transition option, as networks change over from IPv4 to IPv6. The software supports these tunnels in Default-VR.

---

**Note**

IPv6 tunnels are supported only in Default-VR. IPv6 tunnels are not supported for ExtremeSwitching X440-G2 and X620 switches.

The ExtremeXOS software supports the use of IPv6-in-IPv4 tunnels (known as configured tunnels or 6in4 tunnels) and IPv6-to-IPv4 tunnels (known as 6to4 tunnels). Both types of tunnels are used to connect regions of IPv6 routing across a region of IPv4 routing. From the perspective of the router, the tunnel across the IPv4 region is one hop, even if multiple IPv4 routers are traversed during transport.

A 6in4 tunnel connects one IPv6 region to one other IPv6 region.

Multiple 6in4 tunnels can be configured on a single router to connect with multiple IPv6 regions. Dynamic and static routing can be configured across a 6in4 tunnel. Hosts in the IPv6 regions need not know anything about the configured tunnel, since packets destined for remote regions are sent over the tunnel like any other type of routing interface.

A 6to4 tunnel connects one IPv6 region with multiple IPv6 regions. Only one 6to4 tunnel can be configured on a single router.

GRE (Generic Router Encapsulation) is a tunneling mechanism where the customer network IP packet is encapsulated by a IP+GRE header across a network infrastructure. The decapsulation is done at the remote gateway providing the original IP datagram delivered to the peers local network. The GRE tunnel is a point-to-point path between two sites, in most cases the tunnel is used to enable
communication between sites using private address spaces across a service provider network or third-party network.

**Specifying IPv6 Addresses**

IPv6 Addresses are 128 bits (16 bytes) when compared to the 32 bit IPv4 addresses. The ExtremeXOS software accepts two standard representations for IPv6 addresses, as described in RFC 3513, section 2.2, items 1, 2, and 3.

For example, the 128 bits of the address can be represented by eight, four-digit hexadecimal numbers separated by colons:

```
```

Leading zeros in a four-digit group can be omitted.

There is a special use of a double colon (::) in an address. The double colon stands for one or more groups of 16 bits of zeros and can only be used once in an address. For example, the following addresses:

```
fe80:0:0:0:af34:2345:4afe:0
fe80:0:0:111:0:0:0:fe11
3c12:0:0:0:89:ff:3415
```

can be represented as:

```
fe80::af34:2345:4afe:0
fe80::111::fe11
3c12::89:ff:3415
```

Additionally, you can specify an address in a mixed IPv4/IPv6 mode that uses six, four-digit hexadecimal numbers for the highest-order part of the address, and uses the IPv4 dotted decimal representation for the lowest-order remaining portion.

For example:

```
0:0:0:0:0:192.168.1.1
0:0:0:0:ffff:10.0.14.254
```

These can be represented as:

```
::192.168.1.1
::ffff:10.0.14.254
```

Both global and link-local IP addresses can be configured on a *VLAN* or tunnel interface, using the following commands:
configure [{vlan} vlan_name | {tunnel} tunnel_name] ipaddress [ {eui64} ipv6_address_mask | ipv6-link-local]

configure tunnel tunnel_name ipaddress [ipv6-link-local | {eui64} ipv6_address_mask ]

where ipaddress refers to the address specified in the above format.

The IPv6 address configuration can be verified using the following commands:

show vlan {vlan_name}

show ipconfig ipv6 {vlan vlan_name | tunnel tunnelname}

Scoped Addresses

IPv6 uses a category of addresses called link-local addresses that are used solely on a local subnet. Every IPv6 VLAN must have at least one link-local address. If a global IP address is configured on a VLAN that has no link-local address, one is assigned automatically by the switch. The link-local addresses start with the prefix fe80::/64. As a result, a switch can have the same link local address assigned to different VLANs, or different neighbors on different links can use the same link local address. Because of this, there are cases where you need to specify an address and a VLAN/tunnel to indicate which interface to use. For those cases, you can indicate the interface by using a scoped address. To scope the address, append the VLAN/tunnel name to the end of the address, separated by a percent sign (%). For example, to indicate the link local address fe80::2 on VLAN finance, use the following form:

fe80::2%finance

Scoped addresses also appear in the output of display commands.

IPv6 Addresses Used in Examples

For the purposes of documentation, we follow RFC 3849, which indicates that the prefix 2001:db8::/32 can be used as a global unicast address prefix and will not be assigned to any end party.

Neighbor Discovery Protocol

The Neighbor Discovery Protocol (NDP), as defined in RFC 2461, defines mechanisms for the following functions:

- Resolving link-layer addresses of the IPv6 nodes residing on the link.
- Locating routers residing on the attached link.
- Locating the address prefixes that are located on the attached link.
- Learning link parameters such as the link MTU, or Internet parameters such as the hop limit value that has to be used in the outgoing packets.
- Automatic configuration of the IPv6 address for an interface.
Detecting whether the address that a node wants to use is already in use by another node, also known as Duplicate Address Detection (DAD).

Redirecting the traffic to reach a particular destination through a better first-hop.

In IPv4, MAC address resolution is done by ARP. For IPv6, this functionality is handled by NDP. The router maintains a cache of IPv6 addresses and their corresponding MAC addresses and allows the system to respond to requests from other nodes for the MAC address of the IPv6 addresses configured on the interfaces.

Also supported is router discovery—the ability to send out router advertisements that can be used by a host to discover the router. The advertisements sent out contain the prefixes and configuration parameters that allow the end nodes to auto-configure their addresses. The switch also responds to requests from nodes for router advertisements.

The following settings can be configured on an interface to manage router advertisements:

- Settings to control the sending of router advertisements over the interface periodically and to control responding to router solicitations
- The maximum time between sending unsolicited router advertisements
- The minimum time between sending unsolicited router advertisements

You can configure the following values, that are advertised by the switch:

- Managed address configuration flag
- Other stateful configuration flag
- Link MTU
- Retransmit timer
- Current hop limit
- Default lifetime
- Reachable time

Additionally, you can configure the following values for each prefix on the prefix list associated with an interface:

- Valid lifetime of the prefix
- On-link flag
- Preferred lifetime of the prefix
- Autonomous flag

Note

ExtremeXOS software does not support host processing of neighbor router advertisements.

Managing Neighbor Discovery

Create and Delete Static Entries

- Statically configure the MAC address of IPv6 destinations on the attached links.

```
configure neighbor-discovery cache {vr vr_name} add [ipv6address | scoped_link_local] mac
```
configure neighbor-discovery cache {vr vr_name} delete [ipv6address | scoped_link_local]

Configure the Neighbor-Discovery Cache Size

- Configure the maximum number of entries for the neighbor-discovery cache.
  
  configure neighbor-discovery cache {vr <vr_name>} max_entries <max_entry>

- Configure the maximum number of pending entries for the neighbor-discovery cache.
  
  configure neighbor-discovery cache {vr vr_name} max_pending_entries

Manage Neighbor-Discovery Cache Updates

- Configure the timeout period for dynamic entries in the neighbor-discovery cache.
  
  configure neighbor-discovery cache {vr vr_name} timeout timeout

- Enable the refresh of dynamic entries in the neighbor-discovery cache before the timeout period ends.
  
  enable neighbor-discovery {vr vr_name} refresh

- Disable the refresh of dynamic entries in the neighbor-discovery cache before the timeout period ends.
  
  disable neighbor-discovery {vr vr_name} refresh

Clear the Neighbor-Discovery Cache

- The neighbor-discovery entries that are learned dynamically can be cleared using the following command:
  
  clear neighbor-discovery cache ipv6 {ipv6address {vr vr_name} | vlan vlan_name | vr vr_name} refresh

The above CLI command is the IPv6 version of the command to clear IPv6 neighbor discovery entries in the IPv6 neighbor table. An enhancement added in ExtremeXOS 15.7 adds a refresh option so that when "clear neighbor-discovery refresh" is executed, neighbor solicitation will be sent out for each neighbor in the IPv6 neighbor discovery table and only active neighbors will be kept in the neighbor discovery table after the command is completed.

Return to the Neighbor-Discovery Cache Default Configuration

- Return to the neighbor-discovery cache default configuration.
  
  unconfigure neighbor-discovery cache {vr vr_name}

Display Neighbor-Discovery Cache Entries

- Both statically configured and dynamic neighbor-discovery entries can be viewed using the following command:
  
  show neighbor-discovery {cache {ipv6}} [{ipv6_addr | mac | permanent} {vr vr_name}] | vlan vlan_name | vr vr_name}
IPv6 Router Advertisement Options for DNS

Neighbor Discovery (ND) for IP version 6 and IPv6 stateless address autoconfiguration provide ways to configure either fixed or mobile nodes with one or more IPv6 addresses, default routers, and other parameters [RFC4861][RFC4862]. ExtremeXOS now supports two RA options that provide the DNS information needed for an IPv6 host to reach Internet services.

The Recursive DNS Server (RDNSS) option contains the addresses of recursive DNS servers, and the DNS Search List (DNSSL) option for the Domain Search List that maintains parity with the DHCPv6 options, and ensures the necessary functionality to determine the search domains.

The RDNSS option contains one or more IPv6 addresses of recursive DNS servers. All of the addresses share the same lifetime value. If you wish to have different lifetime values, you can use multiple RDNSS options.

The DNSSL option contains one or more domain names of DNS suffixes. All of the domain names share the same lifetime value. If you wish to have different lifetime values, you can use multiple DNSSL options.

The existing ND message (i.e., Router Advertisement) is used to carry this information. An IPv6 host can configure the IPv6 addresses of one or more RDNSSs through RA messages. Using the RDNSS and DNSSL options, along with the prefix information option based on the ND protocol, an IPv6 host can perform the network configuration of its IPv6 address and the DNS information simultaneously without needing DHCPv6 for the DNS configuration. The RA options for RDNSS and DNSSL can be used on any network that supports the use of ND.

For IPv6-only networks that rely only on IPv6 stateless Autoconfiguration as a deployment model, these two options allow a host to configure its DNS information. This is useful when there is no DHCPv6 infrastructure, or hosts do not have a DHCPv6 client. For networks where DHCPv6 is deployed, you might not need an RA-based DNS configuration.

You can configure the RA options for DNS using the following commands:

**Default RDNSS Lifetime**

```
configure {vlan} vlan_name> router-discovery {ipv6} rdnss-lifetime
[<rdnss_lifetime> | infinity | auto]
```

**Add RDNSS Server with Optional RDNSS Lifetime**

```
configure {vlan} vlan_name router-discovery {ipv6} add rdnss ipaddress
{{rdnss-lifetime} [rdnss_lifetime | infinity]}
```

**Default DNSSL Lifetime**

```
configure {vlan} vlan_name router-discovery {ipv6} dnssl-lifetime
[dnssl_lifetime | infinity | auto]
```

**Add a DNS suffix to DNSSL**

```
configure {vlan} vlan_name router-discovery {ipv6} add dnssl dns_suffix
{{dnssl-lifetime} [dnssl_lifetime | infinity]}
```
IPv6 Router Advertisement Filtering

Newly connected IPv6 hosts can automatically discover configuration details by sending link-local router solicitation messages. Once received, an IPv6 router can send IPv6 router advertisements (RAs) back to the host, that include network configuration parameters. Since IPv6 router advertisement packets are used to configure, among other things, the host’s gateway address, unauthorized users employ various methods to spoof IPv6 router advertisements to redirect, or deny service.

The IPv6 Router Advertisement Filtering feature exposes the existing “icmp-type” match criteria to allow IPv6 packets to match RAs and other IPv6 packets that use the ICMPv6 protocol. This functionality provides the ability to flexibly detect certain conditions and take appropriate actions based on network design and expectations.

Limitations

This feature has the following limitations:

- Only ingress ACL (Access Control List)s support the “icmp-type” match criteria for IPv6 packets. This match criteria cannot be used with egress ACLs.
- The IPv6 extension header parsing varies per platform - see “Platforms Supported” section for more detail.
- The IPv6 source-address and destination-address, and the ethernet-source-address and ethernet-destination-address fields cannot be matched in the same rule without enabling “double-wide” mode. Double wide mode is not available on all of the supported platforms and causes a 50% reduction of ACL hardware resources.

Supported Platforms

All ExtremeSwitching and Summit platforms are supported. However, there are per-platform limitations on how many IPv6 extension headers can be parsed while still matching the supplied ICMP (Internet Control Message Protocol) type:

- ExtremeSwitching and Summit X670-G2, X770: up to 2 extension headers.
- All other ExtremeSwitching and Summit switches: 0 extension headers.

The exact field compatibility with this match criteria depends on the platform, but all platforms are able to match the port and protocol (ICMPv6) in single wide mode. Using double wide mode provides access to a 128-bit source address, or source MAC address, for example. All of the above platforms support double wide mode at the expense of reducing ACL scale by 50%. The XGS3 platforms do not support double wide mode at all.

On platforms that support double wide mode, if the layer-2 device is unable to identify whether the packet is an ICMPv6 Router Advertisement message, and the IPv6 Source Address of the packet is a link-local address or is unspecified, the packet is blocked.

You can also use the new “icmp-type” to match other protocol cases such as MLD and MLDv2.

CLI Commands

The existing ACL match criteria `icmp-type type` is exposed in dynamic ACLs and static ACL policies on the target platforms. This same match criteria is already supported for rules that specify IPv4 criteria on the target platforms.
Example Policy

Here is a policy to detect and log a “simple” RA attack, only allow TCP/UDP/ICMP/xyz protocol traffic that can be parsed (i.e., has up to 2 extension headers and, if fragmented, the L4 NH is contained in the first fragment), and deny everything else including “complex” RA attacks:

```c
entry disallow_and_log_RA_attacks
{if
 {protocol icmpv6;icmp-type 134;}
then
 { deny; mirror-cpu; log; count RA_attack;}}
entry allow_tcp
{if {protocol tcp; first-fragments;}
then {permit;}}
entry allow_udp
{if {protocol udp; first-fragments;}
then {permit;}}
entry allow_icmp
{if {protocol icmpv6; first-fragments;}
then {permit;}}
entry allow_xyz
{entry denyall
{if{first-fragments; }
then
 { deny;}}}
```

The above policy works for newer chipsets, but leaves (at least) the following exposure for older chipsets: a malicious user could send an RA with a single extension header and it would be allowed to pass due to rule “allow_icmp” (newer chipsets would block this packet through the first rule). To mitigate this exposure on older chipsets, you could call out each “icmp-type” that is supported (ND, MLD, etc.), and then drop any ICMPv6 with an extension header.

Managing Duplicate Address Detection

The Duplicate Address Detection (DAD) feature checks networks attached to a switch to see if IP addresses configured on the switch are already in use on an attached network. The following sections provide additional information on the DAD feature:

- **DAD Overview** on page 1355
- **Configuring DAD** on page 1357
- **Running a DAD Check** on page 1357
- **Displaying DAD Configuration and Statistics** on page 1357
- **Clearing the DAD Counters** on page 1357

When you configure an active interface with an IPv6 address, the interface must send out an advertisement containing its address.

All other interfaces on the subnet have the opportunity to respond to the newly configured interface, and inform it that the address is a duplicate. Only after this process occurs, can the interface use the
newly configured address. If the interface receives a message that the newly configured address is a duplicate, it cannot use the address.

Until the Duplicate Address Detection (DAD) process completes, the new address is considered tentative, and will be shown as such in any display output. If the address is a duplicate, it will also be labeled as such, and must be reconfigured. On an active interface, the DAD process should occur so quickly that you would not see the address labeled as tentative. However, if you are configuring an interface before enabling it, and you display the configuration, you will see that the address is currently tentative. As soon as you enable the interface, the address should be ready to use, or labeled as duplicate and must be reconfigured.

See RFC 2462, IPv6 Stateless Address Autoconfiguration, for more details.

**DAD Overview**

When enabled on a user VR or **VR-Default**, the Duplicate Address Detection (DAD) feature runs when an IP interface is initialized or when a CLI command initiates a DAD check. The DAD check tests IP addresses by sending a neighbor solicitation to each IP address it checks. If another device replies to the neighbor solicitation, a duplicate IP address is detected.

If a duplicate address is detected, the IP interface remains or becomes inactive, and a warning message is logged. If no duplicate address is detected, the IP interface transitions to or remains in the active state. The switch does not automatically repeat the DAD check after the first check is complete. To manually run a DAD test on an interface or IP address, enter the `run ipv6 dad` command.

Because the automatic DAD check only runs when an interface is initialized, the switch does not detect a duplicate IP address if that address becomes active after the switch interface is initialized. However, if the switch is rebooted or the interface in brought down and then up, the automatic DAD check runs and sets to inactive any interface for which a duplicate IP address is detected.

To successfully test an IPv6 interface, at least one port in the host **VLAN** must be in the Up state. If all ports in the host VLAN are Down, the DAD check does not run. If a port is later added to the host VLAN, or if a port in the host VLAN transitions to Up after the DAD check at initialization is complete, a duplicate IP address can be detected and logged, but the IP interface on the host VLAN remains active.

**Configure DAD**

- Enable or disable the DAD feature and configure feature operation.

```
configure ipv6 dad [off | on] [on] attempts max_solicitations] {{vr} vr_name | vr all}
```

**Note**

For IPv6 interfaces, the DAD feature is automatically enabled on all platforms that support the Edge, Advanced Edge, and Core licenses.

**Run a DAD Test**

- Initiate a DAD test.

```
run ipv6 dad [(vlan) vlan_name | (vr) vr_name] ipaddress
```
Display DAD Configuration and Statistics

- Display DAD configuration and statistics information.

  ```
  show ipv6 dad {{vr vr_name | vr all} | {vlan} vlan_name | {tunnel} tunnel_name} {tentative | valid | duplicate} | {{vr vr_name} ipaddress}} {detail}
  ```

Clear the DAD Counters

- Clear the DAD feature statistics counters.

  ```
  clear ipv6 dad {{vr vr_name} ipaddress} | {vr all} | {vlan} vlan_name} {counters}
  ```

Populating the Routing Table

The switch maintains an IP routing table for both network routes and host routes. The table is populated from the following sources:

- Dynamically, by way of routing protocol packets or by ICMP redirects exchanged with other routers
- Statically, by way of routes entered by the administrator:
  - Default routes, configured by the administrator
  - Locally, by way of interface addresses assigned to the system
  - By other static routes, as configured by the administrator

Once routes are populated using the above method, IPv6 forwarding needs to be enabled on the VLAN using the following command:

  ```
  enable ipforwarding ipv6 {vlan vlan_name | tunnel tunnel_name | vr vr_name}
  ```

Note

If you define a default route and subsequently delete the VLAN on the subnet associated with the default route, the invalid default route entry remains. You must manually delete the configured default route.

Dynamic Routes

Dynamic routes are typically learned by way of RIPng, OSPFv3, BGP, or IS-IS, and routers that use these protocols use advertisements to exchange information in their routing tables. Using dynamic routes, the routing table contains only networks that are reachable.

Dynamic routes are aged out of the table when an update for the network is not received for a period of time, as determined by the routing protocol. For details on the configuration and behavior of IPv6 dynamic routes, please refer to the specific Chapters on RIPng, OSPFv3, and IS-IS in this guide.

Static Routes

Static routes are manually entered into the routing table. Static routes are used to reach networks not advertised by routers.
• Static IPv6 routes can be created using the following command:

```
configure iproute add ipv6Netmask [ipv6Gateway | ipv6ScopedGateway] {metric} {vr vr_name} {multicast | multicast-only | unicast | unicast-only}
```

You can configure IPv6 default and blackhole routes. Traffic to blackhole routes is silently dropped.

The IPv6 gateway can be a global address or a scoped link-local address of an adjacent router.

• You can create static routes, for security reasons, to control which routes you want advertised by the router.

If you want all static routes to be advertised, redistribute the static routes using one of the following commands:

```
enable ripng export [direct | ospfv3 | ospfv3-extern1 | ospfv3-extern2 | ospfv3-inter | ospfv3-intra | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external | bgp | e-bgp i-bgp] [cost number {tag number} | policy policy-name]
```

or

```
disable ripng export [direct | ospfv3 | ospfv3-extern1 | ospfv3-extern2 | ospfv3-inter | ospfv3-intra | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external | bgp e-bgp i-bgp]
```

```
enable ospfv3 export [direct | ripng | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external | bgp e-bgp i-bgp | host-mobility] [cost cost type [ase-type-1 | ase-type-2] | policy_map]
```

or

```
disable ospfv3 export [direct | ripng | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external | bgp e-bgp i-bgp]
```

The default setting is disabled. Static routes are never aged out of the routing table.

• A static route’s nexthop (gateway) must be associated with a valid IP subnet. An IP subnet is associated with a single VLAN by its IP address and subnet mask. If the VLAN is subsequently deleted, the static route entries using that subnet must be deleted manually.

You can view IPv6 routes using the following command:

```
show iproute ipv6 {priority | vlan vlan_name | tunnel tunnel_name | ipv6Netmask | summary {multicast | unicast}} {vr vr_name})
```

• You can view the IPv6 routes based on the type of the route using the following command:

```
show iproute ipv6 origin [auto-peeringdirect | static | blackhole | ripng | ospfv3 | ospfv3-intra | ospfv3-inter | ospfv3-extern1 | ospfv3-extern2 | isis | isis-level-1 | isis-level-2 | isis-level-1-external |
ExtremeXOS® User Guide for version 22.6

ExtremeXOS Resiliency Enhancement for IPv6 Static Routes

The ExtremeXOS Resiliency Enhancement feature provides a resilient way to use Equal-Cost Multi-Path (ECMP) to load balance IPv6 traffic among multiple servers or other specialized devices. ExtremeXOS automatically manages the set of active devices using ECMP static routes configured with ping protection to monitor the health of these routes. Such servers or specialized devices do not require special software to support Bidirectional Forwarding Detection (BFD), or IP routing protocols such as OSPF (Open Shortest Path First)v3, or proprietary protocols to provide keepalive messages. ExtremeXOS uses industry-standard and required protocols ICMPv6/Neighbor Discovery for IPv6 to accomplish the following automatically:

- Initially verify devices and activate their static routes, without waiting for inbound user traffic, and without requiring configuration of device MAC addresses.
- Detect silent device outages and inactivate corresponding static routes.
- Reactivate static routes after device recovery, or hardware replacement with a new MAC address.

ExtremeXOS currently supports similar protection and resiliency using Bidirectional Forwarding Detection (BFD) on IPv4 static routes. However, BFD can only be used when the local and remote device both support BFD.

Multiple Routes

When there are multiple, conflicting choices of a route to a particular destination, the router picks the route with the longest matching network mask. If these are still equal, the router picks the route using the following default criteria (in the order specified):

- Directly attached network interfaces
- Static routes
- ICMP redirects
- Dynamic routes
- Directly attached network interfaces that are not active.

Note

If you define multiple default routes, the route that has the lowest metric is used. If multiple default routes have the same lowest metric, the system picks one of the routes.

The criteria for choosing from multiple routes with the longest matching network mask is set by choosing the relative route priorities.

Relative Route Priorities

Table 139 lists the relative priorities assigned to routes depending on the learned source of the route.

Note

Although these priorities can be changed, do not attempt any manipulation unless you are expertly familiar with the possible consequences.
Table 139: Relative Route Priorities

<table>
<thead>
<tr>
<th>Route Origin</th>
<th>Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>Direct</td>
<td>10</td>
</tr>
<tr>
<td>BlackHole</td>
<td>50</td>
</tr>
<tr>
<td>Static</td>
<td>1100</td>
</tr>
<tr>
<td>HostMobility</td>
<td>1150</td>
</tr>
<tr>
<td>ICMP</td>
<td>1200</td>
</tr>
<tr>
<td>Fabric</td>
<td>1699</td>
</tr>
<tr>
<td>OSPFv3Intra</td>
<td>2200</td>
</tr>
<tr>
<td>OSPFv3Inter</td>
<td>2300</td>
</tr>
<tr>
<td>IS-IS</td>
<td>2350</td>
</tr>
<tr>
<td>IS-IS L1</td>
<td>2360</td>
</tr>
<tr>
<td>IS-IS L2</td>
<td>2370</td>
</tr>
<tr>
<td>RIPng</td>
<td>2400</td>
</tr>
<tr>
<td>OSPFv3 ASExt</td>
<td>3100</td>
</tr>
<tr>
<td>OSPFv3 Extern1</td>
<td>3200</td>
</tr>
<tr>
<td>OSPFv3 Extern2</td>
<td>3300</td>
</tr>
<tr>
<td>IS-IS L1Ext</td>
<td>3400</td>
</tr>
<tr>
<td>IS-IS L2Ext</td>
<td>3500</td>
</tr>
<tr>
<td>EBGP</td>
<td>1700</td>
</tr>
<tr>
<td>IBGP</td>
<td>1900</td>
</tr>
</tbody>
</table>

To change the relative route priority, use the following command:

```
configure iproute ipv6 priority [ripng | blackhole | icmp | host-mobility | static | ospfv3-intra | ospfv3-inter | ospfv3-as-external | ospfv3-extern1 | ospfv3-extern2 | isis | isis-level-1 | isis-level-2 | isis-level-1-external | isis-level-2-external | ebgp | ibgp] priority {vr vr_name}
```

Route priority configurable value is between 11-65,534.

Unique Local Address (ULA) for IPv6

RFC 4193 defines a globally unique address that is used for local communications. For instance, they are routable within a specified site or between sites. These ULAs are similar to private addresses in IPv4 (RFC 1918).

Of the 128 bits available in IPv6 address, the last 64-bits are used as the interface ID.

The remaining 64 bits are used as follows:
First 8 bits are used to define the known prefix FC00::/7 or FD00::/7

40 bits - global ID - Generated using a random algorithm specified in the RFC 4193. ExtremeXOS expects the operator to specify the 40-bit Global ID as ULA address management becomes easier, especially a mult-vendor environment.

16 bits - Used to create subnets within the site.

ULA prefixes should not be accepted by the border routers.

Additionally, ULA prefixes should not be advertised by the border routers. In ExtremeXOS, for BGP and OSPFv3, you must specify the policies to filter ULA prefixes.

There are no new CLI commands introduced to configure ULAs in ExtremeXOS. You can use the following existing command to configure a ULA:

```
configure {vlan} vlan_name ipaddress [ipaddress {ipNetmask} | ipv6-link-local | {eui64} ipv6_address_mask]
```

Here is an example of the command:

```
configure vlan v1 ipaddress fd21:0941:2c55::/48
```

The scope of ULA is global by default in RFC 4193.

All applications treat these addresses in a similar manner as any other type of global IPv6 unicast addresses.

---

**Managing IPv6 Unicast Routing**

You should be familiar with IP Route Sharing for both IPv4 and IPv6. For information about IP route sharing, see Configuring IP Route Sharing on page 1350.

For SummitStack and Summit family switches that support Layer 3 routing, the ExtremeXOS software supports route sharing across up to 2, 4, 8, 16, or 32 next-hop gateways.

---

**Enabling Route Sharing for IPv6**

To enable route sharing for IPv6, use the following command:

```
enable iproute ipv6 sharing
```

---

**Configuring Basic IP Unicast Routing**

To configure basic IP unicast routing, do the following:

1. Create and configure two or more VLANs.
2. Assign each VLAN that will be using routing an IP address using the following command:

   ```
   configure {vlan} vlan_name ipaddress [ipaddress {ipNetmask} | ipv6-link-local | {eui64} ipv6_address_mask]
   ```

   Ensure that each VLAN has a unique IP address.
3 Configure a static route using the following command:

```
configure iproute add ipv6Netmask [ipv6Gateway | ipv6ScopedGateway] (metric) (vr vr_name) {multicast | multicast-only | unicast | unicast-only}
```

or

Configure a default route using the following command:

```
configure iproute add default [{gateway {metric} {vr vr_name} (unicast-only | multicast-only)} | {lsp lsp_name {metric}}]
```

Default routes are used when the router has no other dynamic or static route to the requested destination.

4 Turn on IP routing for one or all VLANs using the following command:

```
enable ipforwarding ipv6 {vlan vlan_name | tunnel tunnel_name | vr vr_name}
```

5 Configure the routing protocol, if required. For a simple network using RIPng, default configuration might be acceptable.

6 Turn on RIPng or OSPFv3 using one of the following commands:

```
enable ripng

enable ospfv3
```

**Note**

BGP does not use ECMP by default, so if you require that functionality you must explicitly issue the `configure bgp maximum-paths max-paths` command with a value greater than 1.

---

**Managing Router Discovery**

**Enable and Disable Router Discovery**

- Enable or disable router discovery on a VLAN.

```
enable router-discovery {ipv6} vlan vlan_name

disable router-discovery {ipv6} vlan vlan_name
```

**Add and Delete Prefixes for Router Discovery**

- Add or delete prefixes for advertisement by router discovery.

```
configure vlan vlan_name router-discovery {ipv6} add prefix prefix

configure vlan vlan_name router-discovery {ipv6} delete prefix [prefix | all]
```
Configure Router Discovery Settings

- Configure the router discovery settings using the following commands:
  - `configure vlan vlan_name router-discovery {ipv6} default-lifetime defaultlifetime`
  - `configure vlan vlan_name router-discovery {ipv6} link-mtu linkmtu`
  - `configure vlan vlan_name router-discovery {ipv6} managed-config-flag on_off`
  - `configure vlan vlan_name router-discovery {ipv6} max-interval maxinterval`
  - `configure vlan vlan_name router-discovery {ipv6} min-interval mininterval`
  - `configure vlan vlan_name router-discovery {ipv6} other-config-flag on_off`
  - `configure vlan vlan_name router-discovery {ipv6} reachable-time reachabletime`
  - `configure vlan vlan_name router-discovery {ipv6} retransmit-time retransm Wittme`
  - `configure vlan vlan_name router-discovery {ipv6} set prefix prefix [autonomous-flag auto_on_off | onlink-flag onlink_on_off | preferred-lifetime preflife | valid-lifetime validlife]`

- Reset all router discovery settings to their default values using the command: `unconfigure vlan vlan_name router-discovery {ipv6}`

- To reset an individual router discovery setting to its default value, enter one of the following commands:
  - `unconfigure vlan vlan_name router-discovery {ipv6} default-lifetime`
  - `unconfigure vlan vlan_name router-discovery {ipv6} hop-limit`
  - `unconfigure vlan vlan_name router-discovery {ipv6} link-mtu`
  - `unconfigure vlan vlan_name router-discovery {ipv6} managed-config-flag`
  - `unconfigure vlan vlan_name router-discovery {ipv6} max-interval`
  - `unconfigure vlan vlan_name router-discovery {ipv6} min-interval`
  - `unconfigure vlan vlan_name router-discovery {ipv6} other-config-flag`
  - `unconfigure vlan vlan_name router-discovery {ipv6} reachable-time`
  - `unconfigure vlan vlan_name router-discovery {ipv6} retransmit-time`

Display Router Discovery Configuration Settings

To display router discovery settings, use the command: `show router-discovery {ipv6} {vlan vlan_name}`

Managing Tunnels

IPv6-in-IPv4 and IPv6-to-IPv4 tunnels are introduced in Tunnels on page 1378.
Create an IPv6-in-IPv4 Tunnel

- Create an IPv6-in-IPv4 tunnel.
  ```
  create tunnel tunnel_name ipv6-in-ipv4destination destination-address source source-address
  ```
  The `source-address` refers to an existing address in the switch, and the `destination-address` is a remote destination accessible from the switch. A maximum of 255 IPv6-in-IPv4 tunnels can be configured.

Create an IPv6-to-IPv4 Tunnel

A 6to4 tunnel connects one IPv6 region with multiple IPv6 regions. Only one 6to4 tunnel can be configured on a single router.
- To create an IPv6-to-IPv4 tunnel, use the command:
  ```
  create tunnel tunnel_name 6to4 source source-address
  ```
  The `source-address` is an existing address in the switch.

Delete a Tunnel

To delete a tunnel, use the command: `delete tunnel tunnel_name`

Configure an IPv6 Address for a Tunnel

To configure or unconfigure IPv6 addresses for the tunnels, use the commands:
```
configure tunnel tunnel_name ipaddress [ipv6-link-local | {eui64} ipv6_address_mask ]
unconfigure tunnel tunnel_name ipaddress ipv6_address_mask
```

Display Tunnel Information

- Display tunnel information.
  ```
  show [{tunnel} {tunnel_name}]
  ```

Verifying the IP Unicast Routing Configuration

- To display the currently configured routes, which includes how each route was learned, use the command: `show iproute ipv6`
  Additional verification commands include:
  ```
  show neighbor-discovery cache ipv6—Displays the neighbor discovery cache of the system.
  show ipconfig ipv6—Displays configuration information for one or more VLANs.
  show ipstats ipv6—Displays the IPv6 statistics for the switch or for the specified VLANs.
Managing IPv6 Routes and Hosts in External Tables

When external LPM tables are supported and configured on a switch, the configuration setting applies only to the external LPM tables. You can configure the external LPM to contain both IPv4 and, or, IPv6 routes. Internal LPM tables only store IPv4 routes.

The configure forwarding external-tables command using the ipv6 and ipv4-and-ipv6 variables supports larger IPv6 route and host scaling in external LPM tables.

When an external LPM table is configured for l3-only ipv6, no IPv6 routes or IPv6 hosts are configured in any of the internal hardware tables. This provides the highest IPv6 scale, and avoids contention with IP Multicast in the L3 Hash hardware table.

IPv6 hardware and slowpath forwarding are supported on user-created Virtual Routers, and IPv6 tunnels are only supported on VR-Default.

The size of the internal LPM tables, and the size of the L3 Hash and Next Hop tables are fixed. For specific information on hardware capacity, refer to the following table, the following table, and the following table in IPv4 Unicast Routing on page 1327.

IPv6 ECMP and 32-Way ECMP

This feature adds IPv6 Equal-Cost Multi-Path (ECMP) support on several new platforms. Additionally, it adds support for 16-way and 32-way ECMP (for both IPv4 and IPv6), using static routes, and up to 8-way ECMP for IPv4 and IPv6 using routing protocols.

Sharing ECMP gateway sets now applies to IPv6 as well as IPv4. Sharing ECMP gateway sets for IPv6 means the entire IPv6 Longest-Prefix Match (LPM) hardware capacity can use ECMP, across up to 32 gateways.

Feature Description

This feature adds IPv6 ECMP support on all platforms.

Additionally, ExtremeXOS supports 16-way and 32-way ECMP for both IPv4 and IPv6 using static routes, and up to 8-way ECMP for IPv4 and IPv6 using routing protocols. Now, the maximum number of gateways in each IPv4 or IPv6 gateway set in the ECMP hardware table can be configured as 16 or 32.

DHCPv6 Relay Remote-ID Option

Available in ExtremeXOS 15.5, the remote-id option is added to the relay forward IPv6 message, if the specific VLAN has only the link local IPv6 address. This remote-id is added to all the request packets received from the client on that VLAN, if it is configured or not on the VLAN. The remoteID option added to the packet after the relay message header has the following format, as defined in RFC 4649:
Figure 216: DHCPv6 Relay Remote-ID Option

If the remote-id is configured through the CLI on a specified VLAN, it can have either a user defined value, or the system-name. If the user does not configure the value or marks “none” as the remote-id, the switch MAC address will be used as the remote-id. The value of the remote-id present in the packet will have the following format: vlan_port_<remoteId>, where remoteId will be either the configured string, or the system name or the switch MAC address. The Enterprise number field will be populated with the Extreme Networks enterprise number, “1916”.

The remote-id is added to the packets on a specified VLAN, only if:

- IPv6 bootprelay is enabled on the VLAN.
- the vlan has only the link local address.

Once a relay agent receives one of the following messages from the client or relay agent, the relay agent will verify if the specific interface has only the link local address:

- DHCPV6_SOLICIT
- DHCPV6_REQUEST
- DHCPV6_CONFIRM
- DHCPV6_RENEW
- DHCPV6_REBIND
- DHCPV6_RELEASE
- DHCPV6_DECLINE
- DHCPV6_INFORMATION_REQUEST
- DHCPV6_RELAY_FORW
- DHCPV6_LEASEQUERY

If so, it verifies if the specific VLAN has a remote-id configured. If a remote-id is present, it is added to the packet along with the VLAN and port, in the format mentioned above. If it is not configured, the default (switch MAC address) will be added as the remote id, along with the VLAN and port.

On the reverse path, if it receives any of the following messages from the server or any other relay agent, and if the interface has only a link local address, it will verify for the presence of remote-id in the packet:
• DHCPV6_ADVERTISE
• DHCPV6_REPLY
• DHCPV6_RECONFIGURE
• DHCPV6_RELAY_FORW
• DHCPV6LEASEQUERY_REPLY

If it is not present, the agent will check for the interface-id. If one of these is present, it will verify if the value matches the local configuration. If it matches, after removing the remote-id and/or interface-id, the packet will be forwarded to the respective client. If the remote-id is present in the packet, and it does not match the configured value, the packet will be dropped. If none of them are present, the packet will be forwarded to the client, based on the IPv6 address of the VLAN.

DHCPv6 Relay Agent Prefix Delegation

DHCPv6 Prefix Delegation options provide a mechanism for automated delegation of IPv6 prefixes using DHCP (Dynamic Host Configuration Protocol). This mechanism is intended for delegating a long-lived prefix from a delegating router to a requesting router, across an administrative boundary, where the delegating router does not have/require knowledge about the topology of the networks to which the requesting router is attached, and the delegating router does not require other information aside from the identity of the requesting router to choose a prefix for delegation.

For example, these options would be used by a service provider to assign a prefix to a Customer Premise Equipment (CPE) device acting as a router between the subscriber’s internal network and the service provider’s core network.

This prefix delegation mechanism is appropriate for use by an ISP to delegate a prefix to a subscriber, where the delegated prefix would possibly be sub-netted and assigned to the links within the subscriber’s network.
The prefix delegation process begins when the requesting router requests configuration information through DHCP. When the delegating router receives the request, it selects and returns an available prefix or prefixes for delegation to the requesting router.

The requesting router now acts as a DHCP server for the subscriber network. It subnets the delegated prefix and assigns the longer prefixes to links in the subscriber’s network. In a typical scenario based on the network shown in Figure 1, the requesting router subnets a single delegated /48 prefix into /64 prefixes and assigns one /64 prefix to each of the links in the subscriber network.

Prefix delegation with DHCP is independent of address assignment with DHCP. A requesting router can use DHCP for just prefix delegation or for prefix delegation along with address assignment and other configuration information.

**Relay Agent Behavior in Prefix Delegation**

A relay agent forwards DHCP messages containing Prefix Delegation options in the same way as other DHCP messages.

RFC 3633 says “If a delegating router communicates with a requesting router through a relay agent (sitting in between the Aggregation device (PE) and the CPE), the delegating router may need a protocol or other out-of-band communication to add routing information for delegated prefixes into the provider edge router.”
The requesting router acts as a DHCPv6 server behind the CPE and assigns IPv6 subnets to the customer devices. Since there is no mechanism to notify the delegating router about the IPv6 subnets assigned by the requesting router, the core routers have no clue about these IPv6 subnets and therefore have no dynamic route added into the routing tables in the core. RFC 3633 leaves it to the implementations to device a mechanism to solve this problem.

When the ExtremeXOS DHCPv6 relay agent relays the DHCP messages with IA_PD options and detects that a successful prefix delegation operation has been completed and a prefix or a set of prefixes have been delegated, it installs one route for each of prefixes that has been delegated. This ensures reachability between the customer devices and the service provider network.

When ExtremeXOS DHCPv6 relay agent detects a successful DHCP prefix delegation transaction (Solicit-Advertise-Request-Reply), it looks into the details of the prefix(es) that are being delegated. Each DHCP message with IA_PD option can have multiple IAPREFIX options in it. Each IAPREFIX option represents a prefix that is being delegated.

ExtremeXOS DHCPv6 relay agent installs one route for each of the delegated prefixes. The route is installed on the VLAN on which the requesting router (CPE) is reachable and with the requesting router (CPE) as the gateway for the route, if the requesting router is directly connected to our ExtremeXOS DHCPv6 Relay agent. If the DHCPv6 messages from the requesting router have been received via another DHCPv6 Relay agent, the route is installed with the next hop DHCPv6 Relay agent as the gateway. If the DHCPv6 packets from the next hop DHCPv6 Relay agent have been IPv6 forwarded via other routers in between (which did not do DHCPv6 Relay, but just IPv6 forwarding), the next hop router to reach the next hop DHCPv6 Relay agent is used as the gateway for the route. ExtremeXOS DHCPv6 Relay uses Route Manager (rtMgr) client library APIs for adding and deleting these routes.

To ensure that the routes are retained across reboots (or restart process netTools), ExtremeXOS DHCPv6 relay agent stores these routes along with their validity times in an internal file. After a reboot, ExtremeXOS DHCPv6 relay agent reads this file and installs the routes once again. This file will be a flat file with the following format: vlanName ipv6Prefix ipv6GatewayAddr startTime validTime.

Only those IPv6 prefixes which are still valid after the reboot are added again. The expired IPv6 prefixes are discarded. As the file format denotes, this file contains the details about the VLAN, the actual delegated IPv6 prefix, the IPv6 Gateway Address, the start time when it got delegated and the time for which the delegated prefix is deemed to be valid (in seconds). This file is internal to ExtremeXOS DHCPv6 relay agent and cannot/should not be edited by anyone else.

ExtremeXOS DHCPv6 relay agent checkpoints the prefix delegations that have been detected.

**Basic Snooping Configuration**

```
create vlan v1

enable bootprelay ipv6
conf bootprelay ipv6 prefix-del snooping on vlan v1

con bootprelay ipv6 prefix-delegation snooping add 5001:db8:3553:bf00::/56
fe80::a440:cfd5:c05b:d324 vlan v1 valid-time 300

* (Engineering) Slot-1 Sharmila_DUT1_Stack--->.13 # sh bootprelay ipv6 prefix-delegation snooping

Delegated Prefix                              Interface
```
### DHCPv6 Client

ExtremeXOS supports Dynamic Host Configuration Protocol version 6 (DHCPv6) clients, receiving its IPv6 address and corresponding parameters for any VLAN interface from an external DHCPv6 server. For the ExtremeXOS device to operate as a DHCPv6 client, we need to enable DHCPv6 client on a VLAN interface to obtain an IPv6 address from the DHCPv6 server in the network.

ExtremeXOS DHCPv6 client supports only the stateful DHCPv6 mode of operation in this release. This means an external DHCPv6 server is required to configure the IPv6 address and its related configurations.

#### Note
Stateless Auto configuration and stateless DHCPv6 modes are not supported in this release.

The mode of operation of the DHCPv6 client is based on the autonomous (A), managed (M) and other configuration (O) flags in the received router advertisement (RA) messages. If the managed bit is 1 and the other configuration bit is 0, the DHCPv6 client will act as a stateful client. In stateful mode, the client receives IPv6 addresses from the DHCPv6 server, based on the identity association for nontemporary addresses (IA_NA) assignment.
In other words ExtremeXOS DHCPv6 client sends IA_NA option as part of the DHCPv6 message.

**Note**
Identity association for temporary address (IA_TA) and Identity association for prefix delegation (IA_PD) is not supported in this release.

If the incoming RA points to act the interface in stateless DHCPv6 mode (managed bit is 0 and the other configuration bit is 1) or DHCPv6 auto configuration mode (autonomous bit is 1 and managed, other configuration bit is 0) ExtremeXOS will release the assigned (if already assigned using stateful DHCPv6 client mode) DHCPv6 IP and other parameters for this VLAN interface on which this RA is received.

This is because the mode of operation needs to be changed because ExtremeXOS did not support stateless DHCPv6 and auto configuration DHCPv6 client modes and there will not be any subsequent operation. In the stateful DHCPv6 client mode, the DHCPv6 client requests global addresses from the DHCPv6 server. Based on the DHCPv6 server’s response, the DHCPv6 client assigns the global addresses to interfaces and sets a lease time for all valid responses. When the lease time expires, the DHCPv6 client renews the lease from the DHCPv6 server. To configure stateful DHCPv6 client based on identity association of non-temporary (IA_NA) address assignment for a VLAN interface use the following command.

```
enable dhcp ipv6 vlan vlan_name
```

To unconfigure the stateful DHCPv6 client for an interface use:

```
disable dhcp ipv6 vlan vlan_name
```

To display the current status of the DHCPv6 client VLAN state use:

```
show dhcp-client ipv6 state {vlan}
```

DHCPv6 client is not supported on VR-MGMT.

**DHCP Unique Identifier**

Each DHCP client and server has a DHCP unique identifier (DUID). A DHCP server uses DUIDs to identify clients for the selection of configuration parameters. DHCP clients use DUIDs to identify a server in messages where a server needs to be identified. Clients and servers treat DUIDs as opaque values and use it compare for equality.

The DUID is not required in all the DHCP messages. It has to be unique across all DHCP clients and servers. It has to be stable for any specific client or server - for example, a device’s DUID should not change as a result of a change in the VLAN’s port.

**DHCP Unique Identifier Content**

A DHCP unique identifier (DUID) consists of a two-octet type code followed by a variable number of octets that make up the actual identifier. A DUID can be no more than 128 octets long (not including the type code). The following types are currently defined:

- Link-layer address plus time
• Vendor-assigned unique ID based on Enterprise Number
• Link-layer address

ExtremeXOS uses Link-layer address plus time as its default client DUID. To configure DHCPv6 client identifier type for the client use:

```bash
configure dhcp ipv6 client identifier-type [ link-layer | link-layer-plus-time | vendor-specific ]
```

### Client Requested DHCPv6 Options

The following default options are encapsulated by the DHCPv6 client when requesting DHCPv6 server.

1. **OPTION_CLIENTID (code 1).** The Client Identifier option is used to carry a DUID identifying a client between a client and a server.

2. **OPTION_SERVERID (code 2).** The Server Identifier option is used to carry a DUID identifying a server between a client and a server.

**Note**

OPTION_SERVERID option is included if DHCPv6 client is responding to a particular server.

3. **OPTION_IA_NA (code 3).** The client uses IA_NA options to request the assignment of non-temporary address assignment.

4. **OPTION_IAADDR (code 5).** The IA_ADDR is used to specify the IPv6 addresses associated with IA_NA or IA_TA option.

**Note**

OPTION_IAADDR is included only if the client lease is present.

5. **OPTION_ORO (code 6).** The Option Request option is used to identify a list of options in a message between client and server. A client includes an Option Request option in a Solicit, Request, Renew, Rebind, Confirm or Information-request message to inform the server about options the client is interested in.

The following are the Default requested options included by the ExtremeXOS DHCPv6 client as part of Option Request Option (OPTION_ORO) option:

1. **OPTION_DNS_SERVERS (code 23).**

3. **OPTION_ELAPSED_TIME (code 8).** A client MUST include an Elapsed Time option in messages to indicate how long the client has been trying to complete a DHCP message exchange.

### Configuring DHCPv6 BOOTP Relay

To configure the relay function:
1. Configure VLANs and IP unicast routing.

Note: As in DHCPv4, when you create an IPv6 VLAN interface, the corresponding disabledV6VlanList has an entry. The VLAN interface entry is removed whenever the bootpRelayv6 for the respective VLAN is enabled, and vice versa.

2. Enable the DHCP or BOOTP relay function using the following commands:

   enable bootprelay {ipv4|ipv6} {vlan[vlan_name] | {vr} vr_name} | all [{vr} vr_name]
   enable bootprelay {vlan[vlan_name] | {vr} vr_name} | all [{vr} vr_name]

3. Configure the addresses to which DHCP or BOOTP requests should be directed using the following command:

   configure bootprelay {ipv4 | ipv6} [vlan[vlan_name] | {vr} vr_name] | all [{vr} vr_name]
   configure bootprelay {ipv4 | ipv6} add ip_address {vr vrid}

   Note: Use the configure bootprelay ipv6 option interface-id InterfaceIDName vlan {vlan_name} command to set up a unique interface-id. It can be MAC-ID, or port-vlan combination. You can also use this command to set up dhcpv6 server/next hop for each VLAN interface, or across VR. A configuration applied to the VR level is populated to all VLAN V6 interfaces.

4. To delete an entry, use the following command:

   configure bootprelay {ipv4 | ipv6} delete [ip_address | all] {vr vrid}

5. To disable BOOTP relay on one or more VLANs, use the following command:

   disable bootprelay {ipv4 | ipv6} {vlan[vlan_name] | {vr} vr_name} | all [{vr} vr_name]
   disable bootprelay {vlan[vlan_name] | {vr} vr_name} | all [{vr} vr_name]

   Note: When VRRP (Virtual Router Redundancy Protocol) and BOOTP/DHCP relay are both enabled on the switch, the relayed BOOTP agent IP address is the actual switch IP address, not the virtual IP address.

---

**Configure Route Compression**

This helps with route optimization and scaling. This feature allows you to install only less specific routes in the table when overlapping routes with the same nexthop exist. For detailed information about route compression, see Hardware Routing Table Management.

Note: This feature is enabled by default starting from ExtremeXOS 15.6.
• Enable this feature.

    enable iproute ipv6 compression {vr vrname}

• Disable this feature.

    disable iproute ipv6 compression {vr vrname}

### Hardware Forwarding Behavior

Table 140 shows the Extreme switch platforms and the ExtremeXOS software versions that provide hardware forwarding support for IPv6 unicast features.

### Hardware Forwarding Limitations

All switches can use hardware forwarding when the route mask is 64 bits or less. If the route mask is greater than 64 bits, limitations apply based on the hardware platform.

This support was added in ExtremeXOS Release 12.4 by using some of the slices previously used for ACL support to create a Greater Than 64 Bit (GT64B) table. The GT64B table stores only those routes with a mask greater than 64 bits. When IPv6 forwarding is enabled, the switch behavior is as follows:

• Fewer slices are available for ACLs.

Use show access-list usage acl-slice to check if any slice is unused. If no slice is available, consider disabling a feature that is consuming ACL slices if that feature is not required. Features that are
enabled by default such as IGMP (Internet Group Management Protocol) Snooping or MLD Snooping can be disabled to free up ACL resources if not required.

- Table-full messages appear when there is no more space in the GT64B table.
- If an eligible route cannot be added to the GT64B table (because the table is full), there is no guarantee that traffic for that route will be properly routed.
- If enabled, route compression for IPv6 can make room for additional routes by reducing the number of entries in the GT64B table.
- When an IPv6 address with a mask greater that 64 bits is configured on a VLAN or tunnel, that address is automatically added to the GT64B table.

All switches support hardware forwarding routes with masks greater than 64 bits. For number of routes supported, see the limits for the particular switch in the ExtremeXOS Release Notes.

Starting with ExtremeXOS 22.5, the `ipv6-mask-length` option provides greater hardware route scale and IP route sharing (ECMP (Equal Cost Multi Paths)) support for IPv6 “long-mask routes”, meaning IPv6 subnets with mask lengths 65–128 bits. This provides additional scale and resilience for IPv6 host routes whose mask length is 128 bits. Increasing scale and providing ECMP for IPv6 mask 65–128 routes decreases IPv4 route scale. The default IPv6 mask length is 64.

The `configure forwarding internal-tables [ l2-and-l3 | more [l2 | l3-and-ipmc | routes {ipv6-mask-length [64 | 128]}] ]` command provides the ability to support additional L2 and L3 hosts, routes, or multicast table entries.

This support was added in ExtremeXOS Release 12.4 by using a hardware table designed for this purpose. When IPv6 forwarding is enabled, the switch behavior is as follows:

- If no space is available in the hardware table, there is no guarantee that traffic for that route will be properly routed.
- If enabled, route compression for IPv6 can make room for additional routes by reducing the number of entries in the hardware table.
- When an IPv6 address with a mask greater that 64 bits is configured on a VLAN or tunnel, that address is automatically added to the hardware table.

**Hardware Tunnel Support**

The platforms and software versions that provide hardware forwarding support for IPv6 traffic for both IPv6-in-IPv4 and 6to4 tunnels for various platforms are shown in the following table. In all the other platforms, tunnel traffic is forwarded in software and the statistics can be viewed from the `show ipstats ipv6` command.

**Note**

The MTU for IPv6 Tunnels is set to 1480 bytes, and is not user-configurable. Configuring jumbo frames has no effect on the MTU size for IPv6 tunnels.

**Routing Configuration Example**

*Figure 218 on page 1406 illustrates a switch with three VLANs defined as follows:*

- Finance
• Protocol-sensitive VLAN using IPv6 protocol
  • All ports on slots 1 and 3 have been assigned.
  • IP address 2001:db8:35::1/48.
• Personnel
  • Protocol-sensitive VLAN using the IPv6 protocol.
  • All ports on slots 2 and 4 have been assigned.
  • IP address 2001:db8:36::1/48.
• MyCompany
  • Port-based VLAN.
  • All ports on slots 1 through 4 have been assigned.

Figure 218: IPv6 Unicast Routing Configuration Example

The stations connected to the system generate a combination of IPv6 traffic and NetBIOS traffic. The IPv6 traffic is filtered by the protocol-sensitive VLANs. All other traffic is directed to the VLAN MyCompany.

In this configuration, all IPv6 traffic from stations connected to slots 1 and 3 have access to the router by way of the VLAN Finance. Ports on slots 2 and 4 reach the router by way of the VLAN Personnel. All other traffic (NetBIOS) is part of the VLAN MyCompany.

The example is configured as follows:

```bash
create vlan Finance tag 10
create vlan Personnel tag 11
create vlan MyCompany
configure Finance protocol ipv6
configure Personnel protocol ipv6
configure Finance add port 1:*,3:* tag
```
Tunnel Configuration Examples

6in4 Tunnel Configuration Example

Figure 219 illustrates a 6in4 tunnel configured between two IPv6 regions across an IPv4 region.

Figure 219: 6in4 Tunnel Example

Router A has an interface to an IPv4 region with the address 192.168.1.1 (for this example we are using private IPv4 addresses, but to tunnel across the Internet, you would use a public address). Router B has an IPv4 interface of 10.2.0.1. The IPv4 interface must be created before the tunnel is configured and cannot be deleted until the tunnel is deleted.

This example has one subnet in each IPv6 region, 2001:db8:1::/64 for Router A and 2001:db8:2::/64 for Router B. Hosts A and B are configured to use IPv6 addresses 2001:db8:1::101 and 2001:db8:2::101 respectively.
For traffic to move from one region to the other, there must be a route. In this example, a static route is created, but you could enable RIPng or OSPFv3 on the tunnel interface.

In this example, we assume that the IPv4 network can route from Router A to Router B (in other words, some IPv4 routing protocol is running on the public-ipv4 interfaces). For platforms on which hardware based tunneling is supported (See the following table), IPv4 forwarding needs to be enabled on the tunnel source VLAN. However, in platforms on which IPv6-in-IPv4 tunnels are supported in software only, you do not need to enable IPv4 forwarding on the public interfaces in this example unless you are also routing IPv4 traffic on them (in this example, it is assumed you are running no IPv4 traffic inside your respective IPv6 networks, although you could).

When Host A needs to send a packet to 2001:db8:2::101 (Host B), it forwards it to Router A. Router A receives an IPv6 packet from the IPv6 source address 2001:db8:1::101 to the destination 2001:db8:2::101. Router A has the static route, for the route 2001:db8:2::/64 with next hop 2001:db8:a::2 (Router B) through the tunnel interface. So Router A encapsulates the IPv6 packet inside an IPv4 header with the source address 192.168.1.1 and destination address 10.2.0.1. The encapsulated IPv6 packet passes through the IPv4 network and reaches the other end of the tunnel—Router B. Router B decapsulates the packet and removes the IPv4 header. Router B then forwards the IPv6 packet to the destination host—Host B.

Note
Each IPv6 packet is encapsulated inside an IPv4 header (20 bytes) before it is forwarded via a IPv6-in-IPv4 tunnel. For example, a 66-byte packet from Host A will be encapsulated and forwarded as a 86-byte packet by Router A.

**Router A**
configure vlan default delete port all  
create vlan public-ipv4  
configure vlan public-ipv4 add port 1 untagged  
configure vlan public-ipv4 ipaddress 192.168.1.1/24  
create tunnel public6in4 ipv6-in-ipv4 destination 10.2.0.1 source 192.168.1.1  
configure tunnel public6in4 ipaddress 2001:db8:a::1/64  
enable ipforwarding ipv6 public6in4  
create vlan private-ipv6  
configure vlan private-ipv6 add port 2 untagged  
enable ipforwarding ipv6 private-ipv6  
configure iproute add 2001:db8:2::/64 2001:db8:a::2  
enable ipforwarding public-ipv4

**Router B**
configure vlan default delete port all  
create vlan public-ipv4  
configure vlan public-ipv4 add port 1 untagged  
configure vlan public-ipv4 ipaddress 10.2.0.1/24  
create tunnel public6in4 ipv6-in-ipv4 destination 192.168.1.1 source 10.2.0.1  
configure tunnel public6in4 ipaddress 2001:db8:a::2/64  
enable ipforwarding ipv6 public6in4  
create vlan private-ipv6  
configure vlan private-ipv6 add port 2 untagged  
enable ipforwarding ipv6 private-ipv6  
configure iproute add 2001:db8:1::/64 2001:db8:a::1  
enable ipforwarding public-ipv4
6to4 Tunnel Configuration Example

Figure 220 illustrates a 6to4 tunnel configured between two IPv6 regions across an IPv4 region.

Router 1 has an interface to an IPv4 region with the address 192.168.1.1 (for this example we are using private IPv4 addresses, but to tunnel across the Internet, you would use a public address). Router 2 has an IPv4 interface of 10.0.0.1. The IPv4 interface must be created before the tunnel is configured and cannot be deleted until the tunnel is deleted.

The IPv6 endpoints of 6to4 tunnels must follow the standard 6to4 address requirement. The address must be of the form 2002:<IPv4_source_endpoint>::/16, where <IPv4_source_endpoint> is replaced by the IPv4 source address of the endpoint, in hexadecimal, colon separated form. For example, for a tunnel endpoint located at IPv4 address 10.20.30.40, the tunnel address would be 2002:0a14:1e28::/16. In hex, 10 is 0a, 20 is 14, 30 is 1e and 40 is 28.

This example shows a simple setup on the Router 1 side (one big /48 IPv6 routing domain with no subnets), and a slightly more complex setup on the Router 2 side (two subnets :0001: and :0002: that are /64 in length). Hosts 1, 2, and 3 will communicate using their global 2002: addresses.

The hosts in this example configure themselves using the EUI64 interface identifier derived from their MAC addresses. Refer to your host OS vendor’s documentation for configuring IPv6 addresses and routes.
In this example, we assume that the IPv4 network can route from Router 1 to Router 2 (in other words, some IPv4 routing protocol is running on the public-ipv4 interfaces). However, you do not need to enable IPv4 forwarding on the public interfaces in this example unless you are also routing IPv4 traffic on them (in this example, it is assumed you are running no IPv4 traffic inside your respective IPv6 networks, although you could).

**Router 1**

```plaintext
configure vlan default delete port all
create vlan public-ipv4
configure vlan public-ipv4 add port 1 untagged
create tunnel public6to4 6to4 source 192.168.1.1
enable ipforwarding ipv6 public6to4
create vlan private-ipv6
configure vlan private-ipv6 add port 2 untagged
enable ipforwarding ipv6 private-ipv6
```

**Router 2**

```plaintext
configure vlan default delete port all
create vlan public-ipv4
configure vlan public-ipv4 add port 1 untagged
create tunnel public6to4 6to4 source 10.0.0.1
enable ipforwarding ipv6 public6to4
create vlan private-ipv6-sub1
configure vlan private-ipv6-sub1 add port 2 untagged
enable ipforwarding ipv6 private-ipv6-sub1
create vlan private-ipv6-sub2
configure vlan private-ipv6-sub2 add port 3 untagged
enable ipforwarding ipv6 private-ipv6-sub2
```

**Host Configurations**

The IPv6 addresses of these hosts are based on their MAC address-derived EUI64 interface identifiers and the address prefixes for their subnets. Each host must also have a static route configured on it for 6to4 addresses.

**Host 1:**
- MAC address—00:04:96:1F:A5:2A
- IPv6 address—2002:c0a8:0101::0204:96ff:fe1f:a52a/48
- Static route—destination 2002::/16, gateway 2002:c0a8:0101::2

**Host 2:**
- MAC address—00:04:96:1F:A4:32
- IP address—2002:a00:0001:0001:0204:96ff:fe1f:a432/64
- Static route—destination 2002::/16, gateway 2002:a00:0001:0001::1

**Host 3:**
- MAC address—00:01:30:00:C2:00
• IP address—2002:0a00:0001:0002:0201:30ff:fe00:c200/64
• Static route—destination 2002::/16, gateway 2002:0a00:0001:0002:1

GRE Tunnel Configuration Example

**Router 1 Configuration**

```bash
unconfigure switch all
configure default del port all
create vlan inet
configure vlan inet add port 24
configure vlan inet ipa 1.1.1.1/24
create vlan users
configure vlan users add port 1
configure vlan users ipa 100.0.0.1/24
create tunnel mytunnel gre destination 1.1.1.2 source 1.1.1.1
configure tunnel "mytunnel" ipaddress 2.0.0.1/24
configure iproute add 200.0.0.0/24 2.0.0.2
enable ipforwarding
```

**Router 2 Configuration**

```bash
create vlan inet
configure vlan inet add port 10:1
configure vlan inet ipa 1.1.1.2/24
create vlan users
configure vlan users add port 10:2
configure vlan users ipa 200.0.0.1/24
create tunnel mytunnel gre destination 1.1.1.1 source 1.1.1.2
configure tunnel "mytunnel" ipaddress 2.0.0.2/24
configure iproute add 100.0.0.0/24 2.0.0.1
enable ipforwarding
```

Host IP connected to router 1-100.0.0.1
Host IP connected to router 2-200.0.0.1

**Note**

If a transit node is present between the tunneling sites, you should configure static or enable IBGP between the sites for network connectivity.
This chapter assumes that you are already familiar with IP unicast routing. If not, refer to the following publications for additional information:

- RFC 1058—Routing Information Protocol (RIP)
- RFC 1723—RIP Version 2
- Interconnections: Bridges and Routers, by Radia Perlman. ISBN 0-201-56332-0. Published by Addison-Wesley Publishing Company.

**Note**

RIP is available on platforms with an Edge, Advanced Edge or Core license. For specific information regarding RIP licensing, see the ExtremeXOS 22.6 Feature License Requirements document.

### IGPs Overview

The switch supports the use of the following interior gateway protocols (IGPs):

- **RIP (Routing Information Protocol)**
- **OSPF (Open Shortest Path First)**
- Intermediate System-Intermediate System (IS-IS)

RIP is a distance-vector protocol, based on the Bellman-Ford (or distance-vector) algorithm. The distance-vector algorithm has been in use for many years and is widely deployed and understood.

OSPF and IS-IS are link-state protocols, based on the Dijkstra link-state algorithm. OSPF and IS-IS are newer IGPs and solve a number of problems associated with using RIP on today’s complex networks.

**Note**

RIP can be enabled on a VLAN (Virtual LAN) with either OSPF or IS-IS. OSPF and IS-IS cannot be enabled on the same VLAN.

RIP is described in this chapter, OSPF is described in [OSPF](#) on page 1423 and IS-IS is described in [IS-IS](#) on page 1450.
RIP Versus OSPF and IS-IS

The distinction between RIP and the OSPF and IS-IS link-state protocols lies in the fundamental differences between distance-vector protocols and link-state protocols.

Using a distance-vector protocol, each router creates a unique routing table from summarized information obtained from neighboring routers. Using a link-state protocol, every router maintains an identical routing table created from information obtained from all routers in the autonomous system (AS). Each router builds a shortest path tree, using itself as the root. The link-state protocol ensures that updates sent to neighboring routers are acknowledged by the neighbors, verifying that all routers have a consistent network map.

Advantages of RIP, OSPF, and IS-IS

The biggest advantage of using RIP is that it is relatively simple to understand and to implement, and it has been the de facto routing standard for many years.

RIP has a number of limitations that can cause problems in large networks, including the following:

- A limit of 15 hops between the source and destination networks
- A large amount of bandwidth taken up by periodic broadcasts of the entire routing table
- Slow convergence
- Routing decisions based on hop count; no concept of link costs or delay
- Flat networks; no concept of areas or boundaries

OSPF and IS-IS offer many advantages over RIP, including the following:

- No limitation on hop count
- Route updates multicast only when changes occur
- Faster convergence
- Support for load balancing to multiple routers based on the actual cost of the link
- Support for hierarchical topologies where the network is divided into areas

The details of RIP are explained later in this chapter.

Overview of RIP

RIP is an IGP first used in computer routing in the Advanced Research Projects Agency Network (ARPAnet) as early as 1969. It is primarily intended for use in homogeneous networks of moderate size.

To determine the best path to a distant network, a router using RIP always selects the path that has the least number of hops. Each router that data must traverse is considered to be one hop.

Routing Table

The routing table in a router using RIP contains an entry for every known destination network.

Each routing table entry contains the following information:

- IP address of the destination network
- Metric (hop count) to the destination network
• IP address of the next router
• Timer that tracks the amount of time since the entry was last updated

The router exchanges an update message with each neighbor every 30 seconds (default value), or when there is a change to the overall routed topology (also called triggered updates). If a router does not receive an update message from its neighbor within the route timeout period (180 seconds by default), the router assumes the connection between it and its neighbor is no longer available.

**Split Horizon**

Split horizon is a scheme for avoiding problems caused by including routes in updates sent to the router from which the route was learned.

Split horizon omits routes learned from a neighbor in updates sent to that neighbor.

**Poison Reverse**

Like split horizon, poison reverse is a scheme for eliminating the possibility of loops in the routed topology.

In this case, a router advertises a route over the same interface that supplied the route, but the route uses a hop count of 16, which defines that router as unreachable.

**Triggered Updates**

Triggered updates occur whenever a router changes the metric for a route.

The router is required to send an update message immediately, even if it is not yet time for a regular update message to be sent. This generally results in faster convergence, but may also result in more RIP-related traffic.

**Route Advertisement of VLANs**

Virtual LANs (VLANs) that are configured with an IP address but are configured to not route IP or are not configured to run RIP, do not have their subnets advertised by RIP.

RIP advertises only those VLANs that are configured with an IP address, are configured to route IP, and run RIP.

**RIP Version 1 Versus RIP Version 2**

A new version of RIP, called RIP version 2, expands the functionality of RIP version 1 to include the following:

• Variable-length subnet masks (VLSMs).
• Support for next-hop addresses, which allows for optimization of routes in certain environments.
• Multicasting.
RIP version 2 packets can be multicast instead of being broadcast, reducing the load on hosts that do not support routing protocols.

**Note**
If you are using RIP with supernetting/Classless Inter-Domain Routing (CIDR), you must use RIPv2 only.

---

**Route Redistribution**

More than one routing protocol can be enabled simultaneously on the switch.

Route redistribution allows the switch to exchange routes, including static routes, between the routing protocols. Figure 221 is an example of route redistribution between an OSPF AS and a RIP AS.

**Figure 221: RIP Route Redistribution**

**Configuring Route Redistribution**

Exporting routes from one protocol to another and from that protocol to the first one are discrete configuration functions. For example, to run OSPF and RIP simultaneously, you must first configure both protocols and then verify the independent operation of each. Then you can configure the routes to export from OSPF to RIP and the routes to export from RIP to OSPF. Likewise, for any other combinations of protocols, you must separately configure each to export routes to the other.

**Redistribute Routes into RIP**

- Enable or disable the exporting of static, direct, BGP (Border Gateway Protocol)-learned, and OSPF-learned routes into the RIP domain.

  ```
  enable rip export [bgp | direct | e-bgp | i-bgp | ospf | ospf-extern1 | ospf-extern2 | ospf-inter | ospf-intra | static | isis | isis-
  ```
level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external ] [cost number {tag number} | policy policy-name]

disable rip export [bgp | direct | e-bgp | i-bgp | ospf | ospf-extern1 | ospf-extern2 | ospf-inter | ospf-intra | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external ]

These commands enable or disable the exporting of static, direct, and OSPF-learned routes into the RIP domain.

- You can choose which types of OSPF routes are injected, or you can simply choose ospf, which will inject all learned OSPF routes regardless of type.

The default setting is disabled.

**RIP Configuration Example**

Figure 222 on page 1417 illustrates a switch with three VLANs defined as follows:

- **Finance**
  - Protocol-sensitive VLAN using the IP protocol.
  - All ports on slots 1 and 3 have been assigned.
  - IP address 192.207.35.1.

- **Personnel**
  - Protocol-sensitive VLAN using the IP protocol.
  - All ports on slots 2 and 4 have been assigned.
  - IP address 192.207.36.1.

- **MyCompany**
  - Port-based VLAN.
  - All ports on slots 1 through 4 have been assigned.

This example does use protocol-sensitive VLANs that admit only IP packets. This is not a common requirement for most networks. In most cases, VLANs will admit different types of packets to be forwarded to the hosts and servers on the network.
The stations connected to the system generate a combination of IP traffic and NetBIOS traffic. The IP traffic is filtered by the protocol-sensitive VLANs. All other traffic is directed to the VLAN MyCompany.

In this configuration, all IP traffic from stations connected to slots 1 and 3 have access to the router by way of the VLAN Finance. Ports on slots 2 and 4 reach the router by way of the VLAN Personnel. All other traffic (NetBIOS) is part of the VLAN MyCompany.

The example in Figure 222 is configured as follows:

```bash
create vlan Finance
create vlan Personnel
create vlan MyCompany
configure Finance protocol ip
configure Personnel protocol ip
configure Finance add port 1:*,3:*
configure Personnel add port 2:*,4:*
configure MyCompany add port all
configure Finance ipaddress 192.207.35.1
configure Personnel ipaddress 192.207.36.1
enable ipforwarding
configure rip add vlan all
enable rip
```

More commonly, NetBIOS traffic would be allowed on the Finance and Personnel VLANs, but this example shows how to exclude that traffic. To allow the NetBIOS traffic (or other type of traffic) along with the IP traffic, remove the `configure finance protocol ip` and `configure Personnel protocol ip` commands from the example.
This chapter describes the RIPng (Routing Information Protocol Next Generation) interior gateway protocol for IPv6 networks. It provides the various protocol schemes available, commands for configuring redistribution, and an example for configuring multiple protocols on one switch. This chapter assumes that you are already familiar with IP unicast routing. If not, refer to the following publication for additional information:

- RFC 2080—RIPng for IPv6

Note

RIPng is available on platforms with an Edge, Advanced Edge or Core license. For specific information regarding RIPng licensing, see the ExtremeXOS 22.6 Feature License Requirements document.

RIPng Overview

RIPng is an interior gateway protocol (IGP) developed for IPv6 networks.

The analogous protocol used in IPv4 networks is called RIP (Routing Information Protocol). Like RIP, RIPng is a relatively simple protocol for the communication of routing information among routers. Many concepts and features of RIPng are directly parallel to those same features in RIP.

RIPng is a distance-vector protocol, based on the Bellman-Ford (or distance-vector) algorithm. The distance-vector algorithm has been in use for many years and is widely deployed and understood. The other common IGPs for IPv6 are OSPFv3 (Open Shortest Path First version 3) and Intermediate System-Intermediate System (IS-IS), which are link-state protocols.

Note

RIPng can be enabled on a VLAN (Virtual LAN) with either OSPFv3 or IS-IS. OSPFv3 and ISIS cannot be enabled on the same VLAN.

RIPng versus OSPFv3 and IS-IS

The distinction between RIPng and the link-state protocols (OSPFv3 and IS-IS) lies in the fundamental differences between distance-vector protocols (RIPng) and link-state protocols.

Using a distance-vector protocol, each router creates a unique routing table from summarized information obtained from neighboring routers. Using a link-state protocol, every router maintains an identical routing table created from information obtained from all routers in the autonomous system.
Each router builds a shortest path tree, using itself as the root. The link-state protocol ensures that updates sent to neighboring routers are acknowledged by the neighbors, verifying that all routers have a consistent network map.

Advantages of RIPng, OSPFv3, and IS-IS

The biggest advantage of using RIPng is that it is relatively simple to understand and implement, and it has been the de facto routing standard for many years.

RIPng has a number of limitations that can cause problems in large networks, including the following:

- A limit of 15 hops between the source and destination networks
- A large amount of bandwidth taken up by periodic broadcasts of the entire routing table
- Slow convergence
- Routing decisions based on hop count; no concept of link costs or delay
- Flat networks; no concept of areas or boundaries

OSPFv3 and IS-IS offer many advantages over RIPng, including the following:

- No limitation on hop count
- Route updates multicast only when changes occur
- Faster convergence
- Support for load balancing to multiple routers based on the actual cost of the link
- Support for hierarchical topologies where the network is divided into areas

The details of RIPng are explained later in this chapter.

RIPng Routing

RIPng is primarily intended for use in homogeneous networks of moderate size.

To determine the best path to a distant network, a router using RIPng always selects the path that has the least number of hops. Each router that data must traverse is considered to be one hop.

Routing Table

The routing table in a router using RIPng contains an entry for every known destination network.

Each routing table entry contains the following information:

- IP address and prefix length of the destination network
- Metric (hop count) to the destination network
- IP address of the next hop router, if the destination is not directly connected
- Interface for the next hop
- Timer that tracks the amount of time since the entry was last updated
- A flag that indicates if the entry is a new one since the last update
- The source of the route, for example, static, RIPng, OSPFv3, etc.
The router exchanges an update message with each neighbor every 30 seconds (default value), or when there is a change to the overall routed topology (also called triggered updates). If a router does not receive an update message from its neighbor within the route timeout period (180 seconds by default), the router assumes the connection between it and its neighbor is no longer available.

**Split Horizon**

Split horizon is a scheme for avoiding problems caused by including routes in updates sent to the router from which the route was learned.

Split horizon omits routes learned from a neighbor in updates sent to that neighbor.

**Poison Reverse**

Like split horizon, poison reverse is a scheme for eliminating the possibility of loops in the routed topology.

In this case, a router advertises a route over the same interface that supplied the route, but the route uses a hop count of 16, which defines that router as unreachable.

**Triggered Updates**

Triggered updates occur whenever a router changes the metric for a route.

The router is required to send an update message immediately, even if it is not yet time for a regular update message to be sent. This generally results in faster convergence, but may also result in more RIPng-related traffic.

**Route Advertisement of VLANs**

RIP advertises only those VLANs that are configured with an IP address, are configured to route IP, and run RIP.

**Route Redistribution**

More than one routing protocol can be enabled simultaneously on the switch. Route redistribution allows the switch to exchange routes, including static routes, between the routing protocols. Route redistribution is also called route export.

**Configuring Route Redistribution**

Exporting routes from one protocol to another and from that protocol to the first one are discrete configuration functions.

For example, to run OSPFv3 and RIPng simultaneously, you must first configure both protocols and then verify the independent operation of each. Then you can configure the routes to export from OSPFv3 to...
RIPng and the routes to export from RIPng to OSPFv3. Likewise, for any other combinations of protocols, you must separately configure each to export routes to the other.

**Redistributing Routes into RIPng**

- **Enable or disable the exporting of static, direct, or other protocol-learned routes into the RIPng domain using the following commands:**

  ```
  enable ripng export [direct | ospfv3 | ospfv3-external | ospfv3-external2 | ospfv3-inter | ospfv3-intra | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external | bgp | e-bgp i-bgp] [cost number {tag number} | policy policy-name]
  ```

- **Disable RIPng originate-default**

  ```
  disable ripng originate-default
  ```

  These commands enable or disable the exporting of static, direct, and OSPFv3-learned routes into the RIPng domain.

- **You can choose which types of OSPFv3 routes are injected, or you can simply choose ospf, which will inject all learned OSPFv3 routes regardless of type. The default setting is disabled.**

**RIPng Configuration Example**

The following configuration is similar to the example in the RIP chapter, but uses IPv6 addresses. It illustrates a switch with three VLANs defined as follows:

- **Finance**
  - All ports on slots 1 and 3 have been assigned.

- **Personnel**
  - All ports on slots 2 and 4 have been assigned.

- **MyCompany**
  - Port-based VLAN.
  - All ports on slots 1 through 4 have been assigned.

The stations connected to the system generate a combination of IPv6 traffic and NetBIOS traffic.

In this configuration, all traffic from stations connected to slots 1 and 3 have access to the router by way of the VLAN Finance. Ports on slots 2 and 4 reach the router by way of the VLAN Personnel. All traffic (NetBIOS and IPv6) is part of the VLAN MyCompany.

The example is configured as follows:

```
create vlan Finance
create vlan Personnel
create vlan MyCompany
configure Finance add port 1:*,3:*
configure Personnel add port 2:*,4:*
configure MyCompany add port all
configure Finance ipaddress 2001:db8:35::1/48
configure Personnel ipaddress 2001:db8:36::1/48
enable ipforwarding ipv6
configure ripng add vlan Finance
```
configure ripng add vlan Personnel
enable ripng
OSPF Overview
Route Redistribution
Configuring OSPF
OSPF Configuration Example
Displaying OSPF Settings

This chapter discusses the OSPF (Open Shortest Path First) protocol for distributing routing information between routers belonging to an autonomous system. This chapter provides an overview of the protocol’s features and example configuration commands.

This chapter assumes that you are already familiar with IP unicast routing. If not, refer to the following publications for additional information:

- RFC 2328—OSPF Version 2
- RFC 1765—OSPF Database Overflow
- RFC 2370—The OSPF Opaque LSA Option
- RFC 3101—The OSPF Not-So-Stubby Area (NSSA) Option
- RFC 3623—Graceful OSPF Restart

Note
OSPF is available on platforms with an Advanced Edge or Core license. For specific information regarding OSPF licensing, see the ExtremeXOS 22.6 Feature License Requirements document.

OSPF Overview

OSPF is a link state protocol that distributes routing information between routers belonging to a single IP domain; the IP domain is also known as an autonomous system (AS).

In a link-state routing protocol, each router maintains a database describing the topology of the AS. Each participating router has an identical database maintained from the perspective of that router.

From the LSDB (link state database), each router constructs a tree of shortest paths, using itself as the root. The shortest path tree provides the route to each destination in the AS. When several equal-cost routes to a destination exist, traffic can be distributed among them. The cost of a route is described by a single metric.
OSPF is an IGP (interior gateway protocol), as is RIP (Routing Information Protocol), the other common IGP. OSPF and RIP are compared in RIP on page 1412.

**Note**

Two types of OSPF functionality are available and each has a different licensing requirement. One is the complete OSPF functionality and the other is OSPF Edge Mode, a subset of OSPF that is described below. For specific information regarding OSPF licensing, see the ExtremeXOS 22.6 Feature License Requirements document.

**OSPF Edge Mode**

OSPF Edge Mode is a subset of OSPF available on platforms with an Advanced Edge license.

There are two restrictions on OSPF Edge Mode:

- At most, four Active OSPF VLAN (Virtual LAN) interfaces are permitted. There is no restriction on the number of Passive interfaces.
- The OSPF Priority on VLANs is 0, and is not configurable. This prevents the system from acting as a DR or BDR.

**BFD for OSPF**

The BFD for OSPF feature gives OSPF routing protocol the ability to utilize BFD’s fast failure detection to monitor OSPF neighbor adjacencies. CLI commands are provided to configure BFD protection for OSPF, so that as a registered BFD client, OSPF can request BFD protection for interested OSPF neighbors, and receive notifications about BFD session setup status and BFD session status updates (after establishing) from the BFD server. When BFD detects a communication failure between neighbors, it informs OSPF, which causes the OSPF neighbor state be marked as “down.” This allows OSPF protocol to quickly begin network convergence and use alternate paths to the affected neighbor.

![Figure 223: Basic Operational Flow of OSPF BFD](image-url)
Establishing a BFD Session for OSPF Neighbor

1. OSPF discovers a neighbor.
2. If BFD for OSPF is configured, OSPF on both routers sends a request to the local BFD server to initiate a BFD neighbor session with the OSPF neighbor router.
3. The BFD neighbor session with the OSPF neighbor router is established on both sides if BFD session limit is not reached.

If the BFD session limit is reached, the OSPF neighbor will be marked as BFD session failed if synchronous request is used, or pending if asynchronous request is used, and the BFD server will send an asynchronous notification when the session registration passes later. (The asynchronous request is not available until the BFD client session create API is enhanced.)

Eliminating the OSPF Neighbor Relationship by BFD Fault Detection

1. A failure occurs in the network.
2. The BFD neighbor session with the OSPF neighbor router is removed because the BFD timer expired.
3. On both Router A and Router B, BFD notifies the local OSPF process that the BFD neighbor is DOWN.
4. The local OSPF process tears down the OSPF neighbor relationship by marking neighbor state DOWN. (If an alternative path is available, the routers will immediately start converging on it.)

Figure 224: OSPF Neighbor Relationship Eliminated by BFD Fault Detection

OSPF will request the BFD server to delete the BFD session for OSPF neighbor moved to DOWN state. When the link failure is later resolved, OSPF needs to register the re-discovered neighbor to BFD again to initiate BFD session creation.

Removing BFD Protection for OSPF

1. BFD protection is removed from OSPF interface on Router A, OSPF process requests BFD server to delete all BFD sessions for neighbors learned on that interface.
2. BFD server will stop sending session status update to local OSPF process on Router A.
3. Before actually deleting any sessions, BFD server on Router A will first notify Router B to mark those session status as "Admin Down," which will cause Router B to stop using BFD protection for those OSPF neighbors.
4. When BFD protection is removed from OSPF interface on Router B, BFD sessions can be deleted immediately since they are already in "Admin Down" state.

When BFD for OSPF is configured on broadcast interface, the default behavior is to register only OSPF neighbors in FULL state with the BFD server. Separate BFD sessions are created for each neighbor.
learned on the same interface. If multiple clients ask for the same neighbor on the same interface, then single BFD sessions are established between the peers.

**OSPF Neighbor State Determination**

With active BFD protection, OSPF combines the BFD session state with the associated interface admin and operational states to determine the OSPF neighbor adjacency discovered on that OSPF interface. Regarding OSPF neighbor relationships, OSPF reacts directly to BFD session state changes only in the following circumstances:

- If BFD is enabled on the interface, and
- If BFD for OSPF is configured on the OSPF interface, and
- If a BFD session has been established to the neighbor, and
- If the BFD session has passed the INIT_COMPLETE state then:

1. The OSPF neighbor relationship will remain as FULL if the operational state of the BFD session is "UP" and the operational state of the associated VLAN interface is UP.
2. The OSPF neighbor relationship will be considered as DOWN if the operational state of the BFD session is DOWN or the operational state of the associated VLAN interface is DOWN.

In all other cases, the BFD session state is not considered as part of the reported OSPF neighbor state, and the OSPF neighbor state reverts to the operational state of the OSPF interface only. When the BFD session is in ADMIN_DOWN state, OSPF ignores BFD events and OSPF neighbor adjacency is not be affected by the BFD session state change.

**Link State Database**

Upon initialization, each router transmits a link state advertisement (LSA) on each of its interfaces. LSAs are collected by each router and entered into the LSDB of each router. After all LSAs are received, the router uses the link state database (LSDB) to calculate the best routes for use in the IP routing table. **OSPF** uses flooding to distribute LSAs between routers. Any change in routing information is sent to all of the routers in the network. All routers within an area have the exact same LSDB.

Table 141 describes LSA type numbers.

**Table 141: LSA Type Numbers**

<table>

Database Overflow

The OSPF database overflow feature allows you to limit the size of the LSDB and to maintain a consistent LSDB across all the routers in the domain, which ensures that all routers have a consistent view of the network.

Consistency is achieved by:

• Limiting the number of external LSAs in the database of each router.
• Ensuring that all routers have identical LSAs.

To configure OSPF database overflow, use the following command:

configure ospf ase-limit number {timeout seconds}

Where:

• number—Specifies the number of external LSAs that the system supports before it goes into overflow state. A limit value of 0 disables the functionality. When the LSDB size limit is reached, OSPF database overflow flushes LSAs from the LSDB. OSPF database overflow flushes the same LSAs from all the routers, which maintains consistency.
• timeout—Specifies the timeout, in seconds, after which the system ceases to be in overflow state. A timeout value of 0 leaves the system in overflow state until OSPF is disabled and re-enabled.

Opaque LSAs

Opaque LSAs are a generic OSPF mechanism used to carry auxiliary information in the OSPF database. Opaque LSAs are most commonly used to support OSPF traffic engineering.

Normally, support for opaque LSAs is autonegotiated between OSPF neighbors.

• In the event that you experience interoperability problems, you can disable opaque LSAs across the entire system using the following command:
  disable ospf capability opaque-lsa
• Re-enable opaque LSAs across the entire system:
  enable ospf capability opaque-lsa

If your network uses opaque LSAs, we recommend that all routers on your OSPF network support opaque LSAs. Routers that do not support opaque LSAs do not store or flood them. At minimum a well interconnected subsection of your OSPF network must support opaque LSAs to maintain reliability of their transmission.

Graceful OSPF Restart

RFC 3623 describes a way for OSPF control functions to restart without disrupting traffic forwarding.

Without graceful restart, adjacent routers will assume that information previously received from the restarting router is stale and will not be used to forward traffic to that router. However, in many cases, two conditions exist that allow the router restarting OSPF to continue to forward traffic correctly. The first condition is that forwarding can continue while the control function is restarted. Most modern router system designs separate the forwarding function from the control function so that traffic can still be forwarded independent of the state of the OSPF function. Routes learned through OSPF remain in the routing table and packets continue to be forwarded. The second condition required for graceful restart is that the network remain stable during the restart period. If the network topology is not
changing, the current routing table remains correct. Often, networks can remain stable during the time for restarting OSPF.

**Restarting and Helper Mode**

Routers involved with graceful restart fill one of two roles: the restarting router or the helper router.

With graceful restart, the router that is restarting sends out Grace-LSAs informing its neighbors that it is in graceful restart mode, how long the helper router should assist with the restart (the grace period), and why the restart occurred. If the neighboring routers are configured to help with the graceful restart (helper-mode), they will continue to advertise the restarting router as if it was fully adjacent. Traffic continues to be routed as though the restarting router is fully functional. If the network topology changes, the helper routers will stop advertising the restarting router. The helper router will continue in helper mode until the restarting router indicates successful termination of graceful restart, the Grace-LSAs expire, or the network topology changes. A router can be configured for graceful restart, and for helper-mode separately. A router can be a helper when its neighbor restarts, and can in turn be helped by a neighbor if it restarts.

**Planned and Unplanned Restarts**

Two types of graceful restarts are defined: planned and unplanned.

A planned restart would occur if the software module for OSPF was upgraded, or if the router operator decided to restart the OSPF control function for some reason. The router has advance warning, and is able to inform its neighbors in advance that OSPF is restarting.

An unplanned restart would occur if there was some kind of system failure that caused a remote reboot or a crash of OSPF, or a failover occurs. As OSPF restarts, it informs its neighbors that it is in the midst of an unplanned restart.

You can decide to configure a router to enter graceful restart for only planned restarts, for only unplanned restarts, or for both. Also, you can separately decide to configure a router to be a helper for only planned, only unplanned, or for both kinds of restarts.

**Configuring Graceful OSPF Restart**

- Configure a router to perform graceful OSPF restart:
  ```
  configure ospf restart [none | planned | unplanned | both]
  ```

  Since a router can act as a restart helper router to multiple neighbors, you will specify which neighbors to help.

- Configure a router to act as a graceful OSPF restart helper:
  ```
  configure ospf [vlan [all | vlan-name] | area area-identifier | virtual-link router-identifier area-identifier] restart-helper [none | planned | unplanned | both]
  ```

- The graceful restart period sent out to helper routers can be configured with the following command:
  ```
  configure ospf restart grace-period seconds
  ```

  By default, a helper router will terminate graceful restart if received LSAs would affect the restarting router.
This will occur when the restart-helper receives an LSA that will be flooded to the restarting router or when there is a changed LSA on the restarting router’s retransmission list when graceful restart is initiated.

- Disable this behavior:

  ```
  disable ospf [vlan [all {vr vrf_name} | vlan-name] | area area-identifier | virtual-link router-identifier area-identifier] restart-helper-lsa-check
  ```

**Areas**

*OSPF* allows parts of a network to be grouped together into areas.

The topology within an area is hidden from the rest of the AS. Hiding this information enables a significant reduction in LSA traffic and reduces the computations needed to maintain the LSDB. Routing within the area is determined only by the topology of the area.

The three types of routers defined by *OSPF* are as follows:

- **Internal router (IR)**—An internal router has all of its interfaces within the same area.
- **Area border router (ABR)**—An ABR has interfaces in multiple areas. It is responsible for exchanging summary advertisements with other ABRs.
- **Autonomous system border router (ASBR)**—An ASBR acts as a gateway between OSPF and other routing protocols, or other autonomous systems.

**Backbone Area (Area 0.0.0.0)**

Any *OSPF* network that contains more than one area is required to have an area configured as area 0.0.0.0, also called the backbone. All areas in an AS must be connected to the backbone. When designing networks, you should start with area 0.0.0.0 and then expand into other areas.

**Note**

Area 0.0.0.0 exists by default and cannot be deleted or changed.

The backbone allows summary information to be exchanged between area border routers (ABRs). Every ABR hears the area summaries from all other ABRs. The ABR then forms a picture of the distance to all networks outside of its area by examining the collected advertisements and adding in the backbone distance to each advertising router.

When a *VLAN* is configured to run OSPF, you must configure the area for the VLAN.

- If you want to configure the VLAN to be part of a different OSPF area, use the following command:

  ```
  configure ospf vlan vlan-name area area-identifier
  ```

- If this is the first instance of the OSPF area being used, you must create the area first using the following command:

  ```
  create ospf area area-identifier
  ```

**Stub Areas**

*OSPF* allows certain areas to be configured as stub areas. A stub area is connected to only one other area. The area that connects to a stub area can be the backbone area. External route information is not
distributed into stub areas. Stub areas are used to reduce memory consumption and computational requirements on OSPF routers.

Use the following command to configure an OSPF area as a stub area:

```
configure ospf area area-identifier stub [summary | nosummary] stub-default-cost cost
```

**Not-So-Stubby-Areas**

Not-so-stubby-areas (NSSAs) are similar to the existing OSPF stub area configuration option but have the following two additional capabilities:

- External routes originating from an ASBR connected to the NSSA can be advertised within the NSSA.
- External routes originating from the NSSA can be propagated to other areas, including the backbone area.

The CLI command to control the NSSA function is similar to the command used for configuring a stub area, as follows:

```
configure ospf area area-identifier nssa [summary | nosummary] stub-default-cost cost {translate}
```

The `translate` option determines whether type 7 LSAs are translated into type 5 LSAs. When configuring an OSPF area as an NSSA, `translate` should only be used on NSSA border routers, where translation is to be enforced. If `translate` is not used on any NSSA border router in a NSSA, one of the ABRs for that NSSA is elected to perform translation (as indicated in the NSSA specification). The option should not be used on NSSA internal routers. Doing so inhibits correct operation of the election algorithm.

**Normal Area**

A normal area is an area that is not:

- Area 0
- Stub area
- NSSA

Virtual links can be configured through normal areas. External routes can be distributed into normal areas.

**Virtual Links**

In the situation when a new area is introduced that does not have a direct physical attachment to the backbone, a virtual link is used.

A virtual link provides a logical path between the ABR of the disconnected area and the ABR of the normal area that connects to the backbone. A virtual link must be established between two ABRs that have a common area, with one ABR connected to the backbone. Figure 225 illustrates a virtual link.
Virtual links cannot be configured through a stub or NSSA area.

Virtual links are also used to repair a discontiguous backbone area. For example, in Figure 226, if the connection between ABR 1 and the backbone fails, the connection using ABR 2 provides redundancy so that the discontiguous area can continue to communicate with the backbone using the virtual link.

**Figure 226: Virtual Link Providing Redundancy**

**Point-to-Point Support**

You can manually configure the OSPF link type for a VLAN. Table 142 describes the link types.
Table 142: OSPF Link Types

<table>
<thead>
<tr>
<th>Link Type</th>
<th>Number of Routers</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto</td>
<td>Varies</td>
<td>ExtremeXOS automatically determines the OSPF link type based on the interface type. This is the default setting.</td>
</tr>
<tr>
<td>Broadcast</td>
<td>Any</td>
<td>Routers must elect a designated router (DR) and a backup designated router (BDR) during synchronization. Ethernet is an example of a broadcast link.</td>
</tr>
<tr>
<td>Point-to-point</td>
<td>Up to 2</td>
<td>This type synchronizes faster than a broadcast link because routers do not elect a DR or BDR. It does not operate with more than two routers on the same VLAN. The Point-to-Point Protocol (PPP) is an example of a point-to-point link. An OSPF point-to-point link supports only zero to two OSPF routers and does not elect a designated router (DR) or backup designated router (BDR). If you have three or more routers on the VLAN, OSPF fails to synchronize if the neighbor is not configured.</td>
</tr>
<tr>
<td>Passive</td>
<td></td>
<td>A passive link does not send or receive OSPF packets.</td>
</tr>
</tbody>
</table>

Note
The number of routers in an OSPF point-to-point link is determined per VLAN, not per link. All routers in the VLAN must have the same OSPF link type. If there is a mismatch, OSPF attempts to operate, but it may not be reliable.

Route Redistribution

More than one routing protocol can be enabled simultaneously on the switch.

Route redistribution allows the switch to exchange routes, including static routes, between the routing protocols. Figure 227 is an example of route redistribution between an OSPF AS and a RIP AS.

Figure 227: OSPF Route Redistribution
Import Policy

Prior to ExtremeXOS 15.7, routing protocol OSPFv2 applied routing policies with keyword “import-policy”, which can only be used to change the attributes of routes installed into the switch routing table. ExtremeXOS 15.7 provides the flexibility of using import policy to determine the routes to be added to or removed from the routing table.

To prevent a route being added to the routing table, the policy file must contain a matching rule with action “deny”. If there is no matching rule for a particular route, or the keyword “deny” is missing in the rule, the default action is “permit”, which means that route will be installed into the routing table. Refer to the following policy file example:

```
entry entry-one {
    if {
        nlri 11.22.0.0/16;
    }
    then {
        cost 100;
    }
}
entry entry-two {
    if {
        nlri 22.33.0.0/16;
    }
    then {
        deny;
    }
}
```

In the above policy example, entry-one is used to change the cost of any matching routes, and entry-two is used to remove those matching routes from the routing table.

Note

Only “Network Layer Reachability Information” (NLRI) and “route origin” can be used as matching criteria in policy rules; using “next_hop” as a matching criteria is not supported. Any other policy attribute is not recognized and is ignored.

Configuring Route Redistribution

Exporting routes from one protocol to another and from that protocol to the first one are discrete configuration functions.

For example, to run OSPF and RIP simultaneously, you must first configure both protocols and then verify the independent operation of each. Then you can configure the routes to export from OSPF to RIP and the routes to export from RIP to OSPF. Likewise, for any other combinations of protocols, you must separately configure each to export routes to the other.

Redistribute Routes into OSPF

To enable or disable the exporting of BGP (Border Gateway Protocol), RIP, static, and direct (interface) routes to OSPF, use the following commands:
enable ospf export [bgp | direct | e-bgp | i-bgp | rip | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external | host-mobility] [cost cost type [ase-type-1 | ase-type-2] {tag number} | policy-map]

disable ospf export [bgp | direct | host-mobility | e-bgp | i-bgp | rip | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external]

These commands enable or disable the exporting of RIP, static, and direct routes by way of LSA to other OSPF routers as AS-external type 1 or type 2 routes. The default setting is disabled.

The cost metric is inserted for all Border Gateway Protocol (BGP), RIP, static, and direct routes injected into OSPF. If the cost metric is set to 0, the cost is inserted from the route. For example, in the case of BGP export, the cost equals the multiple exit discriminator (MED) or the path length. The tag value is used only by special routing applications. Use 0 if you do not have specific requirements for using a tag. (The tag value in this instance has no relationship with IEEE 802.1Q VLAN tagging.)

The same cost, type, and tag values can be inserted for all the export routes, or policies can be used for selective insertion. When a policy is associated with the export command, the policy is applied on every exported route.

The exported routes can also be filtered using policies.

**Note**

For routes exported to OSPF via a policy file, any refresh applied on that policy may result in temporary withdrawal and then immediate readvertising of those routes.

Verify the configuration using the command `show ospf`.

**OSPF Timers and Authentication**

Configuring OSPF timers and authentication on a per-area basis is a shortcut to applying the timers and authentication to each VLAN in the area at the time of configuration. If you add more VLANs to the area, you must configure the timers and authentication for the new VLANs explicitly.

Use the command:

```
configure ospf vlan [vlan-name | all] timer retransmit-interval transit-delay hello-interval dead-interval {wait-timer-interval}
```

**Configuring OSPF**

Each switch that is configured to run OSPF must have a unique router ID.

We recommend that you manually set the router ID of the switches participating in OSPF, instead of having the switch automatically choose its router ID based on the highest interface IP address. Not performing this configuration in larger, dynamic environments could result in an older LSDB remaining in use.
Configuring OSPF Wait Interval

ExtremeXOS allows you to configure the OSPF wait interval, rather than using the router dead interval.

**Caution**
Do not configure OSPF timers unless you are comfortable exceeding OSPF specifications. Non-standard settings may not be reliable under all circumstances.

To specify the timer intervals, enter the following commands:

```plaintext
configure ospf area area-identifier timer retransmit-interval transit-delay hello-interval dead-interval \{wait-timer-interval\}

configure ospf virtual-link router-identifier area-identifier timer retransmit-interval transit-delay hello-interval dead-interval

configure ospf vlan [vlan-name | all] timer retransmit-interval transit-delay hello-interval dead-interval \{wait-timer-interval\}
```

**OSPF Wait Interval Parameters**

You can configure the following parameters:

- **Retransmit interval**—The length of time that the router waits before retransmitting an LSA that is not acknowledged. If you set an interval that is too short, unnecessary retransmissions result. The default value is 5 seconds.
- **Transit delay**—The length of time it takes to transmit an LSA packet over the interface. The transit delay must be greater than 0.
- **Hello interval**—The interval at which routers send hello packets. Shorter times allow routers to discover each other more quickly but also increase network traffic. The default value is 10 seconds.
- **Dead router wait interval (Dead Interval)**—The interval after which a neighboring router is declared down because hello packets are no longer received from the neighbor. This interval should be a multiple of the hello interval. The default value is 40 seconds.
- **Router wait interval (Wait Timer Interval)**—The interval between the interface coming up and the election of the DR and BDR. This interval should be greater than the hello interval. If this time is close to the hello interval, the network synchronizes very quickly but might not elect the correct DR or BDR. The default value is equal to the dead router wait interval.

**Note**
The OSPF standard specifies that wait times are equal to the dead router wait interval.

**OSPF Configuration Example**

Figure 228 is an example of an autonomous system using OSPF routers. The details of this network follow.
Area 0 is the backbone area. It is located at the headquarters and has the following characteristics:

- Two internal routers (IR1 and IR2)
- Two area border routers (ABR 1 and ABR 2)
- Network number 10.0.x.x
- Two identified VLANs (HQ_10_0_2 and HQ_10_0_3)

Area 5 is connected to the backbone area by way of ABR 1 and ABR 2. It is located in Chicago and has the following characteristics:

- Network number 160.26.x.x
- One identified VLAN (Chi_160_26_26)
- Two internal routers

Area 6 is a stub area connected to the backbone by way of ABR 1. It is located in Los Angeles and has the following characteristics:

- Network number 161.48.x.x
- One identified VLAN (LA_161_48_2)
Three internal routers
Uses default routes for inter-area routing

Configuration for ABR 1 on page 1437 and Configuration for IR 1 on page 1437 provide two router configurations for the example in Figure 228 on page 1436.

Configuration for ABR 1
The router labeled ABR 1 has the following configuration:

```
create vlan HQ_10_0_2
create vlan HQ_10_0_3
create vlan LA_161_48_2
create vlan Chi_160_26_26
configure vlan HQ_10_0_2 ipaddress 10.0.2.1 255.255.255.0
configure vlan HQ_10_0_3 ipaddress 10.0.3.1 255.255.255.0
configure vlan LA_161_48_2 ipaddress 161.48.2.2 255.255.255.0
configure vlan Chi_160_26_26 ipaddress 160.26.26.1 255.255.255.0
create ospf area 0.0.0.5
create ospf area 0.0.0.6
enable ipforwarding
configure ospf area 0.0.0.6 stub nosummary stub-default-cost 10
configure ospf add vlan LA_161_48_2 area 0.0.0.6
configure ospf add vlan Chi_160_26_26 area 0.0.0.5
configure ospf add vlan HQ_10_0_2 area 0.0.0.0
configure ospf add vlan HQ_10_0_3 area 0.0.0.0
configure ospf vlan LA_161_48_2 priority 10
configure ospf vlan Chi_160_26_26 priority 10
configure ospf vlan HQ_10_0_2 priority 5
configure ospf vlan HQ_10_0_3 priority 5
enable ospf
```

Configuration for IR 1
The router labeled IR 1 has the following configuration:

```
configure vlan HQ_10_0_1 ipaddress 10.0.1.2 255.255.255.0
configure vlan HQ_10_0_2 ipaddress 10.0.2.2 255.255.255.0
enable ipforwarding
configure ospf add vlan all area 0.0.0.0
configure ospf area 0.0.0.0 priority 10
enable ospf
```

Note
In OSPF edge mode, the VLAN priority is “0” and cannot be set. (Refer to OSPF Edge Mode on page 1424.) When the license is upgraded to a Core license, the VLAN priority of "0" needs to be reset in order to participate in DR/BDR election.

Displaying OSPF Settings
You can use a number of commands to display settings for OSPF.

- To show global OSPF information, use the `show ospf` command with no options.
- To display information about one or all OSPF areas, enter:
  show ospf area (detail | area-identifier)
The **detail** option displays information about all OSPF areas in a detail format.

- To display information about OSPF interfaces for an area, a VLAN, or for all interfaces enter:
  \[
  \text{show ospf interfaces} \begin{cases} \\
  \text{vlan} \text{ vlan-name} | \text{area} \text{ area-identifier} | \text{enabled}
  \end{cases}
  \]

The **detail** option displays information about all OSPF interfaces in a detail format.

ExtremeXOS provides several filtering criteria for the **show ospf lsdb** command.

You can specify multiple search criteria, and only those results matching all of the criteria are displayed. This allows you to control the displayed entries in large routing tables.

- To display the current link-state database, enter:
  \[
  \text{show ospf lsdb} \begin{cases} \\
  \text{detail} | \text{stats} \begin{cases} \\
  \text{area} \begin{cases} \\
  \text{area-identifier} | \text{all}
  \end{cases}
  \end{cases}
  \end{cases}
  \begin{cases} \\
  \text{lstype} \begin{cases} \\
  \text{lstype} | \text{all}
  \end{cases}
  \end{cases}
  \begin{cases} \\
  \text{lsid} \begin{cases} \\
  \text{lsid-address} \text{lsid-mask}
  \end{cases}
  \end{cases}
  \begin{cases} \\
  \text{routerid} \begin{cases} \\
  \text{routerid-address} \text{routerid-mask}
  \end{cases}
  \end{cases}
  \begin{cases} \\
  \text{interface} \begin{cases} \\
  \text{ip-address} \text{ip-mask}
  \end{cases}
  \end{cases}
  \end{cases}
  \begin{cases} \\
  \text{ipNetmask} | \text{vlan} \text{vlan-name}
  \end{cases}
  \end{cases}
  \]

The **detail** option displays all fields of matching LSAs in a multiline format. The **summary** option displays several important fields of matching LSAs, one line per LSA. The **stats** option displays the number of matching LSAs but not any of their contents. If not specified, the default is to display in the summary format.

A common use of this command is to omit all optional parameters, resulting in the following shortened form:

\[
\text{show ospf lsdb}
\]

The shortened form displays LSAs from all areas and all types in a summary format.
OSPFv3 Overview

This chapter discusses the OSPFv3 (Open Shortest Path First version 3) protocol for distributing routing information between routers belonging to an autonomous system. This chapter provides an overview of the protocol’s features and example configuration commands.

Note
OSPFv3 is available on platforms with an Advanced Edge or Core license. For information about OSPFv3 licensing, see the ExtremeXOS 22.6 Feature License Requirements document.

OSPFv3 Overview

OSPF (Open Shortest Path First) is a link state protocol that distributes routing information between routers belonging to a single IP domain; the IP domain is also known as an Autonomous System (AS).

In a link-state routing protocol, each router maintains a database describing the topology of the AS. Each participating router has an identical database for an area maintained from the perspective of that router.

From the LSDB (Link State Database), each router constructs a tree of shortest paths, using itself as the root. The shortest path tree provides the route to each destination in the AS. When several equal-cost routes to a destination exist, traffic can be distributed among them. The cost of a route is described by a single metric.

OSPFv3 supports IPv6, and uses commands only slightly modified from that used to support IPv4. OSPFv3 has retained the use of the 4-byte, dotted decimal numbers for router IDs, LSA IDs, and area IDs.

OSPFv3 is an IGP (Interior Gateway Protocol), as is the other common IGP for IPv6, RIPng (Routing Information Protocol Next Generation). OSPFv3 and RIPng are compared in RIPng.

Note
Two types of OSPFv3 functionality are available and each has a different licensing requirement. One is the complete OSPFv3 functionality and the other is OSPFv3 Edge Mode, a subset of OSPFv3 that is described below. For specific information regarding OSPFv3 licensing, see the ExtremeXOS 22.6 Feature License Requirements document.

OSPFv3 Edge Mode

OSPFv3 Edge Mode is a subset of OSPFv3 available on platforms with an Advanced Edge license.

There are two restrictions on OSPFv3 Edge Mode:
• At most, four Active OSPFv3 VLAN (Virtual LAN) interfaces are permitted. There is no restriction on the number of Passive interfaces.
• The OSPFv3 Priority on VLANs is 0, and is not configurable. This prevents the system from acting as a DR or BDR.

**BFD for OSPFv3**

The BFD for OSPFv3 feature gives OSPFv3 routing protocol the ability to utilize BFD’s fast failure detection to monitor OSPFv3 neighbor adjacencies. CLI commands are provided to configure BFD protection for OSPFv3, so that as a registered BFD client, OSPFv3 can request BFD protection for interested OSPFv3 neighbors, and receive notifications about BFD session setup status and BFD session status updates (after establishing) from the BFD server. When BFD detects a communication failure between neighbors, it informs OSPFv3, which causes the OSPFv3 neighbor state be marked as “down.” This allows OSPFv3 protocol to quickly begin network convergence and use alternate paths to the affected neighbor.

![Figure 229: Basic Operational Flow of OSPFv3 BFD](image)

*Establishing a BFD Session for OSPFv3 Neighbor*

1. OSPFv3 discovers a neighbor.
2. If BFD for OSPFv3 is configured, OSPFv3 on both routers sends a request to the local BFD server to initiate a BFD neighbor session with the OSPFv3 neighbor router.
3. The BFD neighbor session with the OSPFv3 neighbor router is established on both sides if BFD session limit is not reached.

If the BFD session limit is reached, the OSPFv3 neighbor will be marked as BFD session failed if synchronous request is used, or pending if asynchronous request is used, and the BFD server will send an asynchronous notification when the session registration passes later. (The asynchronous request is not available until the BFD client session create API is enhanced.)
Eliminating the OSPFv3 Neighbor Relationship by BFD Fault Detection

1. A failure occurs in the network.
2. The BFD neighbor session with the OSPFv3 neighbor router is removed because the BFD timer expired.
3. On both Router A and Router B, BFD notifies the local OSPFv3 process that the BFD neighbor is DOWN.
4. The local OSPFv3 process tears down the OSPFv3 neighbor relationship by marking neighbor state DOWN. (If an alternative path is available, the routers will immediately start converging on it.)

**Figure 230: OSPFv3 Neighbor Relationship Eliminated by BFD Fault Detection**

OSPFv3 will request the BFD server to delete the BFD session for OSPFv3 neighbor moved to DOWN state. When the link failure is later resolved, OSPFv3 needs to register the re-discovered neighbor to BFD again to initiate BFD session creation.

Removing BFD Protection for OSPFv3

1. BFD protection is removed from OSPFv3 interface on Router A, OSPFv3 process requests BFD server to delete all BFD sessions for neighbors learned on that interface.
2. BFD server will stop sending session status update to local OSPFv3 process on Router A.
3. Before actually deleting any sessions, BFD server on Router A will first notify Router B to mark those session status as "Admin Down," which will cause Router B to stop using BFD protection for those OSPFv3 neighbors.
4. When BFD protection is removed from OSPFv3 interface on Router B, BFD sessions can be deleted immediately since they are already in "Admin Down" state.

When BFD for OSPFv3 is configured on broadcast interface, the default behavior is to register only OSPFv3 neighbors in FULL state with the BFD server. Separate BFD sessions are created for each neighbor learned on the same interface. If multiple clients ask for the same neighbor on the same interface, then single BFD sessions are established between the peers.

**OSPFv3 Neighbor State Determination**

With active BFD protection, OSPFv3 combines the BFD session state with the associated interface admin and operational states to determine the OSPFv3 neighbor adjacency discovered on that OSPFv3 interface. Regarding OSPFv3 neighbor relationships, OSPFv3 reacts directly to BFD session state changes only in the following circumstances:

- If BFD is enabled on the interface, and
- If BFD for OSPFv3 is configured on the OSPFv3 interface, and
If a BFD session has been established to the neighbor, and
If the BFD session has passed the INIT_COMPLETE state then:
1. The OSPFv3 neighbor relationship will remain as FULL if the operational state of the BFD session is "UP" and the operational state of the associated VLAN interface is UP.
2. The OSPFv3 neighbor relationship will be considered as DOWN if the operational state of the BFD session is DOWN or the operational state of the associated VLAN interface is DOWN.

In all other cases, the BFD session state is not considered as part of the reported OSPFv3 neighbor state, and the OSPFv3 neighbor state reverts to the operational state of the OSPFv3 interface only.

When the BFD session is in ADMIN_DOWN state, OSPFv3 ignores BFD events and OSPFv3 neighbor adjacency is not be affected by the BFD session state change.

Link State Database

Upon initialization, each router transmits a LSA (Link State Advertisement) on each of its interfaces. LSAs are collected by each router and stored into the LSDB of each router. After all LSAs are received, the router uses the LSDB to calculate the best routes for use in the IP routing table. OSPFv3 uses flooding to distribute LSAs between routers.

Any change in routing information is sent to all of the routers in the network. All routers within an area have the exact same LSDB.

Table 143 describes LSA type numbers.

Table 143: Selected OSPFv3 LSA Types

Graceful OSPFv3 Restart

RFC 3623 describes a way for OSPF control functions to restart without disrupting traffic forwarding.

Without graceful restart, adjacent routers will assume that information previously received from the restarting router is stale and will not be used to forward traffic to that router. However, in many cases, two conditions exist that allow the router restarting OSPFv3 to continue to forward traffic correctly. The first condition is that forwarding can continue while the control function is restarted. Most modern router system designs separate the forwarding function from the control function so that traffic can still be forwarded independent of the state of the OSPFv3 function. Routes learned through OSPFv3 remain
in the routing table and packets continue to be forwarded. The second condition required for graceful restart is that the network remain stable during the restart period. If the network topology is not changing, the current routing table remains correct. Often, networks can remain stable during the time for restarting OSPFv3.

**Restarting and Helper Mode**

Routers involved with graceful restart fill one of two roles: the restarting router or the helper router.

With graceful restart, the router that is restarting sends out Grace-LSAs informing its neighbors that it is in graceful restart mode, how long the helper router should assist with the restart (the grace period), and why the restart occurred. If the neighboring routers are configured to help with the graceful restart (helper-mode), they will continue to advertise the restarting router as if it was fully adjacent. Traffic continues to be routed as though the restarting router is fully functional. If the network topology changes, the helper routers will stop advertising the restarting router. The helper router will continue in helper mode until the restarting router indicates successful termination of graceful restart, the Grace-LSAs expire, or the network topology changes. A router can be configured for graceful restart, and for helper-mode separately. A router can be a helper when its neighbor restarts, and can in turn be helped by a neighbor if it restarts.

**Planned and Unplanned Restarts**

Two types of graceful restarts are defined: planned and unplanned.

A planned restart would occur if the software module for OSPFv3 was upgraded, or if the router operator decided to restart the OSPFv3 control function for some reason. The router has advance warning, and is able to inform its neighbors in advance that OSPFv3 is restarting.

An unplanned restart would occur if there was some kind of system failure that caused a remote reboot or a crash of OSPFv3, or a failover occurs. As OSPFv3 restarts, it informs its neighbors that it is in the midst of an unplanned restart.

You can decide to configure a router to enter graceful restart for only planned restarts, for only unplanned restarts, or for both. Also, you can separately decide to configure a router to be a helper for only planned, only unplanned, or for both kinds of restarts.

**Configuring Graceful OSPFv3 Restart**

- Configure a router to perform graceful OSPFv3 restart:
  ```
  configure ospfv3 restart [none | planned | unplanned | both]
  ```

  Since a router can act as a restart helper router to multiple neighbors, you will specify which neighbors to help.

- Configure a router interface to act as a graceful OSPFv3 restart helper:
  ```
  configure ospfv3 [[vlan | tunnel] all | {vlan} vlan-name | {tunnel} tunnel-name | area area-identifier] restart-helper [none | planned | unplanned | both]
  ```

  configure ospfv3 virtual-link {routerid} router_identifier {area} area_identifier timer [retransmit-interval] retransmit_interval 
  {transit-delay} transit_delay {hello-interval} hello_interval {dead-interval} dead_interval
• The graceful restart period sent out to helper routers can be configured with the following command:

```
configure ospfv3 restart grace-period seconds
```

By default, a helper router will terminate graceful restart if received LSAs would affect the restarting router.

This will occur when the restart-helper receives an LSA that will be flooded to the restarting router or when there is a changed LSA on the restarting router’s retransmission list when graceful restart is initiated.

• Disable or enable helper router LSA check:

## Areas

**OSPFv3** allows parts of a network to be grouped together into areas.

The topology within an area is hidden from the rest of the AS. Hiding this information enables a significant reduction in LSA traffic and reduces the computations needed to maintain the LSDB. Routing within the area is determined only by the topology of the area.

The three types of routers defined by OSPFv3 are as follows:

• **Internal router (IR)**—An internal router has all of its interfaces within the same area.

• **Area border router (ABR)**—An ABR has interfaces in multiple areas. It is responsible for exchanging summary advertisements with other ABRs.

• **Autonomous system border router (ASBR)**—An ASBR acts as a gateway between OSPFv3 and other routing protocols, or other autonomous systems.

### Note

Configuring inter-area and external filters causes all of the neighbors in the area to be reset.

---

**Backbone Area (Area 0.0.0.0)**

Any **OSPFv3** network that contains more than one area is required to have an area configured as area 0.0.0.0, also called the backbone.

All areas in an AS must be connected to the backbone. When designing networks, you should start with area 0.0.0.0 and then expand into other areas.

### Note

Area 0.0.0.0 exists by default and cannot be deleted or changed.

The backbone allows summary information to be exchanged between area border routers (ABRs). Every ABR hears the area summaries from all other ABRs. The ABR then forms a picture of the distance to all networks outside of its area by examining the collected advertisements and adding in the backbone distance to each advertising router.

When a **VLAN** is configured to run OSPFv3, you must configure the area for the VLAN.

If you want to configure the VLAN to be part of a different OSPFv3 area, use the following command:
configure ospfv3 vlan vlan-name area area-identifier

If this is the first instance of the OSPFv3 area being used, you must create the area first using the following command:

create ospfv3 area area_identifier

Stub Areas

OSPFv3 allows non-Backbone areas to be configured as stub areas.

A stub area is connected to only one other area. The area that connects to a stub area can be the backbone area. External route information is not distributed into stub areas. Stub areas are used to reduce memory consumption and computational requirements on OSPFv3 routers. To configure an OSPFv3 area as a stub area, use the following command:

configure ospfv3 area area_identifier stub [summary | nosummary] stub-default-cost cost

Not-So-Stubby-Areas

Not-so-stubby-areas (NSSAs) are similar to the existing OSPFv3 stub area configuration option but have the following two additional capabilities:

- External routes originating from an ASBR connected to the NSSA can be advertised within the NSSA.
- External routes originating from the NSSA can be propagated to other areas, including the backbone area.

The CLI command to control the NSSA function is similar to the command used for configuring a stub area, as follows:

configure ospfv3 area area-identifier nssa [summary | nosummary] stub-default-cost cost {translate}

The translate option in ABR determines whether it is either always translating type 7 LSAs are translated to type 5 LSAs or a candidate for election. When configuring an OSPFv3 area as an NSSA, translate should only be used on NSSA border routers, where translation is to be enforced. If translate is not used on any NSSA border router in a NSSA, one of the ABRs for that NSSA is elected to perform translation (as indicated in the NSSA specification). The option should not be used on NSSA internal routers. Doing so inhibits correct operation of the election algorithm.

Normal Area

A normal area is an area that is not:

- Area 0
- Stub area
- NSSA

Virtual links can be configured through normal areas. External routes can be distributed into normal areas.
Virtual Links

In a situation where a new area is introduced that does not have a direct physical attachment to the backbone, a virtual link is used.

A virtual link provides a logical path between the ABR of the disconnected area and the ABR of the normal area that connects to the backbone. A virtual link must be established between two ABRs that have a common area, with one ABR connected to the backbone. Figure 231 illustrates a virtual link.

![Figure 231: Virtual Link Using Area 1 as a Transit Area](image)

**Note**
Virtual links cannot be configured through a stub or NSSA area.

Virtual links are also used to repair a discontiguous backbone area. For example, in Figure 232, if the connection between ABR1 and the backbone fails, the connection using ABR2 provides redundancy so that the discontiguous area can continue to communicate with the backbone using the virtual link.

![Figure 232: Virtual Link Providing Redundancy](image)

**Link-Type Support**

You can manually configure the OSPFv3 link type for a VLAN. The following table describes the link types.
Table 144: OSPFv3 Link Types

<table>
<thead>
<tr>
<th>Link Type</th>
<th>Number of Routers</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto</td>
<td>Varies</td>
<td>ExtremeXOS automatically determines the OSPFv3 link type based on the</td>
</tr>
<tr>
<td></td>
<td></td>

<td>designated router (BDR). If you have three or more routers on the VLAN,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>OSPF fails to synchronize if the neighbor is not configured.</td>
</tr>
<tr>
<td>Passive</td>
<td></td>
<td>A passive link does not send or receive OSPFv3 packets.</td>
</tr>
</tbody>
</table>

**Note**

The number of routers in an OSPFv3 point-to-point link is determined per VLAN, not per link. All routers in the VLAN must have the same OSPFv3 link type. If there is a mismatch, OSPFv3 attempts to operate, but it may not be reliable.

**Import Policy**

Prior to ExtremeXOS 15.7, routing protocol OSPFv3 applied routing policies with keyword “import-policy”, which can only be used to change the attributes of routes installed into the switch routing table. ExtremeXOS 15.7 provides the flexibility of using import policy to determine the routes to be added to or removed from the routing table.

To prevent a route being added to the routing table, the policy file must contain a matching rule with action “deny”. If there is no matching rule for a particular route, or the keyword “deny” is missing in the rule, the default action is “permit”, which means that route will be installed into the routing table. Refer to the following policy file example:

```plaintext
entry entry-one {
  if {
    nlri 1001:0:0:1:0:0:0:0/64 exact;
  }
  then {
    cost 100;
  }
}
entry entry-two {
  if {
    nlri 2001:0:0:1:0:0:0:0/64 exact;
  }
  then {
    deny;
  }
}
```
In the above policy example, entry-one is used to change the cost of any matching routes, and entry-two is used to remove those matching routes from the routing table.

Note

Only “Network Layer Reachability Information” (NLRI) and “route origin” can be used as matching criteria in policy rules; using “next_hop” as a matching criteria is not supported. Any other policy attribute is not recognized and is ignored.

Route Redistribution

More than one routing protocol can be enabled simultaneously on the switch.

Route redistribution allows the switch to exchange routes, including static routes, between the routing protocols. Figure 233 is an example of route redistribution between an OSPFv3 AS and a RIPng AS.

![Figure 233: OSPFv3 Route Redistribution](image)

Configuring Route Redistribution

Exporting routes from one protocol to another and from that protocol to the first one are discrete configuration functions.

For example, to run OSPFv3 and RIPng simultaneously, you must first configure both protocols and then verify the independent operation of each. Then you can configure the routes to export from OSPFv3 to RIPng and the routes to export from RIPng to OSPFv3. Likewise, for any other combinations of protocols, you must separately configure each to export routes to the other.

Redistributing Routes into OSPFv3

To enable or disable the exporting of RIPng, static, and direct (interface) routes to OSPFv3, use the following command:

```
enable ospfv3 export [direct | ripng | static | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external | bgp | e-
```
These commands enable or disable the exporting of RIPng, static, and direct routes by way of LSA to other OSPFv3 routers as AS-external type 1 or type 2 routes. The default setting is disabled.

The cost metric is inserted for all RIPng, static, and direct routes injected into OSPFv3. If the cost metric is set to 0, the cost is inserted from the route. The tag value is used only by special routing applications. Use 0 if you do not have specific requirements for using a tag. (The tag value in this instance has no relationship with IEEE 802.1Q VLAN tagging.)

The same cost, type, and tag values can be inserted for all the export routes, or policies can be used for selective insertion. When a policy is associated with the export command, the policy is applied on every exported route. The exported routes can also be filtered using policies.

**Note**
For routes exported to OSPFv3 via a policy file, any refresh applied on that policy may result in temporary withdrawal and then immediate readvertising of those routes.

Verify the configuration using the command:

```
show ospfv3
```

**OSPFv3 Timers**

Configuring OSPFv3 timers on a per area basis is a shortcut to applying the timers to each VLAN in the area at the time of configuration.

If you add more VLANs to the area, you must configure the timers for the new VLANs explicitly. Use the command:

```
configure ospfv3 [vlan vlan-name | tunnel tunnel-name | [vlan | tunnel] all] timer {retransmit-interval} retransmit-interval {transit-delay} transit-delay {hello-interval} hello-interval {dead-interval} dead-interval
```

**Virtual Routing and Forwarding (VRF) for OSPFv3**

ExtremeXOS supports multiple Virtual Routing and Forwarding (VRFs) in the same virtual router (VR). Each VRF can have a separate instance of a routing protocol with its own routing table. OSPFv3 can run in a Non-VPN VRF and support multiple instances of the protocol in different VRFs at the same time. This allows more scalable deployments of OSPFv3 as ExtremeXOS can have more VRFs than VRs, and OSPFv3 VRF instances belonging to the same VR run in a single ExtremeXOS process. Each VR still has its own process, so different VRs have very low impact on one another.

**Limitations**

- Only non-VPN VRFs are supported. OSPFv3 is blocked on VPN VRFs.
- **BGP** (Border Gateway Protocol) does not support VPN-IPv6 routes, so PE-CE support is not available.
This chapter introduces IS-IS, a link state protocol that distributes routing information between routers belonging to an autonomous system. It provides configuration commands and examples and information about configuring, displaying, and managing IS-IS on a network. This chapter assumes that you are already familiar with Intermediate System-Intermediate System (IS-IS) and IP routing.

If not, refer to the following publications for additional information:

- RFC 1195—Use of OSI IS-IS for Routing in TCP/IP and Dual Environments
- RFC 2763—Dynamic Hostname Exchange Mechanism for IS-IS
- RFC 2966—Domain-Wide Prefix Distribution with Two-Level IS-IS
- RFC 2973—IS-IS Mesh Groups
- RFC 3373—Three-Way Handshaking for IS-IS Point-to-Point Adjacencies
- RFC 3719—Recommendations for Interoperable Networks using Intermediate System to Intermediate System (IS-IS)
- RFC 3787—Recommendations for Interoperable IP Networks using Intermediate System to Intermediate System (IS-IS)
- draft-ietf-isis-ipv6-06—Routing IPv6 with IS-IS
- draft-ietf-isis-restart-02—Restart signaling for IS-IS

IS-IS Overview

IS-IS is a link state protocol that distributes routing information between routers belonging to a single IP domain; the IP domain is also known as an autonomous system (AS). In a link-state routing protocol,
each router maintains a database describing the topology of the AS. Each participating router has an identical database maintained from the perspective of that router.

From the link state database (LSDB), each router constructs a tree of shortest paths, using itself as the root. The shortest path tree provides the route to each destination in the AS. When several equal-cost routes to a destination exist, traffic can be distributed among them. The cost of a route is described by a single metric.

IS-IS is an interior gateway protocol (IGP), as are RIP (Routing Information Protocol) and OSPF (Open Shortest Path First). Unlike RIP and OSPF, IS-IS was not initially designed for IP. RFC 1195 specifies how IS-IS can run in an IP environment. The Extreme Networks implementation supports IS-IS only in IP environments. RIP, OSPF, and IS-IS are compared in RIP. The IPv6 versions of these protocols are compared in RIPng.

### Establishing Adjacencies

An adjacency is an acknowledged relationship between two IS-IS routers. An adjacency must be established before two IS-IS routers can exchange routing information.

IS-IS routers establish adjacencies by exchanging hello PDUs, which are also called Intermediate System to Intermediate System Hellos (IIHs). Hello PDUs contain some interface configuration and capability information. Once a pair of neighbors exchanges hello PDUs with acceptably matching configuration and capabilities, an adjacency is formed. Hello PDUs are sent periodically by each party to maintain the adjacency.

After an adjacency is formed, information about the adjacency is stored in a link state PDU (LSP), which is stored in the router link state database (LSDB). Routers periodically flood all of their LSPs to all other network nodes. When a router receives LSPs, it adds the LSPs to its LSDB, and uses the LSDB to calculate routes to other routers. These database maintenance operations are performed a little differently for the two adjacency types, point-to-point, and broadcast.

#### Point-to-Point Adjacency

Point-to-point adjacencies can include no more than two routers in the same VLAN (Virtual LAN). Figure 234 shows a point-to-point adjacency.
Once a point-to-point adjacency is established, each router sends a CSNP (Complete Sequence Number PDU) listing a summary of all its LSPs. When a router receives its neighbor’s CSNP, it sends any LSP it has that is either not present in the CSNP or is newer than the version in the CSNP. In a point-to-point adjacency, partial sequence number PDUs (PSNPs) are used to acknowledge each LSP a router receives from its neighbor. If a PSNP is not received within a configurable period of time, unacknowledged LSPs are re-sent.

A disadvantage to point-to-point adjacencies is that they do not scale well. **Figure 235** shows a four-router network with point-to-point adjacencies.

In this network, each of the ellipses represents a point-to-point adjacency. Each of the four routers periodically sends all of its LSPs to the other three routers. Each, in turn, will flood the received LSPs to the other two since they have no way of knowing which routers have already received them, generating...
N2 LSPs. This network routing traffic reduces the bandwidth available for data traffic. For networks that only have two routers and are not likely to grow, a point-to-point adjacency is appropriate.

**Broadcast Adjacency**

Broadcast adjacencies can include two or more routers in a single adjacency. Figure 236 depicts a broadcast adjacency.

![Figure 236: Broadcast Adjacencies in a Four-Router Network](image)

When broadcast adjacencies are formed, one of the routers participating in the adjacency is elected designated intermediate system (DIS). The election is determined by a DIS priority configured for each router. In the event of a tie, the router with the numerically highest MAC address wins.

A broadcast network can be considered a virtual node, or pseudonode, to which all routers have a zero-cost adjacency.

The DIS acts on behalf of the pseudonode by advertising an LSP listing all routers in the adjacency with zero-cost metric. The DIS also periodically sends a complete sequence number PDU (CSNP), which lists all LSPs in the link-state database. If a router sees that it is missing one or more of the entries, it multicasts a request for them using a PSNP. Only the DIS responds to this request by sending the requested LSPs. All routers multicast their originated LSPs as they are refreshed, and multicast periodic hellos to the network.

The default configuration creates broadcast adjacencies.

**IS-IS Hierarchy**

IS-IS has a two-level hierarchy. IS-IS routers may participate in either level or both. Figure 237 shows a basic IS-IS AS.
Figure 237: Basic Autonomous System

In the network in the above figure, each of the ellipses represents an adjacency. Level 1 (L1) routers within an area need only know the topology within that area as well as the location of the nearest L1/L2 attached router. An attached router is one that participates in both levels and can reach at least one other L1/L2 or L2 router with a different area address.

In an AS, there is only one L2 area, and it serves as a backbone area between L1 areas. This L2 area is also called a domain (not to be confused with the entire AS routing domain). L2 routers communicate with one another irrespective of L1 area membership or L2 area address.

Note

On any switch, the maximum number of L1/L2 adjacencies is one half the maximum number of L1 or L2 adjacencies because an L1/L2 adjacency defines both an L1 adjacency and an L2 adjacency. The supported adjacency limits are defined in the ExtremeXOS Release Notes.

For information on creating and managing IS-IS areas, see Managing an IS-IS Area Address on page 1467.

IS-IS and IP Routing

IS-IS is not inherently an IP Routing protocol. Its control packets do not use IP. RFC 1195 specifies the use of IS-IS for IP Routing.
The ExtremeXOS software implementation of IS-IS requires that at least one IPv4 or IPv6 address be assigned to an interface.

IP addresses and subnets can be assigned independent of area structure provided that neighboring interfaces are on the same subnet. L1 routers exchange directly reachable IP address/mask/metric tuples. When routing in an L1 area, packets are routed via L1 if the destination address is reachable within the area. Otherwise packets are forwarded to the nearest L2 router. L2 routers advertise all IP addresses reachable in their L1 area (if they are a member of one), as well as directly reachable addresses.

Summary Addresses

Routers can be manually configured to advertise abbreviated versions of reachable addresses, which are called summary addresses. By aggregating many routes into one summary address, route computation and lookup can be made more efficient. If packets arrive at the router as a result of the summary address but have no actual route (as a result of the summary address covering more address space than is actually used), the packets are discarded.

For instructions on managing summary addresses, see Managing IP Summary Addresses on page 1467.

External Connectivity

Externally reachable IP addresses are those learned or exported from other routing protocols like RIP, BGP (Border Gateway Protocol), and OSPF. When using narrow metrics, external routes may use internal or external metrics. When calculating SPF, routes with internal metrics are preferred over routes with external metrics. When external metrics are used to compare routes, the internal cost is not considered unless the external metrics are equal.

Authentication

Entire packets (as opposed to individual TLVs in a packet) can be authenticated. If authentication fails on a packet, the entire packet is discarded. Multi-part packets are authenticated separately. Routers are not required to support authentication. The ExtremeXOS software provides optional support for plain-text authentication.

Dynamic Hostname

The dynamic hostname exchange extension helps address the usability issues of maintaining IS-IS routers. IS-IS system IDs (which default to the switch MAC address) are not very readable. When the dynamic hostname feature is enabled, learned IS-IS hostnames are used in place of system IDs in log entries where possible. In addition, hostname TLVs appear in the show isis lsdb detail command display.

For instructions on managing the dynamic hostname feature, see Configuring the Dynamic Hostname Feature on page 1463.

Route Leaking

Route leaking allows L2 LSPs to be sent into L1 areas. Route leaking is configured with the command:
configure isis area area_name interlevel-filter level 2-to-1 [policy | block-all | allow-all] {ipv4 | ipv6}

The supplied policy defines what route or routes should be leaked.

**Caution**
Route leaking can reduce scalability and performance.

**Note**
Tracert does not work if the VRF leaked route is one of the hop(s) to destination.

**Metric Types**
Interface metrics are available in two sizes: a 6-bit narrow metric and a 24-bit wide metric. By default only narrow metrics are used. Wide metrics allow for greater flexibility, however, and are required in order to use some extensions of IS-IS, such as IPv6. All routers in an IS-IS area must use the same metric style.

For instructions on configuring interface metric style and values, see Configuring VLAN Interface Metrics on page 1468. Refer to RFC 3787, Section 5.1, for migration details. Note that the ExtremeXOS software does not support section 5.2.

**IS-IS Restart**
When an IS-IS router restarts, neighbors time out adjacencies and the network converges around it. IS-IS restart support, with the help of restart helper neighbors, can prevent this. A restarting router can send a restart request to indicate to its neighbors that it is restarting. Neighbors—provided they are helpers—send the restarting router a CSNP so that it can reconstruct its LSDB by tracking which LSPs it has and has not received. Neighbors can still time out the adjacency, so this might not work in environments with low hold timers.

IS-IS restart can be configured for planned and unplanned events. Planned events are user-initiated process restarts and user-initiated failovers. Unplanned events are process restarts or failovers that are not administratively initiated.

For information on configuring IS-IS restart, see Configuring the Graceful Restart Feature on page 1462.

**IPv4 and IPv6 Topology Modes**
Interfaces can be IS-IS-enabled for IPv4, IPv6, or both. Within an IS-IS area, IPv4 and IPv6 can be supported in a single topology or in a multiple topology. A transition configuration is provide for migrating between the single and multiple topologies.

In a single topology, all interfaces in an area must be configured for IPv4, IPv6, or both IPv4 and IPv6. Adjacencies are denied if the topology configuration between two routers does not match. A single SPF calculation is performed for each route in a single topology area.
In a multiple topology area, each interface can be configured for IPv4, IPv6, or both IPv4 and IPv6. The router creates separate topologies for IPv4 and IPv6. Adjacencies are permitted between interfaces with different configurations, provided that the neighbors support at least one common protocol. Separate SPF calculations are computed for IPv4 and IPv6 routes.

**Note**

Although the IPv4 and IPv6 topologies can be different when multiple topologies are enabled, the topologies must be convex. That is, no IPv4 interface can be reachable only through traversal of IPv6 interfaces, and vice versa. All routers in an area must use the same topology mode.

When the transition topology mode is configured, the router allows adjacencies between any two interfaces, and distributes both single topology and multiple topology TLVs. Transition mode permits both single and multiple topologies to coexist, but it generates more traffic. Transition mode should be used only for transitioning between modes and should be disabled after the transition is complete.

By default, a single topology is used for both IPv4 and IPv6. As a result, all interfaces must be homogeneously ISIS-enabled for IPv4, IPv6, or both.

To change the configured topology mode, see *Configure the Multi-Topology Feature* on page 1464.

**Route Redistribution**

More than one routing protocol can be enabled simultaneously on a network. Route redistribution allows the switch to exchange routes, including static routes, between the active routing protocols. *Figure 238* shows a network that is running two routing protocols, IS-IS and RIP.

![Figure 238: AS External Route Redistribution](image-url)
By default, the IS-IS/RIP node does not inject its learned RIP routes into IS-IS—and it does not need to if originate-default feature is enabled using the command:

```
enable isis area area_name originate-default {ipv4 | ipv6}.
```

If it does redistribute the RIP routes into IS-IS, all L2 IS-IS routers learn the RIP routes as type IS-IS level 2 external. The L2 IS-IS routers do not know that the routes actually originated from RIP. Also, if configured to do so, L1/L2 routers can leak these routes into the L1 areas and all IS-IS routers learn the RIP routes (without knowing that they actually came from RIP and without having to actually participate in RIP).

Route redistribution is configurable on both L2 and L1 using the `enable isis area export` commands. Redistributing routes into L1 generates L1 external routes. The export policy can choose to redistribute external routes with internal metrics into IS-IS.

### Configuring Route Redistribution

Exporting routes from one protocol to another and in the reverse direction are discrete configuration functions. For example, to run IS-IS and RIP simultaneously, you must first configure both protocols and then verify the independent operation of each. Then you can configure the routes to export from IS-IS to RIP and the routes to export from RIP to IS-IS. Likewise, for any other combinations of protocols, you must separately configure each to export routes to the other.

This section describes how to inject routing information learned from other IP routing protocols into an IS-IS domain, thereby advertising their reachability in the IS-IS domain. These routes are included in the locally originated LSPs. For information on exporting routes learned in IS-IS to another routing protocol, see the chapter that describes the destination routing protocol.

When you export routes from another protocol to IS-IS, the metric and the type of metric are configured. You can also configure a policy to filter out unwanted external routes.

- To enable or disable the exporting of BGP, OSPF, RIP, static, and direct (interface) IPv4 routes to IS-IS, use the following commands:

```
enable isis area area_name export {ipv4} route-type [policy | metric mvalue {metric-type [internal | external]}] {level [1 | 2 | both-1-and-2]}
```

```
disable isis area area_name export {ipv4} route-type
```

- To enable or disable the exporting of OSPFv3 (Open Shortest Path First version 3), RIPng (Routing Information Protocol Next Generation), static, and direct (interface) IPv6 routes to IS-IS, use the following commands:

```
enable isis area area_name export ipv6 route-type [policy | metric mvalue] {level [1 | 2 | both-1-and-2]}
```

```
disable isis area area_name export ipv6 route-type
```

The cost metric is inserted for all OSPF, RIP, static, and direct routes injected into IS-IS.

The same cost and type values can be inserted for all the export routes, or policies can be used for selective insertion. When a policy is associated with the export command, the policy is applied on every exported route. The exported routes can also be filtered using policies.

- Verify the configuration using the command:

```
show isis area [area_name | all]
```
Configuring IS-IS

Configuring L1 Routers

To configure a switch to operate as a level 1 IS-IS router, do the following:

1. Prepare the IP interfaces that will support level 1 IS-IS routing as follows:
   - a. Add an IPv4 or IPv6 address.
   - b. Enable IP or IPv6 forwarding.

2. Create the IS-IS routing process, which is also called an area, using the following command:
   
   ```
   create isis area area_name
   ```

3. Configure the routing process to serve as a L1-only router using the following command:
   
   ```
   configure isis area area_name is-type level [1 | 2 | both-1-and-2]
   ```

   Specify 1 for the level option using the following command:

4. Add an IS-IS area level-1 address to the router using the following command:
   
   ```
   configure isis area area_name add area-address area_address
   ```

5. Add IS-IS-eligible interfaces to the area using the following command:
   
   ```
   configure isis add [vlan all | {vlan} vlan_name] area area_name {ipv4 | ipv6}
   ```

   An IS-IS-eligible interface is one that already has the appropriate IP address type (IPv4 or IPv6) address assigned to it.

6. The default IS-IS system ID is the switch MAC address. If you want to change the default IS-IS system ID, using the following command:
   
   ```
   configure isis area area_name system-id [automatic | system_id]
   ```

7. Enable the IS-IS router using the following command:
   
   ```
   enable isis {area area_name}
   ```

Configuring L1/L2 Routers

To configure a switch to operate as a L1/L2 IS-IS router, do the following:

1. Prepare the IP interfaces that will support level 1 IS-IS routing as follows:
   - a. Add an IPv4 or IPv6 address.
   - b. Enable IP or IPv6 forwarding.

2. Create the IS-IS routing process, which is also called an area, using the following command:
   
   ```
   create isis area area_name
   ```
3 Configure the routing process to serve as an L1/L2 router using the following command:

```
configure isis area area_name is-type level [1 | 2 | both-1-and-2]
```

Specify both-1-and-2 for the level option using the following command:

```
Note
When no other L2 processes are defined on the router, the default IS type level is L1/L2, and this command can be omitted.
```

4 Add an IS-IS area level-1 address to the router using the following command:

```
configure isis area area_name add area-address area_address
```

5 Add an IS-IS area level-2 address to the router using the following command:

```
configure isis area area_name add area-address area_address
```

6 Add IS-IS-eligible interfaces to the area using the following command:

```
configure isis add [vlan all | {vlan} vlan_name] area area_name {ipv4 | ipv6}
```

An IS-IS-eligible interface is one that already has the appropriate IP address type (IPv4 or IPv6) address assigned to it.

7 If your topology requires interfaces to operate at a specific topology level, configure the appropriate interfaces with the following command:

```
configure isis [vlan all | {vlan} vlan_name] circuit-type level [1 | 2 | both-1-and-2]
```

8 The default IS-IS system ID is the switch MAC address. If you want to change the default IS-IS system ID, use the following command:

```
configure isis area area_name system-id [automatic | system_id]
```

```
Note
Although the IS-IS protocols manage IP routing, they use the Connectionless Network Protocol (CLNP) for IS-IS communications between routers. The IS-IS system ID is required to identify the router in the AS.
```

9 Enable the IS-IS router using the following command:

```
enable isis {area area_name}
```

### Configuring L2 Routers

To configure a switch to operate as a level 2 IS-IS router, do the following:

1 Prepare the IP interfaces that will support level 2 IS-IS routing as follows:
   a Add an IPv4 or IPv6 address.
   b Enable IP or IPv6 forwarding.

2 Create the IS-IS routing process, which is also called an area, using the following command:

```
create isis area area_name
```

3 Configure the routing process to serve as a L2-only router using the following command:

```
configure isis area area_name is-type level [1 | 2 | both-1-and-2]
```

Specify 2 for the level option.
4 Add an IS-IS area level-2 address to the router using the following command:
   \texttt{configure isis area area\_name add area\_address area\_address}

5 Add IS-IS-eligible interfaces to level 2 using the following command:
   \texttt{configure isis add [vlan all | \{vlan\} vlan\_name] area area\_name [ipv4 | ipv6]}
   An IS-IS-eligible interface is one that already has the appropriate IP address type (IPv4 or IPv6) address assigned to it.

6 Add an IS-IS system ID to the router using the following command:
   \texttt{configure isis area area\_name system\_id [automatic | system\_id]}
   Use the \texttt{automatic} option to assign the switch MAC address to the IS-IS system ID. The default option is \texttt{automatic}, so you can also enter the command without options to select the switch MAC address.

7 Enable the ISIS router using the following command:
   \texttt{enable isis \{area area\_name\}}

### Configuring IS-IS Timers

IS-IS timers allow you to fine tune IS-IS operation. Table 145 lists the IS-IS timers and the command you can use to adjust them.

<table>
<thead>
<tr>
<th>Timer</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>T1 hello restart interval</td>
<td>configure isis [vlan all</td>
</tr>
<tr>
<td>T2 restart timer</td>
<td>configure isis area area_name timer restart seconds {level [1</td>
</tr>
<tr>
<td>T3 restart grace period</td>
<td>configure isis restart grace-period seconds</td>
</tr>
<tr>
<td>LSP generation interval</td>
<td>configure isis area area_name timer lsp-gen-interval seconds {level[1</td>
</tr>
<tr>
<td>LSP maximum lifetime</td>
<td>configure isis area area_name timer max-lsp-lifetime seconds</td>
</tr>
<tr>
<td>LSP refresh interval</td>
<td>configure isis area area_name timer lsp-refresh-interval seconds</td>
</tr>
<tr>
<td>SPF interval</td>
<td>configure isis area area_name timer spf-interval seconds {level[1</td>
</tr>
<tr>
<td>CSNP interval</td>
<td>configure isis [vlan all</td>
</tr>
<tr>
<td>Hello interval</td>
<td>configure isis [vlan all</td>
</tr>
<tr>
<td>Hello multiplier</td>
<td>configure isis [vlan all</td>
</tr>
</tbody>
</table>
Table 145: IS-IS Configuration Timers and Commands (continued)

<table>
<thead>
<tr>
<th>Timer</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSP retransmit interval</td>
<td>configure isis [vlan all</td>
</tr>
<tr>
<td>LSP transmit interval</td>
<td>configure isis [vlan all</td>
</tr>
</tbody>
</table>

Configuring the Graceful Restart Feature

The graceful restart feature enables a router process to restart with minimal impact on the network. Without graceful restart, every other IS-IS router in the network must update its LSDB when the router goes down, and this generates a lot of traffic, and it introduces delays while new routes are established. With graceful restart, the router process requests restart support from its neighbors, and the neighbors wait for a predefined time before declaring routes dead. If the restart completes before the predefined time ends, the restart causes minimal impact on the network operation. For more information on graceful restart, see IS-IS Restart on page 1456.

- To enable or disable the graceful restart feature, use the following commands:
  
  ```
  enable isis restart-helper
  disable isis restart-helper
  ```

- To configure which events trigger a graceful restart, use the following commands:
  ```
  configure isis restart [ none | planned | unplanned | both ]
  ```

- To configure the timers used to control graceful restart operation, use the commands in Table 146.

Table 146: Timers that Control Graceful Restart

<table>
<thead>
<tr>
<th>Timer</th>
<th>Configuration Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>T1 restart hello interval</td>
<td>configure isis [vlan all</td>
</tr>
<tr>
<td>T2 restart timer</td>
<td>configure isis area area_name timer restart seconds {level [1</td>
</tr>
<tr>
<td>T3 restart grace period</td>
<td>configure isis restart grace-period seconds</td>
</tr>
<tr>
<td>Hello interval</td>
<td>configure isis [vlan all</td>
</tr>
<tr>
<td>Hello multiplier</td>
<td>configure isis [vlan all</td>
</tr>
</tbody>
</table>

Configuring Hello Padding

Hello PDUs are padded to the MTU by default, and this is called hello padding. This is to help identify and correct cases where switches have mismatched MTUs. Because IS-IS packets cannot be fragmented in transit, maintaining consistent MTUs is important to ensure the reliability of packets traversing the network. However, this extra padding could be a waste of bandwidth in scenarios where the MTU is fixed throughout the network.
To disable hello padding, use the following command:
```
disable isis [vlan all | {vlan} vlan_name] hello-padding
```
To enable hello padding, use the following command:
```
  enable isis [vlan all | {vlan} vlan_name] hello-padding
```

### Configuring Interlevel Filters

Interlevel filters allow you to control how routes are redistributed between IS-IS levels 1 and 2. The redistribution of routes from level 2 to level 1 is called route leaking. For more information, see Route Leaking on page 1455.

- To set an interlevel filter for redistribution from level 1 to level 2, use the following command:
  ```
  configure isis area area_name interlevel-filter level 1-to-2 [policy | none] {ipv4 | ipv6}
  ```
- To set an interlevel filter for redistribution from level 2 to level 1, use the following command:
  ```
  configure isis area area_name interlevel-filter level 2-to-1 [policy | block-all | allow-all] {ipv4 | ipv6}
  ```

### Configuring the Dynamic Hostname Feature

Dynamic Hostname on page 1455 introduces the dynamic hostname feature, which causes text names to replace numbers in some logs.

- To enable the dynamic hostname feature, use the following command:
  ```
  enable isis area area_name dynamic-hostname [area-name | snmp-name]
  ```
- To disable the dynamic hostname feature, use the following command:
  ```
  disable isis area area_name dynamic-hostname
  ```

### Configuring the Adjacency Check Feature

When enabled, the adjacency check feature permits an adjacency between two IS-IS interfaces only when both are configured for the same IP address type (IPv4 or IPv6) and are configured for the same subnet.

- To enable the adjacency check feature, use the following command:
  ```
  enable isis area area_name adjacency-check {ipv4 | ipv6}
  ```
- To disable the adjacency check feature, use the following command:
  ```
  disable isis area area_name adjacency-check {ipv4 | ipv6}
  ```

### Configuring an Import Policy

When applied to a router process, an import policy controls how routes are imported to the FIB from all IS-IS processes on this virtual router (VR).
To apply a policy to a router process, use the following command:
```
configure isis import-policy [policy-map | none]
```

**Note**
The import policy cannot be used to select which routes are added to the routing table. The import policy can only modify the route attributes as routes are added to the routing table.

### Configure the Multi-Topology Feature

The multi-topology feature is introduced in IPv4 and IPv6 Topology Modes on page 1456.

- To configure the multi topology feature, use the following command:
  ```
  configure isis area area_name topology-mode [single | multi | transition] [level [1 | 2]]
  ```

### Displaying IS-IS Information

#### Displaying General Information for Global IS-IS

- To display general information for global IS-IS, use the following command:
  ```
  show isis
  ```

#### Displaying Router-Specific Information

- To display router-specific information, use the following command:
  ```
  show isis area [area_name | all]
  ```

#### Displaying Router Summary Addresses

- To display router summary addresses, use the following command:
  ```
  show isis area area_name summary-addresses
  ```

#### Displaying IS-IS Interface Information

- To display IS-IS interface information, use the following command:
  ```
  show isis vlan {enabled | { vlan_name | all } }
  ```

#### Displaying Link State Database Information

- To display link state database information, use the following command:
  ```
  show isis lsdb [area area_name {lsp-id lsp_id}] [level [1|2]] (detail | stats)
  ```
Displaying IPv4 and IPv6 Topology Information

- To display IPv4 and IPv6 topology information, use the following command:
  ```
  show isis topology {area area_name [level [1 | 2]]} {ipv4 | ipv6}
  ```

Displaying IS-IS Neighbors

- To display IS-IS neighbor information, use the following command:
  ```
  show isis neighbors {area area_name} {vlan vlan_name} {ipv4 | ipv6} (detail)
  ```

Displaying IS-IS Counter Data

- To display IS-IS counter data, use the following command:
  ```
  show isis counters {area [area_name | all] | vlan [vlan_name | all]}
  ```

Managing IS-IS

Configuring Password Security

The ExtremeXOS software supports passwords for the following IS-IS AS components:

- Level 2 domains
- Level 1 areas
- VLAN interfaces

Domain and area authentication prevents intruders from injecting invalid routing information into the router. Because passwords must be configured to match at both ends of a connection, password security also helps detect unconfigured and misconfigured interfaces. After configuration, the password is inserted into LSP, CSNP, and PSNP PDUs and are validated on the receiving end.

Note

The password configuration commands in this section provide an encrypted option, which controls how the passwords are saved and displayed on the switch. The encrypted option does not encrypt messages that are transmitted on the network. All passwords are transmitted in clear text.

- To configure password security for a level 2 domain, use the following command:
  ```
  configure isis area area_name domain-password [none | {encrypted}
  simple password {authenticate-snp {tx-only}}]
  ```
- To configure password security for a level 1 area, use the following command:
  ```
  configure isis area area_name area-password [none | {encrypted} simple
  password {authenticate-snp {tx-only}}]
  ```
Interface authentication prevents unauthorized routers from forming an adjacency. This is achieved by inserting a password in hello PDUs and validating the password on the receiving end. You can configure password protection separately for level 1 and level 2.

- To configure password security for a VLAN interface, use the following command:
  ```
  configure isis [vlan all | {vlan} vlan_name] password [none | {encrypted} simple password] level [1 | 2]
  ```

Managing Transit Traffic with the Overload Bit

If a router lacks the resources to maintain a complete link state database, routing packets to it could result in a blackhole or routing loop. The overload bit prevents this undesirable behavior by indicating to the other routers that the afflicted router should not be used as a transit router. Packets destined for directly attached routes can still be routed to a router with the overload bit set, but all other routing paths reconverge around it.

- To manually enable the overload bit feature, use the following command:
  ```
  enable isis area area_name overload-bit {suppress [external | interlevel | all]}
  ```

- To configure the router to automatically set the overload bit on startup, use the following command:
  ```
  configure isis area area_name overload-bit on-startup [ off | {suppress [external | interlevel | all]} seconds]
  ```

- To disable the overload bit feature, use the following command:
  ```
  disable isis area area_name overload-bit
  ```

**Note**

Enabling or disabling the overload bit feature does not modify the configuration of the command:
```
configure isis area area_name overload-bit on-startup [ off | {suppress [external | interlevel | all]} seconds]
```

Clearing the IS-IS Counters

The `show isis counters {area [area_name | all] | vlan [vlan_name | all]}` command can display all counters or only those specific to the router process or the configured VLANs.

- To clear the IS-IS counters for the router and the VLANs, use the following command:
  ```
  clear isis counters
  ```

- To clear the IS-IS counters only for the router process, use the following command:
  ```
  clear isis counters area [area_name | all]
  ```

- To clear the IS-IS counters only for one or all VLANs, use the following command:
  ```
  clear isis counters [vlan all | {vlan} vlan_name]
  ```
Originating an L2 Default Route

This feature injects a zero-cost route to 0.0.0.0 in LSPs originated by an L2 router, thereby advertising the router as the default gateway.

- To enable default route origination, use the following command:
  ```plaintext
  enable isis area area_name originate-default {ipv4 | ipv6}
  ```
- To disable default route origination, use the following command:
  ```plaintext
  disable isis area area_name originate-default {ipv4 | ipv6}
  ```

Managing IP Summary Addresses

Summary addresses are introduced in Summary Addresses on page 1455. L2 routers include in their L2 LSPs a list of all destinations reachable in the L1 area attached to them by default. Summarization of the L1 destinations reduces the amount of information stored on each L2 router and helps in scaling to a large routing domain.

- To add summary addresses to an IS-IS router, use the following command:
  ```plaintext
  configure isis area area_name add summary-address [ipv4_address_mask | ipv6_address_mask] {level [1 | 2]}
  ```
- To delete summary addresses from an IS-IS router, use the following command:
  ```plaintext
  configure isis area area_name delete summary-address [ipv4_address_mask | ipv6_address_mask] {level [1 | 2]}
  ```
- To display the configured summary addresses for an IS-IS router, use the following command:
  ```plaintext
  show isis area area_name summary-addresses
  ```

Managing an IS-IS Area Address

IS-IS was not originally designed for IP routing. Some aspects of CLNP routing, such as system IDs and area addresses, exist in the IP extension of IS-IS. The IS-IS area address is required to identify the area in which the router participates.

- Before you can configure the area address, you must create the IS-IS routing process, which is also called an area, using the following command:
  ```plaintext
  create isis area area_name
  ```
- To add an IS-IS area address to the router, use the following command:
  ```plaintext
  configure isis area area_name add area-address area_address
  ```
- To delete an IS-IS area address from a router, use the following command:
  ```plaintext
  configure isis area area_name delete area-address area_address
  ```

Note

The ExtremeXOS software implementation of IS-IS supports no more than three area addresses.

Managing VLAN Interfaces
Adding a VLAN Interface

- To add a VLAN interface to a router, use the following command:

  ```
  configure isis add [vlan all | {vlan} vlan_name] area area_name {ipv4 | ipv6}
  ```

**Note**
The interface is not enabled separately from the area. If the area is enabled, the interface will begin transmitting hellos as soon as this command is executed, provided the interface is in forwarding mode and has active links.

Setting the VLAN Interface Link Type

The default link type is broadcast. You can change the link type to point-to-point.

- To set the link type, use the following command:

  ```
  configure isis [vlan all | {vlan} vlan_name] link-type [broadcast | point-to-point]
  ```

Setting the VLAN Interface Circuit Type

- The circuit type can be level 1, level 2, or both level 1 and level 2. To set the circuit type, use the following command:

  ```
  configure isis [vlan all | {vlan} vlan_name] circuit-type level [1 | 2 | both-1-and-2]
  ```

Configuring VLAN Interface Metrics

Normally, IS-IS metrics can have values up to 63. These metrics are narrow metrics. IS-IS generates two type, length, and value (TLV) codings, one for an IS-IS adjacency (code, length, and value (TLV) 2) and the second for an IP prefix (TLV 128 and TLV 130). During SPF, if the total cost of the path to a destination exceeds 1023, then according to ISO/IEC 10587, the path is ignored.

To overcome these restrictions, a second pair of TLVs is available, one for IP prefixes (TLV 135) and the second for IS-IS adjacency (TLV 22). With these TLVs, IS-IS metrics can have values up 16,777,215 and the maximum path metric allowed is 4,261,412,864. This allows more flexibility while designing a domain. These metrics are wide metrics.

- To configure the metric style used on the router, use the following command:

  ```
  configure isis area area_name metric-style [[[narrow | wide] [transition]] | transition] {level [1 | 2]}
  ```

- To configure the narrow metric used on one or all interfaces, use the following command:

  ```
  configure isis [vlan all | {vlan} vlan_name] metric metric {level [1 | 2]}
  ```
To configure the wide metric used on one or all interfaces, use the following command:

```
configure isis [vlan all | {vlan} vlan_name] wide-metric metric
{level[1 | 2]}
```

**Note**

Configured narrow and wide metrics for a particular interface must be identical in value while migrating from metric style narrow to metric style wide. Only if the metric style is “narrow” or “wide” (that is, no “transition”) is it okay to have different values (because one of the values is not used).

### Configuring the DIS Priority for Broadcast Interfaces

The designated intermediate system (DIS) is introduced in Establishing Adjacencies on page 1451. When you configure the DIS priority, higher priority means higher election precedence (60 gets elected before 50).

- To configure the DIS priority, use the following command:

```
configure isis [vlan all | {vlan} vlan_name] priority priority
{level[1 | 2]}
```

**Note**

DIS priority 0 is the lowest priority value. Unlike an OSPF DR election, a DIS priority of 0 does not make a router ineligible for DIS election.

### Configuring Interface Participation in a Mesh Environment

Fully-meshed point-to-point topologies suffer from a potentially large amount of needless LSP flooding. At the trade-off of resiliency, interfaces can be restricted from flooding received LSPs.

- To configure an interface for a mesh environment, use the following command:

```
configure isis [vlan all | {vlan} vlan_name] mesh [block-none | block-all | block-group group_id]
```

a. To block the flooding of received LSPs altogether, use the `mesh block-all` option.
b. To block the flooding of LSPs received on a specific group of interfaces (which are those with the same mesh group ID), use the `mesh block-group group_id` option.
c. To remove blocking for an interface, use the `mesh block-none` option.

### Resetting a VLAN Interface to the Default Values

- To reset a VLAN interface to the default values, use the following command:

```
unconfigure isis [vlan all | {vlan} vlan_name] {level [1|2]}
```

### Deleting a VLAN Interface

- To delete a VLAN interface from a router, use the following command:

```
configure isis delete [vlan all | {vlan} vlan_name] {area area_name} {ipv4 | ipv6}
```
Managing IS-IS Routers

Adding an IS-IS Router

- To add an IS-IS router, use the following command:
  ```
  create isis area area_name
  ```

Changing the IS-IS Level of a Router

- To change the IS-IS level of a router, use the following command:
  ```
  configure isis area area_name is-type level [1 | 2 | both-1-and-2]
  ```

Resetting an IS-IS Router to the Default Values

- To reset an IS-IS router to the default values, use the following command:
  ```
  unconfigure isis area area_name {level [1|2]}
  ```

Restarting All IS-IS Routers in a Virtual Router

- To restart all IS-IS routers in a virtual router, use the following command and specify the IS-IS process:
  ```
  restart process [class cname | name {msm slot}]
  ```
  For example:
  ```
  restart process isis
  ```

Disabling an IS-IS Router

- To disable an IS-IS router, use the following command:
  ```
  disable isis {area area_name}
  ```

Deleting an IS-IS Router

- To delete an IS-IS router, use the following command:
  ```
  delete isis area [all | area_name]
  ```

Configuration Example

The following example shows the commands that configure an IS-IS router. Some commands apply to IPv4 or IPv6 and are labeled accordingly. Comments in parentheses identify commands that apply to specific applications.

```plaintext
create vlan v1
configure default delete ports 1
configure v1 add ports 1

IPv4:
configure v1 ipaddress 10.0.0.1/24
enable ipforwarding v1

IPv6:
configure v1 ipaddress fe80::204:96ff:fe20:b40a/128
enable ipforwarding ipv6 v1
```
create isis area a1
configure isis area a1 add area-address 01.0101.0202.0303.0404.0505.0606
configure isis area a1 system-id 11aa.22bb.33cc
configure isis area a1 is-type level 1 (For Level 1 Router)
configure isis area a1 is-type level 2 (For Level 2 Router)
configure isis area a1 is-type level both-1-and-2 (For Level 1/2 Router)
configure isis area a1 metric-style wide

IPv4 Mapping:
configure isis add vlan v1 area a1

IPv6 Mapping:
configure isis add vlan v1 area a1 ipv6

enable isis area a1 (or) enable isis
BGP Overview

BGP Overview

**BGP** is an exterior routing protocol that was developed for use in TCP/IP networks. The primary function of BGP is to allow different ASs to exchange network reachability information.

An AS is a set of routers that are under a single technical administration. This set of routers uses a different routing protocol, for example OSPF (Open Shortest Path First), for intra-AS routing. One or more routers in the AS are configured to be border routers, exchanging information with other border routers (in different ASs) on behalf of all of the intra-routers.

BGP can be used as an exterior border gateway protocol (referred to as EBGP), or it can be used within an AS as an interior border gateway protocol (referred to as IBGP).

For more information on BGP, refer to the following documents:

- RFC 1745—BGP/IDRP for IP—OSPF Interaction
- RFC 1771—Border Gateway Protocol version 4 (BGP-4)
- RFC 1965—Autonomous System Confederations for BGP
- RFC 1966—BGP Route Reflection
- RFC 1997—BGP Communities Attribute
- RFC 2385—Protection of BGP Sessions via the TCP RSA Data Security, Inc. MD5 Message-Digest Algorithm Signature Option
- RFC 2439—BGP Route Flap Damping
- RFC 2545—Use of BGP-4 Multiprotocol Extensions for IPv6 Inter-Domain Routing
- RFC 2796—BGP Route Reflection - An Alternative to Full Mesh IBGP
- RFC 2918—Route Refresh Capability for BGP-4
- RFC 3392—Capabilities Advertisement with BGP-4
- RFC 4271—Border Gateway Protocol 4 (BGP-4)
- RFC 4360—BGP Extended Communities Attribute
- RFC 4456—BGP Route Reflection: An Alternative to Full Mesh Internal BGP (IBGP)
- RFC 4486—Subcodes for BGP Cease Notification Message
- RFC 4724—Graceful Restart Mechanism for BGP
• RFC 4760—Multiprotocol Extensions for BGP-4
• RFC 4893—BGP Support for Four-octet AS Number Space
• RFC 5396—Textual Representation of Autonomous System (AS) Numbers
• draft_ieft_idr_restart_10.txt—Graceful Restart Mechanism for BGP

Note
ExtremeXOS supports BGP version 4 only, and does not support connections to peers running older versions of BGP.
For complete information about software licensing, including how to obtain and upgrade your license and what licenses are appropriate for these features, see the ExtremeXOS 22.6 Feature License Requirements document.

BGP Four-Byte AS Numbers
The ExtremeXOS software supports 4-byte AS numbers, which can be entered and displayed in the ASPLAIN and ASDOT formats, which are described in RFC 5396, Textual Representation of Autonomous System (AS) Numbers.

Note
When entering an AS number in a policy file, you must enter a unique 2-byte or 4-byte AS number. The transition AS number, AS 23456, is not supported in policy files.

BGP Attributes
The following BGP attributes are supported by the switch:
• Origin—Defines the origin of the route. Possible values are Interior Gateway Protocol (IGP), Exterior Gateway Protocol (EGP), and incomplete.
• AS_Path—the list of ASs that are traversed for this route. The local AS-path is added to the BGP update packet after the policy is applied.
• AS4_Path—This attribute is used by 4-byte peers when sending updates to 2-byte peers. This attribute carries AS-number information that can be represented only in 4-bytes.
• Next_hop—the IP address of the next hop BGP router to reach the destination listed in the NLRI field.
• Multi_Exit_Discriminator—Used to select a particular border router in another AS when multiple border routers exist.
• Local_Preference—Used to advertise this router’s degree of preference to other routers within the AS.
• Atomic_aggregate—Indicates that the sending border router has used a route aggregate prefix in the route update.
• Aggregator—Identifies the BGP router AS number and router ID for the router that performed route aggregation.
• AS4_Aggregator: This attribute is used by 4-byte peers when sending updates to 2-byte peers. This attribute carries AS-number information that can be represented only in 4-bytes.
• Community—Identifies a group of destinations that share one or more common attributes.
• Cluster_ID—Specifies a 4-byte field used by a route reflector to recognize updates from other route reflectors in the same cluster.
• Originator_ID—Specifies the router ID of the originator of the route in the local AS.
• Extended Community—Provides a mechanism for labeling BGP-4 update messages that carry information.
• Multiprotocol reachable NLRI—Used to advertise a feasible BGP route for the non IPv4-unicast address family.
• Multiprotocol unreachable NLRI—This attribute is used to withdraw multiple unfeasible routes from service.

BGP Community Attributes

A BGP community is a group of BGP destinations that require common handling. ExtremeXOS supports the following well-known BGP community attributes:
• no-export
• no-advertise
• no-export-subconfed

Extended Community Attributes

The extended community attribute provides a mechanism to label BGP routes. It provides two important enhancements over the standard community attribute:
• An expanded range. Extended communities are 8-bytes wide, whereas regular communities were only 4-bytes wide. So, this ensures that extended communities can be assigned for a plethora of uses, without the fear of overlap.
• The addition of a 'Type' field provides structure for the extended community.

The following two types of extended communities are available:
• Route Target (RT)
• Site Of Origin (SOO)

Although these two community types are generally used in L3 VPN network setup, you can also use them in a non-L3 VPN network to control the distribution of BGP routes.

BGP does not send either the extended or standard community attributes to their neighbors by default; you must use the configuration command `configure bgp neighbor send-community`.

Extended Community Processing

When BGP receives the extended community attribute in a route from its neighbor, it validates the community syntax. If the community is syntactically valid, the inbound neighbor route-policy is applied to the route. The inbound route-policy may contain extended-community statements in match block (in other words, an or/and set) of the policy. If the route is not rejected by the inbound route-policy, it is added to the LocRIB of the BGP along with the extended community. The `detail` option of the `show bgp routes` command displays the routes with the extended community attribute if they are present in that route’s path attribute.
**Associating the Extended Community Attribute to the BGP Route**

The extended community attribute can be added to or removed from a BGP route using an ExtremeXOS policy in the same way this action is performed for a regular community attribute.

The extended-community keyword has been added in the Policy Manager, and can be used in the match as well as in the set block of a policy file.

**Syntax in Match block**

```
extended-community "<extended-community-1> <extended-community-2> ..."
```

Where, the syntax of `<extended-community-N>` is

```
[rt|soo]:<2-byte AS num>:<4-byte num> | <4-byte IP Address>:<2-byte num> | <4-byte AS num>L:<2-byte num> | <first two bytes of AS num>.<last two bytes of AS num>:<2-byte num>
```

The attributes are defined as follows:

- **rt**: route target extended community type
- **soo**: site of origin extended community type
- **<2-byte AS number>**: This is a 2-byte AS number; the use of private AS-number is not recommended
- **<4-byte num>**: a 4-byte unsigned number
- **<4-byte IP address>**: a valid host IP address; a network address is not accepted; use of private IP address is not recommended; class-D IP addresses are rejected
- **<4-byte AS num>**: This is a 4-byte AS number; the use of private AS-number is not recommended
- **<first two bytes of AS num>**: This is the number represented by the first two bytes of a four-byte AS number. The use of a private AS-number is not recommended.
- **<last two bytes of AS num>**: This is the number represented by the last two bytes of a four-byte AS number. The use of a private AS-number is not recommended.

**Syntax in Set block**

```
extended-community [set | add | delete] "<extended-community-1> <extended-community-2> ...
extended-community remove
```

Where, the syntax of `<extended-community-N>` is the following:

```
[rt|soo]:<2-byte AS num>:<4-byte num> | <4-byte IP Address>:<2-byte num>
```

The attributes are defined as follows:

- **set**: Replaces the existing extended communities by the new ones as supplied in the policy statement.
- **add**: Adds new extended communities to the existing extended community attribute. If an extended community is already present, then policy will not add a duplicate extended community to the route.
- **delete**: Deletes some of the extended communities from the extended community attribute.
- **remove**: Removes extended community attribute from the route.
• \textbf{rt}: route target extended community type
• \textbf{soo}: site of origin extended community type
• \textbf{<2-byte AS number>}: This is 2-byte AS number. Use of private AS-number is not recommended
• \textbf{<4-byte num>}: 4-byte unsigned number
• \textbf{<4-byte IP address>}: A valid host IP address. Network address is not accepted. Use of private IP address is not recommended. Class-D IP address will be rejected.

\textit{Examples of Extended Communities}

The following are examples of valid extended communities:
• \texttt{rt:10.203.134;56:400}
• \texttt{soo:64500:1600}
• \texttt{rt:64511:2345678}
• \texttt{soo:172.168.45.10:500}
• \texttt{rt:1.15:20000}
• \texttt{soo:65551L:50000}

The following are examples of invalid extended communities:
• \texttt{rt:10.45.87.0:600}: Invalid because the IP address is NOT a valid host IP address
• \texttt{rt:239.1.1:400}: Invalid because IP address belongs to class-D
• \texttt{rt:100.200.300.400:200}: Invalid because the IP address is invalid
• \texttt{soo:12345678:500}: Invalid because the AS number 12345678 is out of the 2-byte AS number range, 1 to 65535

\textit{Extended Community Syntax}

Please note the following details with regard to extended community syntax:
• Only rt and soo extended community types are recognized in the policy file.
• The IP address MUST be a valid host address. Network address, Class-D and experimental IP address are not accepted.
• There should not be any blank spaces inside an extended community. For example, \texttt{rt :100:200} is not a valid extended community because there are spaces between \texttt{rt} and :.
• All three parameters of an extended community must be present, otherwise the extended community is rejected.

\textit{Extended Community Match Rule in Policy}

Regular expressions are not supported for extended communities. In addition, an extended community match statement matches with a route's extended community if at least one of the extended communities in the match statement matches with the route's extended community. There is no need to for all the extended communities in a single match statement to match with the route's extended community.

For example, suppose the policy file is the following:

```
entry one {
if {
  extended-community "rt:64500:20000 rt:10.203.134.5:40 soo:64505:50000
```
The above community statement will match with all BGP routes that have at least one of the following extended communities in their extended community attribute:

- rt:64500:20000
- rt:10.203.134.5:40
- soo:64505:50000
- soo:192.168.34.1:600

Extended Community Set Rule in Policy

A Policy set block can contain several extended community statements. Each set statement is applied to the matching route’s extended community attribute in the top down order. That is, the first set is applied to the extended community attribute of the route, the second set is applied to the result of above, and so forth.

For example, assume that a policy is the following:

```python
entry two {
    if {
        nlri 192.168.34.0/24;
    } then {
        extended-community set "rt:10.45.92.168:300";
        extended-community add "rt:10.203.100.200:40 soo:64500:60000";
        extended-community delete "rt:64505:10000 soo:72.192.34.10:70";
        permit;
    }
}
```

A BGP route 192.168.34.128/25 is received with extended community attribute rt:4567:100 soo:192.168.34.128.

When the above policy entry is applied to the route's extended community attribute, the following is true:

- After applying the 1st set (community set "rt:10.45.92.168:300"), the route's community becomes rt:10.45.92.168:300.
- After applying the 3rd set (community delete "rt:64505:10000 soo:72.192.34.10:70"), the community becomes rt:10.45.92.168:300 rt:10.203.100.200:40 soo:64500:60000. Please note that this delete statement has no effect as none of the communities in the delete statement are present in the community attribute.

Extended Communities and BGP Route Aggregation

When BGP routes are aggregated with the as-match or as-set CLI option, all the component route's extended community attributes are aggregated and the resulting aggregated extended community attributes are attached to the aggregate network.
Aggregation of several extended community attributes is simply the set union of all the extended communities from all of the aggregated routes.

Multiprotocol BGP

Multiprotocol BGP (MBGP), which is also known as BGP4+, is an enhanced BGP that supports more than just IPv4 unicast routes. In this release, MBGP supports:

- IPv4 unicast routing and IPv4 multicast routing on the platforms listed for this feature in the ExtremeXOS 22.6 Feature License Requirements document.
- IPv6 unicast routing and IPv6 multicast routing on the platforms listed for this feature in the ExtremeXOS 22.6 Feature License Requirements document.
- Layer 3 VPN routing on the platforms listed for this feature in the ExtremeXOS 22.6 Feature License Requirements document.

MBGP support for separate unicast and multicast routing tables allows BGP to have non-congruent topologies for unicast and multicast networks. The BGP multicast address-family routes are used by multicast protocols such as Protocol Independent Multicast (PIM) to build data distribution trees.

Route Reflectors

One way to overcome the difficulties of creating a fully meshed AS is to use route reflectors. Route reflectors allow a single router to serve as a central routing point for the AS. All BGP speakers in the AS will peer with the route reflector to learn routes.

A cluster is formed by the route reflector and its client routers. Peer routers that are not part of the cluster must be fully meshed according to the rules of BGP.

A BGP cluster, including the route reflector and its clients, is shown in Figure 239.
This topology minimizes the number of BGP peering sessions required in an AS by using a route reflector.

In this example, although the BGP speakers 3.3.3.3 and 4.4.4.4 do not have a direct BGP peering session between them, these speakers still receive routes from each other indirectly through 2.2.2.2. The router 2.2.2.2 is called a route reflector and is responsible for reflecting routes between its clients. Routes received from the client 3.3.3.3 by the router 2.2.2.2 are reflected to 4.4.4.4 and vice-versa. Routes received from 1.1.1.1 are reflected to all clients.

**Route Confederations**

BGP requires networks to use a fully meshed router configuration. This requirement does not scale well, especially when BGP is used as an IGP. One way to reduce the size of a fully meshed AS is to divide the AS into multiple sub-ASs and to group these sub-ASs into a routing confederation. Within the confederation, each sub-AS must be fully meshed. The confederation is advertised to other networks as a single AS.

Figure 240 shows an example of a confederation.

**Figure 240: Routing Confederation**

In this example, AS 64500 has five BGP speakers. Without a confederation, BGP would require that the routes in AS 64500 be fully meshed. Using the confederation, AS 64500 is split into two sub-ASs: AS 64505 and AS 64510. Each sub-AS is fully meshed, and IBGP is running among its members. EBGP is used between sub-AS 64505 and sub-AS 64510. Router B and router D are EBGP peers. EBGP is also used between the confederation and outside ASs.
Inactive Route Advertisement

BGP inactive routes are defined as those routes that are rated best by BGP and not best in IP routing table. For example, an IGP route to the same destination may be best because it has a higher priority in the IP route table than the BGP best route. The default configuration of the ExtremeXOS software does not advertise BGP inactive routes to BGP neighbors.

The default configuration (no BGP inactive route advertisement) is more consistent with data traffic forwarding. However, when advertisement of inactive BGP routes is enabled, BGP need not depend upon the route manager module to know whether a BGP route is active or not. This actually improves the performance of BGP processing and advertisement.

When BGP inactive route advertising is enabled, inactive BGP routes are considered for BGP route aggregation. When this feature is disabled, inactive BGP routes are ignored while aggregating routes.

Default Route Origination and Advertisement

The default route origination and advertisement feature allows you to originate and advertise a default route to a BGP neighbor (or to all neighbors in a peer group) even though no default route exists in the local IP routing table. It also allows you to associate policy rules to conditionally advertise a default route to BGP neighbors.

When default route origination becomes active, the default route is advertised to the specified BGP neighbors, overriding any previously sent default route. If a default route is added to the local IP routing table while default route origination is active, the default route defined by this feature takes precedence over the new regular default route. If default route origination becomes inactive, and a regular default route exists, the regular default route is advertised to BGP neighbors.

When you use a policy with default route origination, the default route is originated only if the local BGP RIB contains a route that matches the policy match conditions. You can use the following match conditions:
- NLRI
- AS-path
- Community
- Origin

You can also use the following policy actions in the policy to set the route attributes:
- AS-path
- Community
- Origin

After a policy is configured for default route origination, BGP must periodically scan the local BGP RIB to make sure that the policy rules evaluate to true for at least one route in local BGP RIB. If the rules evaluate to true, default origination remains active. If the rules evaluate to false, then default origination becomes inactive and the default routes must be withdrawn.

For more information on policy match conditions, actions, and configuration, see Routing Policies.
Using the Loopback Interface

If you are using BGP as your IGP, you may decide to advertise the interface as available, regardless of the status of any particular interface. The loopback interface can also be used for EBGP multihop. Using the loopback interface eliminates multiple, unnecessary route changes.

Looped AS_Path Attribute

When an EBGP speaker receives a route from its neighbor, it must validate the AS_Path attribute to ensure that there is no loop in the AS_Path. When an EBGP speaker finds its own AS-number in the received EBGP route’s AS_Path attribute, it is considered as a Looped AS Path and by default, the associated EBGP routes are silently discarded.

There are certain cases (such as in a spoke and hub topology) where it becomes necessary to accept and process EBGP routes with a looped AS_Path attribute.

This feature enables you to control the processing of EBGP routes with a looped AS_Path attribute. You can do the following:

- Allow the route with a looped AS_Path to be accepted
- Allow the route with a looped AS_Path to be accepted only if the number of occurrences of its own AS-Number is less than or equal to N, where N is an user-configurable unsigned integer configured
- Silently discard the route with looped AS_Path

Note

A looped AS path is always allowed for IBGP, irrespective of the BGP configuration.

BGP Peer Groups

You can use BGP peer groups to group together up to 512 BGP neighbors. All neighbors within the peer group inherit the parameters of the BGP peer group. The following mandatory parameters are shared by all neighbors in a peer group:

- remote AS
- source-interface
- route-policy
- send-community
- next-hop-self

Each BGP peer group is assigned a unique name when it is created, and each peer supports either IPv4 or IPv6 address families (but not both).

When the first peer is added to a BGP peer group, the peer group adopts the IPv4 or IPv6 address family of the assigned peer. After the first peer is assigned, the peer group does not support any configuration options or capabilities for the IP address family not selected. For example, if an IPv6 peer is the first peer added to a peer group, the peer group no longer supports IPv4 configuration options or capabilities.

Changes made to the parameters of a peer group are applied to all neighbors in the peer group.
Modifying the following parameters will automatically disable and enable the neighbors before changes take effect:

- remote-as
- timer
- source-interface
- soft-in-reset
- password

Bidirectional Forwarding Detection (BFD) for BGP

Bidirectional Forwarding Detection (BFD) protection of BGP peering sessions allows for the rapid detection of link failures such that peering sessions can be taken out of the "established" state within fractions of a second. This allows the protocol to select an alternate path (if available) to a destination immediately after the link failure, rather than waiting until the BGP hold timer expires (180 seconds by default).

This feature applies to both IPv4 and IPv6 peering sessions. Both IPv6 global and link local peering sessions are supported.

**Limitations**

- The BFD setting can be applied on a per-peer basis, but the ability to set BFD on a peer-group or address-family basis is not currently supported.
- The BGP peer must be in the disabled admin state to modify its BFD setting.
- While BFD can be enabled on any BGP peering session, protection is only provided for directly connected EBGP peering sessions.

BGP Route Flap Dampening

Route flap dampening is a BGP feature designed to minimize the propagation of flapping routes across an internetwork. A route is considered to be flapping when it repeatedly alternates between being available and being unavailable. Without route flap dampening, each transition of a route produces a withdrawal or advertisement message, which is propagated throughout the network. Route flapping can generate large numbers of messages, which can impact network bandwidth and availability.

The route flap dampening feature minimizes the flapping problem by halting route advertising and withdrawal messages for the affected route for a period of time. To support route flap dampening, the ExtremeXOS software employs a combination of two techniques. The first technique uses fixed timers to reduce the frequency of route advertisement as specified in RFC 4271. The other technique uses route flap damping algorithms. The software uses a combination of both techniques as specified in RFC 2439.

The fixed timers technique blocks all updates for the flapping route for a period defined by the internal MinRouteAdvertisementInterval (MRAI) timer (which is not configurable). For IBGP routes, this timer is set for 5 seconds. For EBGP routes, this timer is set to 30 seconds. The MRAI timer check is independent of the dampening configuration and is used to limit the frequency of route advertisements.
The route flap dampening algorithm uses configurable timers to manage route flap dampening. Suppose that the route to network 172.25.0.0 flaps. The router (in which route dampening is enabled) responds by doing the following:

- Assigns route 172.25.0.0 a penalty of 1000 and moves it to a history state in which the penalty value is monitored.
- Increments the penalty value by 1000 for each additional route flap.
- Accumulates penalties and compares them to the suppression limit, which is set to 2000 by default.

If the suppression limit is exceeded when the MRAI timer expires, the route is not advertised to neighbors.

A route remains suppressed or dampened until one of the following events occurs:

- The suppression limit is not met when the MRAI timer expires.
- The penalty placed on network 172.25.0.0 is decayed below the reuse limit.
- The maximum suppression timer expires.

The penalty is decayed by reducing the penalty value by one-half at the end of a configurable time period, called the half-life. Routes that flap many times may reach a maximum penalty level, or ceiling, after which no additional penalty is added. The ceiling value is not directly configurable, but the configuration parameter used in practice is the maximum route suppression time. No matter how often a route has flapped, after it stops flapping, it is advertised after the maximum route suppression time.

**BGP Route Selection**

*BGP* selects routes based on the following precedence (from highest to lowest):

- Next-hop must be reachable.
- higher weight
- higher local preference
- shortest length (shortest AS path)
- lowest origin code
- lowest Multi Exit Discriminator (MED)
- route from external peer
- lowest cost to next hop
- lowest routerID
- lowest PeerID

**Private AS Number Removal from Route Updates**

Private AS numbers are AS numbers in the range 64512 through 65534. You can remove private AS numbers from the AS path attribute in updates that are sent to external *BGP* (EBGP) neighbors. Possible reasons for using private AS numbers include:

- The remote AS does not have officially allocated AS numbers.
- You want to conserve AS numbers if you are multihomed to the local AS.
Private AS numbers should not be advertised on the Internet. Private AS numbers can be used only locally within an administrative domain. Therefore, when routes are advertised out to the Internet, the routes can be stripped out from the AS paths of the advertised routes using this feature.

**Route Redistribution**

Multiple protocols, such as **BGP**, **OSPF**, and **RIP (Routing Information Protocol)**, can be enabled simultaneously on the switch. Route redistribution allows the switch to exchange routes, including static and direct routes, between any two routing protocols.

Exporting routes from another protocol to BGP and from BGP to another protocol are discrete configuration functions. For example, to run **OSPFv3 (Open Shortest Path First version 3)** and BGP simultaneously, you must first configure both protocols and then verify the independent operation of each. Then you can configure the routes to export from OSPFv3 to BGP and the routes to export from BGP to OSPFv3.

**BGP ECMP**

The **BGP ECMP (Equal Cost Multi Paths)** feature supports load sharing by creating a multipath to a destination. This multipath contains multiple routes that are determined to have an equal cost because the following parameters are the same for each route:

- Weight
- Local preference (for IBGP multipaths)
- AS path (entire attribute, not just the length)
- Origin code
- Multi Exit Discriminator (MED)
- IGP distance to the next hop
- Source session (EBGP or IBGP)

**Note**

ECMP does not install an additional path if the next hop is the same as that of the best path. All paths within a multipath must have a unique next hop value.

BGP ECMP does not affect the best path selection. For example, the router continues to designate one of the paths as the best path and advertise this best path to its neighbors. EBGP paths are preferred to IBGP paths.

The BGP ECMP feature allows you to define the maximum number of equal cost paths (up to 64) in a multipath. A multipath for an IBGP destination is called an IBGP multipath, and the multipath for an EBGP destination is called an EBGP multipath.

If there are more equal cost paths for a destination than the configured maximum, the BGP identifier for the advertising BGP speaker is used to establish a path priority. The lower BGP identifier values have priority over the higher values. For example, if the configuration supports 4 paths in a multipath, only the four paths with the lowest BGP identifier values become part of the multipath.
**BGP Multipath-Relax**

This feature overrides the default protocol behavior specified in RFC-4271 related to route selection tie breakers and the definition of equal cost. In particular, routes with the same AS-path length, but differing AS numbers in the path are not considered equal cost by default. However, with multipath-relax enabled, routes with the same AS-path length can have differing AS number values in the AS-path and still be considered equal cost.

By default, BGP considers two routes as equal cost if the costs are equal through step (e) of the tie breaker procedure specified in Section 9.1.2.2 of RFC-4271. Step (a) of this procedure specifies that the AS-path length must be the same and the AS values within the path must also be the same. When the multipath-relax feature is enabled, the restriction that the AS values themselves must be the same is "relaxed". So two routes with a different AS values in the path can be consider equal cost provided that the AS-path length is equal and the remaining criteria specified in the tie-breaker procedure [through step (e)] are the also equal. Note that multipath support must be also be enabled on the device both in BGP and RTMGR for this feature to have any effect.

**BGP Static Network**

ExtremeXOS BGP allows users to add static networks in BGP, which will be redistributed (advertised) into the BGP domain if there is a corresponding active route in the IP routing table. Users can associate a policy with the static BGP network to change or to set the route attributes before the route is advertised to the BGP neighbors.

**Graceful BGP Restart**

The graceful BGP restart feature enables the switch BGP process to restart without disrupting traffic forwarding. This feature also enables the BGP process to support the graceful BGP restart of a peer router. Without graceful restart, BGP routes within the restarting router are flushed, and BGP routes through the restarting router are flushed from BGP peers. A non-graceful restart interrupts traffic for the time it takes for BGP to restart and re-establish routes, and expends additional resources during the reconvergence.

**Graceful Restart in the Restarting Switch**

During session startup, BGP peers indicate whether they have the graceful restart capability. When BGP restarts, the restarting router indicates during the new session startup that it is restarting and provides a restart-time value, which defines how long the receiving router will wait for the restart to complete.

In the restarting router, a graceful BGP restart preserves the BGP routes in the routing table, which allows the router to continue to use those routes until one of the following events occurs:

- The BGP restart is complete.
- The restart update delay timer expires.

During the restart, all pre-existing routes are marked stale. BGP receives new routes during the restart, but the Routing Information Base (RIB) is not updated and advertised until the restart is complete. An End of RIB message is sent when the restart is complete if the graceful restart feature is enabled.

An update-delay timer value determines how long the restarting switch will wait before updating the stale routes. If this timer expires before the restarting switch receives updates from the receiving
routers, all stale routes are deleted. If the receiving routers provide updates before this timer expires, the
time-stamps for any matching entries in the local RIB are preserved.

After the new BGP session is established, the new session uses the capabilities established with that
session, which includes any updates to the graceful restart capability or timers.

**Graceful Restart on the Receiving Switch**

During session startup, BGP peers indicate whether they have the graceful restart capability. When BGP
restarts, the receiving router retains routes received from the restarting router and marks those routes
stale. The receiving router continues to advertise the restarting router as if it was fully functional until
one of the following events occurs:

- The restarting router sends the EOR marker, indicating the end of a routing update and the end of
  the graceful restart.
- The restart timer defined by the restarting router expires.
- The stale-route-time timer defined on the receiving router expires.

If the receiving router receives RIB updates and the EOR marker before the timers expire, it updates the
local RIB and deletes any stale entries. If either of the timers on the receiving router expires before the
receiving switch receives the EOR marker from the restarting switch, all stale routes are deleted.

**Planned and Unplanned Restarts**

Two types of graceful restarts are defined: planned and unplanned. A planned restart occurs when the
software module for BGP is upgraded, or the router operator decides to restart the BGP control
function. An unplanned restart occurs when there is some kind of system failure that causes a remote
reboot or a crash of BGP, or when a failover occurs. You can decide to configure a router to enter
graceful restart for only planned restarts, for only unplanned restarts, or for both. Also, you can decide
to configure a router to be a receiver only, and not to do graceful restarts itself.

**Cease Subcodes**

BGP uses the cease subcode in notification message to convey the reason for terminating the session.
The cease subcodes currently supported are given in Table 147.

<table>
<thead>
<tr>
<th>Subcode</th>
<th>Description</th>
<th>Supported?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Maximum Number of Prefixes Reached</td>
<td>Yes</td>
</tr>
<tr>
<td>2</td>
<td>Administrative Shutdown</td>
<td>Yes</td>
</tr>
<tr>
<td>3</td>
<td>Peer De-configured</td>
<td>Yes</td>
</tr>
<tr>
<td>4</td>
<td>Administrative Reset</td>
<td>No</td>
</tr>
<tr>
<td>5</td>
<td>Connection Rejected</td>
<td>Yes</td>
</tr>
<tr>
<td>6</td>
<td>Other Configuration Change</td>
<td>No</td>
</tr>
<tr>
<td>7</td>
<td>Connection Collision Resolution</td>
<td>Yes</td>
</tr>
<tr>
<td>8</td>
<td>Out of Resources</td>
<td>No</td>
</tr>
</tbody>
</table>
Maximum Number of Prefixes Reached

This cease subcode is sent when the number of prefixes from a BGP neighbor exceeds the pre-configured limit. The notification message contains additional data to indicate the maximum prefix limit configured for the neighbor.

Administrative Shutdown

This cease notification subcode is sent to a BGP neighbor in following two situations:

- BGP neighbor is disabled
- BGP protocol is globally disabled. All BGP neighbors that were in the established state send cease notifications with this subcode

Peer De-configured

This cease notification subcode is sent when BGP neighbor is deleted.

Other Configuration Change

This cease notification subcode is sent when the following configuration entities change:

- BGP neighbor is added to a peer group
- BGP neighbor is configured as a route-reflector client
- BGP neighbor is part of a peer group and the following configuration elements of the peer group are changed:
  - Password
  - Remote-as
  - Hold-time, keepalive-time
  - Source interface
  - Soft-in-reset

Connection Collision Resolution

This cease notification subcode is sent when there is a BGP connection collision.

Fast External Fallover

BGP fast external fallover uses the BGP protocol to converge quickly in the event of a link failure that connects it to an EBGP neighbor.

When BGP fast external fallover is enabled, the directly-connected EBGP neighbor session is immediately reset when the connecting link goes down and routes are learned over the BGP session. Failover is not initiated if routes are not learned over the BGP session.

If BGP fast external fallover is disabled, BGP waits until the default hold timer expires (3 keepalives) to reset the neighboring session. In addition, BGP may tear down the session somewhat earlier than hold timer expiry if BGP detects that the TCP session and it’s directly connected link is broken (BGP detects this while sending or receiving data from the TCP socket).
Capability Negotiation

BGP supports the negotiation of the following capabilities between BGP peers:

- IPv4 unicast address family
- IPv4 multicast address family
- IPv6 unicast address family
- IPv6 multicast address family
- Route-refresh (code = 64 and Cisco-style code = 128)
- 4-byte-AS (code = 65)

BGP brings up peering with the minimal common capability for the both sides. For example, if a local router with both unicast and multicast capabilities peers with a remote router with unicast capability, the local router establishes the connection with unicast-only capability.

When there are no common capabilities, BGP sends an Unsupported Capability error and resets the connection. A manual intervention and configuration change might be required in order to establish a BGP peering session in this particular case.

Note

ExtremeXOS version 12.0 and earlier does not negotiate address families. By default, ExtremeXOS version 12.1 advertises MBGP options and is rejected by switches running previous versions, which can delay the establishment of a BGP session. We recommend that you disable the capability advertisement feature of MBGP while peering with switches running previous versions of ExtremeXOS for faster neighbor session establishment.

IPv4 Capability Negotiation

For IPv4 peers, BGP supports the following capabilities by default:

- IPv4 unicast address family
- IPv4 multicast address family
- Route-refresh (code = 64 and Cisco-style code = 128)
- 4-byte-AS (code = 65)

By default, BGP sends those capabilities in its OPEN message. In addition, BGP supports graceful restart.

When BGP receives a notification 2/4 (Unsupported optional parameters) in response to an OPEN, it assumes that the peer does not support capability negotiation and MBGP and sends an OPEN message without any capability.

If the peer speaker sends no capabilities, but the local speaker is configured for the IPv4 unicast capability, the assumption is that the peer speaker is operating in legacy mode, and the session defaults to the exchange of IPv4 unicast NLRIs (a non MBGP session).

If the local speaker is configured explicitly with the IPv4 unicast family disabled, it cannot peer with legacy peers, and it will send the Optional Attribute Error whenever it receives an update packet. Because the IPv4 address family is enabled for Extreme Networks switches by default, it is recommended that you explicitly disable this address family when you desire non-standard behavior.
**IPv6 Capability Negotiation**

For IPv6 peers, the route refresh capability is enabled by default, and no address family is enabled by default. You must enable a common set of capabilities on the local and neighbor peers before peering can be established. For IPv6 capability negotiation, IPv6 peering is set to idle if no common address families are negotiated. IPv6 BGP peering supports only the IPv6 unicast and IPv6 multicast address families; IPv4 address families are not supported.

**Route Refresh**

Route Refresh helps minimize the memory footprint of BGP by not storing the original BGP route path attributes from a neighbor that advertises route refresh capability in an OPEN message. Whenever you execute the command `configure bgp neighbor [remoteAddr | all] {addressfamily [ipv4-unicast | ipv4-multicast]} soft-reset in`, BGP sends a route refresh message to its peer if that peer had advertised route refresh capability in its OPEN message. In response to the route refresh message, the neighbor sends its entire RIB-OUT database for the requested address family. This helps reapply the inbound neighbor policy, if there are any changes.

**Configuring BGP**

**Configuration Overview**

The following procedure configures a basic BGP topology:

1. Configure the interfaces that will connect to BGP neighbors. For each interface, do the following:
   a. Create a VLAN (Virtual LAN).
   b. Assign one or more ports to the VLAN.
   c. Configure a VLAN IP address.
   d. Enable IP forwarding on the VLAN.

   For more information on configuring VLANs, see VLANs on page 503

2. Configure the BGP router ID using the following command:

   ```
   configure bgp routerid router identifier
   ```

3. Configure the AS number to which the router should belong using the following command:

   ```
   configure bgp AS-number number
   ```

4. To add one or more IBGP neighbors, use the following command and specify the AS number to which the router belongs:

   ```
   create bgp neighbor remoteaddr remote-AS-number as-number {multi-hop}
   ```

5. To add one or more EBGP neighbors, use the following command and specify the AS number of the remote AS (which is different from the AS to which the router belongs):

   ```
   create bgp neighbor remoteaddr remote-AS-number as-number {multi-hop}
   ```

6. If you want to simultaneously configure BGP options for multiple neighbors, create and configure peer groups as described in Configuring BGP Peer Groups.
If the BGP network will support IPv4 traffic, you can skip this step. If the BGP network will support any other address family, you must enable support for that address family on BGP neighbors with either of the following commands:

```
enable bgp neighbor [all | remoteaddr] capability [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4 | route-refresh | ipv4-vxlan]
```

```
enable bgp peer-group peer-group-name capability [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4 | route-refresh]
```

To configure additional BGP neighbor options, see Configuring BGP Neighbors.

For instructions on configuring additional BGP features, see the list under Configuring BGP.

Enable BGP neighbors using the following command:

```
enable bgp neighbor [remoteaddr | all]
```

Enable BGP using the following command:

```
enable bgp
```

For instructions on displaying BGP information, see Displaying BGP Information.

### Configuring BGP Router Settings

#### Configure the BGP Router ID

- To configure the BGP router ID, use the following command:

```
configure bgp routerid router-identifier
```

#### Configure the AS Number

- To configure the AS number for the switch, use the following command:

```
configure bgp AS-number number
```

#### Configure the AS Number and Community Display Formats

- To configure the AS number display format, use the following commands:

```
configure bgp as-display-format [asdot | asplain]
```

```
enable bgp community format AS-number : number
```

```
disable bgp community format AS-number : number
```

#### Configure the BGP Local Preference

- To configure the BGP local preference, use the following command:

```
configure bgp local-preference number
```

#### Configure the BGP MED

- To configure the BGP MED, use the following command:

```
configure bgp med [none | bgp_med]
```
enable bgp always-compare-med

disable bgp always-compare-med

**Configure BGP ECMP**

- To enable or disable BGP ECMP, enter the following command:

  ```
  configure bgp maximum-paths max-paths
  ```

  The `max-paths` setting applies to BGP on the current VR. Specify more than 1 path to enable BGP ECMP and define the maximum number of paths for IBGP and EBGP multipaths. Specify 1 path to disable ECMP. To display BGP ECMP configuration information, use the `show bgp` command.

**Configure BGP Multipath-Relax**

- To enable BGP multipath-relax, use the following command:

  ```
  enable bgp multipath-relax
  ```

- To disable BGP multipath-relax, use the following command:

  ```
  disable bgp multipath-relax
  ```

- To display the status or BGP multipath-relax, use the following command:

  ```
  show bgp
  ```

**Configure Graceful BGP Restart**

- To configure a router to perform graceful BGP restart, use the following command:

  ```
  configure bgp restart [none | planned | unplanned | both | aware-only]
  ```

- The address families participating in graceful restart are configured using the following command:

  ```
  configure bgp restart [add | delete] address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast]
  ```

- There are three timers that can be configured with the following commands:

  ```
  configure bgp restart restart-time seconds
  configure bgp restart stale-route-time seconds
  configure bgp restart update-delay seconds
  ```

- You can use the following commands to verify the BGP graceful restart configuration:

  ```
  show bgp
  ```

  ```
  show bgp {neighbor} remoteaddr {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | ipv4-vxlan]} [accepted-routes | received-routes | rejected-routes | transmitted-routes] (detail) [all | as-path path-expression | community [no-advertise | no-export | no-export-subconfed | number community_number | autonomous-system-id : bgp-community] | network [any/netMaskLen | networkPrefixFilter] {exact}]
  ```
Configuring Fast External Fallover

The fast external fallover module consists of two commands; one for enabling fallover (enable bgp fast-external-fallover) and one for disabling fallover (disable bgp fast-external-fallover). Fast external fallover is disabled by default.

These commands apply to all directly-connected external BGP neighbors.

Configuring BGP Neighbors

Create and Delete BGP Neighbors

- To create or delete BGP neighbors, use the following commands:
  
  create bgp neighbor remoteaddr remote-AS-number as-number {multi-hop}
  create bgp neighbor remoteaddr peer-group peer-group-name {multi-hop}
  delete bgp neighbor [remoteaddr | all]

Configure a Description for a Neighbor

- To configure a description for one or all BGP neighbors, use the following command:
  
  configure bgp neighbor [all | remoteaddr] description {description}

Configure a Password for Neighbor Communications

- To configure a password to use for communications with BGP neighbors, use the following command:
  
  configure bgp neighbor [all | remoteaddr] password [none | {encrypted} tcpPassword]

- To configure a password for the neighbors in a peer group, use the following command:
  
  configure bgp peer-group peer-group-name password [none | tcpPassword]

Configure the Supported Address Families and Route Refresh

- All BGP negotiated capabilities (except for the 4-Byte-AS capability) can be enabled and disabled using the following commands:
  
  enable bgp neighbor [all | remoteaddr] capability [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4 | route-refresh | ipv4-vxlan]
  
  disable bgp neighbor [all | remoteaddr] capability [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4 | route-refresh | ipv4-vxlan]

- To configure the capabilities for a peer group, use the following command:

  enable bgp peer-group peer-group-name capability [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4 | route-refresh]
disable bgp peer-group peer-group-name capability [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpn4 | route-refresh]

Note
ExtremeXOS allows the sending and receiving of IPV6 routes over IPV4 peering sessions, and IPV4 routes over IPV6 peering sessions.

Configure Timers for BGP Neighbor Communications

- Configure the timers that apply to communications with a neighbor.
  configure bgp neighbor [remoteaddr | all] timer keep-alive keepalive hold-time holdtime

- Configure the timers that apply to the neighbors in a peer group.
  configure bgp peer-group peer-group-name timer keep-alive seconds hold-time seconds

Configure the Neighbor Shutdown Priority

- To configure the neighbor shutdown priority, use the following command:
  configure bgp neighbor [all | remoteaddr] shutdown-priority number

Configuring Route Acceptance

Assign a Weight Value to Routes Learned from a Neighbor

- To configure the weight value that applies to routes learned from a neighbor, use the following command:
  configure bgp neighbor [remoteaddr | all] weight weight

- To configure the weight value that applies to routes learned from the neighbors in a peer group, use the following command:
  configure bgp peer-group peer-group-name weight weight

Configure the Maximum Number of Prefixes

- To configure the maximum number of prefixes to accept from a BGP neighbor, use the following command:
  configure bgp neighbor [remoteaddr | all] {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpn4]} maximum-prefix number {{threshold percent} {teardown {holddown-interval seconds}} {send-traps}}

- To configure the maximum number of prefixes to accept from the neighbors in a peer group, use the following command:
  configure bgp peer-group peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpn4]} maximum-prefix number {{threshold percent} {teardown {holddown-interval seconds}} {send-traps}}
Configure Acceptance of Looped BGP Routes from Neighbors

- To enable and disable the acceptance of looped routes from one or all neighbors, use the following commands:

```plaintext
configure bgp neighbor [all | remoteaddr] {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} allowas-in {max-as-occurrence as-count}
```

```plaintext
configure bgp neighbor [all | remoteaddr] {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} dont-allowas-in
```

- To enable and disable the acceptance of looped routes from the neighbors in a peer group, use the following commands:

```plaintext
configure bgp peer-group peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} allowas-in {max-as-occurrence as-count}
```

```plaintext
configure bgp peer-group peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} dont-allowas-in
```

Configuring Route Origination

Configure the Source Interface Address

- To configure the source interface address to use for communications with a neighbor, use the following command:

```plaintext
configure bgp neighbor [remoteaddr | all] source-interface [any | ipaddress ipAddr]
```

- To configure the source interface address to use for communications with neighbors in a peer group, use the following command:

```plaintext
configure bgp peer-group peer-group-name source-interface [any | ipaddress ipAddr]
```

Enable and Disable Default Route Origination

- To enable or disable BGP default route origination and advertisement for BGP neighbors, use the following commands:

```plaintext
enable bgp [{neighbor} remoteaddr | neighbor all] {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast]} originate-default {policy policy-name}
```

```plaintext
disable bgp [{neighbor} remoteaddr | neighbor all] {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast]} originate-default
```

- To enable or disable BGP default route origination and advertisement for a peer group, use the following commands:

```plaintext
enable bgp {peer-group} peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast]} originate-default {policy policy-name}
```
disable bgp {peer-group} peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast]} originate-default

Configure Inactive Route Advertisement

This command applies to the specified address family for all neighbors.

- To enable or disable BGP inactive route advertising, use the following commands:
  enable bgp {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast]} advertise-inactive-route
disable bgp {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast]} advertise-inactive-route

Configure the Originating Next Hop Address for Outgoing Updates

- To configure outgoing updates to the specified neighbors to specify the address of the BGP connection originating the update as the next hop address, use the following command:
  configure bgp neighbor [remoteaddr | all] {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} [next-hop-self | no-next-hop-self]
- To make a configuration change for the neighbors in a peer group, use the following command:
  configure bgp peer-group peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} [next-hop-self | no-next-hop-self]

Include or Exclude the Community Path Attribute

- To configure neighbor communications to include or exclude the community path attribute, use the following command:
  configure bgp neighbor [remoteaddr | all] {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} [send-community | dont-send-community] {both | extended | standard}
- To make a configuration change for the neighbors in a peer group, use the following command:
  configure bgp peer-group peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} [send-community | dont-send-community] {both | extended | standard}

Remove Private AS Numbers from Route Updates

- To configure private AS numbers to be removed from updates for neighbors or peer groups, use the following commands:
  enable bgp neighbor [remoteaddr | all] remove-private-AS-numbers
  enable bgp peer-group peer-group-name remove-private-AS-numbers
- To disable this feature, use the following commands:
  disable bgp neighbor [remoteaddr | all] remove-private-AS-numbers
  disable bgp peer-group peer-group-name remove-private-AS-numbers
Configure a Route Map Filter

- To configure a route map filter for one or all BGP neighbors, use the following command:
  ```bash
  configure bgp neighbor [remoteaddr | all] {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} route-policy [in | out] [none | policy]
  ```
- To configure a route map filter for the neighbors in a peer group, use the following command:
  ```bash
  configure bgp peer-group peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} route-policy [in | out] [none | policy]
  ```

Enable and Disable the Soft Input Reset Feature for a Neighbor

- To enable or disable the soft input reset feature for a neighbor, use the following commands:
  ```bash
  enable bgp neighbor [all | remoteaddr] capability [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4 | route-refresh | ipv4-vxlan]
  disable bgp neighbor [all | remoteaddr] capability [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4 | route-refresh | ipv4-vxlan]
  ```
- To enable or disable the soft input reset feature for a peer group.
  ```bash
  enable bgp peer-group peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} soft-in-reset
  disable bgp peer-group peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast]} soft-in-reset
  ```

Configure Route Flap Dampening

You can supply the dampening configuration parameters directly through a command line interface (CLI) command, or use the command to associate a policy that contains the desired parameters.

- To enable route flap dampening for neighbors or a peer group, use the following commands:
  ```bash
  configure bgp neighbor [all | remoteaddr] {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} dampening {{half-life half-life-minutes [reuse-limit reuse-limit-number suppress-limit suppress-limit-number max-suppress max-suppress-minutes] | policy-filter [policy-name | none]}}
  configure bgp peer-group peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} dampening {{half-life half-life-minutes [reuse-limit reuse-limit-number suppress-limit suppress-limit-number max-suppress max-suppress-minutes] | policy-filter [policy-name | none]}}
  ```
- To disable route flap dampening for a BGP neighbor or peer group, use the following commands:
  ```bash
  configure bgp neighbor [remoteaddr | all] {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} no-dampening
  ```
configure bgp peer-group peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} no-dampening

**Note**
When you disable dampening, all the configured dampening parameters are deleted.

**Configuring Bidirectional Forwarding Detection (BFD) on BGP Neighbor**

To enable or disable BFD on BGP neighbor(s):

```bash
configure bgp {neighbor [all | remoteaddr ]} {bfd [on | off]}
```

**Configure Maximum AS Path Length**

- To configure maximum-as-path-length in the switch, use the following command:

**Note**
This configuration is independent of peers, and it is applied to entire BGP.

**Configuring BGP Peer Groups**

**Create or Delete a BGP Peer Group**

To create or delete peer groups, use the following commands:

- create bgp peer-group peer-group-name
- delete bgp peer-group peer-group-name

**Note**
No capabilities are enabled at time of peer-group creation. If an IPv4 peer is the first peer added to the peer-group, the IPv4-unicast and IPv4-multicast capabilities are enabled by default. If the first peer assigned to a peer-group is an IPv6 peer, no capabilities are enabled.

**Add Neighbors to a BGP Peer Group**

- To create a new neighbor and add it to a BGP peer group, use the following command:

  ```bash
  create bgp neighbor remoteaddr peer-group peer-group-name {multi-hop}
  ```

  The new neighbor is created as part of the peer group and inherits all of the existing parameters of the peer group. The peer group must have remote AS configured.

- To add an existing neighbor to a peer group, use the following command:

  ```bash
  configure bgp neighbor [all | remoteaddr] peer-group [peer-group-name | none] {acquire-all}
  ```

  If you do not specify the **acquire-all** option, only the mandatory parameters are inherited from the peer group. If you specify the **acquire-all** option, all of the parameters of the peer group are inherited. This command disables the neighbor before adding it to the peer group.

  To remove a neighbor from a peer group, use the **peer-group none** option.
When you remove a neighbor from a peer group, the neighbor retains the parameter settings of the group. The parameter values are not reset to those the neighbor had before it inherited the peer group values.

Configure a Remote AS Number for a Peer Group

- To configure a remote AS number for a peer group, use the following command:
  ```
  configure bgp peer-group peer-group-name remote-AS-number number
  ```

Create and Delete BGP Static Networks

- To create a static BGP network, use the following command:
  ```
  configure bgp add network {
  address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast]
  ipaddress/masklength {
  network-policy policy
  }
  
  Note
  This command adds the route to BGP only if the route is present in the routing table.
  ```

- To delete a static BGP network, use the following command:
  ```
  configure bgp delete network {
  address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast]
  } [all] [ipaddress/mask length]
  ```

Import Routes from Other Protocols to BGP

Before importing routes from another protocol to BGP, you must first configure both protocols and then verify the independent operation of each. When you import routes from another protocol, the imported routes are limited to those for the respective address family and protocol. For example, you can import IPv4 unicast routes from RIP to BGP, but you cannot import IPv6 unicast routes from RIP to BGP. IPv6 routes can be imported only from IPv6 routing protocols; and IPv4 routes can be imported only from IPv4 routing protocols.

You can use route maps to associate BGP attributes including Community, NextHop, MED, Origin, and Local Preference with the routes. Route maps can also be used to filter out exported routes.

For instructions on importing routes from another protocol to BGP, refer to the chapter for the protocol from which you want to import routes.

- To configure an import policy to apply to imported routes, use the following command:
  ```
  configure bgp import-policy [policy-name | none]
  ```
  For Layer 3 VPNs, a local PE stores the routes received from a remote PE in the VPN-VRF RIB.

- To enable or disable export of these routes as IPv4 unicast routes to the CE, use the following command:
  ```
  enable bgp export remote-vpn {export-policy} policy-name) {
  address-family [ipv4-unicast | vpnv4]
  }
  disable bgp export remote-vpn {address-family [ipv4-unicast | vpnv4]}
  ```
Export BGP Routes to other Protocols

Before exporting routes from BGP to another protocol, you must first configure both protocols and then verify the independent operation of each. When you export routes from BGP, the exported routes are limited to those for the respective address family and protocol. For example, you can export IPv4 unicast routes from BGP to RIP, but you cannot export IPv6 unicast routes from BGP to RIP. IPv6 routes can be exported only from BGP to IPv6 routing protocols; and IPv4 routes can be exported only to IPv4 routing protocols.

You can use route maps to associate BGP attributes including Community, NextHop, MED, Origin, and Local Preference with the routes. Route maps can also be used to filter out exported routes.

- To enable or disable the export of routes into BGP from other routing sources like ospf and rip, use the following commands:

  enable bgp export [blackhole | direct | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external | ospf | ospf-external | ospf-external2 | ospf-inter | ospf-intra | ospfv3 | ospfv3-external | ospfv3-external2 | ospfv3-inter | ospfv3-intra | rip | ripng | static {address-family [{ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast}] {export-policy policy-name}}

  disable bgp export [blackhole | direct | isis | isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external | ospf | ospf-external | ospf-external2 | ospf-inter | ospf-intra | ospfv3 | ospfv3-external | ospfv3-external2 | ospfv3-inter | ospfv3-intra | rip | ripng | static {address-family [{ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast}]}

**Note**

When exporting BGP routes, static routes, configured with the `configure bgp add network` command, take precedence over BGP discovered routes.

For Layer 3 VPNs, a local PE advertises the local customer routes to the remote PE by exporting the BGP routes in the VPN-VRF associated with that customer as VPNv4 routes.

- To enable or disable the export to the remote PE of BGP routes from the CE or static/direct routes in the CE VPN-VRF, use the following commands:

  enable bgp export [bgp | direct | static] {export-policy} policy-name) {address-family [ipv4-unicast | vpnv4]}

  disable bgp export [bgp | direct | static] {address-family [ipv4-unicast | vpnv4]}

Configure Route Aggregation

Route aggregation is the process of combining the characteristics of several routes so that they are advertised as a single route. Aggregation reduces the amount of information that a BGP speaker must store and exchange with other BGP speakers. Reducing the information that is stored and exchanged also reduces the size of the routing table.
To enable or disable BGP route aggregation, use the following commands:

```
enable bgp aggregation
disable bgp aggregation
```

To create or remove aggregate routes, use the following commands:

```
configure bgp add aggregate-address {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast]} ipaddress/masklength {as-match | as-set} {summary-only} {advertise-policy policy} {attribute-policy policy}
```

```
configure bgp delete aggregate-address {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast]} [ip address/masklength | all]
```

**Configure Route Reflectors**

The configuration for a router reflector topology takes place on the router or routers that serve as route reflectors. Route reflector clients must be configured for BGP participation, but no special configuration is required on route reflector clients to support the route reflector.

- To configure a route reflector to treat neighbors or peer group neighbors as route reflector clients, use the following commands:

  ```
  configure bgp neighbor [remoteaddr | all] [route-reflector-client | no-route-reflector-client]
  configure bgp peer-group peer-group-name [route-reflector-client | no-route-reflector-client]
  ```

- If multiple route reflectors are used in a cluster, you must configure the route reflector clients on each route reflector, and you must configure each route reflector with a common cluster ID using the following command:

  ```
  configure bgp cluster-id cluster-id
  ```

**Configure a Route Confederation**

- To configure every router in the confederation with the same confederation ID, use the following command:

  ```
  configure bgp confederation-id confederation-id
  ```

- For each EBGP confederation peer, use the following command to configure the remote AS number as a confederation sub-AS-number:

  ```
  configure bgp add confederation-peer sub-AS-number number
  ```

- To remove the sub-AS-number configuration for an EBGP peer, use the following command:

  ```
  configure bgp delete confederation-peer sub-AS-number number
  ```

**Managing BGP**
Enable and Disable BGP Neighbors

- To enable or disable a BGP neighbor, use the following commands:

  ```
  enable bgp neighbor [remoteaddr | all]
  disable bgp neighbor [remoteaddr | all]
  ```

Enable and Disable a Peer Group

- To enable or disable a peer group, use the following commands:

  ```
  enable bgp peer-group peer-group-name
  disable bgp peer-group peer-group-name
  ```

Enable and Disable BGP

- To enable or disable BGP on the switch, use the following commands:

  ```
  enable bgp
  disable bgp
  ```

Refresh BGP Routes

- To refresh the routes for a BGP neighbor, use the following commands:

  ```
  configure bgp neighbor [remoteaddr | all] {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} soft-reset {in | out}
  configure bgp peer-group peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} soft-reset {in | out}
  ```

Configure BFD for BGP

- BFD protection of BGP peering sessions allows for the rapid detection of link failures such that peering sessions can be taken out of the established state within fractions of a second.

  ```
  configure bgp {neighbor [all | remoteaddr ]} {bfd [on | off]}
  ```

**Note**

The BFD setting can be applied on a per peer basis, the ability to set BFD on a peer-group or address-family basis is not currently supported. The BGP peer must be in the disabled admin state to modify its BFD setting. While BFD can be enabled on any BGP peering session, protection is only be provided for directly connected EBGP/IBGP peering sessions.
Note
Configuring both BFD and graceful restart for BGP on the same switch is counterproductive. When an interface goes down, BFD detects this instantly, stops traffic forwarding and the BGP session goes down, whereas graceful restart forwards traffic despite the interface failure. This behavior might cause traffic loss. Therefore we do not recommend configuring both BFD and graceful restart on the same switch.

Reapply a Policy

- To reapply the route policy associated with the network command, aggregation, import, and redistribution, use the following command:
  ```bash
  configure bgp soft-reconfiguration
  ```

Clear BGP Flap, Session, or Route Statistics

- To clear the BGP flap statistics, use the following command:
  ```bash
  clear bgp {neighbor} remoteaddr {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} flap-statistics [all | rd rd_value | as-path path expression | community [no-advertise | no-export | no-export-subconfed | number community_num | AS_Num:Num] | network [any / netMaskLen | networkPrefixFilter] {exact}]
  ```
  When clearing CE to PE peer sessions, select an IPv4 address family. When clearing PE to PE sessions, select the VPNv4 address family.

Clear BGP Neighbor Counters

- To clear the counters for a BGP neighbor, use the following command:
  ```bash
  clear bgp neighbor [remoteaddr | all] counters
  ```

Displaying BGP Information

Display BGP Router Configuration and Route Statistics

- To display BGP router configuration and route statistics, use the following command:
  ```bash
  show bgp
  ```

Display Peer Group Configuration Information

- To display peer group configuration information, use the following command:
  ```bash
  show bgp peer-group {detail | peer-group-name {detail}}
  ```
Display BGP Route Information

- To display summary route information, enter the following command:
  
  ```
  show bgp routes {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4 | ipv4-vxlan]} summary
  ```

- To display route information and statistics, enter the following command:
  
  ```
  show bgp routes {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | ipv4-vxlan]} {detail} [ipv4-vxlan | all | as-path path-expression | community [no-advertise | no-export | no-export-subconfed | number community-number | autonomous-system-id | bgp-community] | network [any/netMaskLen | networkPrefixFilter] {exact]}
  ```

- To display information about routes exchanged with a neighbor, enter the following command:
  
  ```
  show bgp {neighbor} remoteaddr {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | ipv4-vxlan]} {accepted-routes | received-routes | rejected-routes | transmitted-routes} {detail} [all | as-path path-expression | community [no-advertise | no-export | no-export-subconfed | number community-number | autonomous-system-id : bgp-community] | rd rd value network [any/netMaskLen | networkPrefixFilter] {exact]}
  ```

- To display information about suppressed or dampered routes, enter the following command:
  
  ```
  show bgp {neighbor} remoteaddr {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | ipv4-vxlan]} {accepted-routes | suppressed-routes} {detail} [all | as-path path-expression | community [no-advertise | no-export | no-export-subconfed | number community-number | autonomous-system-id : bgp-community] | rd rd value network [any/netMaskLen | networkPrefixFilter] {exact]}
  ```

Display Layer 3 VPN Peer Session Information

Layer 3 VPN BGP session information can be configured with the same commands used for other BGP sessions. When displaying information for CE to PE peer sessions, select an IPv4 address family. When displaying information for PE to PE sessions, select the VPNv4 address family.
• Use the following commands to display Layer 3 VPN session information:

```
show bgp routes vpnv4 [all | as-path | community | detail | rd | summary]
```

Display BGP Memory Usage

• To display BGP memory usage information, enter the following command:

```
show bgp memory {detail | memoryType}
```

**Configuration Examples**

**BGP IPv6 Example**

*Figure 241* shows the network topology for this example.

![Network Topology Diagram](image_url)

**Switch1 Configuration**

```
create vlan v1
configure v1 ipaddress 2001:db8:1::1/48
create vlan net
configure net add ports 3
configure net ipaddress 2001:db8:22::1/48
enable ipforwarding ipv6
configure bgp AS-number 100
configure bgp routerid 1.1.1.1
create bgp neighbor 2001:db8:2131::2 remote-AS-number 100
enable bgp neighbor all capability ipv6-unicast
enable bgp neighbor all
enable bgp
configure bgp add network address-family ipv6-unicast 2001:db8:22::/48
configure iproute add 2001:db8:2131::/48 2001:db8:1::2
configure ospfv3 routerid 1.1.1.1
configure ospfv3 add vlan v1 area 0.0.0.0
enable ospfv3
```

**Switch2 Configuration**

```
create vlan v1
create vlan v2
create vlan lpback
enable loopback lpback
configure v1 ipaddress 2001:db8:1::2/48
configure v2 ipaddress 2001:db8:2::1/48
configure lpback ipaddress 2001:db8:2131::2/48
enable ipforwarding ipv6
```
configure v1 add ports 1:9
configure v2 add ports 1:11
configure bgp AS-number 100
configure bgp routerid 1.1.1.2
create bgp neighbor 2001:db8:1::1 remote-AS-number 100
create bgp neighbor 2001:db8:2::2 remote-AS-number 200
configure bgp neighbor 2001:db8:1::1 source-interface ipaddress 2001:db8:2131::2
enable bgp neighbor all capability ipv6-unicast
enable bgp neighbor all
enable bgp
configure ospfv3 routerid 1.1.1.2
configure ospfv3 add vlan all area 0.0.0.0
enable ospfv3

Switch3 Configuration

create vlan v1
create vlan net
configure v1 add ports 2:11
configure net add ports 1:23
configure v1 ipaddress 2001:db8:2::2/48
configure net ipaddress 2001:db8:55::1/48
enable ipforwarding ipv6
configure bgp AS-number 200
configure bgp routerid 2.1.1.2
create bgp neighbor 2001:db8:2::1 remote-AS-number 100
enable bgp neighbor all capability ipv6-unicast
enable bgp neighbor all
enable bgp
enable bgp export static address-family ipv6-unicast
enable bgp export direct address-family ipv6-unicast
configure iproute add 2001:db8:66::/48 2001:db8:55::100

Graceful BGP Restart Configuration Example for IPv4

In the following IPv4 configuration example, EXOS-1 is the restarting BGP router, and EXOS-2 is the receiving BGP router.

To configure router EXOS-1, use the following commands:

```
create vlan bgp-restart
configure vlan bgp-restart add port 2:2
configure vlan bgp-restart ipaddress 10.0.0.1/24
enable ipforwarding

configure bgp as-number 100
configure bgp route-id 10.0.0.1
configure bgp restart both
create bgp neighbor 10.0.0.2 remote-as 64500
enable bgp neighbor all
enable bgp
```

To configure router EXOS-2, use the following commands:

```
create vlan bgp-restart
configure vlan bgp-restart add port 2:5
configure vlan bgp-restart ipaddress 10.0.0.2/24
enable ipforwarding

configure bgp as-number 64500
configure bgp route-id 10.0.0.2
configure bgp restart aware-only
create bgp neighbor 10.0.0.1 remote-as 100
enable bgp neighbor all
enable bgp
```

Graceful BGP Restart Configuration Example for IPv6

In the following IPv6 configuration example, EXOS-1 is the restarting BGP router, and EXOS-2 is the receiving BGP router.

To configure router EXOS-1, use the following commands:

```
create vlan bgp-restart
configure vlan bgp-restart add port 2:2
configure vlan bgp-restart ipaddress 2001:db8:1::1/48
enable ipforwarding ipv6

configure bgp as-number 100
configure bgp routerid 10.0.0.1
configure bgp restart both
conf bgp restart add address-family ipv6-unicast
create bgp neighbor 2001:db8:1::2 remote-as 200
enable bgp neighbor all capability ipv6-unicast
enable bgp neighbor all
enable bgp
```
To configure router EXOS-2, use the following commands:

```plaintext
create vlan bgp-restart
configure vlan bgp-restart add port 2:5
configure vlan bgp-restart ipaddress 2001:db8:1::2/48
enable ipforwarding ipv6
configure bgp as-number 200
configure bgp routerid 10.0.0.2
configure bgp restart aware-only
create bgp neighbor 2001:db8:1::1 remote-as 100
enable bgp neighbor all capability ipv6-unicast
enable bgp neighbor all
enable bgp
```

**Route Reflector Example for IPv4**

Figure 239 on page 1478 shows the network topology for this example. Router 1.1.1.1 in this example is a regular BGP peer.

To configure router 1.1.1.1 to connect to the route reflector as a regular BGP peer, use the following commands:

```plaintext
create vlan to_rr
configure vlan to_rr add port 1:1
configure vlan to_rr ipaddress 10.0.0.1/24
enable ipforwarding vlan to_rr

configure bgp router 1.1.1.1
configure bgp as-number 100
create bgp neighbor 10.0.0.2 remote-as 100
enable bgp
enable bgp neighbor all
```

To configure router 2.2.2.2, the route reflector, use the following commands:

```plaintext
create vlan to_nc
configure vlan to_nc add port 1:1
configure vlan to_nc ipaddress 10.0.0.1/24
enable ipforwarding vlan to_nc
create vlan to_c1
configure vlan to_c1 add port 1:2
configure vlan to_c1 ipaddress 10.0.2.2/24
enable ipforwarding vlan to_c1
create vlan to_c2
configure vlan to_c2 add port 1:2
configure vlan to_c2 ipaddress 10.0.3.2/24
enable ipforwarding vlan to_c2

configure bgp router 2.2.2.2
configure bgp as-number 100
create bgp neighbor 10.0.0.1 remote-as 100
create bgp neighbor 10.0.2.1 remote-as 100
create bgp neighbor 10.0.3.1 remote-as 100
create bgp neighbor 10.0.2.1 route-reflector-client
create bgp neighbor 10.0.3.1 route-reflector-client
enable bgp neighbor all
enable bgp
```
To configure router reflector client 3.3.3.3, use the following commands:

```
create vlan to_rr
configure vlan to_rr add port 1:1
configure vlan to_rr ipaddress 10.0.2.1/24
enable ipforwarding vlan to_rr

configure bgp router 3.3.3.3
configure bgp as-number 100
create bgp neighbor 10.0.2.2 remote-as 100
enable bgp neighbor all
enable bgp
```

To configure route reflector client 4.4.4.4, use the following commands:

```
create vlan to_rr
configure vlan to_rr add port 1:1
configure vlan to_rr ipaddress 10.0.3.1/24
enable ipforwarding vlan to_rr

configure bgp router 4.4.4.4
configure bgp as-number 100
create bgp neighbor 10.0.3.2 remote-as 100
enable bgp neighbor all
enable bgp
```

**Route Reflector Example for IPv6**

Figure 242 shows the network topology for this example.

![Route Reflector Example](image)

**Figure 242: Route Reflector Example**

Switch1 is the route reflector, and Switch2 and Switch3 are route reflector clients. Switch4 is a regular neighbor (non-route-reflector client).

**Route Reflector (Switch1) Configuration**

To configure the route reflector, enter the following commands

```
create vlan "v3"
create vlan "v1"
create vlan "v2"
configure vlan v3 add ports 1:16
configure vlan v1 add ports 1:9
configure vlan v2 add ports 1:1
configure v1 ipaddress 2001:db8:1::1/48
configure v2 ipaddress 2001:db8:3::1/48
```
configure v3 ipaddress 2001:db8:5::1/48
enable ipforwarding ipv6
configure bgp AS-number 100
configure bgp routerid 1.1.1.1
create bgp neighbor 2001:db8:1::2 remote-AS-number 100
configure bgp neighbor 2001:db8:1::2 route-reflector-client
create bgp neighbor 2001:db8:3::2 remote-AS-number 100
configure bgp neighbor 2001:db8:3::2 route-reflector-client
create bgp neighbor 2001:db8:5::2 remote-AS-number 100
enable bgp neighbor 2001:db8:1::2 capability ipv6-unicast
enable bgp neighbor 2001:db8:3::2 capability ipv6-unicast
enable bgp neighbor 2001:db8:5::2 capability ipv6-unicast
enable bgp neighbor all
enable bgp
configure ospfv3 routerid 1.1.1.1
configure ospfv3 add vlan all area 0.0.0.0
enable ospfv3

Switch2 Route Reflector Client Configuration
To configure the Switch 2 route reflector client, enter the following commands:

create vlan "v1"
configure vlan v1 add ports 1
configure v1 ipaddress 2001:db8:1::2/48
enable ipforwarding ipv6 vlan v1
configure bgp AS-number 100
configure bgp routerid 1.1.1.2
create bgp neighbor 2001:db8:1::1 remote-AS-number 100
enable bgp neighbor 2001:db8:1::1 capability ipv6-unicast
enable bgp neighbor 2001:db8:1::1 enable
enable bgp
configure ospfv3 routerid 1.1.1.2
configure ospfv3 add vlan v1 area 0.0.0.0
enable ospfv3

Switch3 Route Reflector Client Configuration
To configure the Switch 3 route reflector client, enter the following commands:

create vlan "v1"
configure vlan v1 add ports 1
configure v1 ipaddress 2001:db8:3::2/48
enable ipforwarding ipv6
configure bgp AS-number 100
configure bgp routerid 2.1.1.2
create bgp neighbor 2001:db8:3::1 remote-AS-number 100
enable bgp neighbor 2001:db8:3::1 capability ipv6-unicast
enable bgp neighbor 2001:db8:3::1 enable
enable bgp
configure ospfv3 routerid 2.1.1.2
configure ospfv3 add vlan v1 area 0.0.0.0
enable ospfv3

Switch4 Configuration
Switch4 is not a route reflector client. To configure this switch, enter the following commands:

create vlan "net"
enable loopback-mode vlan net
create vlan "v1"
configure vlan v1 add ports 9
configure v1 ipaddress 2001:db8:5::2/48
configure net ipaddress 2001:db8:2555::1/48
enable ipforwarding ipv6
configure bgp AS-number 100
configure bgp routerid 5.1.1.2
configure bgp add network address-family ipv6-unicast 2001:db8:2555::/48
create bgp neighbor 2001:db8:5::1 remote-AS-number 100
enable bgp neighbor 2001:db8:5::1 capability ipv6-unicast
enable bgp neighbor 2001:db8:5::1
enable bgp
configure ospfv3 routerid 5.1.1.2
configure ospfv3 add vlan v1 area 0.0.0.0
enable ospfv3

Configuration Display for Switch1

The following display shows that the route reflector has two route reflector client peers (r flag), and one regular peer:

* Switch1.30 # show bgp neighbor

<table>
<thead>
<tr>

Route Confederation Example for IPv4

The following figure shows the network topology for this example.

To configure router A, use the following commands:

create vlan ab
configure vlan ab add port 1
configure vlan ab ipaddress 10.1.1.6/30
enable ipforwarding vlan ab
configure ospf add vlan ab area 0.0.0.0

create vlan ac
configure vlan ac add port 2
configure vlan ac ipaddress 10.1.1.17/30
enable ipforwarding vlan ac
configure ospf add vlan ac area 0.0.0.0
enable ospf

configure bgp as-number 64505
configure bgp routerid 10.1.1.17
configure bgp confederation-id 64500
enable bgp

create bgp neighbor 10.1.1.5 remote-AS-number 64505
create bgp neighbor 10.1.1.18 remote-AS-number 64505
enable bgp neighbor all

To configure router B, use the following commands:

create vlan ba
configure vlan ba add port 1
configure vlan ba ipaddress 10.1.1.5/30
enable ipforwarding vlan ba
configure ospf add vlan ba area 0.0.0.0

create vlan bc
configure vlan bc add port 2
configure vlan bc ipaddress 10.1.1.22/30
enable ipforwarding vlan bc
configure ospf add vlan bc area 0.0.0.0

create vlan bd
configure vlan bd add port 3
configure vlan bd ipaddress 10.1.1.9/30
enable ipforwarding vlan bd
configure ospf add vlan bd area 0.0.0.0
enable ospf

configure bgp as-number 64505
configure bgp routerid 10.1.1.22
configure bgp confederation-id 64500
enable bgp

create bgp neighbor 10.1.1.6 remote-AS-number 64505
create bgp neighbor 10.1.1.21 remote-AS-number 64505
create bgp neighbor 10.1.1.10 remote-AS-number 64510
create bgp add confederation-peer sub-AS-number 64510
enable bgp neighbor all

To configure router C, use the following commands:

create vlan ca
configure vlan ca add port 1
configure vlan ca ipaddress 10.1.1.18/30
enable ipforwarding vlan ca
configure ospf add vlan ca area 0.0.0.0

create vlan cb
configure vlan cb add port 2
configure vlan cb ipaddress 10.1.1.21/30
enable ipforwarding vlan cb
To configure router D, use the following commands:

```plaintext
create vlan db
configure vlan db add port 1
configure vlan db ipaddress 10.1.1.10/30
enable ipforwarding vlan db
configure ospf add vlan db area 0.0.0.0

create vlan de
configure vlan de add port 2
configure vlan de ipaddress 10.1.1.14/30
enable ipforwarding vlan de
configure ospf add vlan de area 0.0.0.0

configure bgp as-number 64510
configure bgp routerid 10.1.1.14
configure bgp confederation-id 64500
enable bgp

create bgp neighbor 10.1.1.9 remote-AS-number 64505
create bgp neighbor 10.1.1.13 remote-AS-number 64510
create bgp add confederation-peer sub-AS-number 64505
enable bgp neighbor all
```

To configure router E, use the following commands:

```plaintext
create vlan ed
configure vlan ed add port 1
configure vlan ed ipaddress 10.1.1.13/30
enable ipforwarding vlan ed
configure ospf add vlan ed area 0.0.0.0
enable ospf

configure bgp as-number 64510
configure bgp routerid 10.1.1.13
configure bgp confederation-id 64500
enable bgp

create bgp neighbor 10.1.1.14 remote-AS-number 64510
enable bgp neighbor 10.1.1.14
```

**Route Confederation Example for IPv6**

Figure 240 on page 1479 shows the network topology for this example.

To configure router A, use the following commands:

```plaintext
create vlan ab
configure vlan ab add port 23
configure vlan ab ipaddress 2001:db8:1::6/48
```
enable ipforwarding ipv6 vlan ab
configure ospf add vlan ab area 0.0.0.0
create vlan ac
configure vlan ac add port 16
configure vlan ac ipaddress 2001:db8:3::17/48
enable ipforwarding ipv6 vlan ac
configure ospfv3 routerid 10.1.1.17
configure ospfv3 add vlan ac area 0.0.0.0
enable ospfv3
configure bgp as-number 65001
configure bgp routerid 10.1.1.17
configure bgp confederation-id 200
create bgp neighbor 2001:db8:1::5 remote-AS-number 65001
create bgp neighbor 2001:db8:3::18 remote-AS-number 65001
enable bgp neighbor all capability ipv6-unicast
enable bgp neighbor all
enable bgp

To configure router B, use the following commands:

configure default delete port all
create vlan ba
configure vlan ba add port 5:33
configure vlan ba ipaddress 2001:db8:1::5/48
enable ipforwarding ipv6 vlan ba
configure ospf add vlan ba area 0.0.0.0
create vlan bc
configure vlan bc add port 5:8
configure vlan bc ipaddress 2001:db8:2::22/48
enable ipforwarding ipv6 vlan bc
configure ospf add vlan bc area 0.0.0.0
create vlan bd
configure vlan bd add port 5:4
configure vlan bd ipaddress 2001:db8:4::9/48
enable ipforwarding ipv6 vlan bd
configure ospfv3 add vlan bd area 0.0.0.0
configure ospfv3 routerid 10.1.1.22
enable ospfv3
configure bgp as-number 65001
configure bgp routerid 10.1.1.22
configure bgp confederation-id 200
create bgp neighbor 2001:db8:1::6 remote-AS-number 65001
create bgp neighbor 2001:db8:2::21 remote-AS-number 65001
create bgp neighbor 2001:db8:4::10 remote-AS-number 65002
create bgp add confederation-peer sub-AS-number 65002
enable bgp neighbor all capability ipv6-unicast
enable bgp neighbor all
enable bgp

To configure router C, use the following commands:

configure default delete port all
create vlan ca
configure vlan ca add port 2:16
configure vlan ca ipaddress 2001:db8:3::18/48
enable ipforwarding ipv6 vlan ca
configure ospfv3 add vlan ca area 0.0.0.0
create vlan cb
configure vlan cb add port 2:5
configure vlan cb ipaddress 2001:db8:2::21/48
enable ipforwarding ipv6 vlan cb
configure ospfv3 add vlan cb area 0.0.0.0
create vlan cb
configure ospfv3 routerid 10.1.1.21
enable ospfv3
configure bgp as-number 65001
configure bgp routerid 10.1.1.21
configure bgp confederation-id 200
create bgp neighbor 2001:db8:2::22 remote-AS-number 65001
cREATE bgp neighbor 2001:db8:3::17 remote-AS-number 65001
enable bgp neighbor all capability ipv6-unicast
enable bgp neighbor all
enable bgp

To configure router D, use the following commands:

configure default delete port all
create vlan db
configure vlan db add port 13
configure vlan db ipaddress 2001:db8:4::10/48
enable ipforwarding ipv6 vlan db
configure ospf add vlan db area 0.0.0.0
create vlan de
configure vlan de add port 5
configure vlan de ipaddress 2001:db8:5::14/48
enable ipforwarding ipv6 vlan de
configure ospfv3 add vlan de area 0.0.0.0
configure ospfv3 routerid 10.1.1.14
enable ospfv3
configure bgp as-number 65002
configure bgp routerid 10.1.1.14
configure bgp confederation-id 200
create bgp neighbor 2001:db8:4::9 remote-AS-number 65001
create bgp neighbor 2001:db8:5::13 remote-AS-number 65002
configure bgp add confederation-peer sub-AS-number 65001
enable bgp neighbor all capability ipv6-unicast
enable bgp neighbor all
enable bgp

To configure router E, use the following commands:

configure default delete port all
create vlan ed
configure vlan ed add port 5
configure vlan ed ipaddress 2001:db8:5::13/48
enable ipforwarding ipv6 vlan ed
configure ospfv3 add vlan ed area 0.0.0.0
configure ospfv3 routerid 10.1.1.13
enable ospfv3
configure bgp as-number 65002
configure bgp routerid 10.1.1.13
configure bgp confederation-id 200
create bgp neighbor 2001:db8:5::14 remote-AS-number 65002
enable bgp neighbor all capability ipv6-unicast
enable bgp neighbor all
enable bgp

Default Route Origination Example for IPv4

The following example configures the originate default route feature for BGP neighbor 10.203.134.5 using policy def originate.pol.

def originate.pol
entry prefix_matching {
  if match any {
    nri 192.168.3.0/24;
  } then {
    as-path "64505";
}
permit;
}
}
enable bgp neighbor 10.203.134.5 originate-default policy def_originate

With this configuration, a default route is originated and sent to neighbor 10.203.134.5 only if there is a BGP route in the local RIB which matches the statement nlri 192.168.3.0/24. If a matching route exists, the default route is sent to neighbor 10.203.134.5 with the 64505 as-path prepended. If this is an EBGP neighbor, then the local AS-Number is prepended after 64505.

If the route for the match statement nlri 192.168.3.0/24 goes away and there is no other matching route in the BGP RIB, the default route origination feature becomes inactive and BGP withdraws the 0.0.0.0/0 default route from neighbor 10.203.134.5. When a matching route becomes available again in the local BGP RIB, the default route origination feature becomes active again and the default route 0.0.0.0/0 is advertised to neighbor 10.203.134.5.

Default Route Origination Example for IPv6

The following example configures the originate default route feature for BGP neighbor 2001:db8:1::2 using policy def_originate.pol.

def_originate.pol
entry prefix_matching {
  if match any {
    nlri 2001:db8:2::/48;
  } then {
    as-path "65001";
    permit;
  }
}
enable bgp neighbor 2001:db8:1::2 address-family ipv6-unicast originate-default policy def_originate

With this configuration, a default route is originated and sent to neighbor 2001:db8:1::2 only if there is a BGP route in the local RIB which matches the statement nlri 2001:db8:2::/48. If a matching route exists, the default route is sent to neighbor 2001:db8:1::2 with the 65001 as-path prepended. If this is an EBGP neighbor, then the local AS-Number is prepended after 65001.

If the route for the match statement 2001:db8:2::/48 goes away and there is no other matching route in the BGP RIB, the default route origination feature becomes inactive and BGP withdraws the default route ::/0 from neighbor 2001:db8:1::2. When a matching route becomes available again in the local BGP RIB, the default route origination feature becomes active again and the default route ::/0 is advertised to neighbor 2001:db8:1::2.

BGP Speaker Black Hole Example

Black hole routing is used to protect a service provider’s internal network from distributed denial of service (DDoS) attacks. The strategy is to drop inbound DDoS attack traffic destined to a target network at the edge of the provider network as soon as the target is identified.

Since the attack traffic may enter the service provider network from any of its edge routers, it is not feasible to manually configure a static black hole route entry on each edge router. The problem is
further complicated by the fact that the target network, and the need to block traffic to it, is dynamic. Also, the service provider may serve multiple customers and you don’t want to drop traffic to a customer network until it is identified as a target for an ongoing attack.

Instead, a service provider can use BGP to distribute a black hole route (route entry for the target network with a black hole next-hop) from a single router to all its edge BGP speakers that will then drop traffic destined to the victim’s network right at the provider edge. Figure 243 shows an example topology to achieve this.

![Figure 243: Black Hole Routing Using BGP](image)

**Step 1**

Prior to the attack, select an address for the intended black hole next-hop. Configure the forwarding plane of each edge router so that packets forwarded to this next-hop are dropped:

1. Create a black hole VLAN with an IP address that is in the same subnet as the chosen black hole next-hop.
2. Add an active port to the black hole VLAN (usually an unused port in the switch).
3. Create a static FDB entry that maps a well-chosen, unused MAC address to the black hole VLAN and the active port added to that VLAN.
4. Create a static ARP entry that maps the black hole next-hop to the above MAC address.
5. Create an filter to deny packets that exit the blackhole VLAN.

In the following example configuration, 192.168.2.0/24 is the subnet of the black hole VLAN, “BH_VLAN,” and 192.168.2.66 is the chosen black hole next-hop. The active port 6:9 is added as the egress port for “BH_VLAN.”

```yaml
create vlan BH_VLAN
configure vlan BH_VLAN tag 666
enable loopback-mode vlan BH_VLAN
configure vlan BH_VLAN ipaddress 192.168.2.1 255.255.255.0
enable ipforwarding vlan BH_VLAN
disable igmp snooping vlan BH_VLAN
disable igmp vlan BH_VLAN
create fdb 00:02:03:04:05:06 vlan BH_VLAN port 6:9
configure iparp add 192.168.2.66 vr VR-Default 00:02:03:04:05:06
configure access-list BH_ACL vlan BH_VLAN egress
```
When a packet arrives in the forwarding plane and looks up a route that has the above black hole next-hop as its next-hop, a subsequent ARP and FDB (forwarding database) look-up occurs that forwards the packet to exit the switch using the above black hole VLAN, “BH_VLAN,” and port “6:9.” The packet is dropped due to the deny action in the egress ACL filter.

The following policy file discards any traffic that exits the black hole VLAN, “BH_VLAN.” Note that the match on “source-address 0.0.0.0/0” matches any egress packet ensuring that all packets exiting via the black hole VLAN are dropped:

```
edit policy BH_ACL
entry bh-acl {
  if {
    source-address 0.0.0.0/0;
  } then {
    deny ;
  }
}
```

**Step 2**

- Prior to the attack, configure inbound route-maps on all edge BGP speakers (R2 through R4 in Figure 243 on page 1517).

These inbound policies modify the next-hop of specifically marked BGP network layer reach-ability information (NLRIs) to point to the chosen black hole next-hop. We use BGP community or extended-community attributes to identify NLRIs that need to be black holed (ones whose next-hops have to be modified). The community values that are chosen should be reserved for this purpose within the provider network.

In the following example, a community of 666:0 is chosen for identifying blackhole routes. The next-hop of BGP NLRIs with that community attribute is modified to use the blackhole next-hop.

```
R3.1 # edit policy BH_policy_NH
entry bh-nhset {
  if match any {
    community 666:0;
    nlri any/32 ;
  } then {
    next-hop 192.168.2.66 ;
    permit ;
  }
}
entry bh-default {
  if match any {
  } then {
    permit ;
  }
}
```

**Step 3**

Once the target network has been identified during a DDoS attack, apply an outbound policy or export policy to one router (in our example, R1) within the provider network so that the route to the target network is advertised to the other edge routers within the community 666:0.

The following example creates a static route on R1 to the target network 203.0.113.1/32 with a static export policy that applies to the community. When the attack targets change, you only need to create
or delete static routes to the target networks. The policy exports them to the edge BGP speakers with the selected community attribute values attached.

R1.1  # edit policy BH_COMM_APPLY
entry bh-comm-apply {
  if match any {
    nlri 203.0.113.0/24;
    nlri any/32;
  } then {
    community set "666:0";
  }
}
R1.2  # configure iproute add 203.0.113.1/32 10.0.0.6
R1.3  # enable bgp export static export-policy BH_COMM_APPLY

Alternatively, you can apply the policy as an outbound policy as below:

R1.10 # configure bgp neighbor 10.0.0.2 route-policy out BH_COMM_APPLY
R1.11 # configure bgp neighbor 10.0.0.3 route-policy out BH_COMM_APPLY
R1.12 # configure bgp neighbor 10.0.0.4 route-policy out BH_COMM_APPLY

Output

R4.67  # show bgp route all
Routes:

<table>
<thead>
<tr>
<th>Destination</th>
<th>Peer</th>
<th>Next-Hop</th>
<th>LPre</th>
<th>Weight</th>
<th>MED</th>
<th>AS-Path</th>
</tr>

Origin: (?) Incomplete, (e) EGP, (i) IGP
BGP Route Statistics
Note
For the above solution, the edge routers, R1 through R4, may still export the route to the
target network to external AS(s), but the traffic is dropped at the edge of the provider
network.

An alternative solution for protecting the network is to perform step 1 only on a designated sink router,
(R5 in Figure 243 on page 1517) and redistributes the black hole next-hop using iBGP to R2 through R4.
When traffic arrives at routers R2 through R4, it is forwarded to R5, since R2–R4 have iBGP routes that
resolve the black hole next-hop to R5. Router R5 then discards the traffic.

BGP Route Filtering Example for IPv4
You can use policy files with BGP attributes to filter IPv4 routes. The example in this section is for the
topology shown in Figure 244.

Router A Configuration

```bash
configure vlan default delete ports all
create vlan "vlan_a_b"
create vlan "edge"
configure vlan vlan_a_b add ports 5 untagged
configure vlan edge add ports 23 untagged
configure vlan edge ipaddress 10.10.10.1/24
enable ipforwarding vlan edge
configure vlan vlan_a_b ipaddress 10.20.20.1/24
enable ipforwarding vlan vlan_a_b
configure bgp AS-number 64500
configure bgp routerid 10.10.10.1
enable bgp community format AS-number:number
create bgp neighbor 10.10.10.2 remote-AS-number 64505
enable bgp neighbor 10.10.10.2
create bgp neighbor 10.20.20.2 remote-AS-number 64510
enable bgp neighbor 10.20.20.2
enable bgp neighbor 10.10.10.2 soft-in-reset
```
configure bgp neighbor 10.20.20.2 send-community both
enable bgp

Router B Configuration

create vlan "vlan_B_A"
configure vlan vlan_B_A add ports 25 untagged
configure vlan vlan_B_A ipaddress 10.20.20.2/24
enable ipforwarding vlan vlan_B_A
configure bgp AS-number 64510
configure bgp routerid 10.20.20.2
enable bgp community format AS-number:number
create bgp neighbor 10.20.20.1 remote-AS-number 64500
enable bgp neighbor 10.20.20.1
enable bgp

BGP Routes Before Policy Application

Description
The following example shows the routes in the BGP routing table at Router A after completing the configuration described in the previous two sections:

* Switch.52 # show bgp route all
Routes:
<table>
<thead>
<tr>
<th>Destination</th>
<th>Peer</th>
<th>Next-Hop</th>
<th>LPref</th>
<th>Weight</th>
<th>MED</th>
<th>AS-Path</th>
</tr>

Creating and Applying the Route Filter Policy

Description
The policy described in this section is applied to Router A and does the following:

- Denies routes in network 172.16.1.0/24
- Sets the values of community and MED for routes in network 10.1.0.0/16
- Sets the values of community and MED for routes that contains AS path 64499
The following is a route filter policy named custFilter:

```plaintext
entry et1 {
    if match all {
        nlri 172.16.1.0/24;
    } then {
        deny;
    }
}
entry et2 {
    if match any {
        nlri 10.1.0.0/16;
        as-path 64499;
    } then {
        med set 100;
        community set "2342:6788";
        permit;
    }
}
```

- Apply the custFilter inbound policy.

  * (pacman) DUTA.53 # configure bgp neighbor 10.10.10.2 route-policy in custfilter

**BGP Routes After Policy Application**

The following example shows the routes in the BGP routing table at Router A after applying the custFilter inbound policy:

```plaintext
* Switch.55 # show bgp route all
Routes:
  Destination       Peer           Next-Hop        LPref Weight MED    AS-Path
  ----------------- ------------- --------------- ------- ----- ----- ----- ----- ----- 
  *1> 10.1.1.0/24    10.10.10.2     10.10.10.2      100   1      100    64505 64496 0
  *1> 10.1.2.0/24    10.10.10.2     10.10.10.2      100   1      100    64505 64496 0
  *1> 10.1.3.0/24    10.10.10.2     10.10.10.2      100   1      100    64505 64496 0
  *1> 10.1.34.0/24   10.10.10.2     10.10.10.2      100   1      100    64505 64499
Flags: (*) Preferred BGP route, (>) Active, (d) Suppressed, (h) History
       (s) Stale, (m) Multipath, (u) Unfeasible
Origin: (?) Incomplete, (e) EGP, (i) IGP

**BGP Route Filtering Example for IPv6**

You can use policy files with BGP attributes to filter IPv6 routes. The example in this section is for the topology shown in the following figure.

**Router A Configuration**

```bash
configure vlan default delete ports all
create vlan "a_b"
enable ipforwarding ipv6 vlan a_b
create vlan "edge"
enable ipforwarding ipv6 vlan edge
configure vlan a_b add ports 5 untagged
configure vlan edge add ports 23 untagged
configure edge ipaddress 2001:db8:2000::1/48
configure a_b ipaddress 2001:db8:3000::1/48
configure bgp AS-number 2100
configure bgp routerid 10.10.10.1
enable bgp community format AS-number:number
create bgp neighbor 2001:db8:2000::2 remote-AS-number 1100
```
enable bgp neighbor 2001:db8:2000::2
create bgp neighbor 2001:db8:3000::2 remote-AS-number 3300
enable bgp neighbor 2001:db8:3000::2
capability ipv6-unicast
capability ipv6-multicast
address-family ipv6-unicast soft-in-reset
send-community both
create bgp neighbor 2001:db8:3000::2 capability ipv6-unicast
capability ipv6-multicast
create bgp neighbor 2001:db8:3000::2 send-community both
enable bgp

Router B Configuration

configure vlan default delete ports all
create vlan "b_a"
enable ipforwarding ipv6 vlan b_a
create vlan b_a add ports 25 untagged
configure vlan b_a ipaddress 2001:db8:3000::2/48
configure bgp AS-number 3300

Creating and Applying the Route Filter Policy

The policy described in this section is applied to Router A and does the following:

- Denies routes in network 2001:db8:a004::/48
- Sets the community and MED values for routes in network 2001:db8:4000::/44
- Sets the community and MED values for routes that contain AS path 4977

The following is a route filter policy named custFilter:

```
entry et1 {
  if match all {
    nlri 2001:db8:a004::/48;
  } then {
    deny;
  }
}
entry et2 {
  if match any {
    nlri 2001:db8:4000::/44;
    as-path 4977;
  } then {
    med set 100;
    community set "2342:6788";
    permit;
  }
}
```

Apply the custFilter inbound policy.

```
* Switch.53 # configure bgp neighbor 2001:db8:2000::1 ipv6-unicast route-policy in custfilter
```

BGP Routes After Policy Application

The following example shows the routes in the BGP routing table at Router A after applying the custFilter inbound policy:

```
* Switch.127 # show bgp routes address-family ipv6-unicast all
Routes:
  Destination                     LPref  Weight  MED     Peer           Next-Hop  AS-Path
  +-----------------+----------+----------+---------+----------------+---------+--------
  +-----------------+----------+----------+---------+----------------+---------+--------
```
Route 2001:db8:a004::/48 is not present in the BGP routing table shown above.

The routes were updated because soft-reset is configured for this neighbor.

The following command examples show that the denied routes are not transmitted to the neighbors:

```plaintext
* Switch.130 # show bgp neighbor 2001:db8:3000::2 address-family ipv6-unicast transmitted-routes all
Advertised Routes:
Destination                      LPref Weight MED

This chapter introduces Layer 3 VPN, a way to create a tunnel between customer sites through a Provider Backbone, and its features and options in a BGP (Border Gateway Protocol)/MPLS (Multiprotocol Label Switching) VPN environment. This chapter also provides an example showing L3VPN configuration on a BGP/MPLS setup.

**Overview of Layer 3 VPN**

Layer 3 Virtual Private Networks (L3VPN) is a specific implementation of PPVPN (Provider Provisioned VPN). L3VPN is a way to create a tunnel between customer sites through a Provider Backbone, and that tunnel is established and maintained by the Service Provider.

Within a Layer 3 VPN, the customer advertises IP routing knowledge to the provider network. The ISP then advertises this routing information across its network to the other customer locations. This simple concept requires some coordination between the provider and the customer. Also, the provider must configure its network to support the advertisement of these routes and have a way to segregate the customer routes. This is accomplished with the help of a specially designed Network Layer Reachability Information (NLRI).

Within a L3VPN, several routers will play a different role. On the customer site, there is a CE router (Customer Edge). This router is the property of the customer and is managed by them. This router is outside of the Autonomous System (AS) of the Provider. On the Provider side there are some PE routers (Provider Edge) and P routers (Provider). The PE routers are facing the CE routers. They have all the customer’s IP routing knowledge. The P routers do not have that knowledge; they are not facing any CE routers, and they serve only to transport the data from PE routers to other PE routers. Their knowledge is very limited, and they usually are intended only for swapping MPLS labels. In other words the Provider’s core is pure MPLS and has no knowledge of L3VPN, while the edge is L3VPN aware.
A L3VPN requires an MPLS transport mechanism in the Provider Backbone for the data forwarding and Multiprotocol BGP (MBGP) between the PE routers to exchange VPN-IPv4 routing information.

**Figure 246: Different Router Roles in L3 VPN**

A L3VPN requires an MPLS transport mechanism in the Provider Backbone for the data forwarding and Multiprotocol BGP (MBGP) between the PE routers to exchange VPN-IPv4 routing information.

**Overview of BGP/MPLS Network**

This section introduces the basic concepts of BGP/MPLS VPNs as described in the Internet RFC 4364. Figure 247 illustrates an example BGP/MPLS VPN network configuration that includes two VPNs: VPN-A comprises three sites, and VPN-B comprises two. Both VPNs use the same set of IP addresses as defined in RFC 1918.
Figure 247: BGP/MPLS VPN Example

The Customer Edge boxes represent switches or routers, while the Provider Edge and P(rovider) boxes are routers. If the CE box is a router, then it only needs to peer with the adjacent PE router(s). The PE and P routers form the core MPLS network. The P routers only maintain routing information for the core MPLS network, while the PE routers only maintain routing information for the VPNs they support. This ensures that no single router maintains routing information for all the VPNs.

Since a PE router can support multiple VPNs that may have overlapping address spaces, each PE router must maintain multiple Virtual Routing and Forwarding tables (VRFs). In the example, each site is a member of one VPN, and the PE router is configured to associate a particular VPN with each physical interface to a CE router. The PE router maintains one VRF for each VPN, and packets received from a particular physical interface are forwarded using the VRF for the VPN associated with that interface.

VRFs for a specific VPN are populated in two ways: (1) when the PE router learns routes from a directly-attached CE router that is a member of the VPN, and (2) when the PE router receives routes for the VPN through MBGP from another PE router. The PE router can learn the routes that are reachable at a particular CE router’s site through configuration (static routes), or by routing protocol exchanges with the CE router.
VPN route distribution uses BGP-4 Multiprotocol Extensions that enable BGP to carry routes from multiple address families. The VPN-IPv4 address family supports BGP/MPLS VPNs. A VPN-IPv4 address is a 12-byte entity, beginning with an 8-byte (RD) and ending with a 4-byte IPv4 address. The RD makes it possible to create distinct routes to a common IPv4 address prefix, which is necessary when the same IPv4 address prefix is used in two different VPNs.

The purpose of the RD is solely to allow one to create distinct routes to a common IPv4 address prefix. The Route target attribute is used to identify a set of VRFs. Every VRF is associated with one or more route targets. Export route targets identify the set of route targets that a PE router attaches to a route learned from a particular CE site. Import route targets identify the set of route targets that determine whether a route received from another PE router can be inserted in a particular VRF. A VPN-IPv4 route can only be installed in a particular VRF if there is a route target that is both one of the route’s targets, and one of the VRF’s import route targets. Route targets allow a PE router to only maintain routing information for the VPNs it is supporting. Using import and export route targets offers flexibility in constructing a variety of VPN topologies (such as a fully-meshed closed user group, or a hub-and-spoke architecture). Route Targets are encoded as BGP Extended Communities attributes.

When distributing a VPN route through BGP, a PE router includes its own IP address as the BGP next hop (next-hop-self). The PE router always assigns and distributes an MPLS label for each customer VPN VRF that it receives from directly connected sites (CEs). BGP-distributed MPLS labels require that there be a label switched path between the PE router that installs the BGP-distributed route and the PE router that is the BGP next hop of that route. This is necessary because a multi-label stack is used to forward VPN packets across the MPLS backbone.

The outer MPLS label gets the packet across the backbone. This label is obtained from the MPLS signaling protocols, and is associated with the best LSP to the BGP next hop address of the PE Router that advertised the VPN route. The inner MPLS label is obtained from BGP, and is associated with the best route to the VPN destination address. This label identifies the VRF that the egress PE Router uses to forward the packet to a CE device, and may indicate the outgoing interface that the packet should be forwarded over (along with the appropriate link layer header for that interface).

The use of a two-level MPLS label stack is an important scalability attribute of the model, because it is the two-level label stack that enables the P routers to operate without containing routes for any of the VPNs.

In summary, key aspects of the BGP/MPLS VPN model include:
- Direct peering of customer routers with service provider routers.
- Maintenance of multiple forwarding tables by PE routers.
- Introduction of the VPN-IPv4 address family.
- Constrained distribution of routing information via Route Targets.
- Use of MPLS label switching in the backbone network.

**VPNV4 NLRI**

One of the core principles of operating a VPN is maintaining separation between the customer networks. L3VPN uses a special format to represent customer routes within the provider’s network. This format allows each provider router to uniquely view routes from different customers as separate, even when they advertise the same IPv4 prefix. The format consists of these fields: Mask, MPLS label, route distinguisher, and IPv4 prefix.
Limitations

The following list identifies the limitations of the L3VPN feature:

- **RIP (Routing Information Protocol)** is not supported for PE – CE peering routing protocol.
- IP Multicast BGP/MPLS VPN is not supported.
- OSPFv2 and ISIS is not supported for PE-CE peering routing protocol.
- IPv6 VPN is not supported.
- Graceful restart mechanism for BGP with MPLS (RFC-4781) is not supported.
- Constraint Route distribution for BGP/MPLS VPN (RFC-4684) is not supported.
- Carrier of carriers BGP/MPLS VPN configuration is not supported.
- XML support to configure BGP/MPLS VPN parameters.
- Carrier's carrier (RFC 4364, Section 9).
- Inter-AS / inter-provider VPNs (RFC 4364, Section 10).
- No other BGP related MIB other than RFC 1657 is supported.

Overlapping Customer Address Spaces

VPN customers often manage their own networks and use the RFC-1918 private address space. If globally unique IPv4 addresses are not used, the same 32-bit IPv4 address can be used to identify different systems in different VPNs. This causes routing problems because BGP assumes that each IPv4 address that it carries is globally unique. To solve this problem, BGP/MPLS VPN converts non-unique IPv4 addresses into unique VPN-IPv4 address families. Each IPv4 address is prepended with an 8-bytes long Route Distinguisher (RD).

A VPN-IPv4 address is a 12-byte quantity composed of an 8-byte RD and 4 byte IPv4 address. The 8-byte RD is composed of a 2-bytes type field and a 6-bytes value field. The value of the Type field determines the lengths of the Value field’s two subfields (Administrator and Assigned Number), as well as the semantics of the Administrator field.

Most commonly, the Admin field holds a 2-byte non-private AS number and the Assigned number field holds a 4-byte number assigned by the VPN service provider. Another common format for the RD is the Admin field holds a global 4-byte IPv4 address, and the Assigned number field holds 2 byte number assigned by the VPN service provider.

Multi-protocol BGP Extension

BGP is originally designed to carry routing information for IPv4 address families only. Since VPN-IPv4 addresses are 12 bytes wide, BGP requires some kind of extension to carry VPN-V4 address family routing information. This is achieved by using MBGP extension which allows BGP to carry multiprotocol address families routing information. Therefore, to deploy BGP/MPLS VPNs and to support the distribution of VPN-IPv4 routes, PE routers are required to support the MP-BGP extensions with VPN-IPv4 address family support.

Multiple Forwarding Tables

Each PE router needs to maintain one forwarding table per VPN that it is directly connected. These forwarding tables are called Virtual Routing and Forwarding tables (VRF). When a PE router is configured, each of it’s VRF is associated with one or more VLAN (Virtual LAN)s, that is, there is a many
to one mapping from VLAN to VPN/VRF. When receiving inbound data traffic from a directly attached CE router, PE router determines the VRF for the packet based on which VLAN the packet has been received. The ingress VLAN will uniquely map to a particular VRF in the system. Then, PE router performs a route lookup for the packet’s destination IP address in the associated VRF. In the figure above, both PE1 and PE3 have two VRFs, one each for VPN-A and VPN-B, whereas, PE2 has only one VRF which is for VPN-A.

Quality of Service in BGP/MPLS VPN

The L3VPN implementation uses the existing ACL and QoS (Quality of Service) framework available in ExtremeXOS to achieve QoS on a PE. Please refer to the Quality of Service on page 713 section for more information.

Virtual Routing and Forwarding Instances

The concept of Virtual Routing and Forwarding (VRF) is similar to the virtual router (VR) already present in Extreme Switches. Like a VR, each VRF also has a distinct set of VLANs and ports, as well as a unique name assigned to it across the system. VLANs are created, and ports are added to in the same manner as is done for VRs. Logically separate instances of the same routing protocol may run in the contexts of multiple VRFs of the same switch, simultaneously. In addition, a VRF may also contain a Route Distinguisher (RD), multiple import and export Router Targets (RTs), as well as a VPN ID. These three items allow a VRF to support L3VPNs.

The goal of VRF is to provide separation of overlapping address spaces belonging to separate routing domains. The objective of the VR is to split the switch into multiple routing domains so that traffic originating on one VR never enters another VR. The objective of VRFs is to control the flow of traffic across various VPN sites. As the PE-PE connection is always part of the default VR or a user VR, the forwarding table corresponding to a particular VRF has the incoming interface belonging to the VRF, and egress interfaces belonging to the default, or user VR. Similarly, the forwarding table (MPLS label table) corresponding to a user, or default VR, could have an interface belonging to a VRF as part of its egress interfaces. In this sense a VRF is "associated" with the user, or default VR (also referred to as parent VRs).

A VRF is not the same as a VR. A VRF always requires that you have a Parent VR, and this can either be the default VR or User VR. Protocols running in a VRF run as a separate logical instance within the context of the protocol process that is running in the Parent VR. ExtremeXOS VRFs come in two types:

- **Non-VPN VRFs** - Non-VPN VRFs are used for L3 Routing and Forwarding just like VRs. These provide the ability to scale protocol deployments. BGP and static routing are supported in the Non-VPN VRF.
- **VPN VRFs** - VPN VRFs enable configuration of RD and RT to realize L3VPN topologies.

Note

MPLS and BGP must be configured in the parent VR (PE-facing).

BGP and static routing are supported in the VPN VRF.

Again, a VRF always requires that you have a Parent VR, and this can either be the default VR or User VR. Protocols running in a VRF run as a separate logical instance within the context of the protocol process that is running in the Parent VR. For example, the BGP process for a VR running MPLS will
handle all PE to CE instances of BGP by virtualizing the data structures. This approach of allowing VRFs in a VR is more scalable than having a process for every instance of PE-to-CE routing protocol.

**L3VPN BOOTP Relay**

A DHCP Relay agent relays DHCP requests from the client to the DHCP server and relays the DHCP replies from the server to the client. It acts as a proxy, thereby reducing the number of DHCP servers required in the network. The DHCP relay agent inserts its own IP address in the giaddr field (gateway address) of the DHCP request. The DHCP server can look into this IP address, identify the DHCP client’s subnet and assign an IP address accordingly.

You can enable BOOTP Relay over VRFs and VPN-VRFs in the same manner as with normal VRs. Normally, you must enable BOOTP Relay on both ingress and egress VLANs. However, with BOOTP Relay over L3VPN, you do not need to enable BOOTP Relay on egress VLANs, since ingress and egress VLANs are present in different VRs/VRFs.

**Limitations**

The following are limitations of the BOOTP Relay L3VPN feature:

- VPN-ID is not supported on DHCP-Relay Option 82, which services clients across VPNs.
- IPv6 BOOTP Relay not supported, since there is no IPv6 support for L3VPN.

**L3VPN Configuration Example**

Here is an example of a Layer 3 VPN. In this example CE1 and CE2 are in different AS. You can put them in the same AS by adding the allowas-in command.

In this example, you should be able to ping CE2 "foo1's" IP address from CE1.

This chapter introduces the features and usage of IP multicasting, which allows a single host on a network to send a packet to a group of hosts. For more information on IP multicasting, refer to the following publications:

- RFC 1112—Host Extension for IP Multicasting
- RFC 2236—Internet Group Management Protocol, Version 2
- RFC 3569—SSM for IPv4/IPv6 (only for IPv4)
- PIM-SM Version 2—draft-ietf-pim-sm-v2-new-05
- RFC 4601—PIM SM (only for IPv4)
- RFC 2362 PIM-SM (Edge Mode)
- RFC 3973 PIM-DM (only for IPv4)
- RFC 3569—draft-ietf-ssm-arch-06.txt PIM-SSM PIM Source Specific Multicast
- PIM-DM Draft IETF Dense Mode—draft-ietf-idmr-pimd-05.txt, draft-ietf-pim-dm-new-v2-04.txt
- RFC 3376—Internet Group Management Protocol, Version 3

The following URL points to the website for the IETF PIM Working Group: http://datatracker.ietf.org/wg/pim/documents/.

**Multicast Routing Overview**

Multicast routing and switching is the functionality of a network that allows a single host (the multicast server) to send a packet to a group of hosts. With multicast, the server is not forced to duplicate and send enough packets for all the hosts in a group. Instead, multicast allows the network to duplicate packets for all of the hosts in a group. Multicast greatly reduces the bandwidth required to send data to a group of hosts. IP multicast routing is a function that allows multicast traffic to be forwarded from one subnet to another across a routing domain.

IP multicast routing requires the following functions:

- A router that can forward IP multicast packets
- A router-to-router multicast routing protocol (for example, Protocol Independent Multicast (PIM)) to discover multicast routes
- A method for the IP host to communicate its multicast group membership to a router (for example, IGMP (Internet Group Management Protocol))

Note
You should configure IP unicast routing before you configure IP multicast routing.

**Multicast Table Management**

The ExtremeXOS software uses the following tables to support IP multicast traffic:

- IPv4 multicast route table
- L3 hash table
- IP multicast group table
- FDB table (L2 table)
- L2 multicast table (L2MC table)

**IP Multicast Hardware Lookup Modes**

Extreme platforms support various hardware forwarding lookup modes by using a combination of L3 hash table and L2 (FDB (forwarding database)) table. Refer to Multicast Table Management for details on these tables. The scalability limits vary based on the lookup mode used.

**Configuration Options**

Configuration options allow you to choose the hardware forwarding lookup mode for multicast forwarding. Here is a list of options:

- source-group-vlan -- Uses L3 hash table with S,G,V lookup. This is the default mode for all platforms.
- group-vlan -- Uses L3 hash table with *,G,V lookup.
- mac-vlan -- Uses L2 table with DMAC, VLAN (Virtual LAN) lookup.
- mixed-mode -- Uses both L2 and L3 tables for multicast. In this mode, the following logic is applied on installing the cache entries in the hardware:
  
  Multicast cache entries requiring forwarding across VLANs would be installed in the L3 IP multicast table. This includes PIM, MVR, and PVLAN cache entries.
  
  Multicast cache entries requiring L2 forwarding within a VLAN are installed in the L2 table. This includes entries corresponding to IGMP Snooping, PIM snooping, and MLD snooping.
  
  Any IPv4/v6 reserved multicast addresses (for example, 224.0.0.x or IPv6 equivalent) are installed in the L3 IP multicast table as needed. These reserved addresses map to the following multicast MAC addresses: 01:00:5e:00:00:xx, 33:33:00:00:00:xx, 33:33:00:00:01:xx, or 33:33:ff:xx:xx:xx.

Note
Any change in the lookup key configuration causes all cache entries to be cleared, and traffic is temporarily dropped until the system re-learns the multicast caches and associated subscriptions.

Note
mac-vlan mode helps increase scaling. This mode is supported on all platforms.
Note
mac-vlan and mixed-mode are not supported prior to ExtremeXOS 15.3.1.

The ExtremeXOS multicast process continues to maintain the cache entries as "S,G,V", and interacts with HAL the same way as today. ExtremeXOS hardware abstraction layer (HAL) applies the logic explained above and installs the cache entries in the appropriate hardware table. If the cache entry needs to be installed in the L2 multicast table, HAL derives the MAC address based on the standard logic and installs the MAC entry in the L2 table.

The IP multicast address to MAC address mapping is not validated for the received/forwarded multicast packets in ExtremeXOS to date. If the lookup mode is configured either as "mac-vlan" or "mixed-mode", the multicast kernel module is modified to validate this mapping and, if a packet does not use the standard mapping, the packet is dropped.

IPMC Compression
In order to increase the scaling of multicast entries, ExtremeXOS implements a feature called IPMC compression which allows multiple <S,G,V> (or *
G,V) IP multicast FDB entries to utilize the same IP multicast group table entry when the associated egress port lists are the same. The base IP multicast compression implementation will be reused for achieving L2 multicast entry reuse. In this case, multiple <MAC,VLAN> multicast FDB entries can use a single L2MC index if the egress port lists of the cache entries are the same.

Interactions with Static FDBs
ExtremeXOS allows you to create FDB entries for multicast MAC address using:

```
create fdb mac_addr {vlan} vlan_name ports port_list
```

These entries also get installed in the L2 table and use the L2MC table for hardware forwarding. If there is a dynamic <MAC,VLAN> entry from MCMGR and a static entry from FDB manager, the static entry takes precedence and the dynamic entry would get deleted in hardware. Compression of L2MC indices is not supported on these types of entries. Each newly created static multicast FDB will cause the allocation of a new L2MC index.

Interactions with Dynamic FDBs
When IP multicast forwarding entries are utilizing the L2 MAC table, the multicast entries are installed as static in the hardware L2 table to avoid undesirable interactions with L2 protocol or user administered FDB flushing. These multicast L2 entries also take precedence over dynamic unicast L2 MAC entries. If there is a hash bucket collision upon inserting an L2 multicast entry, it will replace another dynamic unicast L2 entry if one exists in the same hash bucket.

Virtual Router Support
Current IPMC cache hardware entries stored as <S,G,V> additionally include the VRID associated with the ingress virtual router (VR). In this feature, <MAC, VLAN> cache entries are stored in the L2 table which does not additionally include the VRID. However, user VRs are still supported since the VLAN portion of the lookup key is unique across all VRs.
**IPMC Cache Rate Limiting**

Based on the number of cache entries supported on each platform, there is a software cache limiting implementation present in ExtremeXOS multicast. The HAL module informs MCMGR about the supported limit, MCMGR creates cache entries up to MAX supported limit, and the remaining traffic is dropped in software.

**Supported Platforms**

This feature is implemented on all platforms.

**Limitations**

The following limitations exist for the L2MC table feature:

- When using the "mac-vlan" configuration option:
  - PIMv4/V6, MVR features cannot be used.
  - IGMPv3 should not be used in conjunction with this mode
  - Private VLAN multicast should not be used.
  - Issues with IP multicast address to MAC address mapping:

All IPv4 multicast frames use multicast mac addresses starting with 01:00:5e:xx:xx:xx. The lower order 23 bits of the IP multicast address is used in the MAC address derivation. As only 23 bits of MAC addresses are available for mapping layer 3 IP multicast addresses to layer 2 MAC addresses, this mapping results in 32:1 address ambiguity.

When traffic is received for 1 out of these 32 overlapping address, then the MAC, Vlan entry is installed in hardware based on the IGMP group membership of received traffic's destination multicast IP address. After this installation, traffic to any of the remaining 31 addresses is delivered based on the existing cache entry and the actual receiver list of the remaining 31 addresses will not be honored.

IPv6 multicast streams use multicast MAC addresses in the form 33:33:xx:xx:xx:xx. The lower 24 bits of the IPv6 multicast address are used to derive the MAC address. So, the address ambiguity issue is also applicable to IPv6 with more severity. Given this condition, we do not recommend using overlapping IP multicast addresses with this mode.

This limitation applies to "mixed-mode", too.

- IPv4 multicast addresses consist of a block of addresses (224.0.0.x) used for network control traffic. Packets having IP destination addresses from the LNCB are always flooded to all ports of the VLAN. The address ambiguity issue discussed above is applicable for the addresses in this block too. For example, 224.0.0.5 (address used for **OSPF (Open Shortest Path First)**) and 225.0.0.5 would use the same MAC address 01:00:5e:00:00:05. If a mac based multicast FDB entry is installed on the hardware for 01:00:5e:00:00:05 based on the 225.0.0.5 join list, it would break OSPF functionality. Hence, MAC addresses mapping to the LNCB block will not be installed in the L2 table, resulting in software forwarding for those streams. We recommend that you avoid using multicast addresses that map to the 01:00:5e:00:00:xx MAC address range.

- As per RFC 3307, IANA assigned reserved IPv6 multicast addresses could be in the group Id range of 0x00000001 to 0x3FFFFFFF. As a result, ExtremeXOS switches flood traffic addressed to ff02::/98 to all ports of the VLAN. Since the lower 32 bits of IPv6 multicast addresses are mapped to the multicast mac address, not installing all of the addresses in this range would make it too...
restrictive. So, installing entries for 33:33:00:00:00:xx in hardware would be avoided, and the traffic would be software forwarded.

In addition, the following important IPv6 multicast addresses cannot be installed as hardware forwarding entries:

- **DHCP (Dynamic Host Configuration Protocol):** All-dhcp-agents address FF02:0:0:0:0:0:1:2
- All-dhcp-servers address FF05:0:0:0:0:0:1:3
- Neighbor Discovery (ND): Solicited-node-address FF02::1:FF00:0000/104

Therefore, the following multicast MAC addresses are not programmed in hardware, and the corresponding packets are handled in slowpath: 33:33:00:00:01:xx , 33:33:ff:xx:xx:xx

- Given the issues with IP multicast address to MAC address mapping, no attempt is made to merge subscriber lists of multiple overlapping IP groups.
- The following limitation regarding IPMC compression is also applicable for this feature, because this feature uses the same L2MC entry for multiple l2 multicast entries with same egress ports.
- When IP multicast forwarding entries are installed as <MAC,VLAN>, IGMP or MLD packets which have a MAC-DA=<group> will cause the refresh of the IP multicast cache, preventing timely entry age-out.
- The L2MC table is limited to 1K entries on all platforms. This means that only up to 1K unique port lists can be addressed from the <MAC,VLAN> IP multicast forwarding entries that are stored in the L2 table. Additionally, statically created multicast FDB entries do not perform L2MC index compression.

### IPv4 Multicast Route Table

Beginning with Release 12.1, all IP multicast routes are stored and maintained in the software multicast route table. Routes are added to the multicast route table from the following sources:

- Multicast static routes (configured manually by the network administrator)
- Multicast dynamic routes (learned through protocols such as MBGP and MISIS)

The multicast route table is used for reverse path forwarding (RPF) checks, not for packet forwarding. The switch uses RPF checks to avoid multicast forwarding loops. When a multicast packet is received, the switch does an RPF lookup, which checks the routing tables to see if the packet arrived on the interface on which the router would send a packet to the source. The switch forwards only those packets that arrive on the interface specified for the source in the routing tables.

The RPF lookup uses the multicast routing table first, and if no entry is found for the source IP address, the RPF lookup uses the unicast routing table.

**Note**

Because the multicast routing table is used only for RPF checks (and not for routing), IP route compression and ECMP (Equal Cost Multi Paths) do not apply to multicast routes in the multicast routing table.

Beginning with ExtremeXOS software version 12.1, the route metric is no longer used to select between multicast and unicast routes. If the RPF lookup finds a route in the multicast table, that route is used. The unicast routing table is used only when no route is found in the multicast table.
The advantage to having separate routing tables for unicast and multicast traffic is that the two types of traffic can be separated, using different paths through the network.

L3 Hash Table

The L3 hash table is introduced in Introduction to Hardware Forwarding Tables on page 1339. The L3 hash table stores entries for IPv4 routes, IPv4 and IPv6 hosts, and IPv4 and IPv6 multicast groups. For multicast, L3 hash table supports <S,G,V> and <*,G,V> lookups. The entry from this table provides an index to IP Multicast Group table.

To make more space available in the L3 hash table for IPv4 and IPv6 multicast groups, you can do the following:

- Configure the extended IPv4 host cache feature to move IPv4 local and remote routes to the LPM table as described in Extended IPv4 Host Cache on page 1339.
- For more information, see the description for the command.

Note

To benefit from the use of the external LPM tables, you must leave the IP multicast compression feature enabled, which is the default setting.

IP Multicast Group Table

The IP multicast group table specifies the egress ports for Layer 2 and Layer 3 multicast traffic groups. To make more space available in the IP multicast group table, you can Leave IP multicast compression enabled (it is enabled by default). This allows multiple L3 hash entries to share the same IP multicast group entry if the egress list is the same.

PIM Overview

Protocol Independent Multicast (PIM) is the de-facto standard for routing multicast traffic over the Internet. Other multicast routing protocols such as DVMRP and MOSPF are sometimes used in controlled environment, but are not widely deployed. PIM does not depend on a particular unicast routing protocol for its operation. Also, it does not have any mechanism of its own for route discovery. PIM operation is based on the routing table being populated by another routing protocol, or by the user. This provides flexibility in routing unicast and multicast traffic based on a common database.

PIM has two flavors, sparse and dense mode, that are deployed in different topologies. These two flavors, called PIM-SM and PIM-DM, are different in operation. PIM-SM is based on a “join protocol”, where traffic is not forwarded on a segment unless an explicit request originates (typically through IGMP) from the network segment. PIM-DM is based on a “flood and prune” mechanism, where every one receives traffic until they explicitly inform (through the PIM-DM prune mechanism) that they do not want that particular stream. Thus, PIM-DM is typically deployed in topologies where listeners are densely populated. And PIM-SM is typically deployed where the receivers are sparsely populated over the network, so that most of the network segments’ bandwidth is conserved.

You can configure dense mode or sparse mode on a per-interface basis. After they are enabled, some interfaces can run dense mode, while others run sparse mode. The switch supports both dense mode and sparse mode operation.
The switch also supports PIM snooping.

**PIM Edge Mode**

PIM Edge Mode is a subset of PIM that operates with the following restrictions:

- The switch does not act as a candidate rendezvous point (CRP).
- The switch does not act as a candidate bootstrap router (CBSR).
- At most, four active PIM-SM interfaces are permitted. There is no restriction on the number of passive interfaces (within the limit of the maximum IP interfaces).
- Only PIM Sparse Mode (PIM-SM) is supported.

**Note**

This feature is supported at and above the license level listed for this feature in the license tables in the *ExtremeXOS 22.6 Feature License Requirements* document.

Active PIM interfaces can have other PIM enabled routers on them. Passive interfaces should only have hosts sourcing or receiving multicast traffic. If another PIM router is connected to a multi-access VLAN, then passive mode should not be enabled for that respective VLAN. *OSPF* passive mode should not be enabled for a VLAN when a PIM neighbor is present.

**PIM Dense Mode**

Protocol-Independent Multicast - Dense Mode (PIM-DM) is a multicast routing protocol. PIM dense-mode is a flood and prune-based protocol. Convergence is based on the downstream routers’ response for the traffic received. The downstream router in turn floods the traffic to its own downstream interfaces. Each router sends prune to the interface on which it received the traffic under the following conditions:

- Traffic was not received on RPF interface towards the source.
- The PIM router is a leaf router, and there are no *IGMP/MLD* members.
- All the downstream PIM routers have pruned the stream, and there are no *IGMP/MLD* members.

A new feature, called PIM-DM state refresh, creates two PIM-DM operating modes, which are described in the following sections:

**Note**

**PIM-DM Without State Refresh**

PIM-DM is a broadcast and prune protocol, which means that multicast servers initially broadcast traffic to all destinations, and then switches later prune paths on which there are no receivers. *Figure 249* shows a dense mode multicast tree with an active branch and a pruned branch.
Multicast traffic is flowing from VLAN V1 connected to switch S1. S1 floods multicast traffic to both neighbors S2 and S3 which in turn flood multicast traffic to S4 and S5. S4 has IGMP members, so it floods multicast traffic down to VLAN V6. S5, which has no multicast members, sends a prune upstream towards the source. The green line shows the flow of traffic on the active branch, and the red line shows the prune sent upstream for the pruned branch. After outgoing interface V2 is pruned from the multicast tree, subsequent multicast traffic from S1 flows only through S2 and S4 and is not forwarded to S3.

After S3 sends a prune upstream, S3 starts a prune hold time timer on outgoing interface V5. When this timer expires, S3 adds V5 back to the multicast egress list and sends a graft upstream to pull multicast traffic down again. When multicast traffic arrives from S1, it is forwarded to S5, which repeats the upstream prune message because it still has no members. This prune, time-out, and flood process repeats as long as the traffic flow exists and no members are on the pruned branch, and this process consumes bandwidth during every cycle.

**Note**
This feature is supported at and above the license level listed for this feature in the license tables in the ExtremeXOS 22.6 Feature License Requirements document.

PIM-DM routers perform reverse path multicasting (RPM). However, instead of exchanging its own unicast route tables for the RPM algorithm, PIM-DM uses the existing unicast routing table for the reverse path. As a result, PIM-DM requires less system memory.

**PIM-DM with State Refresh**

The PIM-DM State Refresh feature keeps the PIM-DM prune state from timing out by periodically sending a state refresh control message down the source tree. These control messages reset the prune hold time timer on each pruned interface and prevent the bandwidth waste that occurs with each prune, time-out, and flood cycle.
When a topology change occurs, the PIM-DM State Refresh feature improves network convergence. For example, suppose that an S, G entry on S5 in the following figure is removed due to non-availability of a route. Without PIM-DM State Refresh, multicast traffic is blocked for minutes (due to a time-out on the upstream routers). In the meantime if an IGMP member or a PIM-DM neighbor joins S5, there is no way to pull traffic down immediately because S5 does not have any S, G information. State refresh control messages solve this problem by indicating S, G state information periodically to all downstream routers. When S5 receives a state refresh from S3, it scans the S, G information and all pending requests from PIM-DM neighbors and IGMP members. If there are pending requests for the group in the state refresh message, S5 can immediately send a graft message upstream to circumvent the upstream timers and pull multicast traffic to its members and neighbors.

- To enable, configure, and disable the PIM-DM State Refresh feature, use the following commands:
  
  configure pim state-refresh {vlan} [vlanname | all] [on | off]
  configure pim state-refresh timer origination-interval interval
  configure pim state-refresh timer source-active-timer interval
  configure pim state-refresh ttl ttlvalue

**PIM Sparse Mode**

Unlike PIM-DM, Protocol-Independent Multicast - Sparse Mode (PIM-SM) is an explicit join protocol, which means that multicast receivers, and the routers that support them, must join multicast groups before they receive multicast traffic. When all receivers on a network branch leave a multicast group, that branch is pruned so that the multicast traffic does not continue to consume bandwidth on that branch. PIM-SM supports shared trees as well as shortest path trees (SPTs). PIM-SM is beneficial for large networks that have group members that are sparsely distributed.

**Note**

This feature is supported at and above the license level listed for this feature in the license tables in the ExtremeXOS 22.6 Feature License Requirements document.

Using PIM-SM, the router sends a join message to the rendezvous point (RP). The RP is a central multicast router that is responsible for receiving and distributing the initial multicast packets. You can configure a dynamic or static RP.

When a router has a multicast packet to distribute, it encapsulates the packet in a unicast message and sends it to the RP. The RP decapsulates the multicast packet and distributes it among all member routers.

When a router determines that the multicast rate has exceeded a configured threshold, that router can send an explicit join to the originating router. When this occurs, the receiving router gets the multicast directly from the sending router and bypasses the RP.

**Note**

You can run either PIM-DM or PIM-SM per VLAN.
PIM Mode Interoperation

An Extreme Networks switch can function as a PIM multicast border router (PMBR). A PMBR integrates PIM-SM and PIM-DM traffic.

When forwarding PIM-DM traffic into a PIM-SM network, the PMBR acts as a virtual first hop and encapsulates the initial traffic for the RP. The PMBR forwards PIM-DM multicast packets to the RP, which, in turn, forwards the packets to those routers that have joined the multicast group.

The PMBR also forwards PIM-SM traffic to a PIM-DM network, based on the (*.*.RP) entry. The PMBR sends a (*.*.RP) join message to the RP, and the PMBR forwards traffic from the RP into the PIM-DM network.

No commands are required to enable PIM mode interoperation. PIM mode interoperation is automatically enabled when a dense mode interface and a sparse mode interface are enabled on the same switch.

PIM Source Specific Multicast

PIM-SM works well in many-to-many multicasting situations. For example, in video conferencing, each participating site multicasts a stream that is sent to all the other participating sites. However, PIM-SM is overly complex for one-to-many multicast situations, such as multimedia content distribution or streaming stock quotes. In these and similar applications, the listener is silent and can know the source of the multicast in advance, or can obtain it. In these situations, there is no need to join an RP, as the join request can be made directly towards the source.

Note

This feature is supported at and above the license level listed for this feature in the license tables in the ExtremeXOS 22.6 Feature License Requirements document.

Note

(*;G)s are created for groups inside the SSM range if SSM is not enabled.

PIM Source Specific Multicast (PIM-SSM) is a special case of PIM-SM, in which a host explicitly sends a request to receive a stream from a specific source, rather than from any source.

IGMPv3 hosts can use PIM SSM directly, because the ability to request a stream from a specific source first became available with IGMPv3. The PIM-SSM capable router interprets the IGMPv3 message to initiate a PIM-SM join towards the source.

Note

IGMPv1 and IGMPv2 hosts can use PIM SSM if IGMP-SSM mapping is enabled and configured on the ExtremeXOS switch. For more information, see Using IGMP-SSM Mapping.

</table>

PIM-SSM has the following advantages:

- No overhead of switching to the source-specific tree and waiting for the first packet to arrive
- No need to learn and maintain an RP
- Fewer states to maintain on each router
- No need for the complex register mechanism from the source to the RP
- Better security, as each stream is forwarded from sources known in advance

PIM-SSM has the following requirements:

- Any host that participates directly in PIM-SSM must use IGMPv3. For PIM IPv6 host must use MLDv2.
- To support IGMPv1 and IGMPv2 hosts, IGMP-SSM mapping must be enabled and configured. To support MLDv1 hosts, MLD-SSM mapping must be enabled and configured.

PIM-SSM is designed as a subset of PIM-SM and all messages are compliant with PIM-SM. PIM-SSM and PIM-SM can coexist in a PIM network; only the last hop router need to be configured for PIM-SSM if both source and receivers are present all the time. However, to avoid any JOIN delay, it is recommended that you enable all routers along the (s,g) path for PIM-SSM.

**Configuring the PIM-SSM Address Range**

A range of multicast addresses is used for PIM-SSM. Within that address range, non-IGMPv3 messages are ignored, and any IGMPv3 exclude messages are ignored. These messages are ignored for all router interfaces, even those not configured for PIM-SSM. By default there is no PIM-SSM range specified on the router. If you choose the default keyword in the CLI when specifying the PIM-SSM range, you configure the range 232.0.0.0/8 and default PIM-SSM range for IPv6 is FF3x::/96. You can also choose to specify a different range for PIM-SSM by using a policy file.
To configure the PIM-SSM address range, use the following command:

```
configure pim ssm range [default | policy policy-name]
```

**PIM Snooping**

PIM snooping provides a solution for handling multicast traffic on a shared media network more efficiently. In networks where routers are connected to a L2 switch, multicast traffic is essentially treated as broadcast traffic (see Figure 250).

**Figure 250: Multicast Without PIM Snooping**

IGMP snooping does not solve this flooding issue when routers are connected to a L2 switch. Switch ports are flooded with multicast packets. PIM snooping addresses this flooding behavior by efficiently replicating multicast traffic only onto ports which routers advertise the PIM join requests (see Figure 251).
PIM snooping does not require PIM to be enabled. However, IGMP snooping must be disabled on VLANs that use PIM snooping. PIM snooping and MVR cannot be enabled on the same VLAN.

To enable PIM snooping on one or all VLANs, use the following command:

```
enable pim snooping {{vlan} name}
```

To disable PIM snooping on one or all VLANs, use the following command:

```
disable pim snooping {{vlan} name}
```

**Note**

PIM snooping can be enabled only between PIM SM enabled switches. It should not enabled between PIM DM enabled switches.

**PIM Register Policy**

This feature allows you to filter register messages based on the policy file configured at the First Hop Router (FHR) and Rendezvous Point (RP) in PIM-SM domain. You can use the register policy to filter out specific PIM register messages that have encapsulated specific (S,G) packets. This feature allows you to detect and deny malicious multicast packets from flowing into a multicast shared tree, and causing a
potential service blackout. The PIM Register Policy feature is supported in both the PIM IPV4 and PIM IPV6 mode.

Filtering at FHR

- FHR receives the source multicast packet and sends a register message towards the RP. Before it sends the register message to the RP, the FHR checks the configured register filter policy. If the (S,G) is denied by the policy, the register will not send a message to the RP. The FHR adds the L3 entries to stop the packet from arriving at the CPU. An EMS message is logged.
- The FHR checks the register policy before generating a NULL register packet. If the policy is denied by the filter then the NULL register is not sent to the RP.
- If the cache’s Group is in the SSM range, or is received in the PIM dense circuit, then this filtering is not applicable. The cache miss packet will go thru the normal processing.
- If a non-SSM (S,G) cache already exists but is denied by the filter policy, then (S,G) cache is removed. The cache miss comes to the CPU for register processing if the traffic is still flowing.

The PIM filtering policy is configured at the FHR using the configure pim {ipv4 | ipv6} register-policy [policy | none] command.

Filtering at RP

- When an encapsulated PIM register packet or PIM NULL register is received by the RP, and is denied by the registering filter policy, the register message is discarded. Additionally, no (S,G) cache is created in the PIM cache.
- The register drop counter is incremented, and the EMS message is logged.
- If a register is received from the MSDP (Multicast Source Discovery Protocol), it also goes through the RP filtering policy.

The PIM filtering policy is configured at RP using the following command:

```
configure pim {ipv4 | ipv6} register-policy rp [rp_policy_name | none]
```

Example

PIM Register policy rules can be created only on the Source IP address and group address, as shown in the following.

**SAMPLE POLICY 1:**

If the matching entry is not found, then the entry permission is considered as denied. Need wildcard entries to permit the unmatched entries. The following policy file permits the matched entries and wildcard entries deny the unmatched source:

```plaintext
entry policy1 {
    if match any{
        nlri 10.10.10.0/24;
        nlri 20.20.20.0/24;
    }                       <= Permit these sources for group
    then {
        nlri 226.1.1.0/24;
        nlri 227.1.1.0/24;
        permit;
    }
}
```
entry policy2 {
    if match any{
        nlri 10.10.10.0/24;
    }
    then {
        nlri 228.1.1.0/24;
        deny;
    }
}

entry policy3 {
    if match any{
    }
    then {
        <- deny all other source;
        deny;
    }
}

**SAMPLE POLICY 2:**
The following policy file denies the matched entries and wildcard entry permits the unmatched source:

entry policy1 {
    if match any{
        nlri 10.10.10.0/24;
        nlri 20.20.20.0/24 ;
    } <- deny these sources for group
    then {
        nlri 226.1.1.0/24;
        nlri 227.1.1.0/24;
        deny;
    }
}

entry policy2 {
    if match any{
        nlri 10.10.10.0/24;
    }
    then {
        nlri 228.1.1.0/24;
        deny;
    }
}

entry policy3 {
    if match any{
    }
    then {
        <- permit all other source;
        permit;
    }
}

**SAMPLE POLICY 3:**
The following policy file denies the matched entries and unmatched entries. Since the wildcard permit entry is not present in this policy file, by default all the unmatched entries are denied:

entry policy1 {
    if match any{
        nlri 10.10.10.0/24;
        nlri 20.20.20.0/24 ;
    } <- deny these sources for group
    then {
        nlri 226.1.1.0/24;
    }
}
PIM DR Priority

The DR_Priority option allows a network administrator to give preference to a particular router in the DR election process by giving it a numerically larger DR Priority. The DR_Priority option is included in every Hello message, even if no DR Priority is explicitly configured on that interface. This is necessary because priority-based DR election is only enabled when all neighbors on an interface advertise that they are capable of using the DR_Priority Option. The default priority is 1.

DR Priority is a 32-bit unsigned number, and the numerically larger priority is always preferred. A router’s idea of the current DR on an interface can change when a PIM Hello message is received, when a neighbor times out, or when a router’s own DR Priority changes. If the router becomes the DR or ceases to be the DR, this will normally cause the DR Register state machine to change state. Subsequent actions are determined by that state machine.

The DR election process on the interface consists of the following:

- If any one of the neighbors on the interface is not advertised, the DR priority (not DR capable) will not considered for the all the neighbors in the circuit and the primary IP address will be considered for all the neighbors.
- Higher DR priority or higher primary address will be elected as DR.

Use the following command to configure PIM DR Priority:

```
configure pim {ipv4 | ipv6} [vlan] [vlan_name] dr-priority priority
```

PIM ECMP Load Splitting

The PIM ECMP feature allows downstream PIM routers to choose multiple ECMP paths to source via hash from one of following selections without affecting existing unicast routing algorithm:

- Source
- Group
- Source-Group
- Source-Group-Next Hop

This feature operates on a per (S,G) basis splitting the load onto available equal-cost paths by hashing according to the selection criteria configured by the user. It does not operate by counting the flows. Load splitting need not balance the traffic on the available paths. PIM ECMP load splitting uses a hash algorithm based on the selected criteria to pick up the path to use and will result in load-sharing the
traffic when there are many multicast streams that utilize approximately the same amount of bandwidth.

**PIM ECMP Load Splitting Based on Source Address**

When you enable PIM ECMP load splitting based on source address, the RPF interface for each (*, G) or (S,G) state is selected among the equal cost paths based on the hash derived from the source address. For an (S, G) state, the address considered for hashing is the source address of the state. For a (*, G) state, the address considered for hashing is the address of the RP that is associated with the state’s group address. There is no randomization applied when calculating the hash value. The same hash value is generated on all the ExtremeXOS routers for a given source address. If there are two equal cost paths (“left” and “right”) available at the last hop router and at each of the intermediate routers for a given source, each of these routers pick the same hash, and the traffic flows can get skewed (to either “left” or “right” paths).

**PIM ECMP Load Splitting Based on Group Address**

When you enable PIM ECMP load splitting based on group address, the RPF interface for each (*, G) or (S,G) state is selected among the equal cost paths based on the hash derived from the group address. If multiple equal cost common paths exist to the multicast source and the RP that is associated with the state’s group address, the same hash will be chosen for both (*, G) and (S, G) states as the same group address is used in deriving the hash. There is no randomization applied when calculating the hash value. The same hash value is generated on all the ExtremeXOS routers for a given group address. If there are two equal cost paths (“left” and “right”) available at the last hop router and at each of the intermediate routers for a given group, each of these routers pick the same hash and the traffic flows can get skewed (to either “left” or “right” paths).

**PIM ECMP Load Splitting Based on Source-Group Addresses**

When you enable PIM ECMP load splitting based on source-group address, the RPF interface for each (*, G) or (S,G) state is selected among the equal cost paths based on the hash derived from the source and group addresses. For an (S, G) state, the address considered for hashing is the source address of the state. For a (*, G) state, the address considered for hashing is the address of the RP that is associated with the state’s group address. There is no randomization applied when calculating the hash value. The same hash value is generated on all the ExtremeXOS routers for a given source-group address. If there are two equal cost paths (“left” and “right”) available at the last hop router and at each of the intermediate routers for a given source-group, each of these routers pick the same hash and the traffic flows can get skewed (to either “left” or “right” paths).

**PIM ECMP Load Splitting Based on Source-Group-Next Hop Addresses**

When you enable PIM ECMP load splitting based on source-group-next hop address, the RPF interface for each (*, G) or (S,G) state is selected among the equal cost paths based on the hash derived from the source, group and next hop addresses. The hash value derived after introducing the next hop address is still predictable as there is no randomization applied when calculating the hash value. However, since the next hop address used at each of the routers vary, the hash value generated on each of the ExtremeXOS routers is different. As the hash value is different on each of the routers, the problem of traffic path skew present in the above mentioned schemes does not exist in this scheme.

**Reconvergence Due to Unicast Routing Changes**

When a unicast route to a source or RP address changes (when a path goes down or a new path becomes available), all the (*, G) and (S, G) states change based on the available unicast route.
information provided by Route Manager process. If one of the paths goes down and comes back up, multicast forwarding will reconverge to same RPF path that was used before the path went down. The hash function based on Source-Group-Next Hop avoids skewing of traffic flows because it introduces the actual next-hop IP address of PIM neighbors into the calculation resulting in different hash value being computed for each router. The Source-Group-Next Hop based hash function doesn’t take the total number of available paths into consideration and so it increases stability of the paths chosen during path failures. During path failures, the multicast states that were using the failed path would need to reconverge onto the remaining paths. All other states using the unaffected paths are not affected.

Limitations

- Cannot be used along with static multicast routes.
- Not supported for ExtremeXOS Multicast Tools (mtrace and mrinfo) in current release.
- Load splitting is not applied for configured static multicast routes and multicast routes present in the multicast routing table.
- Load splitting is only effective when the equal cost paths are upstream PIM neighbors on different interfaces. When the equal cost paths are PIM neighbors on the same shared VLAN, PIM assert mechanism chooses one path to avoid traffic duplication. The path chosen by PIM assert mechanism overrides the path selected by Multicast ECMP load splitting.

IPv6 Specific Features

Apart from adding support for IPv6 addresses, PIMv6 adds the following functionality to existing PIM implementation:

- Secondary address list - This is a new option which will be added to the V6 Hello messages sent. The list includes all addresses assigned to an interface, including the link local addresses. The receiving router must process these addresses and must associate the same with the neighbor that sent the message.
- Tunnel interface - This is similar to a VLAN interface. APIs are now added to get callbacks from VLAN manager client for IP address configuration for a tunnel, etc.

Secondary address list

The Address List Option, in a Hello message, advertises all the secondary addresses associated with the source interface of the router originating the message. These addresses are associated with the neighbor, and are used to compute the neighbor’s primary address. The function NBR uses information gathered through PIM Hello messages to map the IP address A of a directly connected PIM neighbor on interface I to the primary IP address of the same router. The primary IP address of a neighbor is the address that it uses as the source of its PIM Hello messages.

Tunnel interfaces

Two PIMv6 domains can be connected through an IPv4 network. In this case, PIMv6 routers across the domains communicate over the IPv4 network by tunneling the IPv6 packets inside IPv4 headers. To enable such communication, PIMv6 provides support for Tunnel interfaces.

The following tunnel types are supported:

- 6-in-4
- 6-to-4
Configuration details

PIMv6 is incorporated into all CLI commands that currently support the PIM implementation. New keywords are added to support IPv6, and show command output is modified to display IPv6 related information. For specific configuration details, refer to the *ExtremeXOS 22.6 Command Reference Guide*.

**IGMP Overview**

*IGMP* is a protocol used by an IP host to register its IP multicast group membership with a router. A host that intends to receive multicast packets destined for a particular multicast address registers as a member of that multicast address group. Periodically, the router queries the multicast group to see if the group is still in use. If the group is still active, a single IP host responds to the query, and group registration is maintained.

IGMPv2 is enabled by default on the switch, and the ExtremeXOS software supports IGMPv3. However, the switch can be configured to disable the generation of periodic IGMP query packets. IGMP should be enabled when the switch is configured to perform IP multicast routing.

IETF standards require that a router accept and process IGMPv2 and IGMPv3 packets only when the router-alert option is set in received IGMP packets.

By default, the ExtremeXOS software receives and processes all IGMP packets, regardless of the setting of the router-alert option within a packet. When the switch will be used with third-party switches that expect IETF compliant behavior, use the following command to manage this feature:

```
configure igmp router-alert receive-required [on | off] {{vlan} vlan_name}
```

```
configure igmp router-alert transmit [on | off] {{vlan} vlan_name}
```

By default, IGMP report/leave message for the local multicast address (224.0.0.x/24 groups) will always have the router-alert option set, regardless of IGMP router-alert transmit option (on and off) setting by the user.

IGMPv3, specified in RFC 3376, adds support for source filtering. Source filtering is the ability for a system to report interest in receiving packets only from specific source addresses (filter mode include) or from all sources except for specific addresses (filter mode exclude). IGMPv3 is designed to be interoperable with IGMPv1 and IGMPv2.

**Note**
The ExtremeXOS software supports IGMPv3 source include mode filtering, but it does not support IGMPv3 specific source exclude mode filtering.

**IGMP Snooping**

*IGMP* snooping is a Layer 2 function of the switch; it does not require multicast routing to be enabled. In IGMP snooping, the Layer 2 switch keeps track of IGMP reports and only forwards multicast traffic to that part of the local network that requires it. IGMP snooping optimizes the use of network bandwidth and prevents multicast traffic from being flooded to parts of the local network that do not need it. The switch does not reduce any IP multicast traffic in the local multicast domain (224.0.0.x).
IGMP snooping is enabled by default on all VLANs and VMANs in the switch. If IGMP snooping is disabled on a VLAN or VMAN, all IGMP and IP multicast traffic floods within the VLAN or VMAN. IGMP snooping expects at least one device on every VLAN to periodically generate IGMP query messages.

To enable or disable IGMP snooping, use the following command:

```
enable igmp snooping {forward-mcrouter-only | {vlan} name | with-proxy vr vrname}
```

```
disable igmp snooping {forward-mcrouter-only | {vlan} name | with-proxy vr vrname}
```

**Note**
IGMP snooping is not supported on SVLANs on any platform.

The IGMP snooping proxy feature represented by "with-proxy" in the above commands is enabled by default. This feature optimizes the forwarding of IGMPv1 and IGMPv2 reports. The following is true for each group:

- Only the first received IGMP join is forwarded upstream.
- Only the IGMP leave for last host is forwarded upstream.

When a switch receives an IGMP leave message on a port, it sends a group-specific query on that port if proxy is enabled (even if it is a non-querier). The switch removes the port from the group after leave timeout (The timeout value is configurable, with a default value of 1000 ms., and a range from 0 to 175000 ms). If all the ports are removed from the group, the group is deleted and the IGMP leave is forwarded upstream. If IGMP snooping proxy is disabled, then all the IGMP reports are forwarded upstream.

**Note**
IGMP snooping proxy does not apply to IGMPv3 reports.

IGMP snooping is implemented primarily through ACLs, which are processed on the interfaces. These special purpose ACLs are called IGMP snooping hardware filters. The software allows you to choose between two types of IGMP snooping hardware filters: per-port filters (the default) and per-VLAN filters.

The two types of IGMP snooping hardware filters use switch hardware resources in different ways. The two primary hardware resources to consider when selecting the IGMP snooping hardware filters are the Layer 3 multicast forwarding table, and the interface ACL (Access Control List) s. The size of both of these hardware resources is determined by the switch model. In general, the per-port filters consume more resources from the multicast table and less resources from the ACL table. The per-VLAN filters consume less space from the multicast table, and more from the ACL table.

Using the per-port filters can fill up the multicast table and place an extra load on the CPU. To avoid this, configure the switch to use the per-VLAN filters.

**Note**
The impact of the per-VLAN filters on the ACL table increases with the number of VLANs configured on the switch. If you have a large number of configured VLANs, we suggest that you use the per-port filters.
IGMP Snooping Filters

IGMP snooping filters allow you to configure a policy file on a port to allow or deny IGMP report and leave packets coming into the port. (For details on creating policy files, see Policy Manager on page 632.) The IGMP snooping filter feature is supported by IGMPv2 and IGMPv3.

Note
Do not confuse IGMP snooping filters with IGMP snooping hardware filters explained in previous section. IGMP snooping filters are software filters, and the action is applied at the software level by the ExtremeXOS multicast manager.

For the policies used as IGMP snooping filters, all the entries should be IP address type entries, and the IP address of each entry must be in the class-D multicast address space but should not be in the multicast control subnet range (224.0.0.x/24).

1 Use the following template to create a snooping filter policy file that denies IGMP report and leave packets for the 239.11.0.0/16 and 239.10.10.4/32 multicast groups:

```
# Add your group addresses between "Start" and "end"
# Do not touch the rest of the file!!!!
entry igmpFilter {
  if match any {
    #------------------ Start of group addresses ------------------
    nlri 239.11.0.0/16;
    nlri 239.10.10.4/32;
    #------------------- end of group addresses -------------------
  } then {
    deny;
  }
}
entry catch_all {
  if {
    then {
      permit;
    }
  }
}
```

2 After you create a policy file, use the following command to associate the policy file and filter to a set of ports:

```
configure igmp snooping vlan vlanname ports portlist filter [policy | none]
```

3 To remove the filter, use the none option.

4 To display the IGMP snooping filters, use the following command:

```
show igmp snooping {vlan} name filter
```

Static IGMP

To receive multicast traffic, a host must explicitly join a multicast group by sending an IGMP report; then, the traffic is forwarded to that host. In some situations, you might like multicast traffic to be forwarded to a port where a multicast-enabled host is not available (for example, when you test multicast configurations).

Static IGMP emulates a host or router attached to a switch port, so that multicast traffic is forwarded to that port, and the switch sends a proxy join for all the statically configured IGMP groups when an IGMP
query is received. You can emulate a host to forward a particular multicast group to a port; and you may emulate a router to forward all multicast groups to a port. Static IGMP is only available with IGMPv2.

- To emulate a host on a port, use the following command:
  ```bash
  configure igmp snooping {vlan} vlan_name {ports port_list} add static
  group ip_address
  ```

- To emulate a multicast router on a port, use the following command:
  ```bash
  configure igmp snooping {vlan} vlan_name {ports port_list} add static
  router
  ```

- To remove these entries, use the corresponding commands:
  ```bash
  configure igmp snooping {vlan} vlan_name {ports port_list} delete
  static group [ip_address | all]
  configure igmp snooping vlan vlan_name {ports port_list} delete
  static router
  ```

- To display the IGMP snooping static groups, use the following command:
  ```bash
  show igmp snooping {vlan} vlan_name static [group | router]
  ```

**IGMP Loopback**

Prior to ExtremeXOS 15.3.2, you could configure static groups, but it was necessary to specify port(s). As of ExtremeXOS Release 15.3.2, the configuration of dynamic groups is supported. The IGMP Loopback feature, along with the existing static group feature, supports the configuration of static and/or dynamic groups with or without ports.

A VLAN in loopback mode may not have ports associated with it, but its operational status is up. However, it is not possible to have multicast receivers on a VLAN without having a port. Sometimes there is a need to pull the multicast traffic from upstream to the loopback VLAN for troubleshooting. The traffic need not always be forwarded to any ports/receivers. The IGMP Loopback feature allows you to configure groups on a VLAN without specifying a port, so the traffic is pulled from upstream but not forwarded to any port.

The loopback (Lpbk) port is the logical port on a VLAN in the application context. If you configure a group on a VLAN but do not specify the port, the switch forms an IGMPv2 join and assumes it to be received on the Lpbk port. A dynamic group ages out after the membership timeout if there are no other receivers. Membership joins refresh the dynamic group. The static group remains until it is removed from the configuration.

The following command is used to configure static or dynamic group entry:

```bash
configure igmp snooping {vlan} vlan_name {ports port_list} add [static |
dynamic] group ip_address
```

**Limiting the Number of Multicast Sessions on a Port**

- The default configuration places no limit on the number of multicast sessions on each VLAN port. To place a limit on the number of learned IGMP groups, use the following command:
  ```bash
  configure igmp snooping {vlan} vlan_name ports port_list set join-
  limit {num}
  ```
• To remove a session limit, use the following command:
  
  unconfigure igmp snooping {vlan} vlan_name ports port_list set join-limit

Enabling and Disabling IGMP Snooping Fast Leave

When the fast leave feature is enabled and the last host leaves a multicast group, the router immediately removes the port from the multicast group. The router does not query the port for other members of the multicast group before removing the group, and/or the port.

The default setting for IGMP snooping fast leave is disabled.

• To enable the fast leave feature, use the following command:
  enable igmp snooping {vlan} name fast-leave

• To disable the fast leave feature, use the following command:
  disable igmp snooping {vlan} name fast-leave

IGMP-SSM Mapping

The IGMP-SSM Mapping feature allows IGMPv1 and IGMPv2 hosts to participate in SSM functionality, and eliminates the need for IGMPv3. You can configure SSM map entries that specify the sources used for a group/group range for which SSM functionality has to be applied. You also have the option to configure the domain name and DNS server to use to obtain the source list.

When a IGMPv1 or IGMPv2 report is received, the configured sources are provided to PIM so that it can send source specific joins. When the host leaves or when the membership times out, PIM is informed so that it can consider sending prunes.

In a multi-access network (where more than one router is receiving IGMP messages from the hosts), only the designated router sends joins towards the source, so it is desirable to have same configuration for SSM group range and SSM Mapping range on all routers in a VLAN.

Limitations

• A single group address or range can be mapped to a maximum of 50 sources. If more than 50 sources are configured, the switch uses the 50 longest-matching prefixes.

• We recommend a maximum of 500 mappings per switch, but no limit is imposed by the software.

Configuring IGMP-SSM Mapping

To support PIM-SSM for IGMPv1 and IGMPv2 clients, a PIM-SSM range must be configured, and that range should include all groups to which the clients want access. If IGMPv1 and IGMPv2 clients request group addresses outside the PIM-SSM range, those addresses are ignored by PIM-SSM and forwarded to PIM as (*, G) requests.

• To enable IGMP-SSM mapping, first configure a PIM-SSM range, and then enable IGMP-SSM mapping using the following commands:
  configure pim ssm range [default | policy policy-name]
enable igmp ssm-map {vr vr-name}

- To configure an IGMP-SSM mapping, use the following command:
  
  `configure igmp ssm-map add group_ip [prefix | mask] [source_ip | src_domain_name] {vr vr-name}`

- To remove a single IGMP-SSM mapping, use the following command:
  
  `configure igmp ssm-map delete group_ip [ prefix] | mask] [source_ip | all] vr vr-name`

- To remove all IGMP-SSM mappings on a VR, use the following command:
  
  `unconfigure igmp ssm-map {vr vr-name}
  
- To disable IGMP-SSM mapping on a virtual router, use the following command:

  `disable igmp ssm-map {vr vr-name}

Displaying IGMP-SSM Mappings

To see whether or not IGMP-SSM mapping is enabled or disabled and to view the configured mappings for a multicast IP address, use the following command:

`show igmp ssm-map {group_ip} {vr vr-name}

Configuring EAPS Support for Multicast Traffic

The ExtremeXOS software provides several commands for configuring how EAPS (Extreme Automatic Protection Switching) supports multicast traffic after an EAPS topology change. For more information, see the descriptions for the following commands:

`configure eaps multicast add-ring-ports [on | off]`

`configure eaps multicast send-query [on | off]`

`configure eaps multicast temporary-flooding [on | off]`

These commands apply for both IGMP and MLD.

**Note**

Using the `configure eaps multicast send-query` command applies to both IGMP and MLD. This also replaces the `configure eaps multicast send-igmp-query` command.

Configuring IP Multicast Routing

**Enabling Multicast Forwarding**

To enable IP multicast forwarding:

1. Configure the system for IP unicast routing.

2. Enable multicast forwarding on the interface.

   `enable ipmcforwarding {vlan name}`
Configuring PIM

To configure PIM multicast routing, enable multicast forwarding as described in Enabling Multicast Forwarding on page 1569 and do the following:

1. Configure PIM on all IP multicast routing interfaces using the following command:
   ```bash
   configure pim {ipv4 | ipv6} add vlan [vlan-name | all] {dense | sparse} {passive}
   ```

2. To enable and configure the PIM-DM state refresh feature on one or all VLANs, use the following commands:
   ```bash
   configure pim {ipv4 | ipv6} state-refresh {vlan} [vlan_name | all] [on | off]
   configure pim {ipv4 | ipv6} state-refresh timer origination-interval interval
   configure pim {ipv4 | ipv6} state-refresh timer source-active-timer interval
   configure pim {ipv4 | ipv6} state-refresh ttl ttlvalue
   ```

3. For PIM-SSM, specify the PIM-SSM range, enable IGMPv3, and enable PIM-SSM on the interfaces using the following commands:
   ```bash
   configure pim {ipv4 | ipv6} ssm range [default | policy policy-name]
   enable igmp {vlan vlan name} {IGMPv1 | IGMPv2 | IGMPv3}
   enable pim {ipv4 | ipv6} ssm vlan [vlan_name | all]
   ```

4. Enable PIM on the router using the following command:
   ```bash
   enable pim
   ```

Configuring Multicast Static Routes

Note
Multicast static routes are supported in the IPv4 address family, but not the IPv6 address family.

Static routes are used to reach networks not advertised by routers, and are manually entered into the routing table.

- You can use either of two commands to create multicast static routes. The recommended command is the following:
  ```bash
  configure iproute add [ipNetmask | ip_addr mask] gateway {metric}
  {multicast | multicast-only | unicast | unicast-only} {vr vrname}
  ```
  For example:
  ```bash
  configure iproute add 55.1.10.0/24 44.1.12.33 multicast
  ```

- The following command is still supported for backward compatibility with earlier ExtremeXOS software releases:
  ```bash
  configure ipmroute add [source-net mask-len | source-net mask]
  {{protocol} protocol} rpf-address {metric} {vr vr-name}
  ```
In the following example, the configure ipmroute add command is used to specify protocol information for a route:

```
configure ipmroute add 58.1.10.0/24 ospf 44.1.12.33
```

**Note**

Ipmroute not supported for IPv6.

When a static route is configured with protocol information, the route is shown as UP only when the protocol route is available. Otherwise, the route is Down. In the example above, the multicast static route 58.1.10.0/24 is shown as UP only when the OSPF route is available to reach the network 58.1.10.0/24.

Static routes are stored in the switch configuration and can be viewed with the show configuration command. Static multicast routes that do not include protocol information are displayed using the configure iproute command format, even if they were created using the configure ipmroute command. Static routes that are created with a protocol field are displayed using the configure ipmroute command format.

### Disabling IP Multicast Compression

The IP multicast compression feature is enabled by default. You should only disable this feature if you suspect that switch processing resources are limited or if you think this feature is causing problems on the switch.

- To disable or enable IP multicast compression, use the following command:

```
configure forwarding ipmc compression {group-table | off}
```

### Multicast Over MLAG Configuration

For sample topology for MLAG (Multi-switch Link Aggregation Group), see Layer 3 IP Multicast using PIM-SM on page 251.

### PIM Configuration Examples

#### PIM-DM Configuration Example

In Figure 252, the system labeled IR 1 is configured for IP multicast routing, using PIM-DM.
Figure 252: IP Multicast Routing Using PIM-DM Configuration Example

The above figure is used in the OSPF section to describe the OSPF configuration on a switch.

The router labeled IR1 has the following configuration:

```
configure vlan HQ_10_0_1 ipaddress 10.0.1.2 255.255.255.0
configure vlan HQ_10_0_2 ipaddress 10.0.2.2 255.255.255.0
configure ospf add vlan all area 0.0.0.0
enable ipforwarding
enable ospf
enable pim
configure pim add vlan all dense
enable pim
configure pim state-refresh vlan all on
```

**PIM-SM Configuration Example**

In Figure 253, the system labeled ABR1 is configured for IP multicast routing using PIM-SM.
Figure 253: IP Multicast Routing Using PIM-SM Configuration Example

Note
The above figure is used in the OSPF section to describe the OSPF configuration on a switch.

The router labeled ABR1 has the following configuration:

```plaintext
configure vlan HQ_10_0_2 ipaddress 10.0.2.1 255.255.255.0
configure vlan HQ_10_0_3 ipaddress 10.0.3.1 255.255.255.0
configure vlan LA_161_48_2 ipaddress 161.48.2.2 255.255.255.0
configure vlan CHI_160_26_26 ipaddress 160.26.26.1 255.255.255.0
configure ospf add vlan all area 0.0.0.0
enable ipforwarding
enable ipmcforwarding
configure pim add vlan all sparse
   tftp TFTP_SERV -g -r rp_list.pol
   configure pim crp HQ_10_0_3 rp_list 30
   configure pim cbsr HQ_10_0_3 30
```

The policy file, rp_list.pol, contains the list of multicast group addresses serviced by this RP. This set of group addresses are advertised as candidate RPs. Each router then elects the common RP for a group address based on a common algorithm. This group to RP mapping should be consistent on all routers.
The following is a policy file that configures the CRP for the address ranges 239.0.0.0/24 and 232.144.27.0:

```
entry extreme1 {
  if match any {
  }
  then {
    nlri 239.0.0.0/24 ;
    nlri 232.144.27.0/24 ;
  }
}
```

**PIM-SSM Configuration Example**

In the following example, the default PIM-SSM range of 232.0.0.0/8 is configured. For all interfaces, non-IGMPv3 messages and IGMPv3 exclude messages are ignored for addresses in this range. Hosts that use IGMPv3 on VLAN v13 can request and receive source specific multicast streams for addresses in the PIM-SSM range.

```
create vlan v12
create vlan v13
configure v12 add port 1
configure v13 add port 2
configure v12 ipaddress 12.1.1.1/24
configure v13 ipaddress 11.1.1.1/24
configure pim add vlan all sparse
enable ipforwarding
enable ipmcforwarding
enable igmp IGMPv3
configure pim ssm range default
enable pim ssm vlan v13
enable pim
```

**Note**

(*;G)s are created for groups outside the SSM range. SSM may not be enabled for the ingress VLAN (see Table 148 on page 1553).

**PIM Snooping Configuration Example**

Figure 254 shows a network configuration that supports PIM snooping.
In Figure 254 Layer 3 switches S2, S3, S4, and S5 are connected using the Layer 2 switch S1 through the VLAN comm_vlan. Switches S3, S4, and S5 are multicast capable switches, and switch S2 is a non-multicast capable switch, which has no multicast routing protocol running.

Without PIM snooping, any ingress multicast data traffic on comm_vlan is flooded to all the switches, including switch S2, which does not support multicast traffic. IGMP snooping does not reduceflooding because it floods the multicast traffic to all router ports.

The network design calls for most multicast traffic to egress switch S5. PIM snooping helps by intercepting the PIM joins received from the downstream routers and forwarding multicast traffic only to those ports that received PIM joins.

**Switch S1 (PIM Snooping Switch) Configuration Commands**

The following is an example configuration for the PIM snooping switch S1:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1,2,3,4
disable igmp snooping
disable igmp_snooping comm_vlan
enable pim snooping
enable pim snooping comm_vlan
```

**Switch S3 Configuration Commands**

The following is an example configuration for switch S3, which also serves as an RP:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1
configure comm_vlan ipa 10.172.168.4/24
enable ipforwarding comm_vlan
enable ipmcforwarding comm_vlan
configure pim add vlan comm_vlan sparse
configure ospf add vlan comm_vlan area 0.0.0.0
create vlan sender_vlan
configure vlan sender_vlan add port 2
```
Switch S5 Configuration Commands

The following is an example configuration for switch S5, which serves as the last hop router for multicast traffic:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1
configure comm_vlan ipa 10.172.168.2/24
enable ipforwarding comm_vlan
enable ipmcfowarding comm_vlan
configure pim add vlan comm_vlan sparse
configure ospf add vlan comm_vlan area 0.0.0.0

create vlan receiver_vlan
configure vlan sender_vlan add port 1
configure sender_vlan ipa 10.172.170.4/24
enable ipforwarding comm_vlan
enable ipmcfowarding comm_vlan
configure pim add vlan comm_vlan sparse
configure ospf add vlan comm_vlan area 0.0.0.0

enable pim
enable ospf

configure pim crp static 10.172.169.4 pim_policy // RP is configured using the policy pim_policy for the group 224.0.0.0/4
```

Switch S4 Configuration Commands

The following is an example configuration for switch S4, which is neither an LHR nor a RP:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1
configure comm_vlan ipa 10.172.168.3/24
enable ipforwarding comm_vlan
enable ipmcfowarding comm_vlan
configure pim add vlan comm_vlan sparse
configure ospf add vlan comm_vlan area 0.0.0.0

enable pim
enable ospf

configure pim crp static 10.172.169.4 pim_policy // RP is configured using the policy pim_policy for the group 224.0.0.0/4
```

Switch S2 Configuration Commands

The following is an example configuration for switch S2, which is not enabled for PIM:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1
configure comm_vlan ipa 10.172.168.6/24
```
enable ipforwarding comm_vlan
enable ipmcforwarding comm_vlan
configure ospf add vlan comm_vlan area 0.0.0.0
enable ospf

**PIM Snooping Example Configuration Displays**

After the example configuration is complete, multicast receivers connect to the network through switch S5 and multicast sources connect through switch S3.

When switch S5 receives an IGMP request from the receiver_vlan for group 225.1.1.1, it sends a PIM (*, G) join towards switch S3, which is the RP. The PIM snooping feature on switch S1 snoops the (*, G) join, and the resulting entry can be viewed by entering the following command at switch S1:

```
# show pim snooping vlan comm_vlan
```

<table>
<thead>
<tr>
<th>Source</th>
<th>Group</th>
<th>RP</th>
<th>UpPort</th>
<th>DownPort</th>
<th>Age</th>
<th>HoldTime</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>225.1.1.1</td>
<td>10.172.169.4</td>
<td>1</td>
<td>2</td>
<td>15</td>
<td>210</td>
</tr>
</tbody>
</table>

Neighbor IP    DR Port Age Hold Time
10.1272.168.4 YES 1 2 105
10.1272.168.2 NO 2 2 105
10.1272.168.3 NO 3 2 105

Once multicast traffic arrives from the sender_vlan, the LHR (switch S2) sends the (S, G) join message, which is snooped by the PIM snooping switch, switch S1. The resulting entries can be viewed by entering the following command at switch S1:

```
# show pim snooping vlan comm_vlan
```

<table>
<thead>
<tr>
<th>Source</th>
<th>Group</th>
<th>RP</th>
<th>UpPort</th>
<th>DownPort</th>
<th>Age</th>
<th>HoldTime</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.172.169.10</td>
<td>225.1.1.1</td>
<td>10.172.169.4</td>
<td>1</td>
<td>2</td>
<td>15</td>
<td>210</td>
</tr>
</tbody>
</table>

Neighbor IP    DR Port Age Hold Time
10.1272.168.4 YES 1 2 105
10.1272.168.2 NO 2 2 105
10.1272.168.3 NO 3 2 105

Multicast traffic is forwarded only to those ports that have received (*, G) or (S, G) joins and designated router (DR) ports.

**Multicast VLAN Registration**

Multicast VLAN Registration (MVR) is designed to support distributing multicast streams for IPTV to subscribers over a Layer 2 network. In a standard Layer 2 network, a multicast stream received on a VLAN is not forwarded to another VLAN. The streams are confined to the Layer 2 broadcast domain. In an IGMP snooping environment, streams are forwarded only to interested hosts on a VLAN. For inter-VLAN forwarding (routing) a multicast routing protocol, such as PIM/DVMRP must be deployed.

MVR breaks this basic rule, so that a stream received over Layer 2 VLANs is forwarded to another VLAN, eliminating the need for a Layer 3 routing protocol. It simplifies the multicast stream distribution and is a better solution for IPTV-like services. With MVR, a multicast stream is forwarded to all VLANs containing interested hosts.
Figure 255: Standard VLAN Compared to an MVR VLAN

In the above figure, the left side shows a standard VLAN carrying a multicast stream.

The host H1 receives the multicast stream because it resides on VLAN Vlan1, but host H2 does not receive the multicast traffic because no IP multicast routing protocol forwards the stream to VLAN Vlan2. On the right side of the figure, H2 does receive the multicast stream. Because Vlan1 was configured as an MVR VLAN, the multicast stream is forwarded to the other VLANs on the switch containing hosts that have requested the stream. To configure a VLAN as an MVR VLAN, use the following command: `configure mvr add vlan vlan-name`

Typically, IGMP snooping is enabled, so only hosts that have requested a stream can see the multicast traffic. For example, another host on VLAN2 cannot receive the traffic unless it has sent an IGMP request to be included in the group.

Notice that only VLAN1 is MVR enabled. Configure MVR only on the ingress VLAN. To enable MVR on the switch, use the following command: `enable mvr`

Basic MVR Deployment

Because MVR is primarily targeted for IPTV and similar applications, a basic deployment for that application is shown Figure 256. In the figure, an IPTV server is connected through a router to a network of switches. Switch 1 has three customer VLANs, Vlan2, Vlan3, and Vlan4. The multicast streams are delivered through the network core (Metro Ethernets), which often use a ring topology and some kind of redundant protection to provide high availability. For example, McastVlan forms a ring through switches Switch1 through Switch4. The link from Switch2 to Switch4 is shown as blocked, as it would be if some form of protection (such as EAPS) is used.
Without MVR, there are two ways to distribute multicast streams in this topology:

- Extend subscriber VLANs (Vlan2, Vlan3, and Vlan4) to the network core, by tagging the ports connecting the switches.
- Configure all VLANS with an IP address and run PIM or DVMRP on each switch.

There are problems with both of these approaches. In the first approach, multiple copies of the same stream (IPTV channel) would be transmitted in the core, wasting bandwidth. In the second approach, all switches in the network core would have to be Layer 3 multicast aware, and would have to run a multicast protocol. Typical network cores are Layer 2 only.

MVR provides a simple solution to this problem if McastVlan in Switch1 is configured with MVR, it leaks the traffic into the local subscriber VLANs that contain hosts that request the traffic. For simple cases, perform these configuration steps:

- Configure MVR on McastVlan.
- Configure an IP address and enable IGMP and IGMP snooping on the subscriber VLANs (by default IGMP and IGMP snooping are enabled on Extreme Networks switches).
- For all the multicast streams (IPTV channels), configure static IGMP snooping membership on the router on McastVlan.
- Enable MVR on the switches in the network.

**Note**

MVR works best with IGMPv1 and IGMPv2. We recommend that you do not use MVR with IGMPv3.
The strategy above conserves bandwidth in the core and does not require running PIM on the subscriber switches.

In this topology, a host (for example, a cable box or desktop PC) joins a channel through an IGMP join message. Switch1 snoops this message and adds the virtual port to the corresponding cache’s egress list. This is possible because an MVR enabled VLAN can leak traffic to any other VLAN. When the user switches to another channel, the host sends an IGMP leave for the old channel and a join for the new channel. The corresponding virtual port is removed from the cache for the old channel and is added to the cache for the new channel.

As discussed in Static and Dynamic MVR on page 1580, McastVlan also proxies IGMP joins learned on other VLANS to the router. On an MVR network it is not mandatory to have a router to serve the multicast stream. All that is required is to have a designated IGMP querier on McastVlan. The IPTV server can also be directly connected to McastVlan.

Static and Dynamic MVR

Static MVR

In a typical IPTV network, there are several high demand basic channels. At any instant there is at least one viewer for each of these channels (streams), and they should always be available at the core (ring). When a user requests one of these channels, it is quickly pulled locally from the multicast VLAN. You have the option to use the static router configuration in each of the switches in the core. But this will cause all the channels to be available in the core, which may not be desired. For example, on an Extreme Networks router, you can use the following commands:

configure igmp snooping {vlan} vlan_name ports port_list add static router

You can use the static MVR configuration and choose the groups for which the multicast stream should be flooded. If a multicast stream for a group in the static MVR range is received on an MVR enabled VLAN, it is always flooded on the MVR VLAN. This allows the neighbor switch in the ring to receive all the static MVR streams.

Dynamic MVR

In contrast, since a video content provider would like to provide a variety of on-demand and other premium channels, there are often many lower demand (fewer viewers) premium channels that cannot all be made available simultaneously at the core network. These should be streamed from the router only if requested by a host.

IGMP is the standard method used by a host to request a stream. However, IGMP packets are constrained to a VLAN. Thus, subscribers’ IGMP join requests on the VLAN cannot be forwarded onto other VLANS. You can use a dynamic MVR configuration, and choose the groups for which the IGMP join requests should be proxied over the MVR VLAN. Thus, in Figure 256 on page 1579, McastVlan sends join and leave messages on behalf of Vlan2, Vlan3, and Vlan4. The router receives the messages on McastVlan and streams corresponding channels onto the core network. This provides on-demand service, and an administrator does not need to configure static IGMP on the router for each of these channels.
Configuring MVR Address Range

By default, all multicast groups belong to MVR address range. Use the following command to specify the MVR address range:

```
configure mvr vlan vlan-name mvr-address (policy-name | none)
```

- Only the groups listed in the policy with "allow" action belong to MVR address range.
- For non-MVR groups, snoop cache is created and join requests are not proxied over MVR VLAN.

Configuring Static and Dynamic MVR

By default, all MVR streams are static.

- Use the following command to specify which groups are static:
  
  ```
  configure mvr vlan vlan-name static group (policy-name | none)
  ```

- Only the groups listed in policy with "allow" action are static. Any other groups in MVR address range are dynamic.
- The groups in policy with "deny" action are dynamic. Any other groups in MVR address range are also dynamic, unless explicitly configured in the policy with "allow" action.
- A group should not be configured to be both static and dynamic.

MVR Configuration Example

The following example configuration is a two DUT scenario, in L2 mode, with no routing protocol or PIM configured.

- DUT-1 is sender
- DUT-2 is receiver
- VLAN v1 spans over DUT-1 and DUT-2, DUT-2 also has v2 where IGMP joins are coming IN (225.1.1.1)
- DUT-2 has a VLAN v3, which also has a receiver connected sending IGMP join for same group as v2 (225.1.1.1)
- VLAN v1 in the DUT-2 has another port apart from the trunk port, no joins are being sent on this port.

Configure MVR on vlan v1 on DUT-2

```
# show config "mcmgr"
#
# Module mcmgr configuration.
#
enable mvr vr VR-Default
configure mvr add vlan v1
configure mvr vlan v1 mvr-address none
configure mvr vlan v1 static group none*
  *X460-48t.158 
```

The traffic will be flooded for the group only on MVR vlan (v1).

Since there are IGMP joins coming in on v2 and v3, v2, v3, and the second port in the MVR vlan v1 will receive traffic.

Configure the following policy file;

```
# vi mvrPolicy.polentry policy1 {
if match any { 
```
When applying this policy file under static group on DUT-2:

```
# configure mvr vlan v1 static group mvrPolicy
# configure mvr vlan v1 mvr-address none
```

When the policy file contains "permit", the traffic flows to v2, v3, and the second port in MVR VLAN.

When the policy file is changed to "deny", the second port in the MVR VLAN v1 will stop receiving the traffic.

If you configure static policy (by default – permit), traffic for that group range will always be available in the MVR VLAN, that is, it will be forwarded to all the ports in MVR VLAN.

When applying this policy file under mvr-address (Dynamic) on DUT-2:

```
# configure mvr vlan v1 static group none
# configure mvr vlan v1 mvr-address mvrPolicy
```

When the policy file contains "permit", the traffic flows to v2, v3 and the second port in MVR vlan.

When the policy file is changed to "deny", the second port in MVR VLAN v1 continues receiving traffic, but VLAN v2 and v3 stop receiving traffic, in spite of IGMP groups being learned. This is because the join on v2 and v3 will not be leaked to MVR VLAN.

Essentially, the dynamic policy does not directly apply on traffic, but it affects the joins, based on which traffic is forwarded or blocked.

Dynamic means only if the join is sent then traffic is forwarded.

The join is leaked to MVR VLAN so traffic from MVR VLAN will be received by other VLANs (v2 and v3).

To confirm if a join was leaked to MVR VLAN use the show igmp group command. It should have the group learned on MVR VLAN (v1) with port as "MVR".

**MVR Forwarding**

The goal for MVR is to limit the multicast traffic in the core Layer 2 network to only the designated multicast VLAN. If the backbone Layer 2 port is tagged with multiple VLANs, as shown in Figure 257 on page 1583, a set of rules is needed to restrict the multicast streams to only one VLAN in the core.
The core network has 2 more VLANs, vc1 and vc2, to provide other services. With MVR, multicast traffic should be confined to McastVlan, and should not be forwarded to vc1 and vc2. It should be noted that MVR is configured only on the ingress VLAN (McastVlan). MVR is not configured on any other VLANs.

In the same way as the IGMP snooping forwarding rules, the multicast stream is forwarded onto member ports and router ports on the VLAN. For a stream received on MVR enabled ports, this rule is extended to extend membership and router ports to all other VLANs. This rule works well on the topology in Figure 257. However, in a tagged core topology, this rule forwards traffic onto VLANs, such as vc1 and vc2, on ports PC1 and PC2. This results in multiple copies of same stream on the core network, thus reintroducing the problem that MVR was intended to solve.

To avoid multiple copies of the same stream, MVR forwards traffic with some special restrictions. MVR traffic is not forwarded to another VLAN unless a host is detected on the port. On the ingress MVR VLAN, packets are not duplicated to ports belonging to MVR VLANs. This is to prevent duplicate multicast traffic streams on ingress ports. Streams belonging to static MVR groups are always forwarded on MVR VLANs so that any host can join such channels immediately. However, dynamic groups are streamed from the server only if some host is interested in them. A command is provided to receive traffic on a port which is excluded by MVR. However, regular IGMP rules still apply to these ports, so the ports must have a router connected or an IGMP host to receive the stream.

These rules are to prevent multicast packets from leaking into an undesired virtual port, such as p2 on VLAN pc2 in Figure 257. These rules also allow that, in most topologies, MVR can be deployed with minimal configuration. However, unlike EAPS and STP (Spanning Tree Protocol), MVR is not intended to be a Layer 2 protocol to solve packet looping problems. Since multicast packets leak across VLANs, one can misconfigure and end up with a multicast storm. MVR does not attempt to solve such problems.

**Note**

If a port is blocked by Layer 2 protocols, that port is removed from the egress list of the cache. This is done dynamically per the port state.

For most situations, you do not need to manually configure ports to receive the MVR multicast streams. But if one of the forwarding rules denies forwarding to a port that requires the streams, you can manually receive the MVR multicast streams by using the following command:

```
configure mvr vlan vlan_name add receiver port port-list
```
Inter-Multicast VLAN Forwarding

In Basic MVR Deployment on page 1578, only simple topologies are considered, in which subscribers on different VLANs access a multicast VLAN. There are topologies where streams need to be forwarded onto another multicast VLAN, as shown in Figure 258. In this figure, a Multicast Service Provider (MSP) multicast VLAN is attached to ports 1:1-2 on both switches, SW1 and SW2. On the customer side, another multicast VLAN, delivers multicast streams to other switches around the ring.

Figure 258: Inter-Multicast VLAN Forwarding

In this topology, a multicast stream can be leaked into the customer multicast network through either switch SW1 or SW2. However, as described in MVR Forwarding on page 1582, packets are not forwarded to router ports (ports 1:4 and 1:5 can be router ports if SW2 is an IGMP querier). To get around this, MVR needs to be configured on CustVlan either on SW1 or SW2. Since the forwarding rules apply only to non-MVR VLANs, traffic from one MVR VLAN is leaked into the router ports of another VLAN, if MVR is enabled on that.

In the topology above, the MSP multicast VLAN is carried on two switches that also carry the customer multicast VLAN. When multiple switches carry both multicast VLANs, it is imperative that MVR is configured on only one switch. Only that switch should be used as the transit point for multicast streams from one multicast ring into another. Otherwise, duplicate packets are forwarded. Also on the non-MVR switches, the ring ports should be configured as static router ports, so that ring ports are excluded from forwarding packets onto the customer ring. There is no mechanism to elect a designated MVR forwarder, so it must be configured correctly.

MVR Configurations

MVR enables Layer 2 network installations to deliver bandwidth intensive multicast streams. It is primarily aimed at delivering IPTV over Layer 2 networks, but it is valuable in many existing EAPS or STP installations. This section explores a few possible deployment scenarios and configuration details. Of course, real world networks can be lot different from these examples. This section is meant to present some ideas on how to deploy MVR over existing networks, as well as to design new networks that support MVR.
**MVR with EAPS**

Since MVR is designed with a Layer 2 ring topology in mind, it is strongly recommended that it should be deployed with EAPS. The MVR plus EAPS combination provides a superior solution for any triple play network, where the service provider intends to provide data, voice, and video services. EAPS is a proven solution for providing sub-second SONET-like protection to Layer 2 rings. For more detail on EAPS refer to EAPS on page 1043.

Consider a typical EAPS topology in Figure 259, where 3 VLANs on the core ring serve various clients on each switch. To provide video service, one of the VLANs on the EAPS ring is designated as a multicast VLAN. MVR is enabled only on this VLAN (mcastvlan). V1 is the control VLAN, and V2 is another protected VLAN. A router serving the multicast feed would typically run PIM on mcastvlan, to support the static and dynamic IGMP membership on the VLAN.

![Figure 259: MVR on an EAPS Ring](image)

The following is a typical configuration for the router and switches.

**Router1:**

```plaintext
create vlan mcastvlan
configure mcastvlan add port 1:1
create vlan server
configure server add port 1:2
configure mcastvlan ipaddress 10.1.1.1/24
configure server ipaddress 11.1.1.1/24
configure igmp snooping mcastvlan port 1:1 add static group 239.1.1.1
enable ipforwarding
enable ipmfcforwarding
configure igmp snooping leave-timeout 2000
```
configure pim add vlan all
enable pim

Switch1:
create vlan mcastvlan
create vlan v1
create vlan v2
create vlan vlan2
configure vlan vlan2 add port 1:3
configure vlan vlan2 ipaddress 10.20.1.1/24
configure mcastvlan tag 20
configure mcastvlan add port 1:1,1:2 tag
configure mvr add vlan mcastvlan
configure vlan v1 tag 30
configure v1 add port 1:1,1:2 tag
configure vlan v2 tag 40
configure v2 add port 1:1,1:2 tag
create eaps e1
configure eaps e1 mode transit
configure eaps e1 add control vlan v1
configure eaps e1 add protect vlan mcastvlan
configure eaps e1 add protect vlan v2
configure eaps port primary port 1:1
configure eaps port secondary port 1:2
enable eaps
enable mvr

Switch3:
create vlan McastVlan
create vlan v1
create vlan v2
configure mcastvlan tag 20
configure mcastvlan add port 1:2,1:3 tag
configure mcastvlan add port 1:1
configure mvr add vlan mcastvlan
configure vlan v1 tag 30
configure v1 add port 1:2,1:3 tag
configure vlan v2 tag 40
configure v2 add port 1:2,1:3 tag
create eaps e1
configure eaps e1 mode master
configure eaps e1 add control vlan v1
configure eaps e1 add protect vlan mcastvlan
configure eaps e1 add protect vlan v2
configure eaps port primary port 1:3
configure eaps port secondary port 1:2
enable eaps
enable mvr

Note
In this example, Switch3 is the EAPS master, but any of the other switches in the ring could have been configured as the master.

MVR with STP

In a Layer 2 ring topology, MVR works with STP as it works with EAPS. However, in other Layer 2 topologies, additional configuration steps may be needed to make sure that multicast feeds reach all
network segments. Extra configuration is required because all ports in the VLAN are part of an STP domain, so that solely by examining the configuration it is not clear whether a port is part of bigger ring or is just serving a few hosts. In EAPS this problem is solved by distinguishing between configured primary or secondary ports from other VLAN ports. Consider a simplified Layer 2 STP network as shown in Figure 260.

![Figure 260: MVR with STP](image)

In this topology, subscribers are in a Layer 2 cloud on VLAN V1.

STP is configured for all ports of V1. Since V1 spans on the ring as well, multicast cannot be forwarded on V1 blindly. Forwarding rules (described in MVR Forwarding on page 1582), dictate that multicast traffic is not forwarded on STP enabled ports. This is to make sure that multiple copies of multicast packets are not forwarded on the ring. However, since other STP enabled ports on V1 (1:3, 1:4) are not part of the ring multicast stream, they need to be configured so that they get the packets. To configure the ports to receive packets, use the following command (mentioned in MVR Forwarding on page 1582):

```bash
configure mvr vlan vlan-name add receiver port port-list
```

**Note**

If the Layer 2 cloud is connected back to ring ports, traffic may end up leaking into VLAN V1 in the ring. There is no way to avoid that. So, such topologies must be avoided.

The following is a typical configuration for Switch 1:

```bash
create vlan v1
configure v1 tag 200
configure v1 add port 1:1, 1:2 tag
configure v1 add port 1:3, 1:4
create vlan mvlan
configure mvlan add port 1:1, 1:2
configure mvr add vlan mvlan
create stpd stp1
```
configure stp1 add vlan v1 port all
enable stpd stp1 port all
configure mvr vlan v1 add receiver port 1:3,1:4
enable mvr

MVR in a VMAN Environment

In the case of a VMAN, a packet is tagged with a VMAN tag in addition to a possible VLAN tag. This is to provide VLAN aggregation for all customer traffic in the VMAN ring. Each customer is given its own VLAN, and traffic from all customers can be tunneled on a single VMAN tag into the metro ring to an outside Broadband Remote Access Server (BRAS). In a VMAN network, multicast traffic can be distributed over a separate VLAN in the metro core. These packets are not subjected to VMAN tunneling. Thus, IPTV service can be provided on this multicast VLAN on a VMAN network.

MVR deployment in a VMAN environment is not any different from that in an EAPS environment, since a separate multicast VLAN on the metro ring is used for multicasting. However, it provides interesting capabilities to MSPs for their video offerings. Different service bundles can be offered on separate VLANs. Packets are not forwarded to any metro link segments where a stream is not required.

Figure 261 illustrates an example design for MVR in a VMAN environment. Any multicast packet entering on MVlan is forwarded on MVlan to the next switch. These multicast packets are not tunneled.

With MVR, switches on the VMAN do not have to run any routing protocol. If MVR is enabled on the multicast VLAN, MVlan, traffic is pulled from the IPTV server. Such multicast packets egressing from the CE port are always untagged. The downstream DSLAM distributes untagged multicast packets to the respective subscriber VLANs.
The following is a typical configuration for Switch 1 in the above figure:

```bash
create vman vman2
configure vman vman2 tag 300
configure vman vman2 add port 2:2-2:3 untagged
configure vman vman2 add port 1:1,1:2 tagged
enable port 2:*
enable port 1:*
create vlan mvlan
configure vlan mvlan tag 200
configure vlan mvlan add port 1:1,1:2 tag
configure mvr add vlan mvlan
enable mvr
```

### Displaying Multicast Information

#### Displaying the Multicast Routing Table

- To display part or all of the entries in the multicast routing table, use the following command:

  ```bash
  show iproute {ipv4} {{vlan} name | [ipaddress netmask | ipNetmask] | origin [direct | static | mbgp | imbgp | embgp]} multicast {vr vr_name}
  ```
Displaying the Multicast Cache

- The multicast cache stores information about multicast groups. To display part or all of the entries in the multicast cache, use the following command:

```
show mcast cache {{vlan vlan_name} {{[group grpaddressMask | grpaddressMask] {source sourceIP | sourceIP}}} {type [snooping | pim | mvr]}} {summary}}
```

Looking Up a Multicast Route

- To look up the multicast route to a specific destination, use the following command with the `multicast` option:

```
rtlookup [ipv4_address | ipv6_address] { unicast | multicast | rpf } {vr vr_name}
```

Looking Up the RPF for a Multicast Source

- To look up the RPF for a multicast source, use the following command with the `rpf` option:

```
rtlookup [ipv4_address | ipv6_address] { unicast | multicast | rpf } {vr vr_name}
```

Displaying the PIM Snooping Configuration

- To display the PIM snooping configuration for a `VLAN`, use the following command:

```
show pim snooping {vlan} vlan_name
```

Troubleshooting PIM

**Multicast Trace Tool**

The multicast trace tool is the multicast equivalent of unicast trace route mechanism and is an effective tool for debugging multicast reachability problems. This tool is based on an IETF draft and uses IGMP. Because it is harder to trace a multicast path from the source to the destination, a multicast trace is run from the destination to the source. The multicast trace can be used to do the following:

- Locate where a multicast traffic flow stops
- Identify sub-optimal multicast paths

A multicast trace is used for tracing both potential and actual multicast forwarding tree paths. When the multicast tree is established and traffic is flowing, this tool traces the actual traffic flow. If there is no traffic while executing the command, this tool displays the potential path for the group and source being traced.

You can direct a multicast trace to any network destination, which can be a multicast source or destination, or a node located between a source and destination. After you initiate the trace, a multicast trace query packet is sent to the last-hop multicast router for the specified destination. The query
packet contains the source address, group address, destination/receiver address, response address, maximum number of hops, and TTL to be used for the multicast trace response.

The previous hop router selection is based on the multicast routing protocol and the state for the S,G entry in the processing router.

For example:
- If there is no S,G state in the router, the parent closest to the RP is chosen as the previous hop.
- If the S,G state exists in the router, the parent closest to the source is chosen as the previous hop.

The last hop router converts the multicast trace query into a unicast traceroute request by appending response data (for the last hop router) into the received query packet, and the last hop router forwards the request packet to the router that it believes is the proper previous hop for the given source and group.

Each multicast router adds its response data to the end of the request packet, and then forwards the modified unicast request to the previous hop.

The first hop router (the router that determines that packets from the source originate on one of its directly connected networks) changes the packet type to response packet and sends the completed response to the query generator. If a router along the multicast route is unable to determine the forwarding state for a multicast group, that router sends a response back to the originator with NO ROUTE forwarding code.

To initiate a multicast trace, use the following command:

```bash
mtrace source src_address {destination dest_address} {group grp_address} {from from_address} {gateway gw_address} {timeout seconds} {maximum-hops number} {router-alert [include | exclude]} {vr vrname}
```

**Multicast Router Information Tool**

The multicast router information tool is an ExtremeXOS command that allows you to request information from a specific multicast router. For more information, see the command description for the following command:

```bash
mrinfo {router_address} {from from_address} {timeout seconds} {multiple-response-timeout multi_resp_timeout} {vr vrname}
```
Multicast Listener Discovery (MLD) Overview
Managing MLD

This chapter introduces IPv6 multicast, which allows a single IPv6 host to send a packet to a group of IPv6 hosts, and the features and configuration of the Multicast Listener Discovery (MLD) protocol. For more information on IPv6 multicasting, refer to the following publications:
- RFC 2710—Multicast Listener Discovery (MLD) for IPv6
- RFC 3810—Multicast Listener Discovery Version 2 (MLDv2) for IPv6

Multicast Listener Discovery (MLD) Overview

Multicast Listener Discovery (MLD) is a protocol used by an IPv6 host to register its IP multicast group membership with a router. To receive multicast traffic, a host must explicitly join a multicast group by sending an MLD report; then, the traffic is forwarded to that host. Periodically, the router queries the multicast group to see if the group is still in use. If the group is still active, a single IP host responds to the query, and group registration is maintained.

MLD is the IPv6 equivalent to IGMP (Internet Group Management Protocol), and MLDv1 is equivalent to IGMPv2. The ExtremeXOS software supports both MLDv1 and MLDv2 protocol.

Note
This release does not support MVR, PVLAN, VLAN (Virtual LAN) Aggregation, and Multicast Troubleshooting tools for MLD/IPv6.

ExtremeXOS Resiliency Enhancement for IPv6 Static Routes

The ExtremeXOS Resiliency Enhancement feature provides a resilient way to use ECMP (Equal Cost Multi Paths) to load balance IPv6 traffic among multiple servers or other specialized devices. ExtremeXOS automatically manages the set of active devices using ECMP static routes configured with ping protection to monitor the health of these routes. Such servers or specialized devices do not require special software to support Bidirectional Forwarding Detection (BFD), or IP routing protocols such as OSPF (Open Shortest Path First), or proprietary protocols to provide keepalive messages. ExtremeXOS uses industry-standard and required protocols ICMPv6/Neighbor Discovery for IPv6 to accomplish the following automatically:
- Initially verify devices and activate their static routes, without waiting for inbound user traffic, and without requiring configuration of device MAC addresses.
- Detect silent device outages and inactivate corresponding static routes.
- Reactivate static routes after device recovery, or hardware replacement with a new MAC address.
ExtremeXOS currently supports similar protection and resiliency using Bidirectional Forwarding Detection (BFD) on IPv4 and IPv6 static routes. However, BFD can only be used when the local and remote device both support BFD.

**Managing MLD**

**Enabling and Disabling MLD on a VLAN**

MLD is disabled by default on all VLANs. You can enable MLD using the `enable mld {vlan vlan name} {MLDv1 | MLDv2}` command.

This allows IPv6 hosts to register with IPv6 multicast groups and receive IPv6 multicast traffic.

- To disable MLD on a VLAN after it has been enabled, use the `disable mld {vlan name}` command.
- To enable MLD on a VLAN after it has been disabled, use the `enable mld {vlan vlan_name} {MLDv1 | MLDv2}` command.

**MLD Snooping**

Similar to IGMP snooping, MLD snooping is a Layer 2 function of the switch; it does not require multicast routing to be enabled. In MLD snooping, the Layer 2 switch keeps track of MLD reports and only forwards multicast traffic to the part of the local network that requires it. MLD snooping optimizes the use of network bandwidth and prevents multicast traffic from being flooded to parts of the local network that do not need it.

MLD snooping is disabled by default on all VLANs in the switch.

When MLD snooping is disabled on a VLAN, all MLD and IPv6 multicast traffic floods within the VLAN.

MLD snooping expects at least one device on every VLAN to periodically generate MLD query messages.

- Enable or disable MLD snooping:

  
  ```
  enable mld snooping
  ```

  ```
  disable mld snooping
  ```

Multicast packets with a scope id less than 2 are not forwarded by the MLD snooping enabled switch. Kill entry is installed in the hardware for this traffic.

Multicast packets with a scope id of 2 and group address in the range of FF02::/111 (Addresses allocated by IANA as per RFC 3307) are always flooded to all ports of the VLAN by hardware and a copy of the packet is provided to slow path. There are no cache entries in software or hardware for these addresses.

- Multicast packets with a scope id of 2 and group address as solicited multicast address (FF02::!FFXX:XXXX/104) are flooded to all ports of VLAN for 135 seconds (Default MLD query interval + Maximum response time), if there are no members for this group.
Otherwise, the traffic is forwarded based on the snooping database. Multicast cache entries for these addresses are maintained only in the software and traffic is always slow path forwarded.

Multicast addresses with a scope id of 2 and that do not qualify in the above categories will be forwarded based on the snooping database.

Cache entries for these multicast addresses will be installed in hardware. Unregistered packets are dropped.

- In general, all multicast data traffic on a PIMv6 enabled VLAN is controlled by the PIMv6 protocol. However, multicast traffic with either the group address or source address as the link local address will not be controlled by PIMv6. Instead, it will be L2 forwarded based on the snooping database.

For multicast packets with a scope id greater than 2 on PIMv6 enabled VLANs, cache entries are controlled by the PIMv6 protocol.

PIMv6 provides a list of egress VLANs for which packets need to be forwarded. The snooping database is used to construct the set of ports for ingress VLANs as well as for each egress VLAN.

On PIMv6 disabled VLANs, traffic is forwarded based on the snooping database on the ingress VLAN.

In both cases, cache entry is installed in the hardware, and traffic is fast path forwarded.

- The MLD snooping proxy feature is enabled automatically when MLD snooping is enabled. This feature optimizes the forwarding of MLDv1 reports. The following conditions apply for each group:
  - Only the first received MLD join is forwarded upstream.
  - Only the MLD leave for last host is forwarded upstream.

  When a switch receives an MLD leave message on a port, it sends a group-specific query on that port if proxy is enabled (even if it is a non-querier). The switch removes the port from the group after the leave timeout (a configurable value from 0 - 175000ms with a default of 1000ms). If all the ports are removed from the group, the group is deleted and the MLD leave is forwarded upstream. If MLD snooping proxy is disabled, then all the MLD reports are forwarded upstream.

  **Note** MLD snooping proxy does not apply to MLDv2 reports.

- MLD snooping is implemented primarily through ACLs, which are processed on the interfaces. These special purpose ACLs are called MLD snooping hardware filters. The software allows you to choose between two types of MLD snooping hardware filters: per-port filters (the default) and per-VLAN filters.

  The two types of MLD snooping hardware filters use switch hardware resources in different ways.

- The two primary hardware resources to consider when selecting the MLD snooping hardware filters are the Layer 3 multicast forwarding table, and the interface ACLs. The size of both of these hardware resources is determined by the switch model. In general, the per-port filters consume more...
resources from the multicast table and less resource from the ACL table. The per-VLAN filters consume less space from the multicast table and more from the ACL table.

- Using the per-port filters can fill up the multicast table and place an extra load on the CPU. To avoid this, configure the switch to use the per-VLAN filters.

**Note**
The impact of the per-VLAN filters on the ACL table increases with the number of VLANs configured on the switch. If you have a large number of configured VLANs, we suggest that you use the per-port filters.

### MLD Snooping Filters
MLD snooping filters allow you to configure a policy file on a port to allow or deny MLD report and leave packets coming into the port.

(For details on creating policy files, see Policy Manager on page 632.) The MLD snooping filter feature is supported by MLDv1 and MLDv2.

**Note**
Do not confuse MLD snooping filters with MLD snooping hardware filters explained in previous section. MLD snooping filters are software filters, and the action is applied at software level by the ExtremeXOS multicast manager.

For the policies used as MLD snooping filters, all the entries should be IPv6 address type entries, and the IPv6 address of each entry must not be in the range of FF02::/96.

Use the following template to create a snooping filter policy file that denies MLD report and leave packets for the FF03::1/128 and FF05::1/112 multicast groups:

```plaintext
# Add your group addresses between "Start" and "end"
# Do not touch the rest of the file!!!!
entry mldFilter {
  if match any {
    #------------------ Start of group addresses ------------------
    nlri FF03::1/128;
    nlri FF05::1/112;
    #------------------- end of group addresses -------------------
  } then {
    deny;
  }
}
entry catch_all {
  if {
    permit;
  }
}
```

After you create a policy file, use the following command to associate the policy file and filter to a set of ports:

```plaintext
configure mld snooping vlan vlan_name ports port_list filter [policy]
```

To remove the filter, use the `none` option.
To display the MLD snooping filters, use the following command:

```
show mld snooping {vlan} name filter
```

**Limiting the Number of Multicast Sessions on a Port**

The default configuration places no limit on the number of multicast sessions on each VLAN port. To place a limit on the number of learned MLD reports, or remove the limit, use the command:

```
configure mld snooping {vlan} vlan_name ports port_list join-limit [num_joins | no-limit]
```

**Configuring MLD Snooping**

- To configure the timers that control MLD operation, use the command:
  
  ```
  configure mld query_interval query_response_interval last_member_query_interval {robustness}
  ```

- Similar to IGMP snooping, MLD snooping is a Layer 2 function of the switch. It does not require multicast routing to be enabled. MLD snooping keeps track of MLD reports, and only forwards multicast traffic to that part of the local network that requires it. MLD snooping is disabled by default on all VLANs. If MLD snooping is disabled on a VLAN, all MLD and IPv6 multicast traffic floods within the VLAN. To enable MLD snooping, use the command:
  
  ```
  enable mld snooping {vlan name}
  ```

**Clearing MLD Group Registration**

To clear a single group or all groups in a VLAN learned through MLD, use the command:

```
clear mld group {v6grpipaddress} {{vlan name}}
```

**Configuring Static MLD**

In some situations, you might want multicast traffic to be forwarded to a port where a multicast-enabled host is not available (for example, when you test multicast configurations). Static MLD emulates a host or router attached to a switch port, so that multicast traffic is forwarded to that port, and the switch sends a proxy join for all the statically configured MLD groups when an MLD query is received. You can emulate a host to forward a particular multicast group to a port; and you may emulate a router to forward all multicast groups to a port.

- To emulate a host on a port, use the command:
  
  ```
  configure mld snooping {vlan} vlan_name{ ports port_list } add static group v6grpipaddress
  ```

- To emulate a multicast router on a port, use the command:
  
  ```
  configure mld snooping {vlan}vlan_name ports port_list add static router
  ```

- To remove these entries, use the corresponding commands:
  
  ```
  configure mld snooping {vlan} vlan_name {ports port_list } delete static group [all | v6grpipaddress]
  ```
  
  ```
  configure mld snooping {vlan} vlan_name ports port_list delete static router
  ```
MLD Loopback

Prior to ExtremeXOS 15.3.2, you could configure static groups, but it was necessary to specify port(s). As of 15.3.2, the configuration of dynamic groups is now supported. The MLD Loopback feature along with the existing static group feature supports the configuration of static and/or dynamic groups with or without ports.

A VLAN in loopback mode may not have ports associated with it, but its operational status is up. However, it is not possible to have multicast receivers on a VLAN without having a port. Sometimes, there is a need to pull the multicast traffic from upstream to the loopback VLAN for troubleshooting. The traffic need not always be forwarded to any ports/receivers. The MLD Loopback feature allows you to configure groups on a VLAN without specifying a port, so the traffic is pulled from upstream but not forwarded to any port.

The loopback (Lpbk) port is the logical port on a VLAN in the application context. When you configure a group on a VLAN but do not specify the port, the switch forms an MLDv1 join and assumes it to be received on the Lpbk port. A dynamic group ages out after the membership timeout if there are no other receivers. Membership joins refresh the dynamic group. The static group remains until it is removed from the configuration.

The following command is used to configure static or dynamic group entry:

```
configure mld snooping {vlan} vlan_name {ports portlist} add [static | dynamic] group ip_address
```

Displaying MLD Information

- To display MLD configuration and operation information, use the command:
  ```
  show mld group {{vlan} {name} | {v6grp|v6ip|v6ipaddress}} {MLDv2}
  ```
- To display the MLD static group information, use the command:
  ```
  show igmp snooping {vlan} name static [group | router]
  ```

MLD SSM Mapping

The MLD-SSM Mapping feature allows MLDv1 hosts to participate in SSM functionality, and eliminates the need for MLDv2. You can configure SSM map entries that specify the sources used for a group/group range for which SSM functionality is applied. You also have the option to configure domain name and DNS server to use to obtain the source list.

When a MLDV1 report is received, the configured sources are provided to PIM so that it can send source specific joins. When the host leaves, or when the membership times out, PIM is informed so that it can consider sending prunes.

**Note**
The sources mapped to only the LPM group are used.
**Feature Implementation Information**

- This feature is implemented as an extension to existing IGMP SSM support.
- The CLI commands for this feature are applicable in VR context.
- PIM is completely unaware of existence of this feature, so there is no change in PIM processing.
- On last hop the (S, G) cache created through MLDv1 join is similar to the (S, G) cache created as a result of RPT to SPT switchover in PIM-SM. There is no indication that the cache is created as result of MLDv1 join, or MLDv2 report.

**Limitations**

- Only 50 sources (static or dynamic) are allowed for each group address, or group range.

**Note**

The DNS server may send only 14 IPv6 source addresses in its response thereby limiting the number of dynamic sources supported.

- Only one DNS name is allowed for each group address/group range.

**SSM Address Range**

The address prefix FF3x::/32 is reserved by IANA for SSM use. All SSM addresses must have P=1, T=1 and plen=0. RFC 3306 mandates that the network prefix is zero, which results in the SSM address range to be in FF3x::/96 range. Since future documents may allow a non-zero network prefix, this feature allows the addresses in range FF3x::/32 in SSM map configuration. The default SSM range is FF3x::/96.

SSM address range is configured from the PIM context using the following command:

```
configure pim ipv6 ssm range default | policy policy_name
```

When this command is issued, PIM notifies MCMGR with the details of the SSM address range. MCMGR applies this range for the MLD SSM feature.

**Handling MLD Reports**

Table 150 captures the enhanced functionality.

<table>
<thead>
<tr>
<th>MLDv1 Join</th>
<th>MLD SSM Map Disabled</th>
<th>MLD SSM Map Enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group in SSM range but no map entries</td>
<td>Dropped</td>
<td>Dropped</td>
</tr>
<tr>
<td>Group in SSM range with map entries</td>
<td>Dropped</td>
<td>SSM map sources included</td>
</tr>
<tr>
<td>Group not in SSM range</td>
<td>SSM map sources not included</td>
<td>SSM map sources not included</td>
</tr>
</tbody>
</table>

MLDv1 reduction messages in the SSM range are accepted and processed normally. Multicast manager will send out a group-specific query and refresh the receivers on receiving joins.

When an MLDv2 report is received, following group records types are ignored if they refer to SSM group range:
• MODE_IS_EXCLUDE
• CHANGE_TO_EXCLUDE_MODE

Other group records in the same report are processed.

**SSM Data Forwarding**

L2 forwarding decision of SSM data traffic is taken by the Multicast manager. Sources configured in the SSM map are considered only when a MLDv1 receiver is connected to a port. For the same group, there may be another port on which only MLDv2 receiver is present. For this port, SSM map sources are not considered.

L3 forwarding decision of SSM data traffic is taken by PIM. PIM provides the list of egress VLANs to be included, and the multicast manager decides the egress ports on each of these VLANs.

**DNS Request/Response**

When a DNS name is configured for a group in an SSM map, a DNS request is sent to resolve the name. If static sources are already configured for the group, it takes precedence and the DNS request is not sent. This feature uses the AAAA record type. For example, if the multicast group is FF30::1234:5678 and the configured domain name is ext.foo.bar, then the DNS request is sent for 8.7.6.5.4.3.2.1.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.3.F.F.ext.xxx.xxx.

The DNS request is not sent every time a report is received. A DNS request is sent only in the following scenarios:

• When a DNS name is configured for a group.
• When the refresh ssm-map command is used.
• When the DNS age timer expires.

The DNS response may contain one or more addresses. These addresses are updated to the SSM mapping table against the specific group.

**Note**

LPM is used to match the group for a DNS response.

If a static source is configured for a group for which DNS resolved addresses are already present, the dynamic sources are flushed and the static sources are added. Static mapped addresses are preferred over DNS resolved addresses.

**DNS Timers**

The DNS age timer is a decrementing timer to zero and applies to a group/group range. The value of this timer is calculated by the following formula:

\[
\text{DNS age} = (\text{value of TTL in the DNS response}) + (\text{wait TTL})
\]

\[
\text{wait TTL} = 260 \text{ seconds}
\]

A DNS request is sent when receiving an MLDv1 report, but the TTL has expired. The source is not removed until the wait TTL time expires.
On receiving the DNS response, the existing DNS resolved addresses which are not in the DNS response are removed. Any new addresses in the DNS response are added and the DNS age timer is refreshed. The L2 SSM data caches are modified for the addresses removed, or added. PIM is notified to take action on L3 SSM caches.

If the DNS response is not received and the DNS age timer expires, the mapping entry is removed (if there are no static addresses). The SSM data traffic forwarding is stopped immediately when the group is removed.

**DNS Server**

This feature does not check or track DNS servers configured in the switch. You must correctly configure and administer the DNS server.

The following command is used to configure the DNS server:

```
configure dns-client add name-server ip_address {vr vr_name}
```

The server(s) are displayed using the following command:

```
# show dns-client
Number of domain suffixes: 0
Number of domain servers: 1
Name Server 0: 10.120.89.75 VR-Default
```

MCMGR uses nettools library to perform DNS lookups. gethostbyname_c is used by specifying the callback function to be invoked when DNS response is received.

**Configuring MLD SSM Mapping**

Use the following commands to configure MLD SSM Mapping in ExtremeXOS:

- Enable or disable MLD SSM Mapping on a VR: `[enable | disable] mld ssm-map { {vr} vrname }
- Add an MLD SSM Mapping entry on a VR: `configure mld ssm-map add v6groupnetmask [v6sourceip | src_domain_name] { {vr} vrname}
- Delete an MLD SSM Mapping entry on a VR: `configure mld ssm-map delete v6groupnetmask [v6sourceip | src_domain_name] { {vr} vrname}
- Delete all MLD SSM Mapping entries on a VR: `unconfigure mld ssm-map { {vr} vrname}
- Display the status of MLD-SSM mapping feature on a VR, and display the MLD-SSM mapping entries: `show mld ssm-map { v6groupnetmask } { {vr} vrname }
- Send out a DNS request for a particular group. On receiving the DNS response, the "DNS Age" in the SSM mapping entry is refreshed: `refresh mld ssm-map v6groupnetmask { {vr} vrname}
- Configure the DNS server: `configure dns-client add name-server ip_address {vr vr_name}
- Display the DNS Servers: `show dns-client
This chapter introduces MSDP (Multicast Source Discovery Protocol), an interdomain multicast protocol used to connect multiple multicast routing domains that run PIM-SM (Protocol Independent Multicast-Sparse Mode). This chapter discusses the features and configuration for PIM border, MSDP peers, mesh groups, anycast RP, SA cache, redundancy, and SNMP (Simple Network Management Protocol) MIBs.

**Note**
For more information about MSDP, refer to RFC 3618.

### MSDP Overview

**MSDP (Multicast Source Discovery Protocol)** is an interdomain multicast protocol used to connect multiple multicast routing domains that run Protocol Independent Multicast-Sparse Mode (PIM-SM).

MSDP speakers are configured on each PIM-SM domain. These speakers establish a peering relationship with other MSDP speakers through secured TCP connections. When the source sends traffic, the MSDP speaker learns about the source through its Rendezvous Point (RP). In turn, the RP advertises the source to its peers through Source Active (SA) messages. The peers receive these advertisements and inform their RPs about the presence of the active source in the other PIM-SM domain, which triggers the normal PIM operation in the corresponding domains.

For example, as businesses expand and networks grow in size, it might become necessary to connect PIM domains to allow multicast applications to reach other offices across the network. MSDP simplifies this process by providing a mechanism to connect those multicast routing domains without reconfiguring existing domains. Each PIM domain remains separate and has its own RP. The RP in each domain establishes an MSDP peering relationship over a TCP connection either with RPs in other domains or with border routers leading to other domains. When an RP learns about a new multicast source in its own domain (using the normal PIM registration process), it then sends a SA message to all of its MSDP peers, letting them know about the new stream. In this way, the network can receive multicast traffic from all over the network without having to reconfigure each existing PIM domain.
Supported Platforms

MSDP is supported on all platforms running a minimum software version of ExtremeXOS 12.0 with the Core license.

Our implementation of MSDP is compliant with RFC 3618 and RFC 3446, and compatible with other devices that are compliant with these standards.

Limitations

The limitations of MSDP are as follows:

• There is no support for MSDP operating with SA cache disabled (transit node). MSDP will always cache/store received SA messages.
• There is no support for logical RP.
• There is no support for MSDP on user-created virtual routers (VRs).
• RIP (Routing Information Protocol) routes are not used for peer-RPF checking. So, our implementation of MSDP does not exactly conform to rule (iii) in section 10.1.3 of RFC 3618. However, our implementation of MSDP uses BGP (Border Gateway Protocol)/OSPF (Open Shortest Path First) for peer-RPF checking as per rule (iii) in section 10.1.3.
• Read-write/read-create access is not supported on MSDP MIB objects.

PIM Border Configuration

To create a PIM-SM domain for MSDP, you must restrict the reach of Bootstrap Router (BSR) advertisements by defining a VLAN (Virtual LAN) border. BSR advertisements are not sent out of a PIM interface configured as a VLAN border, thereby defining a PIM domain for MSDP.

To configure a PIM VLAN border, use the command:

```
configure pim vlan_name border
```

MSDP Peers

MSDP peers exchange messages to advertise active multicast sources. The peer with the higher IP address passively listens to a well-known port number and waits for the side with the lower IP address to establish a Transmission Control Protocol (TCP) connection on port 639. When a PIM-SM RP that is running MSDP becomes aware of a new local source, it sends an SA message over the TCP connection to its MSDP peer. When the SA message is received, a peer-RPF check is performed to make sure the peer is toward the originating RP. If so, the RPF peer floods the message further. If not, the SA message is dropped and the message is rejected.

• Configure an MSDP peer using the command:

  ```
  create msdp peer remoteaddr {remote-as remote-AS} {vr vrname}
  ```

• Delete an MSDP peer using the command:

  ```
  delete msdp peer [all | remoteaddr] {vr vr_name}
  ```

• Display configuration and run-time parameters about an MSDP peer using the command:

  ```
  show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}
  ```
MSDP Default Peers

You can configure a default peer to accept all SA messages. Configuring a default peer simplifies the peer-RPF checking of SA messages. If no policy is specified, the current peer is the default RPF peer for all SA messages.

When configuring a default peer, you can also specify an optional policy filter. If the peer-RPF check fails, and a policy filter is configured, the default peer rule is applied to see if the SA message should be accepted or rejected.

You can configure multiple default peers with different policies. However, all default peers must either be configured with a default policy or not. A mix of default peers, with a policy and without a policy, is not allowed.

• Configure an MSDP default peer, and optional policy filter using the command:
  
  configure msdp peer [remoteaddr | all] default-peer {default-peer-policy filter-name} {vr vrname}

• Remove the default peer using the command:
  
  configure msdp peer [remoteaddr | all] no-default-peer {vr vrname}

• Verify that a default peer is configured using the command:
  
  show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}

Peer Authentication

MSDP supports TCP RSA Data Security, Inc. MD5 (Message-Digest Algorithm 5) Message-Digest Algorithm authentication (RFC 2385) to secure control messages between MSDP peers. You must configure a secret password for an MSDP peer session to enable TCP RSA Data Security, Inc. MD5 Message-Digest Algorithm authentication. When a password is configured, MSDP receives only authenticated MSDP messages from its peers. All MSDP messages that fail TCP RSA Data Security, Inc. MD5 Message-Digest Algorithm authentication are dropped.

• Configure TCP RSA Data Security, Inc. MD5 Message-Digest Algorithm authentication on an MSDP peer using the command:
  
  configure msdp peer [remoteaddr | all] password [none | {encrypted} tcpPassword] {vr vrname}

• Remove the password using the command:
  
  configure msdp peer {all | remoteaddr} password none

  The password displays in encrypted format and cannot be seen as simple text. Additionally, the password is saved in encrypted format.

• Display the password in encrypted format using the command:
  
  show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}

Policy Filters

You can configure a policy filter to control the flow of SA messages going to or coming from an MSDP peer. For example, policy filters can help mitigate state explosion during denial of service (DoS) or other attacks by limiting what is propagated to other domains using MSDP.

You can use the following policy attributes in an SA filter policy. All other attributes are ignored:
• Match:
  • multicast-group
  • multicast-source
  • pim-rp
• Set:
  • permit
  • deny

The following shows some examples of policy files taking into account multicast-source with permit/deny action:

```
entry policy2 {
  if match any{
    nlri 10.10.10.0/24;
  }
  then {
    deny;
  }
}
entry policy1 {
  if match any{
    nlri 10.10.10.0/24;
    nlri 20.20.20.0/24 ;
  }
  then {
    permit;          <= permit these sources
  }
}
```

• To configure an incoming or outgoing policy filter for SA messages:
  
  ```
  configure msdp peer [remoteaddr | all] sa-filter [in | out] [filter-name | none] {vr vr_name}
  ```

• To remove a policy filter for SA messages, use the **none** keyword:
  
  ```
  configure msdp [{peer} remoteaddr | peer all] sa-filter [in | out] none
  ```

• To verify that a policy filter is configured on an MSDP peer:
  
  ```
  show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}
  ```

### SA Request Processing

You can configure the router to accept or reject SA request messages from a specified **MSDP** peer or all peers. If an SA request filter is specified, only SA request messages from those groups permitted are accepted. All others are ignored.

• Configure the router to accept SA request messages from a specified MSDP peer or all peers using the command:
  
  ```
  enable msdp [{peer} remoteaddr | peer all] process-sa-request {sa-request-filter filter-name} {vr vr_name}
  ```

• Configure the router to reject SA request messages from a specified MSDP peer or all peers using the command:
  
  ```
  disable msdp [{peer} remoteaddr | peer all] process-sa-request {vr vrname}
  ```
• Display configuration and run-time parameters about MSDP peers using the command:
  
  \[ \text{show msdp} \ [\text{peer} \ \{\text{detail}\} \ | \ \{\text{peer} \ \text{remoteaddr}\} \ \{\text{vr} \ \text{vr}_\text{name}\}] \]

**MSDP Mesh-Groups**

MSDP can operate in a mesh-group topology. A mesh-group limits the flooding of SA messages to neighboring peers. In a mesh-group, every MSDP peer must be connected to every other peer in the group. In this fully-meshed topology, when an SA message is received from a member of the mesh-group, the SA message is always accepted, but not flooded to other members of the same group. Because MSDP peers are connected to every other peer in the mesh-group, an MSDP peer is not required to forward SA messages to other members of the same mesh-group. However, SA messages are flooded to members of other mesh-groups. An MSDP mesh-group is an easy way to implement inter-domain multicast, as it relaxes the requirement to validate looping of MSDP control traffic (that is, peer-RPF checking is not required). Consequently, SA messages do not loop in the network.

**Note**

We recommend that you configure anycast RP peers in a mesh topology.

• Configure an MSDP mesh-group using the command:
  
  \[ \text{create msdp mesh-group} \ \text{mesh-group-name} \ \{\text{vr} \ \text{vr}_\text{name}\} \]

• Remove an MSDP mesh-group using the command:
  
  \[ \text{delete msdp mesh-group} \ \text{mesh-group-name} \ \{\text{vr} \ \text{vr}_\text{name}\} \]

• Display information about an MSDP mesh-group using the command:
  
  \[ \text{show msdp} \ [\{\text{mesh-group} \ \text{detail}\} \ | \ \{\text{mesh-group} \ \text{mesh-group-name}\}] \ \{\text{vr} \ \text{vr}_\text{name}\} \]

• Configure a peer to be a member of an MSDP mesh-group using the command:
  
  \[ \text{configure msdp peer} \ [\text{remoteaddr} \ | \ \text{all}] \ \text{mesh-group} \ \{\text{mesh-group-name} \ | \ \text{none}\} \ \{\text{vr} \ \text{vr}_\text{name}\} \]

• Remove a peer from an MSDP mesh-group using the command:
  
  \[ \text{configure msdp} \ \{\text{peer} \ \text{remoteaddr} \ | \ \text{peer all}\} \ \text{mesh-group none} \ \{\text{vr} \ \text{vr}_\text{name}\} \]

**Anycast RP**

Anycast RP is an application of MSDP that allows multiple RPs to operate simultaneously in a PIM-SM domain. Without anycast RP, multiple routers can be configured as candidate RPs, but at any point in time, only one router can serve as RP. Because anycast RP allows multiple RPs to be simultaneously active, anycast RP provides both load sharing and redundancy, as each RP serves the receivers that are closest to it in the network and can take over for additional receivers if another RP fails.

In an anycast RP topology, all RPs in a PIM-SM domain are configured with the same IP address on a loopback VLAN. The loopback VLAN IP address should have a 32-bit mask, so that it specifies a host address. All the routers within the PIM-SM domain select the nearest RP for each source and receiver. If the senders and receivers within the PIM-SM domain are distributed evenly, the number of senders that register with each RP is approximately equal.
Another requirement of the anycast RP topology is that MSDP must run on all RPs in the PIM-SM domain, so all RPs are also MSDP peers. We recommend that you configure an MSDP mesh connection between all MSDP peers in the domain.

Whenever any multicast source becomes active, this information is sent in an MSDP SA message to the other MSDP peers in the domain, announcing the presence of the source. If any RP within the domain fails, the IP routing protocol mechanism ensures that next available RP is chosen. If a sender registers with one RP and a receiver joins another RP, the information shared through MSDP enables PIM-SM to establish an SPT between the receiver and the source.

Note
We recommend that you configure anycast RP peers in a mesh topology.

The exchange of information in an anycast RP process works as follows:

- When the first-hop router sends a PIM Register message to the nearest RP, the PIM router checks to see if the nearest RP is the RP for the group.
- If the nearest RP is the RP for the group, an MSDP SA message is created and forwarded to the other MSDP peers.
- The MSDP SA message includes the configured originator ID, which is a mandatory configuration component.
- Each remote peer checks the RPF of the originator ID address and informs the PIM process on that remote router about active multicast sources.
- Remote receivers get data packets through the remote shared tree, and can then switch over to the SPT by sending join messages directly towards the source.

To configure anycast RP, do the following at each anycast RP router:

1. Create and configure a loopback VLAN using the commands:

   ```
   create vlan vlan_name {tag tag} {description vlan-description} {vr name}
   enable loopback-mode vlan vlan_name
   ```

2. Assign the anycast RP address to the loopback VLAN with a 32 bit subnet mask using the command:

   ```
   configure {vlan} vlan_name ipaddress [ipaddress {ipNetmask} | ipv6-link-local | {eui64} ipv6_address_mask]
   ```

   Note
   The anycast RP address must be unique to the loopback VLAN and be the same on all anycast RP peers. It must not match the router IP address, the PIM BSR address, or any other IP addresses used by the router or any other network devices.

3. Enable IP forwarding and IP multicast forwarding on the loopback VLAN using the commands:

   ```
   enable ipforwarding {ipv4 | broadcast} {vlan vlan_name}
   enable ipmcforwarding {vlan name}
   ```
4 Add the loopback VLAN into the unicast routing domain using the appropriate command for your unicast routing protocol:

configure ospf add vlan vlan-name area area-identifier link-type [auto | broadcast | point-to-point] [passive]

configure rip add vlan [vlan_name | all]

configure isis add [vlan all | {vlan} vlan_name] area area_name [ipv4 | ipv6]

5 Add the loopback VLAN into the PIM-SM domain and configure it as an RP using the commands:

configure pim {ipv4 | ipv6} add vlan [vlan-name | all] {dense | sparse} {passive}

configure pim {ipv4 | ipv6} crp static ip_address [none | policy] {priority [0-254]}

6 Enable MSDP and establish a peering relationship with similar anycast RP neighbors using the commands:

create msdp peer remoteaddr {remote-as remote-AS} {vr vrname}

configure msdp peer [remoteaddr | all] password [none | {encrypted} tcpPassword] {vr vrname}

configure msdp peer remoteaddr description {peer-description} {vr vrname}

enable msdp [{peer} remoteaddr | peer all] {vr vr_name}

enable msdp {vr vrname}

7 Configure a unique originator ID for each anycast RP peer using the command:

configure msdp originator-id ip-address {vr vrname}

---

### SA Cache

As an MSDP router learns of new sources either through a PIM-SM Source-Register (SR) message or SA message from its RPF peer, it creates an entry in SA cache (or refreshes the entry if it is already there) and forwards this information to its peers. These entries are refreshed by periodic SA messages received from the MSDP peers. If these entries are not refreshed within six minutes, they will time out. When a PIM-SM RP detects that the source is no longer available it informs MSDP, which in turn removes the SA information from the local database.

Caching makes it easy for local receivers to know immediately about inter-domain multicast sources and to initiate building a source tree towards the source. However, maintaining a cache is heavy both in CPU processing and memory requirements.

---

**Note**

Our implementation of MSDP does not support operating with local cache disabled.

- Remove an SA cache server.
  
  unconfigure msdp sa-cache-server {vr vrname}
As MSDP uses the flood-and-join model to propagate information about sources, there is a restriction that no more than two advertisements per cache entry will be forwarded per advertisement interval. This is helpful in reducing an SA message storm and unnecessarily forwarding them to peers.

By default, the router does not send SA request messages to its MSDP peers when a new member joins a group and wants to receive multicast traffic. The new member simply waits to receive SA messages, which eventually arrive.

- Configure the MSDP router to send SA request messages immediately to the MSDP peer when a new member becomes active in a group.
  ```plaintext
configure msdp sa-cache-server remoteaddr {vr vr_name}
```
- Purge all SA cache entries.
  ```plaintext
clear msdp sa-cache {{ peer remoteaddr | peer all} [group-address grp-addr] {vr vrname}}
```
- Display the SA cache database.
  ```plaintext
show msdp [sa-cache | rejected-sa-cache] [group-address grp-addr] {source-address src-addr} {as-number as-num} {originator-rp originator-rp-addr} {local} {peer remoteaddr} {vr vrname}
```

**Maximum SA Cache Entry Limit**

You can configure a limit on the maximum number of SA cache entries that can be stored in the cache database. Once the number of SA cache entries exceeds the pre-configured limit, any newly received cache entries are discarded. You can configure the limit on a per-peer basis. By default, no SA message limit is set. The router can receive an unlimited number of SA entries from an MSDP peer.

- Configure a limit on the number of SA entries that can be stored in cache.
  ```plaintext
  configure msdp peer [remoteaddr | all] sa-limit max-sa {vr vr_name}
  ```
  To allow an unlimited number of SA entries, use 0 (zero) as the value for max-sa.
- Display the SA cache limit.
  ```plaintext
  show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}
  ```

**SNMP MIBs**

- SNMP MIB access is not supported for MSDP.
This chapter provides instructions for upgrading ExtremeXOS software and firmware, including how to download and install a new image, perform a hitless upgrade, upload and download the configuration using TFTP, and synchronize nodes.

To upgrade your ExtremeXOS images and modules, start with ExtremeXOS Upgrade Process on page 1609.

To install modules on top of an existing ExtremeXOS image that will not be upgraded, see Installing a Modular Software Package on page 1621.

**ExtremeXOS Upgrade Process**

Upgrading your ExtremeXOS image and modules uses the following process:

1. Backup all configuration files (see Creating a Backup Configuration File on page 1611).
2. Download ExtremeXOS and module package images from the Extreme Networks support portal (see Downloading a New Image on page 1615).

   **Note**

   Beginning with ExtremeXOS 16.1, there are two methods available for the upgrade process:
   - `download url filename` - provides a means of downloading multiple files at the same time over TFTP, HTTP, or anonymous FTP.
   - `download image filename` - downloads a single .xos or .xmod file from a TFTP server.

3. Place the image files on a server that your switch can locate (see Installing a Core Image on page 1617).
4. Discover your inactive partition (see Finding the Inactive Partition on page 1616).
5 Use the `download image` command to install each image on the inactive partition (see Installing a Core Image on page 1617).

6 Reboot the switch (see Reboot Options on page 1618).

Upgrade Example

We recommend upgrading ExtremeXOS images and any modular packages at the same time. The following example shows the ExtremeXOS image `summitX-15.7.1.4.xos` being installed before rebooting the switch.

```bash
# show switch

SysName:          DUT1
SysLocation:
SysContact:       support@extremenetworks.com, +1 888 257 3000
System MAC:       00:04:96:97:D1:7B

# reboot

Are you sure you want to reboot the switch? (y/N) Yes
Creating a Backup Configuration File

Before upgrading ExtremeXOS on a switch, it is highly recommended that you create a backup copy of the configuration. Creating a copy of the "Config Booted" configuration file, with the version number of the ExtremeXOS image included in the name of the backup copy, is the simplest method.

To do this:

1. Save the configuration to the database so the switch can reapply the configuration after the switch reboot using the `save` command.
2. Enter `y` at the prompt to save your changes.
3. Execute the `show switch` command to view the "Config Booted" file. The following output is displayed:

```
# show switch
SysName:          XXXXX
SysLocation:      
SysContact:       support@extremenetworks.com, +1 888 257 3000
System MAC:       00:04:96:51:FE:E2
System Type:      XXXXXX
SysHealth check:  Enabled (Normal)
Recovery Mode:    All
System Watchdog:  Enabled
Current Time:     Thu Sep  4 00:57:18 2014
Timezone:         [Auto DST Disabled] GMT Offset: 0 minutes, name is UTC.
Boot Time:        Wed Sep  3 20:07:11 2014
Boot Count:       402
Next Reboot:      None scheduled
System UpTime:    4 hours 50 minutes 7 seconds
Current State:    OPERATIONAL
Image Selected:   primary
Image Booted:     primary
Primary ver:      15.7.1.4
Secondary ver:    15.7.1.5
Config Selected:  ssh-privatekey.cfg
Config Booted:    ssh-privatekey.cfg
                ssh-privatekey.cfg Created by ExtremeXOS version 15.7.1.5
                219131 bytes saved on Mon Jul 14 23:03:08 2014
```

4. Using the ExtremeXOS version shown in the "Config Booted:" line, enter the "copy" command as shown:

   `cp config selected config-booted-exos_ver`

   For example: `cp ssh-privatekey.cfg ssh-privatekey-15_7_1_5`

   **Note**
   For more information about version strings, see Understanding the Image Version String on page 1619.

For more information about ExtremeXOS configuration files, see Configuration Changes on page 1623.

In addition, Extreme Management Center and Ridgeline products have documented methods for backing up and restoring configuration for Extreme devices.
For Extreme Management Center procedures, visit https://extranet.extremenetworks.com/ (a valid customer account is required access this site) or access the online help available from the Help menu in the Extreme Management Center application.

For Ridgeline procedures, see the Configuration Manager section of the Ridgeline Reference Guide.

**Download URL Method**

ExtremeXOS 21.1 provides an enhancement to the download CLI command so that it now accepts a URL as the name of the file to download.

| Note | This feature is not available unless you are currently running ExtremeXOS 21.1 or later. |

URL protocols can be TFTP, HTTP, or anonymous FTP. The format of a URL is:

- `http://10.10.10.1/filename.xos`
- `tftp://10.10.10.1/filename.xos`
- `ftp://10.10.10.1/filename.xmod`

In addition to accepting a URL that ends in .xos or .xmod, the URL filename can now end in .lst.

A .lst file contains filenames at the same location as the .lst file URL and will be downloaded, and then installed one after the other. The .lst file method can define bundles of downloads for:

- Large image file sizes
- Files ending in `.cfg`, `.xsf`, `.pol`, `.xlic`, `.py`, `.ssh`
- Any additional .lst files so that you can create lists of lists
- Any bundling that makes it easier to download with a single command

The .lst file allows you to download .xos, .xmods, and other files at the same time. Once downloaded as a list, simply reboot and the files become active. This feature allows for better organization of downloads across switches.
All of the filenames in any .lst must be available at the same URL path provided in the download command.

Any .xos and .xmod files are installed to the inactive partition.

For any other file types, the /usr/local/cfg directory is used.

See the following for an example of .lst files

**Example**

An HTTP server on 10.68.9.7 for directory 16.1/xxxx/xxxx/release:

This example shows how the .lst file can contain filenames ending in .lst to get a list of lists (of lists etc...)

**cat big.lst – big.lst contains other list file names**

xos.lst

xmod.lst

script.lst

**cat xos.lst – xos.lst contains an ExtremeXOS image**

summitX-16.1.0.18.xos
cat xmod.lst – xmod.lst contains a number of .xmod filenames

summitX-16.1.0.18-debug.xmod
summitX-16.1.0.18-esvt.xmod
summitX-16.1.0.18-LegacyCLI.xmod
summitX-16.1.0.18-reachnxt-1.8.1.8.xmod
summitX-16.1.0.18-techSupport.xmod

cat script.lst – script.lst contains a number of python scripts the user wants to download to a switch

jsonrpc.py
jsontest.py
otst.py
ping.py
readvr.py

A single download command downloads all of the above files. Example uses big.lst:

```bash
X460G2-24t-10G4.1 # download url http://10.68.9.7/big.lst
http://10.68.9.7/xos.lst
Downloading http://10.68.9.7/summitX-16.1.0.18.xos

Downloading to Switch..............................................
Installing to primary partition!
Installing to Switch..............................................

Installing to Switch...
Image installed successfully
Downloading http://10.68.9.7/summitX-16.1.0.18-LegacyCLI.xmod
```
**Downloading a New Image**

The ExtremeXOS core image (.xos) file contains the executable code that runs on the switch and is preinstalled at the factory. An ExtremeXOS module image (.xmod) supplements the core image. Note that the version number of the core image and the module must match. As new versions of this image are released, you should upgrade both the software and modular packages running on your system.

To find and install image files:

1. Point your browser to [http://esupport.extremenetworks.com](http://esupport.extremenetworks.com) and log in with your eSupport account.

   If you do not have an eSupport account, you can request one with the [Request Web Login](http://esupport.extremenetworks.com) link.

   **Note**
   You can also download release notes from the eSupport site. The [ExtremeXOS Release Notes](http://esupport.extremenetworks.com) will always have the most current download and install instructions.

2. Find the ExtremeXOS image and all modules you wish to upgrade. Later you will install all files on the image at the same time.

3. Save the files to a TFTP server on the network. You can also store them on a USB 2.0 device.

4. When you have all images downloaded and saved, proceed to Finding the Inactive Partition on page 1616.

**Image Integrity Checking**

This feature adds digital signature verification in ExtremeXOS image and XMOD modules. Image integrity is checked against the digital signature before actual installation.
**Digital Signature**

Prior to ExtremeXOS 16.1, the ExtremeXOS image or XMOD modules downloaded to the switch were only protected by CRC check. This is sufficient for checking corrupted image. However, it cannot prevent malicious attacks. For example, an attacker can de-package the image, replace certain fields, recompute CRC and then repackage the image.

Digital signature is commonly used to demonstrate of the authenticity of a digital message, in this case, the image downloaded to the switch. Only images with digital signature validated on the switch can be installed. Otherwise, the installation should be aborted.

This features uses the Public Key Infrastructure (PKI) approach. Specifically, with the RSA algorithm, two keys, the private key and the public key are generated using openssl utility. The ExtremeXOS image or XMOD module is digitally signed with the private key. The public key is installed on the switch in the format of a X.509 certificate, which is verified before being used.

When building the image, the signature is computed for the ExtremeXOS image or XMOD module, then included in the final image provided to the customer. On the switch, during downloading process, the signature is verified against the image using the public key previously installed.

In order to deliver the public key to the customer securely, it is also digitally signed and it is distributed in the format of a X.509 certificate. In order to do so, another set of keys are generated to sign this certificate. A self-signed root certificate is also installed on the switch to verify the certificate containing the image signing public key.

All these keys and certificates are generated offline and the private keys should be stored safely.

Transition from an image without signature to one with needs two steps, the first step is to download the ExtremeXOS image and install the public key certificates. At this time, the signature cannot be verified because there is no key to validate the image. But after the first installation, all subsequent downloaded images can be validated using the installed key.

The certificates are only included in the ExtremeXOS image; XMOD modules do not need to include certificates.

Downgrading from an ExtremeXOS version supporting digital signature to one that does not is allowed. No special handling is needed. A warning message is printed on the console to remind the user that the image is not digitally singed. The user does have the choice to either proceed with downgrading or not.

**Hash Verification**

Currently, each ExtremeXOS image or XMOD is posted along side with an MD5 (Message-Digest algorithm 5) hash checksum, which can be verified using any offline tools. As of ExtremeXOS 16.1, an enhancement now provides a stronger SHA256 hash checksum is generated for you to verify offline.

**Finding the Inactive Partition**

A switch can store up to two core images: an active and inactive. When downloading a new image, you must select on which partition to install the new image. You must install the software image to the inactive partition, and must specify that partition while downloading the image to the switch.

To find the inactive partition:
1. From the CLI, enter the command `show switch` (or `show slot detail` on SummitStack).

```
# show switch
SysName:          XXXXXXX
SysLocation:      
SysContact:       support@extremenetworks.com, +1 888 257 3000
System MAC:       00:04:96:51:FE:E2
System Type:      XXXXXXX
SysHealth check:  Enabled (Normal)
Recovery Mode:    All
System Watchdog:  Enabled

Current Time:     Thu Sep  4 00:57:18 2014
Timezone:         [Auto DST Disabled] GMT Offset: 0 minutes, name is UTC.
Boot Time:        Wed Sep  3 20:07:11 2014
Boot Count:       402
Next Reboot:      None scheduled
System Uptime:    4 hours 50 minutes 7 seconds
Current State:    OPERATIONAL
Image Selected:   primary
Image Booted:     primary
Primary ver:      15.7.1.4
Secondary ver:    15.7.1.5
Config Selected:  ssh-privatekey.cfg
Config Booted:    ssh-privatekey.cfg
ssh-privatekey.cfg Created by ExtremeXOS version 15.7.1.5

219131 bytes saved on Mon Jul 14 23:03:08 2014
```

2. Locate the `Image Booted:` line. If it indicates `primary`, you will know to install the images on the secondary partition. If it indicates `secondary`, you will know to install the images on the primary partition.

For help with versions and image filenames, refer to the following:

- Understanding the Image Version String on page 1619
- Image Filename Prefixes on page 1620
- Software Signatures on page 1620

When you know the inactive partition, proceed to Installing a Core Image on page 1617.

**Installing a Core Image**

Once `.xos` and `.xmod` files are stored on a network server (see Downloading a New Image on page 1615), download the image to the switch using the following procedure:

1. Use a login session on the master node of the SummitStack to verify which virtual router (VR) connects to your server. Use one of the following ping commands to confirm which virtual router reaches your server:

   ```
   ping vr vr-Mgmt host
   ping vr vr-Default host
   ```

   At least one of these commands must successfully reach your server for you to download the image. After verifying the virtual router that reaches your server, specify that virtual router when you download the image.
2 Download the new image to the switch using the command:
```
download image [[hostname | ipaddress] filename {\[vr\] vrname} |
memorycard filename] {\{partition\} \{msm slotid | slot slot number\}
```

**Note**
If you configure the switch to write core dump (debug) files to the internal memory card and attempt to download a new software image, you might have insufficient space to complete the image download. If this occurs, you will need to move or delete the core dump files from the internal memory. You will be asked during the download process if you want to remove these files. For more information, see Understanding Core Dump Messages on page 1620.

3 Before the download begins, the switch asks if you want to install the image immediately after the download is finished. Enter y to install the image after download.
   If you enter n to install the image at a later time, the image is still downloaded and saved to the switch, but you must use the `install image` command when ready to install the image.

4 Install .xmod images to the inactive partition using the same command shown above.

5 After installing the .xos and all .xmod images, reboot the switch (see Reboot Options on page 1618).

For information about installing a new BootROM image on a Summit family switch, see Upgrading the BootROM on page 1632.

**Installing a Core Image with NMS**

Depending on your platform, you can use Extreme Management Center or Ridgeline to download the core image.

You can either load the new image to the NMS server on your network or configure it to automatically poll and download newly released images to the server. Follow the instructions described in the NMS documentation to appropriately configure the server for your network environment.

For more information about installing the NMS client and server, configuring it, and the platforms the NMS supports, refer to the NMS documentation that comes with the product or the documentation available from the Extreme Networks website at [www.extremenetworks.com/documentation/](http://www.extremenetworks.com/documentation/).

**Reboot Options**

**Reboot the Switch**

- To reboot the switch immediately, use the following command
  `reboot`

**Note**
The reboot occurs immediately and any previously schedule reboots are cancelled.
On SummitStack, the `reboot` command reboots the active topology and can be run from the master node only.

- To schedule a time to reboot the switch, use the command:
  
  ```
  reboot { [time mon day year hour min sec] | cancel} {slot slot-number} {all}
  ```

  The options use the following format:
  - `date` — in mm dd yyyy format
  - `time` — 24-hour clock in hh mm ss format

  **Note**
  When you configure a timed reboot of the switch, you can use the `show switch` command to see the scheduled time.

- To reboot the entire stack topology, use the command:
  ```
  reboot stack-topology {as-standby}
  ```

  **Note**
  This command can be run on any node and can be used to eliminate the dual master condition manually.

- To cancel a previously scheduled reboot, use the `cancel` option of the `reboot` command.

### Reboot a Node in a SummitStack

To reboot a single node in the SummitStack, use the command:

```
reboot { [time mon day year hour min sec] | cancel} {slot slot-number} {all}
```

The `reboot slot` command works only on the active master node for other slots, and on an active non-master node for its own slot.

The `reboot stack-topology {as-standby}` command can also be used to reboot a single node by specifying the MAC address of the node.

The `reboot node-address` command reboots the specified node from any node.

### Understanding the Image Version String

The image version string contains build information for each version of ExtremeXOS.

You can use the `show version` and `show switch` commands to display the ExtremeXOS version running on your switch. The output will be structured as one of the following:

- ExtremeXOS Version `<major>..<minor>..<sustaining>..<build>`

  In the case of a patch release, the version structure is ExtremeXOS Version `<major>..<minor>..<sustaining>..<build>-patchX-Y` where X is the patch type and Y is the build number for the patch.
Table 151 describes the image version fields.

### Table 151: Image Version Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>major</td>
<td>Specifies the ExtremeXOS major version number.</td>
</tr>
<tr>
<td>minor</td>
<td>Specifies the ExtremeXOS minor version number.</td>
</tr>
<tr>
<td>sustaining</td>
<td>Specifies the ExtremeXOS sustaining version number.</td>
</tr>
<tr>
<td>build</td>
<td>Specifies the ExtremeXOS build number.</td>
</tr>
<tr>
<td>patch</td>
<td>Identifies a specific patch release.</td>
</tr>
</tbody>
</table>

The `show version` command also displays information about the firmware (BootROM) images running on the switch. For more information, see Displaying the BootROM and Firmware Versions on page 1634.

### Image Filename Prefixes

The software image file can be an .xos file, which contains an ExtremeXOS core image, or an .xmod file, which contains an ExtremeXOS modular software package.

#### Filename Prefixes

You can identify the appropriate image or module for your platform based on the file name of the image. The ExtremeSwitching and Summit series switches generally use the `summitX-` filename prefix. The exceptions are the ExtremeSwitching and Summit X590, and X870 series switches, which use the `onie-` prefix (for example: onie-22.2.1.2.xos).

For additional installation requirements see the sections, Installing a Core Image on page 1617 and Installing a Modular Software Package on page 1621.

### Software Signatures

Each ExtremeXOS image contains a unique signature.

The BootROM checks for signature compatibility and denies an incompatible software upgrade. In addition, the software checks both the installed BootROM and software and also denies an incompatible upgrade.

### Understanding Core Dump Messages

If you configure the switch to write core dump (debug) files to the internal memory card and attempt to download a new software image, you might have insufficient space to complete the image download.

If this occurs, move or delete the core dump files from the internal memory. For example, if the switch supports a compact flash card or USB 2.0 storage device and space is available, transfer the files to the storage device. On switches without removable storage devices, transfer the files from the internal
memory card to a TFTP server. This frees up space on the internal memory card while keeping the core
dump files.

The switch displays a message similar to the following and prompts you to take action:

```
Core dumps are present in internal-memory and must be removed before this download can
continue.
(Please refer to documentation for the "configure debug core-dumps" command for
additional information)
Do you want to continue with download and remove existing core dumps? (y/n)
```

Enter y to remove the core dump files and download the new software image. Enter n to cancel this
action and transfer the files before downloading the image.

For information about configuring and sending core dump information, see the `configure debug
core-dumps` and `save debug tracefiles memorycard` commands.

### Installing a Modular Software Package

In addition to the functionality available in the ExtremeXOS core image, you can add functionality to
your switch by installing modular software packages or feature packs. A complete listing of these
feature packs can be found with their availability requirements in the ExtremeXOS 22.6 Feature License
Requirements document.

Modular software packages are contained in files named with the file extension .xmod, while the core
images use the file extension .xos.

Modular software packages are built at the same time as core images and are designed to work in
concert with the core image, so the `<major>.<minor>.<patch>` field of a modular software package must
match the `<major>.<minor>.<patch>` field of the core image that it will be running with. For example,
the modular software package for tech support named:

```
summitX-21.1.1.4-techSupport.xmod
```

Can run only with the core image named:

```
summitX-21.1.1.4.xos
```

You can install a modular software package on the active or inactive partition. You would install on the
active partition if you want to add the package functionality to the currently running core image
without having to reboot the switch. You would install on the inactive partition if you want the
functionality available after a switch reboot.

To install the package on the inactive partition, you use the same process that you use to install a new
core image. Follow the process described in Installing a Core Image on page 1617.

Activate the installed modular software package either by rebooting the switch or by issuing the
following command: `run update`

You can uninstall packages by issuing the following command:
uninstall image $fname$ partition $msm$ $slotid$ {reboot}

**Note**
Do not terminate a process that was installed since the last reboot unless you have saved your configuration. If you have installed a software module and you terminate the newly installed process without saving your configuration, your module may not be loaded when you attempt to restart the process with the `start process` command.

---

**Upgrading a Modular Software Package**

When Extreme Networks introduces a new core software image, a new feature pack or modular software package is also available. If you have a software module installed and upgrade to a new core image, you need to upgrade to the corresponding feature pack at the same time (see ExtremeXOS Upgrade Process on page 1609).

If you wish to upgrade your existing module software package without upgrading your ExtremeXOS image, two methods are available. Regardless of which method you choose, you must terminate and restart the processes associated with the software module.

1. **Method One**
   a. Terminate the processes associated with the software module using one of the following commands:
      ```
      terminate process name [forceful | graceful] (modular switches)
      terminate process name [forceful | graceful] {slot slot} (SummitStack)
      ```
   b. Download the software module from your TFTP server, compact flash card, or USB 2.0 storage device using the following command:
      ```
      download [url url {vr vrname} | image {active | inactive} [[hostname | ipaddress] filename {{vr} vrname} {block-size block_size} | memorycard filename] {partition}
      ```
   c. Activate the installed modular package, if installed on the active partition, using the following command: `run update`
   d. Restart the processes associated with the software module using one of the following commands:
      ```
      start process name $msm$ $slot$ (modular switches)
      start process name $slot$ $slot$ (SummitStack)
      ```
2 Method Two
   a Download the software module from your TFTP server, compact flash card, or USB 2.0 storage device using the following command:

   
   ```
   download [url url {vr vrname} | image [active | inactive] [[hostname | ipaddress] filename {[vr vrname]} {block-size block_size} | memorycard filename] {partition}
   ```

   b Activate the installed modular package, if installed on the active partition, using the following command: run update

   c Terminate and restart the processes associated with the software module using one of the following commands:

   ```
   restart process [class cname | name {msm slot}](modular switches)
   restart process [class cname | name {slot slot}](SummitStack)
   ```

Configuration Changes

Image Configuration Overview

The configuration is the customized set of parameters that you have selected to run on the switch. As you make configuration changes, the new settings are stored in run-time memory. Settings that are stored in run-time memory are not retained by the switch when the switch is rebooted. To retain the settings and have them loaded when you reboot the switch, you must save the configuration to nonvolatile storage.

The switch can store multiple user-defined configuration files, each with its own filename. By default, the switch has two prenamed configurations: a primary and a secondary configuration. When you save configuration changes, you can select to which configuration you want the changes saved or you can save the changes to a new configuration file. If you do not specify a filename, the changes are saved to the configuration file currently in use. Or if you have never saved any configurations, you are asked to save your changes to the primary configuration.

*Note*

Configuration files have a .cfg file extension. When you enter the name of the file in the CLI, the system automatically adds the .cfg file extension.

If you have made a mistake or you must revert to the configuration as it was before you started making changes, you can tell the switch to use the backup configuration on the next reboot.

Each filename must be unique and can be up to 32 characters long. Filenames are also case sensitive. For information about filename restrictions, see the specific command in the *ExtremeXOS 22.6 Command Reference Guide*.

*•* First, save the configuration using the command:

```
save configuration {primary | secondary | existing-config | new-config}
```

Where the options are:
• **primary** — Specifies the primary saved configuration
• **secondary** — Specifies the secondary saved configuration
• **existing-config** — Specifies an existing user-defined configuration (displays a list of available user-defined configuration files)
• **new-config**— Specifies a new user-defined configuration

• You are prompted to save the changes. Enter y to save the changes or enter n to cancel the process.
• Next, use the configuration command:

```plaintext
use configuration file-name
```

Where the options are:
• **primary** — Specifies the primary saved configuration
• **secondary** — Specifies the secondary saved configuration
• **file_name** — Specifies an existing user-defined configuration (displays a list of available user-defined configuration files)

The configuration takes effect on the next reboot.

---

**Note**
When a switch boots up after executing this command, examine the log to determine if a subsequent save and a reboot of the switch or slot is necessary for the configuration to be correctly applied.

---

**Note**
If the switch is rebooted while in the middle of saving a configuration, the switch boots to factory default settings if the previously saved configuration file is overwritten. The configuration that is not in the process of being saved is unaffected.

---

**Automatic Saving of Configuration Files**

The currently running switch configuration can be configured to be saved at automatic intervals. This feature is turned off by default, but can be enabled and configured to save at specified time intervals and to a designated file.

To configure automatic configuration saving, use the command `save configuration automatic {every minutes {primary | secondary | existing-config | new-config} | never}`.

---

**Note**
Automatic save of the running configuration on system reboot, irrespective of the interval between saves is handled for only immediate reboot, not for scheduled reboots or rebooting through other techniques such as SNMP (Simple Network Management Protocol).

---

**View a Configuration**

• To view the current configuration, enter the command: on the switch.

```plaintext
show configuration {module-name} {detail}
```
You can also view just that portion of the configuration that applies to a particular module (for example, SNMP) by using the `module-name` parameter.

Beginning with ExtremeXOS 12.1, when you specify show configuration only, the switch displays configuration information for each of the switch modules excluding the default data.

You can send output from the `show configuration {module-name} {detail}` command to the Extreme Networks Technical Support for problem-solving purposes. The output maintains the command line interface (CLI) format of the current configuration on the switch.

**Comparing Configurations**

You can view the differences between switch configuration files or a configuration file with the running configuration using the command:

```
show configuration difference { from-config-file {to-config-file} } {module-name} {detail} {context lines}
```

When using the `save configuration automatic {every minutes {primary | secondary | existing-config | new-config} | never}` command this can be especially helpful for comparing what changed between the running (or "startup") configuration and the most recently autosaved configuration.

**Restore Factory Defaults**

The following two procedures restore the switch to factory defaults and reboot the switch. Use the first procedure when you can log in to the switch and issue a CLI command and the second when you cannot.

* When you can log in to the switch, use the following command:
  
  unconfigure switch

  This command resets most of the configuration, with the exception of user-configured user accounts and passwords, the date, and the time. On SummitStack, the command also preserves stacking-specific parameters so the stack can be formed after reboot.

* Unset the currently selected configuration image, reset all switch parameters, and reboot the switch.

  unconfigure switch all

* If you cannot log in because the switch is in a continuous booting loop, use the following procedure:
  a Reboot the switch while pressing the space bar. This puts the switch in Bootstrap mode.
  b From the Bootstrap prompt, type `boot` and then press [Enter] and press the spacebar. This puts the switch in BootROM mode.
  c From the BootROM prompt, type `config none`.

    The following appears:
    
    Configuration selected: none

  d From the BootROM prompt, enter `reboot`. The switch reboots and restores the factory defaults.
Uploading ASCII-Formatted Configuration Files

You can upload your current configuration in ASCII format to a TFTP server.

The uploaded ASCII file retains the CLI format and allows you do the following:

- View and modify the configuration using a text editor, and later download a copy of the file to the same switch or to one or more different switches.
- Send a copy of the configuration file to Extreme Networks Technical Support for problem-solving purposes.

Summary of Tasks

The following summary describes only the CLI involved to transfer the configuration and load it on the switch; it is assumed that you know how to modify the configuration file with a text editor. As previously described, to use these commands, use the .xsf file extension, as these steps are not applicable to configurations that use the .cfg file extension.

To work with an ASCII-formatted configuration file, complete the following tasks:

1. Upload the configuration to a network TFTP server using the following command:

   ```
   upload configuration [hostname | ipaddress] filename {vr vr-name} {block-size block_size}
   ```

   After the configuration file is on the TFTP server, use a text editor to enter the desired changes, and rename the file if necessary so it has the .xsf extension.

2. Download the configuration from the TFTP server to the switch using one of the `tftp` and `tftp get` commands.

3. Verify the configuration file is on the switch using the `ls` command.

4. Load and restore the new configuration file on the switch using the following command:

   ```
   load script filename {arg1} {arg2} ... {arg9}
   ```

5. Save the configuration to the configuration database so the switch can reapply the configuration after switch reboot using the following command:

   ```
   save configuration {primary | secondary | existing-config | new-config}
   ```

   When you save the configuration file, the switch automatically adds the .cfg file extension to the filename. This saves the ASCII configuration as an XML-based configuration file.

Note

Configuration files are forward compatible only and not backward compatible. That is, configuration files created in a newer release, such as ExtremeXOS 15.5, might contain commands that do not work properly in an older release, such as ExtremeXOS 15.3.

Upload the ASCII Configuration File To a TFTP Server

To upload the current switch configuration as an ASCII-based file to the TFTP server, use the `upload configuration` command and save the configuration with the .xsf file extension.

For example, to transfer the current switch configuration as an ASCII-based file named `meg_upload_config1.xsf` to the TFTP server with an IP address of 10.10.10.10, do the following:

```plaintext
upload configuration 10.10.10.10 meg_upload_config1.xsf
```
If you successfully upload the configuration to the TFTP server, the switch displays a message similar to the following:

Uploading meg_upload_config1.xsf to 10.10.10.10 ... done!

**Download the ASCII Configuration File to the Switch**

To download the configuration from the TFTP server to the switch, use the `tftp` or `tftp get` command.

For example, to retrieve the configuration file named `meg-upload_config1.xsf` from a TFTP server with IP address of 10.10.10.10, you can use one of the following commands:

```plaintext
tftp 10.10.10.10 -g -r meg_upload_config1.xsf
```

```
tftp get 10.10.10.10 meg_upload_config1.xsf
```

If you successfully download the configuration to the switch, the switch displays a message similar to the following:

Downloading meg_upload_config1.xsf to switch... done!

**Verify that the ASCII Configuration File is on the Switch**

To confirm that the ASCII configuration file is on the switch, use the `ls` command. The file with an .xsf extension is the ASCII configuration.

The following sample output contains an ASCII configuration file:

<table>
<thead>
<tr>
<th>Mode</th>
<th>User</th>
<th>Group</th>
<th>Size</th>
<th>Date</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>-rwx-</td>
<td>root</td>
<td>root</td>
<td>98362</td>
<td>Nov 2 13:53</td>
<td>Nov022005.cfg</td>
</tr>
<tr>
<td>-rwx-</td>
<td>root</td>
<td>root</td>
<td>117136</td>
<td>Dec 12 12:56</td>
<td>ridgeline.cfg</td>
</tr>
<tr>
<td>-rwx-</td>
<td>root</td>
<td>root</td>
<td>68</td>
<td>Oct 26 11:17</td>
<td>mcastgroup.pol</td>
</tr>
<tr>
<td>-rwx-</td>
<td>root</td>
<td>root</td>
<td>21203</td>
<td>Dec 13 15:40</td>
<td>meg_upload_config1.xsf</td>
</tr>
<tr>
<td>-rwx-</td>
<td>root</td>
<td>root</td>
<td>119521</td>
<td>Dec 6 14:35</td>
<td>primary.cfg</td>
</tr>
<tr>
<td>-rwx-</td>
<td>root</td>
<td>root</td>
<td>96931</td>
<td>Nov 11 11:01</td>
<td>primary_11_11_05.cfg</td>
</tr>
<tr>
<td>-rwx-</td>
<td>root</td>
<td>root</td>
<td>92692</td>
<td>Jul 19 16:42</td>
<td>secondary.cfg</td>
</tr>
</tbody>
</table>

**Load the ASCII Configuration File**

After downloading the configuration file, you must load the new configuration on the switch.

To load and restore the ASCII configuration file, use the command:

```
load script filename [arg1] [arg2] ... [arg9]
```

After issuing this command, the ASCII configuration quickly scrolls across the screen.

The following is an example of the type of information displayed when loading the ASCII configuration file:

```plaintext
script.meg_upload_config1.xsf.389 # enable snmp access
script.meg_upload_config1.xsf.390 # enable snmp traps
script.meg_upload_config1.xsf.391 # configure mstp region purple
script.meg_upload_config1.xsf.392 # configure mstp revision 3
script.meg_upload_config1.xsf.393 # configure mstp format 0
script.meg_upload_config1.xsf.394 # create stpd s0
```

Instead of entering each command individually, the script runs and loads the CLI on the switch.
Save the Configuration

After you load the configuration, save it to the configuration database for use by the switch. This allows the switch to reapply the configuration after a switch reboot.

- To save the configuration, use the command:
  ```
  save configuration {primary | secondary | existing-config | new-config}
  ```

  When you save the configuration file, the switch automatically adds the .cfg file extension to the filename. This saves the ASCII configuration as an XML-based configuration file.

  You can use any name for the configuration.

  For example, after loading the file meg_upload_config1.xsf, you need to save it to the switch.

  To save the configuration as configuration1.cfg, enter the command:
  ```
  save configuration configuration1
  ```

Using Autoconfigure and Autoexecute Files

Two features allow you automatically execute scripts that can manage the switch configuration.

**Autoconfigure:**

Configuration commands placed in the default.xsf file are executed by the switch as it comes up and is unable to find its usual configuration file or if the switch is unconfigured or if the configuration file cannot be determined due to a corrupt NVRAM.

This returns the switch to some basic configuration. When default.xsf is executed, the `show switch` command shows default.xsf as the booted configuration file.

The default.xsf file can have any CLI commands as long as they are all executed within 500 seconds.

The script is aborted when the commands are not executed within that time. When the file is loaded, the results can be seen by executing the `show script output default` command.

**Autoexecute:**

Configuration commands placed in the autoexec.xsf file are executed after a switch loads its configuration.

The file is not executed when a default.xsf file has been executed. Use the file to execute commands after a switch is up and running and also to revert changes made to the configuration by UPM scripts that run persistent commands. The commands must be executed within 500 seconds or the script execution is aborted.

When an autoexec.xsf file is executed, the results can be seen by executing the `show script output autoexec` command.

Using TFTP to Upload the Configuration

You can upload the current configuration to a TFTP server on your network. Using TFTP, the uploaded configuration file retains your system configuration and is saved in XML format. This allows you to send a copy of the configuration file to Extreme Networks Technical Support for problem-solving purposes.
• To view your current switch configuration, use the `show configuration {module-name} (detail)` command available on your switch. Do not use a text editor to view or modify your XML-based switch configuration files.

To view your current switch configuration in ASCII-format, see Uploading ASCII-Formatted Configuration Files on page 1626 for more information about uploading and downloading ASCII-formatted configuration files.

For more information about TFTP, see Using the Trivial File Transfer Protocol on page 65.

• To upload the configuration from the switch to a TFTP server, you can use either the `tftp` or the `tftp put` command:

```
tftp [ ip-address | host-name ] { -v vr_name } { -b block_size } [ -g ] [ -p ] [ -l local-file { -r remote-file } | -r remote-file { -l local-file } ]
```

Where the options are:
• `host-name` — Specifies the host name of the TFTP server
• `ip-address` — Specifies the IP address of the TFTP server
• `-p` — Puts the specified file from the local host and copies it to the TFTP server
• `-l local-file` — Specifies the name of the configuration file that you want to save to the TFTP server
• `-r remote-file` — Specifies the name of the configuration file on the TFTP server

```
tftp put [ ip-address | host-name ] {vr vr_name} {block-size block_size}local-file { remote-file}
```

Where the options are:
• `put` — Puts the specified file from the local host and copies it to the TFTP server
• `host-name` — Specifies the host name of the TFTP server
• `ip-address` — Specifies the IP address of the TFTP server
• `local-file` — Specifies the name of the configuration file that you want to save to the TFTP server
• `remote-file` — Specifies the name of the configuration file on the TFTP server

If you upload a configuration file and see the following message:

```
Error: No such file or directory
```

Check to make sure that you entered the filename correctly, including the `.cfg` extension, and that you entered the correct host name or IP address for the TFTP server.

If your upload is successful, the switch displays a message similar to the following:

```
Uploading megtest1.cfg to TFTPhost ... done!
```

You can also upload the current configuration in ASCII format from the switch to a TFTP server on your network. For more information, see Uploading ASCII-Formatted Configuration Files on page 1626.

**Using TFTP to Download the Configuration**

You can download previously saved XML formatted XOS configuration files from a TFTP host to the switch to modify the switch configuration. Do not use a text editor to view or modify your switch configuration files; modify your switch configurations directly in the CLI.
To view your current switch configuration in ASCII-format, see Uploading ASCII-Formatted Configuration Files on page 1626 for more information about uploading and downloading ASCII-formatted configuration files.

For more information about TFTP, see Using the Trivial File Transfer Protocol on page 65.

Note
By default, if you transfer a file with a name that already exists on the system, the switch prompts you to overwrite the existing file. For more information, see the tftp get command in the ExtremeXOS 22.6 Command Reference Guide.

- To download the configuration from a TFTP host to the switch, you can use either the tftp or the tftp get command:

  tftp [ ip-address | host-name ] { -v vr_name } { -b block_size } [ -g | -p ] [ -l local-file { -r remote-file } | -r remote-file { -l local-file } ]

  Where the options are:
  - host-name — Specifies the host name of the TFTP server
  - ip-address — Specifies the IP address of the TFTP server
  - -p — Puts the specified file from the local host and copies it to the TFTP server
  - -l local-file — Specifies the name of the configuration file that you want to save to the TFTP server
  - -r remote-file — Specifies the name of the configuration file on the TFTP server

  tftp get [ ip-address | host-name ] { vr vr_name } { block-size block_size } remote-file local-file { force-overwrite }

  Where the options are:
  - get — Gets the specified file from the TFTP server and copies it to the local host
  - host-name — Is the host name of the TFTP server
  - ip-address — Is the IP address of the TFTP server
  - remote_file — Specifies the name of the configuration file that you want to retrieve from the TFTP server
  - local-file — Specifies the name of the configuration file on the switch
  - force-overwrite — Specifies the switch to automatically overwrite an existing file

If you download a configuration file and see the following message:

Error: Transfer timed out

Make sure that you entered the filename correctly, including the .cfg extension, and that you entered the correct host name or IP address for the TFTP server.

If your download is successful, the switch displays a message similar to the following:

Downloading megtest2.cfg to switch... done!

Configurations are downloaded and saved into the switch nonvolatile memory. The configuration is applied after you reboot the switch.
If the configuration currently running in the switch does not match the configuration that the switch used when it originally booted, an asterisk (*) appears before the command line prompt when using the CLI.

You can also download the current configuration in ASCII format from a TFTP server on your network to the switch. For more information, see Uploading ASCII-Formatted Configuration Files on page 1626.

**Synchronizing Nodes**

Before synchronizing nodes on a SummitStack, confirm that all nodes are active nodes and running ExtremeXOS 12.0 or later, so as to support the **synchronize** command.

On a SummitStack with redundancy, you can take the primary node configurations and images and replicate them on the backup node using the **save configuration** command.

**Caution**

During a synchronization on a SummitStack, the active stack briefly alternates between a ring and daisy-chain topology. When the primary node finishes replicating its configurations and images to the backup node, the full the stack ring is restored.

In addition to replicating the configuration settings and images, this command also replicates which configuration or image the node should use on subsequent reboots. This command does not replicate the run-time configuration. You must use the **save configuration {primary | secondary | existing-config | new-config}** command to store the run-time configuration first.

On a SummitStack, you can synchronize an active node in the stack with the master node using the following command:

```
synchronize {slot slotid}
```

**Note**

You cannot synchronize a master switch running a version earlier than ExtremeXOS 22.2 to a target node running ExtremeXOS 22.2 or later. The command fails and the following error message appears: Error: the target slot's partitions are not compatible with the Master's for synchronize.

**Automatic Synchronization of Configuration Files**

On a SummitStack where redundancy is in use, ExtremeXOS automatically synchronizes all of the configuration files from the primary node to the backup node if the switch detects that the backup node’s configuration file contents are different from the primary node.

You cannot configure this behavior.

The switch deletes the old configuration files on the backup node only upon a successful file synchronization. If an error occurs, the switch does not delete the old configuration files on the backup node. For example, if you install a backup node that contains different configuration files from the primary node, the old configuration files are deleted after a successful bootup of the backup node.

To see a complete listing of the configuration files on your system, use the `ls` command.
For more detailed information, see Replicating Data Between Nodes on page 69.

**Accessing the Bootloader**

The Bootloader of the switch initializes certain important switch variables during the boot process. In the event the switch does not boot properly, you can access some boot option functions through the Bootloader.

Aside from directing which installed ExtremeXOS image to install during bootup, interaction with the Bootloader is required only under special circumstances and should be done only under the direction of Extreme Networks Customer Support. The necessity of using these functions implies a nonstandard problem that requires the assistance of Extreme Networks Customer Support.

To access the Bootloader to select an installed ExtremeXOS image to load:

1. Attach a serial cable to the console port of the switch.
2. Attach the other end of the serial cable to a properly configured terminal or terminal emulator, power cycle the switch, and then press spacebar on the terminal during the bootup process:
   - For all switches, except the ExtremeSwitching X690, X590, and X870 series switches, the BootRom> prompt appears.
   - To see a list of available commands or additional information about a specific command, type `h` or `help`.
   - For the ExtremeSwitching X690, X590, and X870 series switches, the GNU GRUB menu appears.
     - In the GNU GRUB menu a list of installed images that you can load appears.
3. To load a particular installed image:
   - For all switches, except the ExtremeSwitching X690, X590, and X870 series switches, type `boot [1 | 2]`, where 1 loads the image installed on the primary partition, and 2 loads the secondary partition image.
   - For the ExtremeSwitching X690, X590, and X870 series switches, use the arrow keys to select the desired image, and then press `[Enter]`.

**Upgrading the BootROM**

The Summit family switches have a two-stage BootROM. The first stage, called bootstrap, does basic initialization of the switch processor and loads one of two second-stage bootloaders (called primary and secondary).

If the switch does not boot properly, both the bootstrap and the bootloader allow you to access the boot options using the CLI.

If necessary, the bootloader can be updated after the switch has booted, using TFTP. You can upgrade the BootROM from a TFTP server on the network after the switch has booted and only when asked to do so by an Extreme Networks technical representative. For information about loading an image to a TFTP server and verifying which VR connects to your TFTP server, see Installing a Core Image on page 1617.
To upgrade the BootROM, use the following command: 
```
download bootrom [ipaddress | hostname] filename {(vr) vrname}
```

On a SummitStack, the BootROM can be centrally upgraded. Use the command above on the primary (Master) stack node to download a BootROM to all stacking nodes.

To download to a single stacking node, you need to specify the slot parameter:
```
download bootrom [ipaddress | hostname] filename {slot slot-number} {(vr) vrname}
```

**Note**
User-created VRs are supported only on the platforms listed for this feature in the ExtremeXOS 22.6 Feature License Requirements document.

---

### Upgrading the Firmware (ExtremeSwitching X440-G2 and X620 Series Switches Only)

Firmware images are bundled with ExtremeXOS software images. The bundled firmware images include system FPGA and PLD images. When you download and install a new version of ExtremeXOS, ExtremeXOS automatically compares the existing firmware image against the firmware images bundled with the ExtremeXOS image.

After a firmware image upgrade, messages are sent to the log.

1. To install the firmware bundled with the ExtremeXOS image, use the `install firmware {force} {slot slot-number}` command.
   - If the bundled firmware image is newer than the existing firmware image, the switch prompts you to confirm the upgrade.

2. At the prompt:
   - Type `y` to upgrade the firmware.
   - Type `n` to cancel the firmware upgrade for the specified hardware, and continue scanning for other hardware that needs to be upgraded.

3. Press Enter to cancel the upgrade.
   - During the firmware upgrade, the switch also prompts you to save your configuration changes to the current, active configuration.

4. To save your configuration changes to the current, active configuration, type `y` or to discard your changes, type `n`.
   - The new firmware overwrites the older version.

You must reboot the switch to load the newly installed firmware. However, you do not need to do this immediately after a firmware upgrade. Use the `reboot` command to reboot the switch and activate the new firmware. During the firmware upgrade, do not turn off or disrupt the power to the switch. If power is lost, the firmware may be corrupted and need to be recovered. ExtremeXOS automatically attempts to recover corrupted firmware; however, in some situations user intervention is required.
### Displaying the BootROM and Firmware Versions

To display the BootROM (firmware) version on the switch and on all of the modules and PSU controllers, use the `show version` command.

The following is sample output for a standalone ExtremeSwitching X440-G2 series switch:

```
X440G2-48p-10G4.1 # show version detail
Switch : 800618-00-02 1530G-00048 Rev 2.0 BootROM: 1.0.1.7 IMG: 22.2.1.2
    FPGA: 1.1.44.0 PLD1: 1.0.10.0
PSU-1 : Internal Power Supply
PSU-2 :

Image : ExtremeXOS version 22.2.1.2 by release-manager
       on Wed Feb 15 17:52:45 EST 2017
BootROM : 1.0.1.7
Diagnostics : 5.10
Certified Version : EXOS Linux 3.18.24, FIPS fips-ecp-2.0.12

Switch PCB Info: EVTFC48.2A1G
Subsystem PCB Info: EVTFC48.2A1G
```

The following is sample output for a stack of ExtremeSwitching X440-G2 and X620 switches series switches:

```
Slot-1 Stack.3 # show version detail
Slot-1 : 800617-00-00 1443G-00572 Rev 0.0 BootROM: 1.0.1.9 IMG: 22.2.1.2
    FPGA: 1.1.42.0 PLD1: 1.0.10.0
Slot-2 : 800630-00-00 1510G-00210 Rev 0.0 BootROM: 1.0.1.9 IMG: 22.2.1.2

52 Troubleshooting

Troubleshooting Checklists
- LEDs
- Using the Command Line Interface
- Using ELRP to Perform Loop Tests
- Debug Mode
- Saving Debug Information
- Evaluation Precedence for ACLs
- TOP Command
- TFTP Server Requirements
- System Odometer
- Temperature Operating Range
- Understanding the Error Reading Diagnostics Message
- Proactive Tech Support
- Service Verification Test Tool

If you encounter problems when using the switch, this appendix may be helpful. Visit the Extreme Networks Support portal at https://extremeportal.force.com/ if you have a problem not listed here or in the release notes.

Troubleshooting Checklists

This section provides simple troubleshooting checklists for Layer 1, Layer 2, and Layer 3. The commands and recommendations described are applicable to both IPv4 and IPv6 environments unless otherwise specified. If more detailed information about a topic is available, you are referred to the applicable section in this appendix.

Layer 1

When troubleshooting Layer 1 issues, verify:
- The installation of cables and connectors.
- The behavior of LED status lights. For additional information about LEDs, see LEDs.
- That the port is enabled, the link status is active, and speed and duplex parameters match the port settings at the other end of the cable.
  - To display the configuration of one or more ports, use the `show ports configuration` command.
Layer 2

When troubleshooting Layer 2 issues, verify:

- That the MAC addresses are learned, in the correct VLAN (Virtual LAN), and are not blackhole entries.
  - To display FDB (forwarding database) entries, use the show fdb command.
- Your VLAN configuration, including the VLAN tag, ports in the VLAN, and whether or not the ports are tagged.
  - To display detailed information for each VLAN configured on the switch, use the show vlan detail command.
    For additional VLAN troubleshooting tips, see VLANs.
- Your STP (Spanning Tree Protocol) configuration, including the STP domain (STPD (Spanning Tree Domain)) number, VLAN assignment, and port state.
  - To display STP information, use the following commands:
    show stpd detail—Displays the STP settings on the switch
    show stpd ports—Displays the STP state of a port
    show vlan stpd—Displays the STP configuration of the ports assigned to a specific VLAN
    For additional STP troubleshooting tips, see STP.

Layer 3

When troubleshooting Layer 3 issues, verify:
• The IP address assigned to each VLAN router interface.
  a  To display summary information for all of the VLANs configured on the device, use the show vlan command.

• That IP forwarding is enabled, the routing protocol is globally enabled, and the routing protocol is enabled for a VLAN.
  a  To display the configuration information for a specific VLAN, use one of the following commands:
      show ipconfig {ipv4} {vlan vlan_name}—IPv4 environment
      show ipconfig ipv6 {vlan vlan_name | tunnel tunnelname}—IPv6 environment

• Which destination networks are in the routing table and the source of the routing entry.
  a  To display the contents of the routing table or the route origin priority, use one of the following commands:
      show iproute—IPv4 environment
      show iproute ipv6—IPv6 environment
    b  To display the contents of the routing table only for routes of a specified origin, use one of the following commands:
      show iproute origin—IPv4 environment
      show iproute ipv6 origin—IPv6 environment

• That the IP Address Resolution Protocol (ARP) table has the correct entries.

  Note
  The ARP table is applicable only in IPv4 environments.

    a  To display the contents of the IP ARP table, use the show iparp command.

• That the Neighbor Discovery (ND) cache has the correct entries.

  Note
  The ND cache is applicable only in IPv6 environments.

  a  To display the contents of the ND cache, use the show neighbor-discovery cache ipv6 command.

• IP routing protocol statistics for the CPU of the switch.
  a  Only statistics of the packets handled by the CPU are displayed. To display IP statistics for the CPU of the switch, use one of the following commands:
      show ipstats—IPv4 environment
      show ipstats ipv6—IPv6 environment

• Your OSPF (Open Shortest Path First) configuration, including the OSPF area ID, router state, link cost, OSPF timers, interface IP address, and neighbor list.

  Note
  OSPF is applicable only in IPv4 environments.
a To display OSPF information, use the following commands:

- `show ospf`—Displays global OSPF information for the switch
- `show ospf area`—Displays information related to OSPF areas
- `show ospf area detail`—Displays detailed information related to OSPF areas
- `show ospf interfaces detail`—Displays detailed information about OSPF interfaces

b Your OSPFv3 (Open Shortest Path First version 3) configuration, including the OSPFv3 area ID, router state, link cost, OSPFv3 timers, interface IP address, and neighbor list. OSPFv3 is applicable only in IPv6 environments.

a To display OSPFv3 information, use the following commands:

- `show ospfv3`—Displays global OSPFv3 information for the switch
- `show ospfv3 area`—Displays information related to OSPFv3 areas
- `show ospfv3 interfaces`—Displays detailed information about OSPFv3 interfaces

b Your RIP (Routing Information Protocol) configuration, including RIP poison reverse, split horizon, triggered updates, transmit version, and receive version.

Notes:
- RIP is applicable only in IPv4 environments.
- RIP is applicable only in IPv4 environments.
- RIP is applicable only in IPv6 environments.
- RIP is applicable only in IPv6 environments.

a To display detailed information about how you have RIP configured on the switch, use the `show rip` command.

b RIP activity and statistics for all VLANs on the switch.

Notes:
- RIP is applicable only in IPv4 environments.
- RIP is applicable only in IPv4 environments.

a To display RIP-specific statistics for all VLANs, use the `show rip interface detail` command.

b Your RIPng (Routing Information Protocol Next Generation) configuration, including RIPng poison reverse, split horizon, triggered updates, transmit version, and receive version.

Notes:
- RIPng is applicable only in IPv6 environments.
- RIPng is applicable only in IPv6 environments.

a To display detailed information about how you have RIPng configured on the switch, use the `show ripng` command.

b RIPng activity and statistics for all VLANs on the switch.

Notes:
- RIPng is applicable only in IPv6 environments.
- RIPng is applicable only in IPv6 environments.

a To display RIPng-specific statistics for all VLANs, use the `show ripng interface` command.
• End-to-end connectivity.
  a To test for connectivity to a specific host, use the ping command.
• The routed path between the switch and a destination end station.
  a To verify and trace the routed path, use the traceroute command.

LEDs

Power LED does not light:
Check that the power cable is firmly connected to the device and to the supply outlet.

On powering-up, the MGMT LED lights yellow:
The device has failed its Power On Self Test (POST) and you should contact your supplier for advice.

A link is connected, but the Status LED does not light:
Check that:
• All connections are secure.
• Cables are free from damage.
• The devices at both ends of the link are powered-up.
• Both ends of the Gigabit link are set to the same autonegotiation state.

The Gigabit link must be enabled or disabled on both sides. If the two sides are different, typically the side with autonegotiation disabled will have the link LED lit, and the side with autonegotiation enabled will not be lit. The default configuration for a Gigabit port is autonegotiation enabled. Verify by entering the following command:

\[\text{show ports configuration}\]

Predictive Failure LED on the AC power supply blinks amber:
Check the current status of the power supply. If the speed of both fans is above 2000 RPM, the AC power supply unit (PSU) is operating normally and no failure is imminent. To check and view the health of the installed PSU, use the following command:

\[\text{show power \{ps_num\} \{detail\}}\]

Switch does not power up:
All products manufactured by Extreme Networks use digital power supplies with surge protection. In the event of a power surge, the protection circuits shut down the power supply.

To reset the power, unplug the switch for 1 minute, plug it back in, and attempt to power-up the switch. If this does not work, try using a different power source (different power strip/outlet) and power cord.
Using the Command Line Interface

This section describes helpful information for using and understanding the command line interface (CLI).

General Tips and Recommendations

The initial welcome prompt does not appear:

Check that:
• Your terminal or terminal emulator is correctly configured
• Your terminal or terminal emulator has the correct settings:
  • 115200 baud for ExtremeSwitching X690, X590, and X870 switches; or 9600 baud for all other switches
  • 8 data bits
  • 1 stop bit
  • no parity
  • XON/OFF flow control enabled

For console port access, you may need to press [Return] several times before the welcome prompt appears.

The SNMP Network Manager cannot access the device:

Check that:
• The SNMP (Simple Network Management Protocol) access is enabled for the system.
• The device IP address, subnet mask, and default router are correctly configured, and that the device has been reset.
• The device IP address is correctly recorded by the SNMP Network Manager (refer to the user documentation for the Network Manager).
• The community strings configured for the system and Network Manager are the same.
• The SNMPv3 USM, Auth, and VACM configured for the system and Network Manager are the same.

The Telnet workstation cannot access the device:

Check that:
• The device IP address, subnet mask, and default router are correctly configured, and that the device has been reset.
• You entered the IP address of the switch correctly when invoking the Telnet facility.
• Telnet access is enabled for the switch.

If you attempt to log in and the maximum number of Telnet sessions are being used, you should receive an error message indicating so.

Traps are not received by the SNMP Network Manager:

Check that the SNMP Network Manager’s IP address and community string are correctly configured, and that the IP address of the Trap Receiver is configured properly on the system.
The SNMP Network Manager or Telnet workstation can no longer access the device:

Check that:

• Telnet access or SNMP access is enabled for the system.
• The port through which you are trying to access the device has not been disabled. If it is enabled, check the connections and network cabling at the port.
• The port through which you are trying to access the device is in a correctly configured VLAN.
• The community strings configured for the device and the Network Manager are the same.

Try accessing the device through a different port. If you can now access the device, a problem with the original port is indicated. Re-examine the connections and cabling.

A network problem may be preventing you from accessing the device over the network. Try accessing the device through the console port.

Permanent entries remain in the FDB:

If you have made a permanent entry in the FDB that requires you to specify the VLAN to which the entry belongs and then deleted the VLAN, the FDB entry remains. Although this does not harm the system, if you want to removed the entry, you must manually delete it from the FDB.

Default and static routes:

If you have defined static or default routes, those routes remain in the configuration independent of whether the VLAN and VLAN IP address that used them remains. You should manually delete the routes if no VLAN IP address is capable of using them.

You forget your password and cannot log in:

If you are not an administrator, another user having administrator access level can log in, delete your user name, and create a new user name for you, with a new password.

Alternatively, another user having administrator access level can log in and initialize the device. This will return all configuration information (including passwords) to the initial values.

In the case where no one knows a password for an administrator level user, contact your supplier.

The Summit switch displays only the "(pending-AAA) login" prompt

It is possible that the switch has not yet been fully initialized in the SummitStack. Wait for the Authentication Service (AAA) on the master node is now available for login. message to appear and then log in normally.

It is also possible that the stack has no master-capable node. In this case, AAA authentication will not be possible. This can occur when a stack has been deliberately dismantled and stacking was not unconfigured beforehand.

In either case, you may log in to the node using the failsafe account. If you have forgotten this account, and the stack has no master-capable node or has been dismantled, see Rescuing a Stack that has No Master-Capable Node on page 178.

The "(Pending-AAA) login:" prompt on other switches.
Node Prompt—SummitStack Only

You do not know which Node you are connected to:

If you use a console connection to access and configure the switch, you should connect to the console port of the master node.

The word "Slot" followed by a hyphen and a single decimal digit slot number will be inserted into the prompt in stacking mode. A sample of this prompt is:

```
* Slot-6 Stack.21 #
```

The sample indicates a changed configuration (*), the stackable is in stacking mode and is currently using the slot number 6 in the active topology ("Slot-6"), the system name is the default of “Stack”, the command about to be executed is the 21st command, and the user is logged in as the administrator on the Master node (#).

There will be no specific prompt that indicates the node role. Run show switch command to discover the identities of the Master and Backup nodes. A successful login on a Standby node will show the ">" character instead of the "#" character at the end of the prompt.

Command Prompt

You do not know if the switch configuration has been saved:

If an asterisk (*) precedes the command prompt, a new change to the switch configuration has not been saved. To save the configuration, use the `save configuration` command. After you save the configuration, the asterisk (*) no longer precedes the command prompt.

You do not know if you are logged in as an administrator or a user:

Observe the console prompt. If you are logged in as an administrator, the prompt ends with the hash symbol (#). If you are logged in as a user, the prompt ends with a greater than sign (>).

The following is sample output from an administrator-level account:

```
BD-10808.1 #
```

The following is sample output from a user-level account:

```
BD-10808.1 >
```

Port Configuration
**No link light on 10/100 Base port:**

If patching from a switch to another switch, ensure that you are using a category 5 (CAT5) crossover cable. This is a CAT5 cable that has pins 1 and 2 on one end connected to pins 3 and 6 on the other end.

**Excessive RX CRC errors:**

When a device that has autonegotiation disabled is connected to an Extreme Networks switch with autonegotiation enabled, the Extreme Networks switch links at the correct speed, but in half-duplex mode. The Extreme Networks switch 10/100 physical interface uses a method called parallel detection to bring up the link. Because the other network device is not participating in autonegotiation (and does not advertise its capabilities), parallel detection on the Extreme Networks switch is able only to sense 10 Mbps versus 100 Mbps speed and not the duplex mode. Therefore, the switch establishes the link in half-duplex mode using the correct speed.

The only way to establish a full-duplex link is either to force it at both sides, or run autonegotiation on both sides (using full-duplex as an advertised capability, which is the default setting on the Extreme Networks switch).

---

**Note**

A mismatch of duplex mode between the Extreme switch and another network device causes poor network performance. Viewing statistics using the `show ports rxerrors` command on the Extreme Networks switch may display a constant increment of CRC errors. This is characteristic of a duplex mismatch between devices. This is NOT a problem with the Extreme Networks switch.

Always verify that the Extreme Networks switch and the network device match in configuration for speed and duplex.

**No link light on Gigabit fiber port:**

Check that:

- The transmit fiber goes to the receive fiber side of the other device and vice-versa. All Gigabit fiber cables are of the crossover type.
- The Gigabit ports are set to Auto Off (using the command `configure ports port_list {medium [copper | fiber]} auto off speed speed duplex [half | full]`) if you are connecting the Extreme Networks switch to devices that do not support autonegotiation.

By default, the Extreme Networks switch has autonegotiation set to On for Gigabit ports and set to Off for 10 Gigabit ports.

- You are using multimode fiber (MMF) when using a 1000BASE-SX small form-factor pluggable (SFP), and single-mode fiber (SMF) when using a 1000BASE-LX SFP. 1000BASE-SX technology does not work with SMF. The 1000BASE-LX technology works with MMF but requires the use of a mode conditioning patchcord (MCP).
Software License Error Messages

**You do not have the required software license:**
If you attempt to execute a command and you do not have the required license, the switch returns the following message:

Error: This command cannot be executed at the current license level.

**You have reached the limits defined by the current software license level:**
If you attempt to execute a command and you have reached the limits defined by the current license level the switch returns the following message:

Error: You have reached the maximum limit for this feature at this license level.

For more information about licensing requirements, see the *ExtremeXOS 22.6 Feature License Requirements* document.

VLANs

**You cannot add a port to a VLAN:**
If you attempt to add a port to a VLAN and get an error message similar to:

```
localhost:7 # configure vlan marketing add ports 1:1,1:2
Error: Protocol conflict when adding untagged port 1:1. Either add this port as tagged or assign another protocol to this VLAN.
```

You already have a VLAN using untagged traffic on a port. Only one VLAN using untagged traffic can be configured on a single physical port.

You verify the VLAN configuration using the following command:

```
show vlan {virtual-router vr-name}
```

The solution for this error using this example is to remove ports 1 and 2 from the VLAN currently using untagged traffic on those ports.

If this were the “default” VLAN, the command would be:

```
localhost:23 # configure vlan default delete ports 1:1,1:2
```

You can now re-enter the previous command without error:

```
localhost:26 # configure vlan marketing add ports 1:1,1:2
```

**VLAN names:**
There are restrictions on VLAN names. They cannot contain whitespaces and cannot start with a numeric value.
**VLANs, IP addresses, and default routes:**

The system can have an IP address for each configured VLAN. You must configure an IP address associated with a VLAN if you intend to manage (Telnet, SNMP, ping) through that VLAN or route IP traffic.

You can also configure multiple default routes for the system. The system first tries the default route with the lowest cost metric.

**STP**

**You have connected an endstation directly to the switch and the endstation fails to boot correctly:**

The switch has the STP enabled, and the endstation is booting before the STP initialization process is complete. Specify that STP has been disabled for that VLAN, or turn off STP for the switch ports of the endstation and devices to which it is attempting to connect; then, reboot the endstation.

**Spanning Tree Domain names:**

There are restrictions on STPD names. They cannot contain whitespaces and cannot start with a numeric value.

**You cannot add ports within a VLAN to the specified STPD:**

Check to ensure that you are adding ports that already exist in the carrier VLAN.

If you see an error similar to the following:

Error: Cannot add VLAN default port 3:5 to STP domain

You might be attempting to add:

- Another 802.1D mode STP port to a physical port that already contains an 802.1D mode STP port (only one 802.1D encapsulation STP port can be configured on a particular STP port).
- A carrier VLAN port to a different STP domain than the carrier VLAN belongs.
- A VLAN and/or port for which the carrier VLAN does not yet belong.

**Note**

This restriction is only enforced in an active STPD and when you enable STP to make sure you have a legal STP configuration.

**Only one carrier VLAN can exist in an STPD:**

Only one carrier VLAN can exist in a given STPD although some of the ports on the carrier VLAN can be outside the control of any STPD at the same time.

The StpdID must be identical to the VLANid of the carrier VLAN in that STPD.

**The switch keeps aging out endstation entries in the switch FDB:**

If the switch continues to age out endstation entries in the switch FDB:

- Reduce the number of topology changes by disabling STP on those systems that do not use redundant paths.
• Specify that the endstation entries are static or permanent.

ESRP

**ESRP names:**

There are restrictions on Extreme Standby Router Protocol (ESRP) names. They cannot contain whitespaces and cannot start with a numeric value.

**You cannot enable an ESRP domain:**

Before you enable a specific ESRP domain, it must have a domain ID. A domain ID is either a user-configured number or the 802.1Q tag (VLANid) of the tagged master VLAN. The domain ID must be identical on all switches participating in ESRP for that particular domain. If you do not have a domain ID, you cannot enable ESRP on that domain.

Note the following on the interaction of tagging, ESRP, and ESRP domain IDs:

- If you have an untagged Master VLAN, you must specify an ESRP domain ID.
- If you have a tagged master VLAN, ESRP uses the 802.1Q tag (VLANid) of the master VLAN for the ESRP domain ID. If you do not use the VLANid as the domain ID, you must specify a different domain ID.

**You cannot delete the master VLAN from the ESRP domain:**

If you attempt to remove the master VLAN before disabling the ESRP domain, you see an error message similar to the following:

```
ERROR: Failed to delete master vlan for domain "esrp1" ; ESRP is enabled!
```

If this happens:

- Disable the ESRP domain using the disable esrp command.
- Remove the master VLAN from the ESRP domain using the configure esrp delete master command.

VRRP

**You cannot define VRRP virtual router parameters:**

Before configuring any virtual router (VR) parameters for VRRP, you must first create the VRRP instance on the switch.

If you define VRRP parameters before creating the VRRP, you may see an error similar to the following:

```
Error: VRRP VR for vlan vrrp1, vrid 1 does not exist.
Please create the VRRP VR before assigning parameters.
Configuration failed on backup MSM, command execution aborted!
```

If this happens:

- Create a VRRP instance using the `create vrrp vlan vrid` command.
• Configure the VRRP instance's parameters.

Using ELRP to Perform Loop Tests

The Extreme Loop Recovery Protocol (ELRP) is used to detect network loops in a Layer 2 network. A switch running ELRP transmits multicast packets with a special MAC destination address out of some or all of the ports belonging to a VLAN. All of the other switches in the network treat this packet as a regular, multicast packet and flood it to all of the ports belonging to the VLAN. When the packets transmitted by a switch are received back by that switch, this indicates a loop in the Layer 2 network.

After a loop is detected through ELRP, different actions can be taken such as blocking certain ports to prevent loop or logging a message to system log. The action taken is largely dependent on the protocol using ELRP to detect loops in the network.

You can use ELRP on a “standalone” basis or with other protocols such as ESRP (Extreme Standby Router Protocol), as described in Using ELRP with ESRP. Protocols such as EAPS (Extreme Automatic Protection Switching) require that a network have a ring topology to operate. In this case you can use ELRP to ensure that the network has a ring topology.

The “standalone” ELRP commands determine whether or not a network has a Layer 2 loop.

About Standalone ELRP

Standalone ELRP gives you the ability to send ELRP packets, either periodically or on an ad hoc “one-shot” basis on a specified subset of VLAN ports. If any of these transmitted packets is received back then standalone ELRP can perform a configured action such as sending a log message to the system log file, sending a trap to the SNMP manager, and disabling the port where the looped packet arrived.

ELRP uses QP8 to send/receive control packets over the network to detect loops, so it is advisable to not use QP8 in for user traffic in the network.

Standalone ELRP allows you to:
• Configure ELRP packet transmission on specified VLANs.
• Specify some or all the ports of the VLAN for packet transmission. Each VLAN must be configured individually for ELRP.

Note
Reception of packets is not limited to any specific ports of the VLAN and cannot be configured.

• Save and restore standalone ELRP configuration across reboots.
• Request non-periodic or periodic transmission of ELRP packets on specified ports of a VLAN.

Note
Starting with ExtremeXOS 22.2, ELRP works on both static and dynamic VLANs.
Non-periodic ELP Requests

You can specify the number of times ELRP packets must be transmitted and the interval between consecutive transmissions. A message is printed to the console and logged into the system log file indicating detection of network loop when ELRP packets are received back or no packets are received within the specified duration.

Periodic ELRP Requests

You can configure the interval between consecutive transmissions. If ELRP packets are received back, a message is printed to the system log file and/or a trap is sent to the SNMP manager indicating detection of a network loop.

You have the option to configure the switch to automatically disable the port where the looped packet arrived as well as the length of time (in seconds) that the port should remain disabled. When this hold time expires, the port is automatically enabled.

Should a loop occur on multiple ports, only the first port in the VLAN on which the PDU is received is disabled. The second port is ignored for 1 or 2 seconds and then if another PDU is received, that port is disabled until the loop is gone. This prevents shutting down all ports in the VLAN.

ELRP Egress Port Disable

When a loop is detected via ELRP, an option to disable the port where the packet egressed was added to suppress the loop in ExtremeXOS 16.1. All existing functionalities supported on disabling the port where the packet ingressed are supported on this enhancement as well. A log message or SNMP trap will be generated based on the configuration. The user must specify a holdtime or keep the port disabled until a user enables it.

ELRP egress blocking enhancement adds the following value:

- More efficient bandwidth utilization.
- Better loop protection in MLAG (Multi-switch Link Aggregation Group) environment. If an edge device is dual-homed to an MLAG pair and this edge device loses its LAG (Link Aggregation Group) configuration, ELRP will be able to prevent the loop by disabling egress port.
Exclude Port List

When you have configured the switch to automatically disable the port where the looped packet arrived, there may be certain ports that you do not want disabled. You can then create a list of ports that are excluded from this automatic disabling and that remain enabled. This list can also contain EAPS ring ports. When this option is selected, the actual EAPS ring ports do not have to be explicitly listed. You can also specify that VXLAN (Virtual Extensible LAN) remote end points are to be excluded from getting disabled when a loop is detected.

You can configure any port on the switch into the exclude port list. The list can also be edited to add or delete any port on the switch. Then when ELRP detects a loop and the disable feature is enabled, it checks to see if the port from which the PDU arrived is on the user defined exclude port list or is part of a trunk port that is defined on the list. When the port is on the list, ELRP logs the event and does not disable the port. When the port is not on the list, ELRP disables the port.
**Limitations**

The following are limitations to this feature:

- A specified port is added to the list regardless of its corresponding VLAN.
- Only ports on the local switch can be added.
- A loop detected on an excluded port may persist indefinitely until user action is taken.
- MLAG ISC links should not be blocked, therefore they should be added to the excluded port list.

**ELRP with Dynamic VLANs**

Starting with ExtremeXOS 22.2, ELRP supports dynamically created VLANs created by:

- NetLogin
- Extreme Network Virtualization (XNV)
- Multiple Registration Protocol (MVRP)

ELRP on NetLogin-enabled ports is supported.

**Limitations**

ELRP is not supported on dynamic VLANs when created by ONEPolicy or ONEPolicy with NetLogin.

**ELRP with Virtual Extensible LAN (VXLAN)**

Starting with ExtremeXOS 22.4, ELRP is supported on Virtual Extensible LAN (VXLAN).

VXLAN is an encapsulation mechanism. A VXLAN header is added to an L2 (ELRP PDU) frame and encapsulated in a UDP/IP packet. Transit nodes see only an ordinary IP packet. For more information about VXLAN, see VXLAN on page 839.

ELRP detects loops across VXLAN tunnels. If a loop is detected across the tunnel and the `disable-port` option is configured (see Configuring Periodic Requests on page 1651), ELRP takes down the VXLAN remote endpoint.

If the VXLAN remote endpoint has been disabled using the `permanent` option, you can use the following command to re-enable the remote endpoint:

```
enable virtual-network remote-endpoint vxlan [ ipaddress ipaddress {vr vr_name} | all ]
```

To manually disable a remote endpoint, use the following command:

```
disable virtual-network remote-endpoint vxlan [ ipaddress ipaddress {vr vr_name} | all ]
```

To see if a remote endpoint is enabled or disabled, use the following command:

```
show virtual-network {vn_name} remote-endpoint vxlan {vni vni} {ipaddress ipaddress {vr vr_name}}
```

**Configuring Standalone ELRP**

The ELRP client (standalone ELRP) must be enabled globally in order for it to work on any VLAN.
Globally enable the ELRP client for static VLANs:

```bash
enable elrp-client
```

The ELRP client can be disabled globally so that none of the ELRP VLAN configurations take effect.

Globally disable the ELRP client for static VLANs:

```bash
disable elrp-client
```

Globally enable or disable ELRP for dynamic VLANs:

```bash
configure elrp-client dynamic-vlans {mvrp | netlogin | vm-tracking | all} [on | off]
```

### Configuring Non-periodic Requests

- To start one-time, non-periodic ELRP packet transmission on specified ports of a VLAN using a particular count and interval, use one of the following commands:

```bash
configure elrp-client one-shot {vlan} vlan_name ports [ports | all | none] [remote-endpoints vxlan all] {interval interval {seconds | milliseconds}} [retry count] {log | print | print-and-log}
run elrp {vlan} vlan_name ports [ports | all | none] [remote-endpoints vxlan all] {interval interval {seconds | milliseconds}} {retry count}
```

These commands start one-time, non-periodic ELRP packet transmission on the specified ports of the VLAN using the specified count and interval. If any of these transmitted packets is returned, indicating loopback detection, the ELRP client performs the configured actions of logging a message in the system log file and/or printing a log message to the console. There is no need to trap to the SNMP manager for non-periodic requests.

### Configuring Periodic Requests

- To start periodic ELRP packet transmission on specified ports of a VLAN using a particular interval, use the following command:

```bash
configure elrp-client periodic {vlan} vlan_name ports [ports | all | none] [remote-endpoints vxlan all] {interval interval {seconds | milliseconds}} {log | log-and-trap | trap} {disable-port {egress | ingress}} {duration {seconds | permanent}}
```

This command starts periodic ELRP packet transmission on the specified ports of the VLAN using a specified interval. If any of these transmitted packets is returned, indicating loopback detection, the ELRP client performs the configured action of logging a message in the system log file and/or sending a trap to the SNMP manager.
When the option of disabling a port is configured, you choose the duration in seconds as a hold time, or you disable the port permanently. When ELRP disables the port, the operation is not persistent. When the switch is rebooted, the port is enabled when the switch comes up.

**Note**

ELRP detects loops on a per VLAN basis. When you select the **disable-port** option keep in mind that the entire port is disabled. In the case of **VXLAN**, the remote tunnel endpoint’s (RTEP) state is taken down for all VXLAN virtual networks. This may affect connectivity for other VLANs configured on that port that did not have any data loop problems. ELRP also does not distinguish between uplink ports and host ports. When the **disable port** option is selected and ELRP detects a loop, any and all ports where the loop was detected will be disabled, including uplink ports.

- To disable a pending one-shot or periodic ELRP request for a specified VLAN or all dynamic VLANs, use the following command:

  ```
  unconfigure elrp-client {vlan_name | dynamic-vlans}
  ```

**Configuring Exclude Port List**

- To configure an ELRP exclude port list, use the following command:

  ```
  configure elrp-client disable-ports [exclude | include] [ ports | eaps-ring-ports | remote-endpoints vxlan]
  ```

- To unconfigure an ELRP exclude port list, use the following command:

  ```
  unconfigure elrp-client disable-ports
  ```

**Displaying Standalone ELRP Information**

- To display summary ELRP status information, use the following command:

  ```
  show elrp
  ```

- To display information about ELRP disabled ports, use the following command:

  ```
  show elrp disabled-ports
  ```

- To display information ELRP configuration on dynamic VLANs, use the following command:

  ```
  show elrp dynamic-vlans {vm-tracking | netlogin | mvrp | all}
  ```

**Example: ELRP on Protocol-Based VLANs**

For ELRP to detect loops on a protocol-based VLAN (other than the protocol any), you need to add the ethertype 0x00bb to the protocol.

1. Create VLANs:

   ```
   create vlan v1
   create vlan v2
   ```

2. Configure protocol filters:

   ```
   configure vlan v1 protocol IP
   configure vlan v2 protocol decnet
   ```
3 Add ports to the VLANs:
   configure vlan v1 add ports 1
   configure vlan v2 add ports 2

4 Enable ELRP on the created VLANs:
   enable elrp-client
   configure elrp-client periodic v1 ports all interval 5 seconds log
   configure elrp-client periodic v2 ports all interval 5 seconds log

5 Add the ethertype to the protocol:
   configure protocol IP add snap 0x00bb
   configure protocol decnet add snap 0x00bb

VLANs v1 and v2 can now detect the loop on their respective broadcast domains.

**Debug Mode**

The EMS provides a standard way to filter and store messages generated by the switch. With EMS, you must enable debug mode to display debug information. You must have administrator privileges to use these commands. If you do not have administrator privileges, the switch rejects the commands.

- Enable or disable debug mode for EMS:
  
  ```
  enable log debug-mode
  ```

  After debug mode has been enabled, you can configure EMS to capture specific debug information from the switch. Details of EMS can be found in Status Monitoring and Statistics.

**Saving Debug Information**

You can save switch data and statistics to a network TFTP server, an internal memory card that comes pre-installed in the switch or a removable USB 2.0 storage device (ExtremeSwitching and Summit X450-G2, X460-G2, X670-G2, X770, X590, and X870 series switches).

With assistance from Extreme Networks Technical Support personnel, you can configure the switch to capture troubleshooting information, such as a core dump file, to these locations.

The switch only generates core dump files in the following situations:

- If an ExtremeXOS process fails.
- When forced under the guidance of Extreme Networks Technical Support.

The core dump file contains a snapshot of the process when the error occurred.

**Note**

Use the commands described in this section only under the guidance of Extreme Networks Technical Support personnel to troubleshoot the switch.

Before you can enable and save process core dump information to removable storage devices, you must install a compact flash card or USB 2.0 storage device.

**Enabling the Send Debug Information Switch**

This allows information to be sent to the internal memory card or a removable storage device.
Enable the switch to save process core dump information.

```bash
configure debug core-dumps [internal-memory | memorycard | off]
```

A removable storage device is a USB 2.0 storage device on a Summit series switch.

Core dump files have a .gz file extension. The filename format is: core.<process-name.pid>.gz where process-name indicates the name of the process that failed and pid is the numerical identifier of that process.

If you configure the switch to write core dump files to the internal memory card and attempt to download a new software image, you might have insufficient space to complete the image download.

If this occurs, you must decide whether to continue the software download or move or delete the core dump files from the internal memory. For example, if your switch supports a removable storage device with space available, transfer the files to the storage device. On switches that do not have a removable storage device, transfer the files from the internal memory card to a TFTP server. This frees up space on the internal memory card while keeping the core dump files.

---

**Copy Debug Information to Removable Storage Devices**

- Save and copy debug information to the specified compact flash card or USB 2.0 storage device.

```bash
save debug tracefiles memorycard
```

After the switch writes a core dump file or other debug information to the storage device, and before you can view the contents on the device, you must ensure it is safe to remove the device from the switch. Use the `eject memorycard` command to prepare the device for removal. After you issue the `eject memorycard` command, you can manually remove the storage device from the switch and read the data on the device.

To access and read the data on a removable storage device, use a PC with the appropriate hardware, such as a compact flash reader/writer and follow the manufacturer’s instructions to access the compact flash card and read the data.

---

**Copying Debug Information to a TFTP Server**

*SummitStack only*—To get debug information from a node in the SummitStack that is not a master node, you must configure an alternate IP address on the node and have its management port connected. You may then use the `tftp` command to upload specific files. The `upload debug` command functions only on the master node.

1. Save and copy debug information to the specified TFTP server.

```bash
upload debug [ ipaddress | hostname ] {{vr} vrname} {block-size block_size}
```

Progress messages are displayed that indicate the file being copied and when the copying is finished.
Depending on your platform, the switch displays a message similar to the following:

The following files on have been uploaded:
Tarball Name: TechPubsLab_C_09271428.tgz
./primary.cfg

You can also use this command in conjunction with the `show tech` command.

Prior to uploading debug information files, the switch prompts you with the following message to run the `show tech-support` command with the logto file option:

```
Do you want to run show tech logto file first? (y/n)
```

2 Enter y to run the `show tech-support` command before uploading debug information.

If you enter y, the show_tech.log.tgz file is included during the upload. Enter n to upload debug information without running the `show tech` command.

After you upload the debug information, you should see a compressed TAR file on the TFTP server, which contains the debug information.

The TAR file naming convention is

```
<SysName>_({<slot#>|A|B}|I|C>_Current Time>.tgz
```

- Current Time = mmddhhmm ( month(01-12), date(01-31), hour(0-24), minute(00-59) )

Managing Debug Files

For the purposes of this section, it is assumed that you have configured the switch to send core dump information under the guidance of Extreme Networks Technical Support.

Managing the debug files might include any of the following tasks: renaming or copying a core dump file, displaying a comprehensive list of files including core dump files, transferring core dump files, and deleting a core dump file. You can manage the debug files using the same commands that you use to manage other switch files.

**Note**

Filenames are case-sensitive. For information on filename restrictions, refer to the specific command in the *ExtremeXOS 22.6 Command Reference Guide*.

Evaluation Precedence for ACLs

The ACLs on a port are evaluated in the following order:

- Persistent dynamic ACLs
- Host-integrity permit ACLs
- MAC source address deny ACLs
- Source IP lockdown source IP permit ACLs
- Source IP lockdown deny all ACLs
- ARP validation CPU ACLs
- ACLs created using the CLI
• DoS Protect-installed ACLs
• MAC-in-MAC installed ACLs
• ACLs applied with a policy file (see ACLs on page 637 for precedence among these ACLs)

**TOP Command**

The `top` command is a UNIX-based command that displays real-time CPU utilization information by process.

The output contains a list of the most CPU-intensive tasks and can be sorted by CPU usage, memory usage, and run time. For more detailed information about the `top` command, refer to your UNIX documentation.

**TFTP Server Requirements**

We recommend using a TFTP server that supports blocksize negotiation (as described in RFC 2348, TFTP Blocksize Option), to enable faster file downloads and larger file downloads.

**System Odometer**

Each field replaceable component contains a system odometer counter in EEPROM.

The `show odometers` command displays an approximate days of service duration for an individual component since the component was manufactured.

**Monitored Components**

The odometer monitors the following components:

- Switch
- XGN-2xn card

**Recorded Statistics**

*Description*

The following odometer statistics are collected by the switch:

- Service Days—The amount of days that the component has been running
- First Recorded Start Date—The date that the component was powered-up and began running

Depending on the software version running on your switch, additional or different odometer information may appear.

The following is sample output from a Summit series switch:

<table>
<thead>
<tr>
<th>Service Field Replaceable Units</th>
<th>First Recorded Days</th>
<th>Start Date</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Temperature Operating Range

On Summit family switches, if a switch runs outside the expected range, the switch logs an error message, generates a trap, and one of the following actions occurs:

- On a SummitStack slots, the `reset`/`none` option from `configure sys-recovery-level [all | none]` command determines the action that occurs.
- On Summit X430-8p switches, the device is shut down regardless of the recovery level, and after reboot you are prompted whether or not to boot the switch.
- For all switches, other than the X430-8p, only a warning is logged and the switch continues to run with the system state as “overheat.” If the temperature increases further into overheat condition, after the operating temperature exceed a further higher temperature, the hardware resets the switch.

Understanding the Error Reading Diagnostics Message

For more detailed information about error messages and their meanings, see the [ExtremeXOS 22.6 EMS Messages Catalog](#).

If you have never run diagnostics on the switch or stack ports and use the `show diagnostics` command, the switch displays a message similar to the following:

```
Result: FAIL
Test date run is invalid. Please run Diagnostics.
Error reading diagnostics information.
```

This message is normal and expected if you have never run diagnostics on the switch. After running diagnostics, you see information about the executed test using the `show diagnostics` command.

Proactive Tech Support

Proactive tech support functionality allows you to collect system information when support is required. System information is pushed into a cloud-hosted collector where the Extreme TAC can use it to identify problems to provide solutions. Proactive Tech Support provides the following functionality:

- Proactive tech support is implemented as a loadable application, called `techSupport.xmod`. The XMOD is bundled with ExtremeXOS image packages, but can also be upgraded independently at any time without restarting the switch.
- Proactive tech support allows the switch to proactively collect switch status and send the status report to up to four cloud-hosted collectors.
- Proactive tech support allows both automatic and manual status report.
- Proactive tech support allows each collector to have different report data set, report frequency, or report mode. A default collector is configured automatically to minimize the configuration required to enable the feature.
Limitations

- Proactive tech support uses SSL to secure the switch information transmission on the Internet. If the feature is not enabled, the switch information is transmitted as clear text.
- XMOD applications can be dynamically upgraded without restarting the switch. But the upgraded XMOD version needs to match the installed ExtremeXOS version.

Locating a Collector

The switch attempts to locate a data collector using the DNS hostname, or the IP address of a collector. You specify the DNS hostname or IP address of a collector when you add a collector. When a DNS hostname is configured for a collector, the switch attempts to resolve the IP address for the configured DNS hostname before it attempts to connect to the collector. If the process of resolving IP address for a collector fails, the connection process stops and logs an error message.

When you start the feature a default collector is automatically configured with an IP address set to 12.38.14.200; this is a public IP address of a Splunk server hosted in Extreme's internal network. When you enable the feature, the switch automatically attempts to locate the default collector and send switch status information to the collector. You can configure up to four collectors on the switch. If you want to collect switch status information in your own collector (beside the default collector), you can use the configure tech-support add collector command to configure an additional collector. The switch will send independent status reports to each collector based on each collector’s configuration.

By default, the primary IP address on the Mgmt VLAN interface is used for the discovery process of a collector. If an IP address is not found on the Mgmt VLAN, an error message is displayed. Optionally, you can specify a source IP address to connect to a collector. The connection between the switch and a collector is established and maintained with TCP.

Data Collection

These sections discuss various ways that data is collected and presented.

Encrypted or Open Text

Status reports are sent either in encrypted or clear text. By default, this is determined by the installation of the SSL module. If the SSL module is installed, the status report is sent using an SSL over TCP session in encrypted text. Otherwise, the status report is sent over a regular TCP session in clear text. You can disable the SSL transport even if the SSL module is installed by using the configure tech-support collector [hostname | ip_address] tcp-port port {vr vr_name} {from source_ip_address} {ssl [on | off]} command.

Push vs. Pull

For security reasons, status reports are never pushed from a collector out to a switch. The switch always pushes status reports to a collector. The first release of the tech-support application supports local configuration only. The switch pushes status reports to a collector based solely on the local configuration.
Report Format

The status report format is the output of the `show tech-support` command. You can limit the amount of information in the report using the `data-set` configuration parameter. Two data-sets are available in the first release. With SSH, we recommend that you configure the data-set as detail to include all output of the `show tech-support` command in the switch status report. Without SSH, we recommend that you configure the data-set as summary to include certain output of the `show tech area` command in the switch status report for just a few critical areas, such as general, config, log, VLAN, and EPM.

Frequency

You can also configure when the switch sends a status report. The switch can send a report based on a critical severity event occurrence, daily, at boot-up, or manually when directed by the network administrator. Because of the amount of information that can be transmitted, automatic status reports are sent no more frequently than one report per hour. When a series of critical severity events occurs, only the first one triggers the switch to send status reports. All other critical severity events that occur within one hour after the first critical severity event are ignored.

Authentication and Verification

When SSL is enabled, the switch can authenticate the collector during the SSL handshake by verifying whether the collector's certificate is issued by one of switch's trusted Certificate Authorities (CA). In this case, the switch has to know the CA that issued the collector certificate.

When SSL is enabled, the collector can also authenticate the switch during the SSL handshake by requesting that the switch send the certificate, and then verify that the switch's certificate is issued by one of collector's trusted CAs. In this case, the switch has to have a certificate, and the collector has to know the CA that issued the switch the certificate.

To keep the required configuration minimal, the ExtremeXOS 15.4 release of the tech-support application does not perform authentications. The switch does not verify that the collector is a valid, authorized server before the transmission. The collector does not verify that received status reports are transmitted from a valid, authorized device either.

You can discard or purge the status report from the database for the following reasons:
- The status report is not in a valid format.
- The status report does not contain the minimum required information.
- The serial number of the hardware in the status report is invalid or does not match any serial number in Extreme Network's manufacturing database.
- The status report is received from the same device more than once per hour.

Configuring Proactive Tech Support

The examination and reporting of switch status is implemented as a loadable application, called `techSupport.xmod`. You can dynamically upgrade the XMOD applications without restarting the switch by issuing `download image ip_address app.xmod` `run update`, and then `restart process techSupport commands`. 
**Safe Default Startup**

By default proactive tech support services are disabled. You can opt-out of this service either by answering “Yes”, “Y”, or pressing the ENTER key to answer the question that is posed when accessing the switch for the first time. You can also use the `disable tech-support collector` command. Here is the system output prompt for the tech support feature:

The switch will proactively attempt to send basic configuration and operational switch information for the purpose of assisting Extreme Networks resolve customer reported issues. Uploaded data is encrypted if the ssh.xmod is installed. Otherwise, a reduced switch data set is sent in clear text that contains no customer specific information.

Would you like to disable the automatic switch reporting service? [Y/n]:

**Service Verification Test Tool**

The ExtremeXOS Service verification tool (ESVT) tests traffic throughput between two Extreme Networks switches without having to use a traffic generator. Figure 264 shows a typical service verification test tool environment:

![Figure 264: Typical Service Verification Test Tool Environment](image)

In this example, you have an Extreme Networks switch DUT1 installed at a customer location, and customer service is defined to be from the antenna to the Extreme Networks switch DUT2 (and possibly beyond the DUT2). You can use the service verification test tool to test the portion of the service between the DUT1 and the DUT2. The connection between the antenna and the DUT1 is not covered by the test tool. Additionally, any continuation of the service beyond the DUT2 is not included in the test.

Prior to beginning the test, you must provision the part of the network to be tested by the service verification test tool. This includes the VLAN (tagged or untagged on port 9) on the DUT1, any L2 devices in the path through the network, and the VLAN (tagged or untagged on port 3) at the DUT2. Additionally, any L2/L3 protocol packets created in the CPU on any of the above devices, and sent over the same VLAN as the service being verified, will create errors in the test results. All L2/L3 protocols for the service VLAN must be disabled unless specifically included in the test tool instructions.

The most straightforward mode of operation is for the DUT1 to generate sufficient test packets to fill the allocated bandwidth of the service going towards the DUT2. The DUT1 counts the test packets sent towards the DUT2. On the DUT2, the simplest mode of operation is to wrap the received test packets back to the DUT1 using the reverse path of the service connection. The DUT1 counts the received test packets.
packets. At the conclusion of the test, the DUT1 displays the total number of test packets sent and received.

As line rate test traffic cannot be generated by the CPU in the DUT1, generating test packets must make use of some hardware resources. You can form an internal loop by placing a single port into loopback mode. You can generate line rate traffic by placing a test packet into this loop. You can then use a metered (internal) connection to the service VLAN to send test packets into the service under test at the desired bandwidth. You can assign a loopback port using a CLI command that will mimic the QOS of egress port (port 9).

At the DUT2, it is best to update the source MAC address of the test packets as they are forwarded back to the DUT1. This prevents MAC learning problems in any L2 devices between the DUT1 and the DUT2 that might be caused by learning the same source MAC address on two different ports. By making a L3 forwarding decision at the DUT2, the source MAC address of the test packets is modified to be that of the DUT2.

To make an L3 forwarding decision at the DUT2, the destination MAC address of the test packets must be the address of the DUT2. The destination IP address lookup on the DUT2 must point to an IP next hop that is the DUT1. The DUT1 will also modify the destination MAC address of the test packets to be that of the DUT1.

To make the test as simple as possible, you should assign IP addresses to the service VLAN interfaces at the DUT1 and the DUT2. These IP addresses should be from private IP address space, and should be in the same IP subnet. For example, you could assign 15.15.15.14/24 to the DUT1 and 15.15.15.15/24 to the DUT2. These temporary IP addresses should be unconfigured as soon as the service verification test is completed.

**Note**
The service being verified is an L2 service only. The test network must not cross L2 boundaries.

### Supported Platforms
The Service Verification Tool is supported on the following platforms: Summit X450-G2, X460-G2, X670-G2, X770, ExtremeSwitching X440-G2, X620, Stacking.

### Configuring the Service Verification Test Tool
To run a service verification test, issue the following command:

```
run esvt traffic-test {vlan_name} vlan_name loopback-port loopback-port peer-switch-ip ipaddress packet-size packet_size rate rate [Kbps|Mbps|Gbps] duration time [seconds | minutes | hours]
```

Here is an example configuration to run ESVT for the environment shown in Figure 1:

**DUT1**

```
create vlan v1
configure vlan v1 tag 100
configure vlan v1 add port 9 tagged
configure vlan v1 ipaddress 2.2.2.3/24
```
enable ipforwarding v1
run esvt traffic-test v1 loopback-port 2 peer-switch-ip 2.2.2.2 packet-size 64 rate 200 Mbps duration 5 minutes
show esvt traffic-test

DUT2
create vlan v1
configure vlan v1 tag 100
configure vlan v1 add port 3 tagged
configure vlan v1 ipaddress 2.2.2.2/24
enable ipforwarding v1

To stop the service verification test, issue the following command:
stop esvt traffic-test {{vlan vlan_name}}

To show measurements from the service verification test, issue the following command:
show esvt traffic-test {{vlan}vlan_name} =
Supported Standards, Protocols, and MIBs

Extreme Networks Proprietary MIBs
MIB Support Details

This appendix provides information about the MIB support provided by the ExtremeXOS SNMP (Simple Network Management Protocol) agent residing on Extreme Networks devices running ExtremeXOS and Extreme Networks proprietary MIBS.

Note
All information for supported standards and protocols can be found in the following location: http://www.extremenetworks.com/resources. This appendix contains only the MIB support details.

Extreme Networks Proprietary MIBs
The Extreme Networks MIBs are located at http://www.extremenetworks.com/support/policies/mibs/.

EXTREME ACL MIB
The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeAclStatsTable</td>
<td>extremeAclStatsVlanIfIndex</td>
<td>The IfIndex of the VLAN (Virtual LAN) in which this policy/rule is applied</td>
</tr>

</table>
CTRON Alias MIB

The following tables, groups, and variables are supported in this MIB.
<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctAliasTable</td>
<td>The ctAliasTable contains information about the aliases known by the agent. This table is indexed using a unique and arbitrary ID and a TimeFilter to allow a management station to learn all alias entries that have been modified since time X. This table is NOT designed to do a single GET. This Table is designed for MIB Walks only. This table contains objects that map upper-layer network services and entities to the physical location of the associated port, and the MAC address of the associated end-system (node). All entries in this table are deleted when sysUpTime is reset to zero. This table allows for a time filtered view. It is useful for determining what has been modified in the Alias Table since a specified time. If a management station reads the ctAliasTable of an entity at time X, subsequent updates can be realized by performing get-next requests of this table to determine which entries have been modified since time X. Then the management station can use GET requests to retrieve only the records of interest from the Alias table. There is a delay between retrieving the Alias Reference values from this table, and a GET request to retrieve a modified row from the Alias table. The management station should be prepared for two possibilities: 1) the GET request may fail if the Alias table entry has been deleted during the delay, and 2) the entry may have been modified during the delay, so the modification time of the retrieved entry may differ from the modification time of the Delta entry. If the entry in the Alias Control table identified by ctAliasID is marked inactive by management request, and subsequently deleted to free resources, all corresponding entries in this table are also deleted. If the agent needs to free resources, it can delete entries from this table. It SHOULD first remove those which have been marked inactive in the ctAliasControlTable, then it SHOULD remove those entries with the oldest modification times.</td>
<td>Access = not-accessible</td>
</tr>
<tr>
<td>CtAliasEntry</td>
<td>Each entry contains information pertaining to the alias of a node.</td>
<td>Access = not-accessible</td>
</tr>
<tr>
<td>ctAliasTimeFilter</td>

## EXTREME-CFGMGM-MIB

This MIB provides the ability to query configuration activity and to perform switch management operations. The following features are part of this MIB:

- Expose the time and date of the last configuration save operation.
- Issue a notification to NMS upon completion of a database save operation.
- Provide the ability for ExtremeXOS to report on-demand the presence of unsaved configuration changes on the system.
- Issue a notification whenever any system configuration is altered, added, or deleted.

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeLastSaveCfgTable</td>
<td>extremeLastSavedEntry</td>
<td>This group of objects contain details of the last saved configuration operation for the running configure. If the value of extremeLastChangeConfigTime is greater than extremeLastSaveConfigTime, the configuration has been changed but not saved.</td>
</tr>
<tr>
<td>extremeLastSaveConfigSlotId</td>
<td></td>
<td>Specifies the MSM/MM module number of a switch or the slot number currently being used by the active stack node.</td>
</tr>
<tr>
<td>extremeLastSaveConfigTime</td>
<td></td>
<td>This object return the date and time of the last configuration save operation. This data reflects the last command or the last setting of the extremeSaveConfiguration object.</td>
</tr>
<tr>
<td>extremeLastSaveConfigFileName</td>
<td></td>
<td>This object returns the configuration file name of the last save operation.</td>
</tr>

</tbody>
</table>

### ENTERASYS-MAC-AUTHENTICATION-MIB

The following tables, groups, and variables are supported in this MIB.
<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>etsysMACAuthenticationSystemGroup</td>
<td>etsysMACAuthenticationSystemEnable</td>
<td>When enabled(1), all objects in this MIB are fully active. When disabled(2), this object overrides all other object settings in this MIB without affecting their values.</td>
</tr>
<tr>
<td></td>
<td>etsysMACAuthenticationMACUserPassword</td>
<td>This is the string to be used as a password credential when authenticating a MAC address when etsysMACAuthenticationMode is set to sharedSecret(1).</td>
</tr>
<tr>
<td></td>
<td>etsysMACAuthenticationPortUserNameSignificantBits</td>
<td>This object represents the number of significant bits in the MAC addresses to be used starting with the left-most bit of the vendor portion of the MAC address. The significant portion of the MAC address is sent as a user-name credential when the primary attempt to authenticate the full MAC address fails. Any other failure to authenticate the full address, (i.e. authentication server timeout) causes the the next attempt to start once again with a full MAC authentication.”</td>
</tr>
<tr>
<td></td>
<td>etsysMACAuthenticationMode</td>
<td>This object is used to determine the type of password credential to use when authenticating a MAC address. password(1) - Attempt to authenticate a user with the password credential provided by etsysMACAuthenticationMACUserPassword. radiusUsername(2) - Attempt to authenticate a user with a password credential that is the same as their radius username credential.</td>
</tr>
<tr>
<td></td>
<td>etsysMACAuthenticationSystemAccountEnable</td>
<td>When enabled(1), RADIUS accounting start, interim and stop frames are sent to the configured RADIUS server(s). When disabled(2), accounting packets are not sent to the RADIUS server.</td>

</table>

**ENTERASYS-MULTI-AUTH-MIB**

The following tables, groups, and variables are supported in this MIB.
<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multiple Authentication System Group</td>
<td>etsysMultiAuthSystemSupported Types</td>
<td>This object specifies that authentication types that the device supports. A bit will be set for each corresponding type that is supported.</td>
</tr>
<tr>
<td></td>
<td>etsysMultiAuthSystemMaxNumUsers</td>
<td>The maximum number of users the can be actively authenticated or have authentications in progress at one time in the system.</td>
</tr>
<tr>
<td></td>
<td>etsysMultiAuthSystemCurrentNumUsers</td>
<td>The current number of users the are actively authenticated, have authentications in progress, or the device is keeping authentication termination information for in the system.</td>
</tr>
<tr>
<td></td>
<td>etsysMultiAuthSystemMode</td>
<td>The value strictieee8021x(1) will cause the device to authenticate in strict adherence to IEEE Std. 802.1X-2001. In this mode no other authentication mechanisms will be active. While in this mode, changes may be made to other objects in the MIB, but they will have no effect on the operation of the device until such time as the system mode is changed to etsysMultiAuth(2). A set of this object to a value of etsysMultiAuth(2) will cause the device to authenticate using multiple authenticators simultaneously.</td>
</tr>
<tr>
<td></td>
<td>etsysMultiAuthSystemDefaultPrecedence</td>
<td>The precedence that authentication results will be applied to network traffic by default. This object will have a size equal to the number of enumerations specified by the EtsysMultiAuthTypes textual convention.</td>
</tr>
<tr>
<td></td>
<td>etsysMultiAuthSystemAdminPrecedence</td>
<td>This object allows one to modify the default precedence by which authentication results will be applied to network traffic. Sets to this object are not required to specify all of the types that the device supports. If less types are specified than are supported, then all types that were not specified will be given an operational precedence based on that type’s default precedence relative to the last type specified. For example, if the default precedence is ’030102’H and the object is set to ’02’H then operational precedence would be ’020301’H. A set to this object of a zero length octet string will clear the administrative precedence. In this case the operational precedence would be equal to the default precedence.</td>
</tr>
<tr>
<td></td>
<td>etsysMultiAuthSystemOperPrecedence</td>
<td>This object returns the operational precedence of authentication types as they will be applied to network traffic. The value returned by this object is the calculated result of the etsysMultiAuthSystemDefaultPrecedence and etsysMultiAuthSystemAdminPrecedence.</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>etsysMultiAuthSessionAuthServerAddr</td>
<td>The network address of the authentication server for this session. If the etsysMultiAuthSessionAuthServerType leaf for this entry has a value of local(2) then this object MUST return a zero length string.</td>
<td></td>
</tr>
<tr>
<td>The network address of the authentication server for this session. If the etsysMultiAuthSessionAuthServerType leaf for this entry has a value of local(2) then this object MUST return a zero length string.</td>
<td>The Policy Profile Index returned from the authentication server for this session. The value of zero indicates that no policy will be applied for this session. If the etsysMultiAuthSessionStationAuthStatus object returns a value of authSuccess(1), then a value of zero is the result of the policy not being configured on the authorization server. For all other values of etsysMultiAuthSessionStationAuthStatus a value of zero for this object is the result of authorization not succeeding or not having completed. All values other than zero are valid Policy Profile Indexes that specify the policy profile the user will receive on this interface. If a given user has been authenticated by multiple authentication types on the same interface the policy that is applied to the user’s packets is determined by the precedence of the agents as specified by etsysMultiAuthSystemOperPrecedence. These indexes are suitable for indexing in the ENTERASYS-POLICY-PROFILE-MIB.</td>
<td></td>
</tr>
<tr>
<td>etsysMultiAuthSessionIsApplied</td>
<td>This object indicates whether this entry and the policy index contained within it are actively being applied to traffic matching the interface and station address of this entry. A value of true(1) indicates that this entry is being applied. A value of false(2) indicates that the entry is not being applied. Only one authentication type per interface station address ordered pair may be applied at a single time. The operational precedence of the various authentication types determines which if any type will be applied.</td>

<tr>
<td></td>
<td>etsysPolicyProfileTableNextAvailableIndex</td>
<td>This object indicates the numerically lowest available index within this entity, which may be used for the value of etsysPolicyProfileIndex in the creation of a new entry in the etsysPolicyProfileTable. An index is considered available if the index value falls within the range of 1 to 65535 and is not being used to index an existing entry in the etsysPolicyProfileTable contained within this entity. This value should only be considered a guideline for management creation of etsysPolicyProfileEntries, there is no requirement on management to create entries based upon this index value.</td>
</tr>
<tr>
<td></td>
<td>etsysPolicyProfileTable</td>
<td>A table containing policy profiles. A policy is a group of classification rules which may be applied on a per user basis, to ports or to stations.</td>
</tr>
<tr>
<td></td>
<td>etsysPolicyProfileEntry</td>
<td>Conceptually defines a particular entry within the etsysPolicyProfileTable. Entries within this table MUST be considered non-volatile and MUST be maintained across entity resets.</td>
</tr>
<tr>
<td></td>
<td>etsysPolicyProfileIndex</td>
<td>A unique arbitrary identifier for this Policy. Since a policy will be applied to a user regardless of his or her location in the network fabric policy names SHOULD be unique within the entire network fabric. Policy IDs and policy names MUST be unique within the scope of a single managed entity.</td>
</tr>
<tr>
<td></td>
<td>etsysPolicyProfileName</td>
<td>Administratively assigned textual description of this Policy. This object MUST NOT be modifiable while this entry’s RowStatus is active(1).</td>
</tr>
<tr>
<td></td>
<td>etsysPolicyProfileRowStatus</td>
<td>This object allows for the dynamic creation and deletion of entries within the etsysPolicyProfileTable as well as the activation and deactivation of these entries. When this object’s value is active(1) the corresponding row’s etsysPolicyProfilePortVid,</td>
</tr>
<tr>

<td>---------------------</td>
<td>----------</td>
</tr>
<tr>
<td></td>
<td>etsysPolicyProfilePriority, and all entries within the etsysPolicyClassificationTable indexed by this row’s etsysPolicyProfileIndex are available to be applied to network access ports or stations on the managed entity. All ports corresponding to rows within the etsysPortPolicyProfileTable whose etsysPortPolicyProfileOperID is equal to the etsysPolicyProfileIndex, shall have the corresponding policy applied. Likewise, all stations corresponding to rows within the etsysStationPolicyProfileTable whose etsysStationPolicyProfileOperID is equal to the etsysPolicyProfileIndex, shall have the corresponding policy applied. The value of etsysPortPolicyProfileOperID for each such row in the etsysPortPolicyProfileTable will be equal to the etsysPortPolicyProfileAdminID, unless the authorization information from a source such as a RADIUS server indicates to the contrary. Refer to the specific objects within this MIB as well as RFC2674, the CTRON-PRIORITY-CLASSIFY-MIB, the CTRON-VLAN-CLASSIFY-MIB, and the CTRON-RATE-POLICING-MIB for a complete explanation of the application and behavior of these objects. When this object’s value is set to notInService(2) this policy will not be applied to any rows within the etsysPortPolicyProfileTable. To allow policy profiles to be applied for security implementations, setting this object’s value from active(1) to notInService(2) or destroy(6) SHALL fail if one or more instances of etsysPortPolicyProfileOperID or etsysStationPolicyProfileOperID currently reference this entry’s associated policy due to a set by an underlying security protocol such as RADIUS. For network functionality and clarity, setting this object to destroy(6) SHALL fail if one or more instances of etsysPortPolicyProfileOperID or etsysStationPolicyProfileOperID currently references this entry’s etsysPolicyProfileIndex. Refer to the RowStatus convention for further details on the behavior of this object.</td>

<td></td>
</tr>
<tr>
<td>etsysPolicyRFC3580MapPolicyIndex</td>
<td>The index of a Policy Profile as defined in the etsysPolicyProfileTable. A value of 0 indicates that the row is functionally non-operational (no mapping exists). Devices which support the ENTERASYS-VLAN-AUTHORIZATION-MIB, and for which the value of etsysVlanAuthorizationEnable is Enabled and the value of etsysVlanAuthorizationStatus is Enabled on the port referenced by the authorization request, should then use the VlanIndex provisioned (e.g. from the Tunnel-Private-Group-ID RADIUS attribute) as defined by RFC3580, otherwise, the device should treat the result as if no matching Policy Profile had been found (e.g. as a simple success). In the case where a Policy Profile is already being applied to the referenced station, but no mapping exists, the device MUST treat the Tunnel-Private-Group-ID as an override to the etsysPolicyProfilePortVid defined by that profile (any matched classification rules which explicit provision a VLAN MUST still override both the etsysPolicyProfilePortVid and the Tunnel-Private-Group-ID.) A non-zero value of this object indicates that the VlanIndex provisioned (e.g. from the Tunnel-Private-Group-ID RADIUS attribute) should be mapped to a Policy Profile as defined in the etsysPolicyProfileTable, and that policy applied as if the Policy name had been provisioned instead (e.g. in the Filter-ID RADIUS attribute). If the mapping references a non-existent row of the etsysPolicyProfileTable, or the referenced row has a etsysPolicyProfileRowStatus value other than Active, the device MUST behave as if the mapping did not exist (apply the vlan-tunnel-attribute). The etsysPolicyRFC3580MapInvalidMapping MUST then be incremented.</td>

The following tables, groups, and variables are supported in this MIB.
<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIB Objects</td>
<td>etsysRadiusAcctClientEnable</td>
<td>This object indicates whether or not RADIUS Accounting is enabled or disabled. This parameter value is maintained across system reboots.</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientUpdateInterval</td>
<td>This indicates how many seconds elapse between accounting interim updates. This parameter value is maintained across system reboots. A value of zero means no Interim Updates. If the value is less than etsysRadiusAcctClientIntervalMinimum, the etsysRadiusAcctClientIntervalMinimum value will be used for the update interval time. If RADIUS Accounting is not enabled, this object is ignored. Note that Accounting Interim Updates are not issued by the RADIUS Accounting Client, unless so requested by the RADIUS Server in an Access Accept packet.</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientIntervalMinimum</td>
<td>This indicates the minimum value in seconds between accounting interim updates supported by the managed entity. This parameter value is maintained across system reboots. If RADIUS Accounting is not enabled, this object is ignored.</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientServerTable</td>
<td>The (conceptual) table listing the RADIUS Accounting servers.</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientServerEntry</td>
<td>An entry (conceptual row) representing a RADIUS Accounting server with which the client shares a secret. If RADIUS Accounting is not enabled, this table is ignored. All created conceptual rows are non-volatile and as such must be maintained upon restart of the agent.</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientServerIndex</td>
<td>A number uniquely identifying each conceptual row in the etsysRadiusAcctClientServerTable. In the event of an agent restart, the same value of etsysRadiusAcctClientServerIndex must be used to identify each conceptual row in etsysRadiusAcctClientServerTable as was used prior to the restart.</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientServerAddressType</td>
<td>The type of Internet address by which the RADIUS Accounting server is reachable.</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientServerAddress</td>
<td>The Internet address for the RADIUS Accounting server. Note that implementations must limit themselves to a single entry in this table per reachable server. The etsysRadiusAcctClientServerAddress may not be empty due to the SIZE restriction. Also the size of a DNS name is limited to 64 characters.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------</td>
<td>----------</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientServerPort Number</td>
<td>The UDP port number (1-65535) the client is using to send requests to this server. The officially assigned port number for RADIUS Accounting is 1813. This parameter value is maintained across system reboots.</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientServerSecret</td>
<td>This object is the secret shared between the RADIUS Accounting server and RADIUS client. This parameter value is maintained across system reboots. While the ‘official’ MAX-ACCESS for this object is read-create, all security-conscious implementations will ‘lie’ on a read, and return a null-string, or something else that is fairly innocuous. The ability to read back passwords and secret encryption keys is generally a Bad Thing (tm).</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientServerSecretEntered</td>
<td>This indicates the existence of a shared secret.</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientServerRetryTimeout</td>
<td>The number of seconds to wait for a RADIUS Accounting Server to respond to a request. This parameter value is maintained across system reboots. A value of -1 indicates that the appropriate realm value should be used - etsysRadiusAcctClientMgmtRetryTimeout or etsysRadiusAcctClientNetworkRetryTimeout.</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientServerRetries</td>
<td>The number of times to resend an accounting packet if a RADIUS Accounting Server does not respond to a request. This parameter value is maintained across system reboots.</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientServerClearTime</td>
<td>On a read, this value indicates the number of seconds since the counters, as defined in the IETF standard RADIUS Accounting Client MIB (RFC2618), were cleared. On a write, the client counters will be cleared and the clear time will be set to zero.</td>
</tr>
<tr>
<td></td>
<td>etsysRadiusAcctClientServerStatus</td>
<td>Lets users create and delete RADIUS Accounting server entries on systems that support this capability. Rules 1 When creating a RADIUS Accounting Client, it is up to the management station to determine a suitable etsysRadiusAcctClientServerIndex. To facilitate interoperability, agents should not put any restrictions on the etsysRadiusAcctClientServerIndex beyond</td>

<td>------------------------</td>
<td>--------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| The Syslog Server Defaults | etsysSyslogServerDefaultUdpPort      | The default UDP port number that the managed entity is using to send syslog messages. This value will be used as the default value for etsysSyslogServerUdpPort when creating rows in the etsysSyslogServerTable and either:  
• no value is specified for etsysSyslogServerUdpPort  
• etsysSyslogServerUdpPort is implemented read-only.  
If etsysSyslogServerUdpPort is implemented read-only, and this value is changed, it should affect the UDP port that is used to send syslog messages to all servers as soon as it is practical. This parameter value is maintained across system reboots. etsysSyslogServerDefaultUdpPort value is 514. Read-only |
|                        | etsysSyslogServerDefaultFacility    | The default syslog facility (local0-local7) that will be encoded in syslog messages. This value will be used as the default value for etsysSyslogServerFacility when creating rows in the etsysSyslogServerTable and either:  
• no value is specified for etsysSyslogServerFacility  
• etsysSyslogServerFacility is implemented read-only.  
If etsysSyslogServerFacility is implemented read-only, and this value is changed, it should affect the syslog facility that is encoded in all syslog messages as soon as it is practical. This parameter value is maintained across system reboots. etsysSyslogServerDefaultFacility value is local0(16). Read-only |
|                        | etsysSyslogServerDefaultSeverity    | The default syslog message severity level that will be used to filter all syslog messages. This value will be used as the default value for etsysSyslogServerSeverity when creating rows in the etsysSyslogServerTable and either: |
Table/Group | Supported Variables | Comments
--- | --- | ---
**etsysSyslogServerSeverity** |  | • no value is specified for etsysSyslogServerSeverity • etsysSyslogServerSeverity is implemented read-only. The higher the severity level, the less critical it is. If etsysSyslogServerSeverity is implemented read-only, and this value is changed, it should affect the syslog message severity level that will be used to filter all syslog messages as soon as it is practical. This parameter value is maintained across system reboots. etsysSyslogServerDefaultSeverity value is debug(8). Read-only

The mapping between Syslog MIB severity (for example, etsysSyslogServerSeverity) and ExtremeXOS severity is not one-to-one as ExtremeXOS does not support “emergency” and “alert” severity; and Syslog MIB does not support “debug-data”, “debug-verbose” and “debug-summary” severity.

The following table shows the mapping between the two:

<table>
<thead>
<tr>
<th>etsysSyslogServerSeverity</th>
<th>ExtremeXOS Syslog Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>emergency, alert, critical</td>
<td>critical</td>
</tr>
<tr>
<td>Error</td>
<td>error</td>
</tr>
<tr>
<td>Warning</td>
<td>warning</td>
</tr>
<tr>
<td>Notice</td>
<td>notice</td>
</tr>
<tr>
<td>Info</td>
<td>info</td>
</tr>
<tr>
<td>debug</td>
<td>debug-data, debug-verbose, debug-summary</td>
</tr>
</tbody>
</table>

**ENTERASYS-VLAN-AUTHORIZATION-MIB**

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>etsysVlanAuthorizationEnable</td>
<td>All objects</td>
<td>The enable/disable state for the VLAN authorization feature. When disabled, no modifications to the VLAN attributes related to packet switching should be enforced.</td>
</tr>
<tr>
<td>etsysVlanAuthorizationTable</td>
<td>All objects</td>
<td>Extensions to the table that contains information about every port that is associated with this transparent bridge.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>---------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>etsysVlanAuthorizationEntry</td>
<td>All objects</td>
<td>A list of extensions that support the management of proprietary features for each port of a transparent bridge. This is indexed by dot1dBasePort.</td>
</tr>
<tr>
<td>etsysVlanAuthorizationStatus</td>
<td>All objects</td>
<td>The enabled/disabled status for the application of VLAN authorization on this port, if disabled, the information returned in the VLAN-Tunnel-Type from the authentication will not be applied to the port (although it should be represented in this table).</td>
</tr>
<tr>
<td>etsysVlanAuthorizationAdminEgress</td>
<td>All objects</td>
<td>Controls the modification of the current vlan egress list (of the vlan returned in the VLAN-Tunnel-Type, and reported by etsysVlanAuthorizationVlanID) upon successful authentication in the following manner: none(1) No egress manipulation will be made. tagged(2) The authenticating port will be added to the current egress for the VLAN-ID returned. untagged(3) The authenticating port will be added to the current untagged egress for the VLAN-ID returned. dynamic(4) The authenticating port will use information returned in the authentication response to modify the current egress lists. This value is supported only if the device supports a mechanism through which the egress status may be returned through the RADIUS response. Should etsysVlanAuthorizationEnable become disabled, etsysVlanAuthorizationStatus become disabled for a port, or should etsysVlanAuthorizationVlanID become 0 or 4095, all effect on the port egress MUST be removed.</td>
</tr>
<tr>
<td>etsysVlanAuthorizationOperEgress</td>
<td>All objects</td>
<td>Reports the current state of modification to the current vlan egress list (of the vlan returned in the VLAN-Tunnel-Type) upon successful authentication, if etsysVlanAuthorizationStatus is enabled, in the following manner: none(1) No egress manipulation will be made. tagged(2) The authenticating port will be added to the current egress for the VLAN-ID returned. untagged(3) The authenticating port will be added to the current untagged egress for the VLAN-ID returned. The purpose of this leaf is to report, specifically when etsysVlanAuthorizationAdminEgress has been set to dynamic(4), the currently enforced egress modification. If the port is unauthenticated, or no VLAN-ID has been applied, this leaf should return none(1).</td>
</tr>
</tbody>
</table>
### EtsysVlanAuthorizationVlanID

<table>
<thead>
<tr>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>All objects</td>
<td>The 12 bit VLAN identifier for a given port, used to override the PVID of the given port, obtained as a result of an authentication. A value of zero indicates that there is no authenticated VLAN ID for the given port. Should a port become unauthenticated this value MUST be returned to zero. A value of 4095 indicates that a the port has been authenticated, but that the VLAN returned could not be applied to the port (possibly because of resource constraints or misconfiguration). In this instance, the original PVID should still be applied. Should the feature become disabled or the session terminate, all effect on the Port VLAN ID MUST be removed.</td>
</tr>
</tbody>
</table>

<td>The status of the row. All columns must have a valid value before a row can be activated.</td>
</tr>
<tr>
<td>extremeCfmGroupMepDbTable</td>
<td>extremeCfmGroupMepDbEntry</td>
<td>Maintains information about other MEPS in that group. Complex index including Maintenance Domain, MaNet, MEP and Group indices along with RMEP ID to identify a row in this table. Not accessible.</td>
</tr>
<tr>
<td></td>
<td>extremeCfmGroupMepDbRMepId</td>
<td>Maintenance association End Point Identifier of a remote MEP whose information from the group MEP database is to be returned. Not accessible.</td>
</tr>
<tr>
<td></td>
<td>extremeCfmGroupMepDbRowStatus</td>
<td>The status of the row. All columns must have a valid value before a row can be activated.</td>
</tr>
<tr>
<td>extremeCfmGroupStatusDownUpAlarm</td>
<td>extremeCfmGroupStatus</td>
<td>A notification (DownUpAlarm) is sent to the management entity with the OID of the group that has detected the status change.</td>
</tr>
</tbody>
</table>

**EXTREME-CLEARFLOW-MIB**

This MIB defines the following Extreme-specific CLEAR-Flow traps generated by Extreme Networks devices.
Clearflow Message Trap

The varbinds supported in this trap are:

- extremeClearflowMsgId
  - User-defined message ID.
- extremeClearflowMsg
  - User-defined message.
- extremeClearflowPolicyName
  - Policy file name.
- extremeClearflowRuleName
  - Rule name which triggered this message.
- extremeClearflowRuleValue
  - Calculated rule value.
- extremeClearflowRuleThreshold
  - Rule threshold value.
- extremeClearflowRuleInterval
  - Rule sampling and evaluation interval.
- extremeClearflowVlanName
  - VLAN name on which this policy is applied.
- extremeClearflowPortName
  - Port name on which this policy is applied.

EXTREME-EAPS-MIB

Managed objects for EAPS MIB are defined proprietary on ExtremeXOS.

Table 152 lists the existing traps supported in this MIB.

Table 152: EAPS MIB Traps

<table>
<thead>
<tr>
<th>Trap</th>
<th>Varbinds</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeEapsStateChange</td>
<td>extremeEapsName, extremeEapsMode, extremeEapsPrevState, extremeEapsState, extremeEapsFailedFlag, extremeEapsPrimaryStatus, extremeEapsSecondaryStatus</td>
<td>Send on Master/Transit Nodes</td>
</tr>

<tr>
<td></td>
<td>extremeEntityFRUOdometerUnit</td>
<td>Time unit used to represent value reported by extremeEntityFRUOdometer. Depends on the underlying hardware capability.</td>
</tr>
</tbody>
</table>

EXTREME-ERPS-MIB

Managed objects for ERPS MIB are defined proprietary on ExtremeXOS. Groups and tables are implemented as read only.

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeErpsProtectedVlanTable</td>
<td>All objects</td>
<td>Contains the grouping of set of protected VLANs.</td>
</tr>
<tr>
<td>extremeErpsRingTable</td>
<td>All objects</td>
<td>Contains information for each ERPS ring present in the switch.</td>
</tr>
<tr>
<td>extremeErpsStatsTable</td>
<td>All objects</td>
<td>Contains statistics information for each of the ring present in the switch.</td>
</tr>
<tr>
<td>extremeErpsGlobalInfo</td>
<td></td>
<td>Contains the information of ERPS configured globally in the switch.</td>
</tr>
<tr>
<td>extremeErpsNotification</td>
<td></td>
<td>Contains two types of traps: extremeErpsStateChangeTrap and extremeErpsFailureTrap. extremeErpsStateChangeTrap is generated on the following events: • Local SF is received for the ring. • Local Clear SF is received for the ring. • Remote failure is detected on this ring. • Remote failure is cleared on this ring. • Force Switch is issued for a ring. • Manual Switch is issued for a ring.</td>
</tr>
</tbody>
</table>
### EXTREME-ESRP-MIB

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeEsrpDomainTable</td>
<td>All objects</td>
<td>This table contains information for domains on this device.</td>

<tr>
<td>extremeFdbMacExosFdbTable</td>
<td>extremeFdbMacExosFdbEntry</td>
<td>A table that contains information about the hardware MAC FDB (forwarding database) table. Supported only on switches running ExtremeXOS. Supports SNMP get and get next operations only.</td>
</tr>
<tr>
<td>extremeFdbMacFdbCounterTable</td>
<td>All objects</td>
<td>Supports SNMP get and get next operations only.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Trap</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeMACTrackingAdd</td>
<td>The specified MAC address was added to the FDB on the mentioned port and VLAN.</td>
</tr>
<tr>
<td>extremeMACTrackingDel</td>
<td>The specified MAC address was deleted from the FDB on the mentioned port and VLAN.</td>
</tr>
<tr>
<td>extremeMACTrackingMove</td>
<td>The specified MAC address was moved from the previous port to the new port on the specified VLAN.</td>
</tr>
</tbody>
</table>
EXTREME-MAC-AUTH-MIB

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeMacAuthClientTable</td>
<td>All objects</td>
<td>This table contains client authentication based on the source MAC address of the traffic received on a port.</td>
</tr>
<tr>
<td>ExtremeMacAuthClientEntry</td>
<td></td>
<td>An entry in the MAC authentication table. Each entry represents a MAC authentication client</td>
</tr>
<tr>
<td>extremeMacAuthClientAddress</td>
<td></td>
<td>The MAC address of the client.</td>
</tr>
<tr>
<td>extremeMacAuthClientInitialize</td>
<td></td>
<td>Remove the entry for the client from extremeMacAuthClientTable.</td>
</tr>
<tr>
<td>extremeMacAuthClientReauthenticate</td>
<td></td>
<td>Re-authenticate the client on all ports on which the client is connected.</td>
</tr>
</tbody>
</table>

EXTREME MLAG MIB

The following tables, groups, and variables are supported in this MIB.

Note

EXTREME MLAG MIB objects such as extremeMlagLocalAddrType, extremeMlagLocalIP, extremeMlagAlternateLocalAddrType, extremeMlagAlternateLocalIP are defined with a maximum access of read-create and are populated automatically based on MLAG peer info.

<table>
<thead>
<tr>
<th>Table/Group</th>

**EXTREME-MPLS-MIB**

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeMplsNotifications</td>
<td>extremepwUpDownNotificationEnable</td>
<td>If this object is set to true (1), then it enables the emission of pwUp and pwDown notifications; otherwise these notifications are not emitted.</td>
</tr>
<tr>
<td></td>
<td>extremepwDeletedNotificationEnable</td>
<td>If this object is set to true (1), then it enables the emission of pwDeleted notification; otherwise this notification is not emitted.</td>
</tr>
<tr>
<td></td>
<td>pwNotificationMaxRate</td>
<td>This variable indicates the maximum number of notifications issued per second. If events occur more rapidly, the implementation may simply fail to emit these notifications during that period, or might queue them until an appropriate time. A value of 0 means no throttling is applied and events might be notified at the rate at which they occur.</td>
</tr>
<tr>
<td></td>
<td>extremepwNotificationPwIndex</td>
<td>This variable indicates the index of the PW that either went up, down, or was deleted as reported by the corresponding notification.</td>
</tr>
<tr>
<td></td>
<td>extremepwNotificationPwOperStatus</td>
<td>This variable is used to report the value of pwOperStatus in pwTable (RFC 5601) associated with the PW that went up or down.</td>
</tr>
<tr>
<td></td>
<td>extremepwNotificationPeerAddrType</td>
<td>Denotes the address type of the peer node.</td>
</tr>
<tr>
<td></td>
<td>extremepwNotificationPeerAddr</td>
<td>This object contains the value of the peer node address.</td>
</tr>
<tr>
<td></td>
<td>extremeMplsNotifTunnelIndex</td>
<td>Uniquely identifies a set of tunnel instances between a pair of ingress and egress LSRs. Contains part of the index of a TE tunnel that underwent state change. The same tunnel can also be looked up in the TE MIB.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>extremeMplsNotifTunnelInstance</td>
<td>Uniquely identifies a particular instance of a tunnel between a pair of ingress and egress LSRs.</td>
</tr>
<tr>
<td></td>
<td>extremeMplsNotifTunnelIngressLSRid</td>
<td>Identity of the ingress LSR associated with this tunnel instance.</td>
</tr>
<tr>
<td></td>
<td>extremeMplsNotifTunnelEgressLSRId</td>
<td>Identity of the egress LSR associated with this tunnel instance.</td>
</tr>
<tr>
<td></td>
<td>extremeMplsNotifTunnelAdminStatus</td>
<td>Reports the desired operational status of this tunnel.</td>
</tr>
<tr>
<td></td>
<td>extremeMplsNotifTunnelOperStatus</td>
<td>Reports the actual operational status of this tunnel, which is typically but not limited to, a function of the state of individual segments of this tunnel.</td>
</tr>
<tr>
<td></td>
<td>extremeMplsNotifLdpEntityLdpId</td>
<td>The LDP identifier. This is the primary index to identify a row in the mplsLdpEntityTable (RFC 3815).</td>
</tr>
<tr>
<td></td>
<td>extremeMplsNotifLdpEntityIndex</td>
<td>This index is used as a secondary index to uniquely identify a row in the mplsLdpEntityTable (RFC 3815). This object is meaningful to some, but not all, LDP implementations.</td>
</tr>
<tr>
<td></td>
<td>extremeMplsNotifLdpPeerLdpId</td>
<td>The LDP identifier of this LDP Peer.</td>
</tr>
<tr>
<td></td>
<td>extremeMplsNotifLdpSessionState</td>
<td>The current state of the session, all of the states 1 to 5 are based on the state machine for session negotiation behavior.</td>
</tr>
<tr>
<td></td>
<td>extremeMplsNotifLdpSessionDiscontinuityTime</td>
<td>The initial value of this object is the value of sysUpTime when the entry was created in this table. Subsequent notifications report the time when the session between a given entity and peer goes away or a new session is established.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsNotifConfigIndex</td>
<td>Unique index for the conceptual row identifying a VPLS service in the vplsConfigTable.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsNotifConfigVpnId</td>
<td>This objects indicates the IEEE 802-1990 VPN ID of the associated VPLS service. This object has the same value as vplsConfigVpnId in the vplsConfigTable for an index value equal to extremeVplsNotifConfigIndex sent in the notification.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsNotifConfigAdminStatus</td>
<td>The administrative state of the VPLS service. This object has the same value as vplsConfigAdminStatus in the vplsConfigTable for an index value equal to extremeVplsNotifConfigIndex sent in the notification.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------</td>
<td>----------</td>
</tr>
<tr>
<td></td>
<td>extremeVplsNotifStatusOperStatus</td>
<td>The current operational state of this VPLS service. A value of up (1) indicates that all PWs for this VPLS are up and the attachment circuit is up. A value of degraded (2) indicates that at least one PW for this VPLS is up and the attachment circuit is up. A value of down (3) indicates that all PWs for this VPLS are down or the attachment circuit is down.</td>
</tr>
<tr>
<td></td>
<td>extremePwStatusChange</td>
<td>This notification is generated when the pwOperStatus object for a pseudowire transitions from up (1) to down (2) or from down (2) to up (1).</td>
</tr>
<tr>
<td></td>
<td>extremePwDeleted</td>
<td>This notification is generated when a PW has been deleted.</td>
</tr>
<tr>
<td></td>
<td>extremeMplsTunnelStatusChange</td>
<td>This notification is generated when the mplsTunnelOperStatus object for a TE-LSP transitions from up (1) to down (2) or from down (2) to up (1). This new state is indicated by the included value of mplsTunnelOperStatus.</td>
</tr>
<tr>
<td></td>
<td>extremeMplsLdpSessionStatusChange</td>
<td>This notification is generated when the value of 'mplsLdpSessionState' (RFC3815) enters or leaves the operational (5) state.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsStatusChange</td>
<td>This notification is generated to inform recipients of the state of the VPLS. When all PWs in this VPLS are up or ready and the attachment circuit is up, extremeVplsNotifStatusOperStatus is set to vplsOperStatusUp (1) in the notification. When at least one PW in this VPLS is up or ready and the attachment circuit is up, extremeVplsNotifStatusOperStatus is set to vplsOperStatusDegraded (2) in the notification. When all PWs in this VPLS are down or the attachment circuit is down, extremeVplsNotifStatusOperStatus is set to vplsOperStatusDown (3) in the notification. Once a notification has been sent with vplsOperStatusDegraded (2), no further notification will be sent until extremeVplsNotifStatusOperStatus transitions to vplsOperStatusUp (1) or vplsOperStatusDown (3).</td>
</tr>
<tr>
<td></td>
<td>extremeVplsConfigTable</td>
<td>This table specifies information for configuring and monitoring VPLS.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsConfigEntry</td>
<td>A row in this table represents a VPLS in a packet network. It is indexed by extremeVplsConfigIndex, which uniquely identifies a single VPLS.</td>
</tr>
<tr>

<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ExtremeVplsConfigEntry</td>
<td>extremeVplsConfigIndex</td>
<td>Unique index for the conceptual row identifying a VPLS service.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsConfigRedunType</td>
<td>This variable indicates the redundancy type for this VPLS. Redundancy states can be None, EAPS, ESRP, and STP.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsConfigEAPSSstatus</td>
<td>This variable indicates the EAPS redundancy status for this VPLS. It displays Protected if the VLAN is protected, else Not Protected. EAPS status displays the following values: Waiting—If waiting on EAPS status. Connected—if EAPS ring status is connected to VLAN. PW is not installed in this state. Disconnected—if EAPS ring state is disconnected. PW is installed in this state. Unknown—if EAPS is not found.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsConfigESRPState</td>
<td>This variable indicates the ESRP redundancy state for this VPLS. ESRP states can have two values: master and slave. PW is installed only when ESRP is in the master state.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsStatusTable</td>
<td>This table specifies information for configuring and monitoring VPLS.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsStatusIndex</td>
<td>This index uniquely identifies a single VPLS.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsOperStatus</td>
<td>This variable indicates the VPLS operation status. This is different from the VPLS PW status shown in the standard MIB. Supported values are: Up—all PWs are in the Up or Ready state. Degraded—At least one PW is in the Up or Ready state. Down—None of the PWs are in Up or Ready state.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsPeerTable</td>
<td>This table provides information for monitoring VPLS peer entries.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsPeerIndex</td>
<td>This entry contains information for all the peers belonging to a particular VPLS.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsPeerIndex</td>
<td>This index uniquely identifies a VPLS service.</td>
</tr>
<tr>
<td></td>
<td>extremeVplsPwBindIndex</td>
<td>Secondary index for the conceptual row identifying a PW within the PwEntry which must match an entry from the PW-STD-MIB’s PwTable, which represents an already-provisioned PW that is then associated with this VPLS instance.</td>
</tr>

<td></td>
<td>extremePwInstalled</td>
<td>Boolean true or false, indicating if PW is installed.</td>
</tr>
<tr>
<td></td>
<td>extremePwMode</td>
<td>The peer mode of this PW. It indicates its current mode and the mode of the switch it is connected to. It can have the following values: Core-to-core, Core-to-Spoke, and Spoke-to-Core.</td>
</tr>
<tr>
<td></td>
<td>extremePwConfiguredRole</td>
<td>The configured role of this PW. It applies only in the case the PWMode is Core-to-core. In this case, the configured role can either be Primary or Secondary. For all the other PW modes, the configured role does not apply.</td>
</tr>
</tbody>
</table>

The following traps can be generated:

<table>
<thead>
<tr>
<th>Trap</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwStatusChange</td>
<td>This notification is generated when the pwOperStatus object for a PW transitions from up (1) to down (2) or from down (2) to up (1).</td>
</tr>
<tr>
<td>pwDeleted</td>
<td>This notification is generated when a PW has been deleted.</td>
</tr>
<tr>
<td>extremeMPLSTrapsEnable</td>
<td>MPLS trap status. If enabled then all the MPLS related traps are sent out.</td>
</tr>
<tr>
<td>extremeL2VpnTrapsEnable</td>
<td>L2VPN trap status. If enabled then all the L2VPN related traps are sent out.</td>
</tr>
</tbody>
</table>

**EXTREME-MPLS-TE-MIB**

The following tables, groups, and variables are supported in this MIB:
## Table/Group | Supported Variables | Comments
--- | --- | ---
**extremeMplsTunnelTable** | mplsTunnelIndex | The mplsTunnelTable (see RFC3812) allows new MPLS tunnels to be created between an LSR and a remote endpoint, and existing tunnels to be reconfigured or removed. Note that only point-to-point tunnel segments are supported, although multipoint-to-point and point-to-multipoint connections are supported by an LSR acting as a cross-connect. Each MPLS tunnel can thus have one out-segment originating at this LSR and/or one in-segment terminating at this LSR. Extreme Networks MPLS implementation allows tunnel instances with a common endpoint to be grouped at the ingress LSR to provide redundancy. The role of each tunnel in the group must be configured and is indicated by extremeMplsTunnelRedundancyType.

**mplsTunnelInstance** | | Uniquely identifies a particular instance of a tunnel between a pair of ingress and egress LSRs. It is useful to identify multiple instances of tunnels for the purposes of backup and parallel tunnels.

**mplsTunnelIngressLSRId** | | Identity of the ingress LSR associated with this tunnel instance.

**mplsTunnelEgressLSRId** | | Identity of the egress LSR associated with this tunnel instance.

**mplsTunnelRedundancyType** | | Identifies the tunnel redundancy type associated with this tunnel instance. A value of primary (1) or secondary (2) MAY be assigned by the network administrator or by an SNMP manager at the time of setting up the tunnel.

**mplsTunnelRedundancyStatus** | | Indicates the actual redundancy status of this tunnel. When the status is active, the tunnel is the preferred tunnel in the group.

**mplsTunnelTransportStatus** | | Indicates the type of traffic the tunnel group can be used for sending. When the status is allowAllIp (0), IP traffic destined for all IPv4 routes is allowed over any tunnel in the group marked active. When the status is allowAssignedIpOnly (1), IP traffic destined only for IPv4 static routes that have been explicitly configured to use this tunnel group is allowed. When the status is allowAllLayer2Vpn (2), Layer 2 VPN traffic for all Layer 2 VPNs is allowed over any tunnel in the group marked active. When the status is allowAssignedLayer2VpnOnly (3), Layer 2 VPN traffic destined only for PWs that have been explicitly configured to use this tunnel group are allowed.

---

</tr>
<tr>
<td>extremePortAdminSpeed</td>
<td></td>
<td>Read-write access. The configured speed of the port. The current actual speed of the port can be determined from ifSpeed</td>
</tr>
<tr>
<td>extremePortDuplex</td>
<td></td>
<td>Read-write access. Indicates whether the port is operating in half-duplex, full-duplex, or auto negotiation mode.</td>
</tr>
<tr>
<td>extremePortMedium</td>
<td></td>
<td>Read-write access. Medium-specific attributes for combination ports.</td>
</tr>
</tbody>
</table>

The following traps can be generated:

<table>
<thead>
<tr>
<th>Trap</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremePortMauChangeTrap</td>
<td>This trap is sent whenever a MAU is inserted or removed. When the MAU is inserted, the value of extremePortMauStatus is 'inserted' and extremePortMauType indicates the type of the MAU inserted. If MAU is removed, the value of extremePortMauStatus is empty and the type of the MAU will be NONE.</td>
</tr>
<tr>
<td>extremeRateLimitExceededAlarm</td>
<td>This notification indicates the first time a poll of a rate-limited port has a non-zero counter.</td>
</tr>
</tbody>
</table>

**Pseudowire LSP Sharing MIB**

By implementing the tables in PW LSP sharing MIB, the SNMP manager is able to observe the transmit packet counters over each LSP that is configured for use by the PW, and aggregated transmit and receive packet counters over PW itself. It consist three tables:

- extremePwPerfTable
- extremePwLspOutboundMappingTable
- extremePwLspPerfTable
There are no standard MIB tables and scalars objects that can be used for Pseudo Wire LSP Sharing. MIB table and object defined here are Extreme Networks proprietary. These three table are implemented in code/ l3protocol/mpls/src/extrememiplsmib.my.

A new SNMP MIB object is introduced for PW LSP Load Sharing: extremePwObjects OBJECT IDENTIFIER ::= { extremeMplsMIB 5 }

extremePwPerfTable
This table contains the aggregated transmit and receive packet counters for in-service PWs.

<table>
<thead>
<tr>
<th>MIB Object</th>
<th>Description</th>
<th>Variable Type</th>
<th>Support Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwPerfInPackets</td>
<td>Receive packet counter per PW</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwPerfInBytes</td>
<td>Receive packet counter in bytes per PW</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwPerfOutPackets</td>
<td>Transmit packet counters per PW</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwPerfOutBytes</td>
<td>Transmit packet counter in bytes per PW</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwPerfInHCPackets</td>
<td>Receive high capacity packet counter per PW</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwPerfInHCBytes</td>
<td>Receive packet counter in bytes per PW</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwPerfOutHCPackets</td>
<td>Transmit packet counters per PW</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwPerfOutHCBytes</td>
<td>Transmit packet counter in bytes per PW</td>
<td>Read</td>
<td>Supported</td>
</tr>
</tbody>
</table>

extremePwLspOutboundMappingTable
This table provides the mapping between PWs and LSPs by providing an LSP index. LSP indexes are assigned uniquely for each PW. Entries in this table indicate that an LSP is being used by an in-service PW. An SNMP notification will be sent when an entry is added or deleted.

<table>
<thead>
<tr>
<th>MIB Object</th>
<th>Description</th>
<th>Variable Type</th>
<th>Support Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>lspIndex</td>
<td>LSP index per LSP used by the PW. It is only unique per PW peer.</td>
<td>Index</td>
<td>Supported</td>
</tr>
<tr>
<td>pwLspOutboundLsrXcIndex</td>
<td>Corresponding entry in the MPLS (MultiProtocol Label Switching)-LSR-STD-MIB</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwLspOutboundTunnelIndex</td>
<td>Corresponding RSVP-TE tunnel index based on LSP index used by the PW</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>MIB Object</td>
<td>Description</td>
<td>Variable Type</td>
<td>Support Status</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------</td>
<td>----------------</td>
</tr>
<tr>
<td>pwLspOutboundTunnelInst ance</td>
<td>Corresponding RSVP-TE tunnel instance based on LSP index used by the PW</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwLspOutboundTunnelLcl LSR</td>
<td>Corresponding RSVP-TE tunnel ingress LSR ID based on LSP index used by the PW</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwLspOutboundTunnelPeer LSR</td>
<td>Corresponding RSVP-TE tunnel egress LSR ID based on LSP index used by the PW</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwLspOutboundTunnelTypeInUse</td>
<td>LSP Type used by the PW. mplsTe value (MIB definition is 1) is being used for RSVP-TE LSPs, and mplsNonTe value (MIB definition is 2) is being used for Static or LDP LSPs.</td>
<td>Read</td>
<td>Supported</td>
</tr>
</tbody>
</table>

**extremePwLspPerfTable**

This table contains the transmit packet and byte counters for traffic sent over a specific PW using a specific LSP.

<table>
<thead>
<tr>
<th>MIB Object</th>
<th>Description</th>
<th>Variable Type</th>
<th>Support Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwLspPerfOutPackets</td>
<td>Receive packet counter per LSP used by the PW.</td>
<td>Index</td>
<td>Supported</td>
</tr>
<tr>
<td>pwLspPerfOutBytes</td>
<td>Receive packet counter in bytes per LSP used by the PW.</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwLspPerfOutHCPackets</td>
<td>Receive high capacity packet counter per LSP used by the PW.</td>
<td>Read</td>
<td>Supported</td>
</tr>
<tr>
<td>pwLspPerfOutHCBytes</td>
<td>Receive high capacity packet counter in bytes per LSP used by the PW.</td>
<td>Read</td>
<td>Supported</td>
</tr>
</tbody>
</table>

**EXTREME-QOS-MIB**

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeQosProfileTable</td>
<td>extremeQosProfileIndex</td>
<td>An index that uniquely identifies an entry in the QoS table.</td>
</tr>
<tr>
<td></td>
<td>extremeQosProfileName</td>
<td>A unique QoS profile name.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>extremeQosProfileMinBw</td>
<td>The minimum percentage of bandwidth that this queue requires. The switch is required to provide the minimum amount of bandwidth to the queue. The lowest possible value is 0%.</td>
</tr>
<tr>
<td></td>
<td>extremeQosProfileMaxBw</td>
<td>The maximum percentage of bandwidth that this queue is permitted to use.</td>
</tr>
<tr>
<td></td>
<td>extremeQosProfilePriority</td>
<td>The level of priority at which this queue will be serviced by the switch.</td>
</tr>
<tr>
<td></td>
<td>extremeQosProfileRowStatus</td>
<td>The status of the extremeQosProfile entry. This object can be set to: active (1); createAndGo (4); createAndWait (5); destroy (6) The following values may be read: active (1); notInService(2); notReady (3)</td>
</tr>
<tr>
<td></td>
<td>extremeIQosProfileTable</td>
<td>The ExtremeXOS software does not support global QoS profile settings in CLI; it supports per port settings only. Walks of this table display the default values with which the ports are initialized.</td>
</tr>
<tr>
<td></td>
<td>extremeIQosProfileIndex</td>
<td>A unique ingress QoS profile name.</td>
</tr>
<tr>
<td></td>
<td>extremeIQosProfileMinBwType</td>
<td>The type of the current minimum bandwidth setting. A value of 1 signifies that the minimum bandwidth value is a percentage of the configurable port bandwidth. A value of 2 or 3 signifies a guaranteed minimum available bandwidth in Kbps or Mbps, respectively.</td>
</tr>
<tr>
<td></td>
<td>extremeIQosProfileMinBw</td>
<td>The guaranteed minimum bandwidth for this queue, expressed as either a percentage or a specific bandwidth value, as specified by the value of extremeIQosProfileMinBwType.</td>
</tr>
<tr>
<td></td>
<td>extremeIQosProfileMaxBwType</td>
<td>The type of the current maximum bandwidth setting. A value of 1 signifies that the maximum bandwidth value is a percentage of the configurable port bandwidth. A value of 2 or 3 signifies a maximum allowed bandwidth in Kbps or Mbps, respectively.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>extremeIQosProfileMaxBw</td>
<td>The maximum allowed input bandwidth for this queue, expressed as either a percentage or a specific bandwidth value, as specified by the value of extremeIQosProfileMaxBwType.</td>
</tr>
<tr>
<td></td>
<td>extremeIQosProfileRED</td>
<td>The random early drop threshold. When the input queue fill ratio exceeds this percentage, frames start to drop randomly with a linear increasing drop probability as the queue fill count approaches the maximum queue size. A value of 100 indicates that this feature is currently disabled.</td>
</tr>
<tr>
<td></td>
<td>extremeIQosProfileMaxBuf</td>
<td>The percentage of the total ingress queue size to use. Lower values can be used to reduce the maximum latency through this queue, but with potentially greater loss with bursty traffic.</td>
</tr>
<tr>
<td>extremePerPortQosTable</td>
<td>extremePerPortQosIndex</td>
<td>The value of this variable is the same as the value of extremeQosProfileIndex of the QoS profile which is overridden (for the port specified by ifIndex) by the definition in this table.</td>
</tr>
<tr>
<td></td>
<td>extremePerPortQosMinBw</td>
<td>The minimum percentage of bandwidth that this queue on the specified port requires. The switch is required to provide the minimum amount of bandwidth to the queue. The lowest possible value is 0%.</td>
</tr>
<tr>
<td></td>
<td>extremePerPortQosMaxBw</td>
<td>The maximum percentage of bandwidth that this queue on the specified port is permitted to use.</td>
</tr>
<tr>
<td></td>
<td>extremePerPortQosPriority</td>
<td>The level of priority at which this queue will be serviced by the switch.</td>
</tr>
<tr>
<td></td>
<td>extremePerPortQosRowStatus</td>
<td>The status of the extremePerPortQos entry. This object can be set to active (1) and createAndGo (4). The following value may be read; active (1). Note that a destroy (6) is not supported. A row will only be deleted from this table when the QoS profile indicated in that row is changed globally.</td>
</tr>
</tbody>
</table>
### Supported Standards, Protocols, and MIBs

#### EXTREME-RMON-MIB

The following tables, groups, and variables are supported in this MIB

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeRtStatsTable</td>
<td>extremeRtStatsIndex</td>
<td>All objects are supported as read-only.</td>
</tr>
<tr>
<td></td>
<td>extremeRtStatsIntervalStart</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeRtStatsCRCAlignErrors</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeRtStatsUndersizePkts</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeRtStatsOversizePkts</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeRtStatsFragments</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeRtStatsJabbers</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeRtStatsCollisions</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeRtStatsTotalErrors</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeRtStatsUtilization</td>
<td></td>
</tr>
</tbody>
</table>

#### EXTREME-PVLAN-MIB

Two MIB tables allow for GET/SET operations to view and configure ExtremeXOS PVLAN objects. The first is a PVLAN name table with PVLAN name as the index, and the second is the PVLAN subscriber table with PVLAN name, member VLAN type, and Subscriber VlanIfIndex as the index. Functionality includes supporting the current set of PVLAN CLI configuration options.
**PVLAN Table (extremePvlanTable)**

<table>
<thead>
<tr>
<th>extremePvlanName (index)</th>
<th>extremePvlanVrName</th>
<th>extremePvlanNetworkVlanIfIndex</th>
</tr>
</thead>
<tbody>
<tr>
<td>DisplayString</td>
<td>DisplayString</td>
<td>InterfaceIndexOrZero</td>
</tr>
<tr>
<td>p1</td>
<td>VR-Default14</td>
<td>14</td>
</tr>
<tr>
<td>foo</td>
<td>VR-Cust1</td>
<td>0</td>
</tr>
</tbody>
</table>

**PVLAN Subscriber Table (extremePvlanSubscriberTable)**

<table>
<thead>
<tr>
<th>extremePvlanName (index)</th>
<th>extremePvlanSubscriberVlanIfIndex (index)</th>
<th>extremePvlanSubscriberType</th>
<th>extremePvlanSubscriberLoopBackPortIfIndex</th>
</tr>
</thead>
<tbody>
<tr>
<td>DisplayString</td>
<td>InterfaceIndex</td>
<td>Integer</td>
<td>InterfaceIndexOrZero</td>
</tr>
<tr>
<td>foo</td>
<td>9</td>
<td>PVLAN_ISOLATED(2)</td>
<td>0</td>
</tr>
<tr>
<td>foo</td>
<td>12</td>
<td>PVLAN_ISOLATED(2)</td>
<td>1002</td>
</tr>
<tr>
<td>p1</td>
<td>1</td>
<td>PVLAN_ISOLATED(2)</td>
<td>0</td>
</tr>
<tr>
<td>p1</td>
<td>6</td>
<td>PVLAN_NON_ISOLATED(1)</td>
<td>1004</td>
</tr>
<tr>
<td>p1</td>
<td>8</td>
<td>PVLAN_ISOLATED(2)</td>
<td>1010</td>
</tr>
<tr>
<td>p1</td>
<td>10</td>
<td>PVLAN_NON_ISOLATED(1)</td>
<td>0</td>
</tr>
</tbody>
</table>

RowStatus is defined as: active(1), createAndGo(4), destroy(6)

**EXTREME-SNMPv3-MIB**

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeTargetAddrExtTable</td>
<td>extremeTargetAddrExtIgnoreMPModel</td>
<td>The value of the snmpTargetParamsMPModel object in the snmpTargetParamsTable is ignored while determining the version of the trap/notification to be sent. When a trap-receiver is created through the RMON trapDestTable or from the CLI command ‘configure snmp add trapreceiver ...’, the value of this object is set to TRUE for the corresponding entry in this table.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When this object is set to TRUE, the management target is treated as a 'standard mode' one, in that any Extreme Networks specific extra varbinds present in a standards-based trap/notification is not sent to this management target. Only the varbinds defined in the standard are sent.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------</td>
<td>----------</td>
</tr>
<tr>
<td></td>
<td>extremeTargetAddrExtTrapDestIndex</td>
<td>This object contains the value of the trapDestIndex in the corresponding entry of the RMON trapDestTable.</td>
</tr>
<tr>
<td></td>
<td>extremeTargetAddrExtUseEventCom</td>
<td>This object is used only when sending RMON alarms as SNMPv3 traps. When it is set to TRUE and an RMON risingAlarm or fallingAlarm is being sent for an event, then the eventCommunity in the RMON event table is compared to the snmpTargetAddrName in the snmpTargetAddrTable. The alarm is sent to the target only when the two are the same. This behavior is exhibited only when the snmpTargetParamsMPModel corresponding to the target indicates an SNMPv3 trap. For SNMPv1/v2c traps, the community in the RMON trapDestTable is used for the comparison, which is the regular method, as per the standards. When this object is set to FALSE, then the RMON alarm (if being sent as an SNMPv3 trap) is sent without using the event community for any comparison.</td>
</tr>
<tr>
<td></td>
<td>extremeTargetAddrExtTrapSrcIp</td>
<td>This object contains the source IP address from which traps have to be sent out. If this object is assigned an IP address that does not belong to the switch, an error is thrown.</td>
</tr>
<tr>
<td></td>
<td>extremeTargetAddrExtVrName</td>
<td>This object contains the VR name through which the SNMP Traps are being sent out.</td>
</tr>
<tr>
<td></td>
<td>extremeUsm3DESPrivProtocol</td>
<td>Supported from ExtremeXOS 12.3</td>
</tr>
<tr>
<td></td>
<td>extremeUsmAesCfb192Protocol</td>
<td>Supported from ExtremeXOS 12.3</td>
</tr>
<tr>
<td></td>
<td>extremeUsmAesCfb256Protocol</td>
<td>Supported from ExtremeXOS 12.3</td>
</tr>
</tbody>
</table>

**EXTREME-STP-EXTENSIONS-MIB**

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>extremeStpDomainTable</td>
<td>All objects</td>
</tr>
<tr>
<td></td>
<td>extremeStpDomainStpdDescription</td>
<td>The description associated with this STP domain.</td>
</tr>
</tbody>
</table>
### EXTREME-STPNOTIFICATIONS-MIB

This MIB defines the following Extreme-specific STP Notifications trap generated by Extreme Networks devices.

<table>
<thead>
<tr>
<th>Trap</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeStpEdgePortLoopDetected</td>
<td>A loop has been detected on the network login edge safeguard port and the port will be disabled.</td>
</tr>
</tbody>
</table>

### EXTREME-SYSTEM-MIB

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeSaveConfiguration</td>
<td></td>
<td>When this object is set, the device copies the contents of the configuration database to a buffer and saves it to the persistent store specified by the value of the object. The save is performed asynchronously, and the SNMP agent continues to respond to both gets and sets while the save is taking place. A network management application may use the extremeSaveStatus object to determine when the asynchronous save operation has completed.</td>
</tr>
<tr>
<td>extremeSaveStatus</td>
<td></td>
<td>This object returns the status of a save operation invoked by setting the extremeSaveConfiguration object. A network management application can read this object to determine that a save operation has completed.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------</td>
<td>----------</td>
</tr>
<tr>
<td></td>
<td>extremeCurrentConfigInUse</td>
<td>Shows which NVRAM configuration store was used at last boot.</td>
</tr>
<tr>
<td></td>
<td>extremeConfigToUseOnReboot</td>
<td>Controls which NVRAM configuration store will be used on next reboot.</td>
</tr>
<tr>
<td></td>
<td>extremeOverTemperatureAlarm</td>
<td>Alarm status of overtemperature sensor in device enclosure.</td>
</tr>
<tr>
<td></td>
<td>extremePrimaryPowerOperational</td>
<td>Not supported. Always returns True.</td>
</tr>
<tr>
<td></td>
<td>extremePowerStatus</td>
<td>Not supported. Always returns presentOK.</td>
</tr>
<tr>
<td></td>
<td>extremePowerAlarm</td>
<td>Not supported. Always returns False.</td>
</tr>
<tr>
<td></td>
<td>extremeRedundantPowerStatus</td>
<td>Not supported. Always returns presentOK.</td>
</tr>
<tr>
<td></td>
<td>extremeRedundantPowerAlarm</td>
<td>Not supported. Always returns presentOK.</td>
</tr>
<tr>
<td></td>
<td>extremeInputPowerVoltage</td>
<td>Contains the input voltage of the latest power-supply to power-on in a system with multiple power-supplies.</td>
</tr>
<tr>
<td></td>
<td>extremePrimarySoftwareRev</td>
<td>This value indicates the revision number of the software image on the primary partition.</td>
</tr>
<tr>
<td></td>
<td>extremeSecondarySoftwareRev</td>
<td>This value indicates the revision number of the software image on the secondary partition.</td>
</tr>
<tr>
<td></td>
<td>ExtremeImageToUseOnReboot</td>
<td>This value indicates the partition where the software image is located and to be used on the next boot.</td>
</tr>
<tr>
<td></td>
<td>extremeSystemID</td>
<td>This represents the system ID of a Summit switch.</td>
</tr>
<tr>
<td></td>
<td>extremeSystemBoardID</td>
<td>Not supported.</td>
</tr>
<tr>
<td></td>
<td>extremeSystemLeftBoardID</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeSystemRightBoardID</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeRmonEnable</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeBootROMVersion</td>
<td>Returns information for the current MSM only.</td>
</tr>
<tr>
<td></td>
<td>extremeDot1dTpFdbTableEnable</td>
<td>Not supported.</td>
</tr>
<tr>
<td></td>
<td>extremeHealthCheckErrorType</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeHealthCheckAction</td>
<td></td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>

<td>extremeAuthFailSrcAddr</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeCpuTransmitPriority</td>
<td></td>
</tr>
<tr>
<td></td>
<td>extremeImageBooted</td>
<td></td>
</tr>
<tr>
<td>extremeFanStatusTable</td>
<td>extremeFanStatusEntry</td>
<td>Operational status of all internal cooling fans.</td>
</tr>
<tr>
<td></td>
<td>extremeFanNumber</td>
<td>Identifier of cooling fan, numbered from the front and/or left side of device.</td>
</tr>
<tr>
<td></td>
<td>extremeFanOperational</td>
<td>Operational status of a cooling fan.</td>
</tr>
<tr>
<td></td>
<td>extremeFanEntPhysicalIndex</td>
<td>The entity index for this fan entity in the entityPhysicalTable table of the entity MIB.</td>
</tr>
<tr>
<td></td>
<td>extremeFanSpeed</td>
<td>The speed (RPM) of a cooling fan in the fantray.</td>
</tr>
<tr>
<td>extremeCpuTaskTable</td>
<td>All objects</td>
<td>Not supported.</td>
</tr>
<tr>
<td>extremeCpuTask2Table</td>
<td>All objects</td>
<td>Not supported.</td>
</tr>
<tr>
<td>extremeSlotTable</td>
<td>All objects</td>
<td>Cards are currently not configurable via SNMP.</td>
</tr>
<tr>
<td>extremePowerSupplyEntPhysicalIndex</td>
<td>extremePowerSupplyEntPhysicalIndex</td>
<td>The entity index for this psu entity in the entityPhysicalTable table of the entity MIB.</td>
</tr>
<tr>
<td>extremePowerSupplyNumber</td>
<td>extremePowerSupplyNumber</td>
<td>Power supply number.</td>
</tr>
<tr>
<td>extremePowerSupplySerialNumber</td>
<td>extremePowerSupplySerialNumber</td>
<td>The serial number of the power supply unit.</td>
</tr>
<tr>
<td>extremePowerSupplySource</td>
<td>extremePowerSupplySource</td>
<td>The power supply unit input source.</td>
</tr>
<tr>
<td>extremePowerSupplyTable</td>
<td>extremePowerSupplyStatus</td>
<td>Status of the power supply.</td>
</tr>
<tr>
<td></td>
<td>extremePowerSupplyInputVoltage</td>
<td>Input voltage of the power supply.</td>
</tr>
<tr>
<td></td>
<td>extremePowerSupplyFan1Speed</td>
<td>The speed of Fan-1 in the power supply unit.</td>
</tr>
<tr>
<td></td>
<td>extremePowerSupplyFan2Speed</td>
<td>The speed of Fan-2 in the power supply unit.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>----------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>extremePowerSupplyInputPowerUsage</td>
<td>Input power usage for the given psu slot. The value 0 in this field indicates the power usage is not supported or that there is a read failure.</td>
<td></td>
</tr>
<tr>
<td>extremePowerMonSupplyNumOutput</td>
<td>Number of output sensors in the power supply unit.</td>
<td></td>
</tr>
<tr>
<td>extremePowerSupplyInputPowerUsageUnitMultiplier</td>
<td>The magnitude of watts for the usage value in extremePowerSupplyInputPowerUsage.</td>
<td></td>
</tr>
<tr>
<td>extremePowerSupplyOutputPowerTable</td>
<td>extremePowerSupplyIndex</td>
<td>Power supply unit slot index.</td>
</tr>
<tr>
<td>extremePowerSupplyOutputSensorIdx</td>
<td>Power supply Sensor index.</td>
<td></td>
</tr>
<tr>
<td>extremePowerSupplyOutputVoltage</td>
<td>Output voltage per sensor for the current PSU slot number. A zero (0) in this field indicates that the PSU does not support output voltage reading or else there is an output voltage read error.</td>
<td></td>
</tr>
<tr>
<td>extremePowerSupplyOutputCurrent</td>
<td>Output current per sensor for the current PSU slot number. A zero (0) in this field indicates that the PSU does not support output current reading or else there is an output current read error.</td>
<td></td>
</tr>
<tr>
<td>extremePowerSupplyOutputUnitMultiplier</td>
<td>The magnitude of volts and amps for the usage value in extremePowerSupplyOutputVoltage and extremePowerSupplyOutputCurrent.</td>
<td></td>
</tr>
<tr>
<td>extremePowerSupplyUsageTable</td>
<td>extremeSlotIndex</td>
<td>Slot number in the stack-based system.</td>
</tr>
<tr>
<td>extremePowerSupplyUsageValue</td>
<td>Power usage of the particular slot in the stack. The power usage is measured in milliwatts.</td>
<td></td>
</tr>
<tr>
<td>extremePowerSupplyUnitMultiplier</td>
<td>The magnitude of watts for the usage value in extremePowerSupplyUsageValue.</td>
<td></td>
</tr>
<tr>
<td>extremeSystemPowerUsage</td>
<td>extremeSystemPowerUsageValue</td>
<td>The current power usage of the system. In stack mode, this variable tells the total power usage of the entire system.</td>

<td>extremeSystemPowerUsageUnitMultiplier</td>
<td>extremeSystemPowerUsageUnitMultiplier</td>
<td>The magnitude of watts for the usage value in extremeSystemPowerUsageValue.</td>
</tr>
<tr>
<td>extremeSystemPowerMonitorTable</td>
<td>extremeSystemPowerMonitorIndex1</td>
<td>Reserved. Can be used for future expansion. Currently set to zero.</td>
</tr>
<tr>
<td></td>
<td>extremeSystemPowerMonitorPollInterval</td>
<td>Configure how often input power is measured. It is configured in seconds with a default value of 60 seconds. If zero (0) is configured, then the input power measurement is disabled.</td>
</tr>
<tr>
<td></td>
<td>extremeSystemPowerMonitorReportChanges</td>
<td>Configure report-changes. Has none or log or trap or log-and-trap, with a default of none.</td>
</tr>
<tr>
<td></td>
<td>extremeSystemPowerMonitorChangeThreshold</td>
<td>Configure the input power change threshold to initiate report-changes action. By default 2 watts is configured. This field is configured in watts.</td>
</tr>
<tr>
<td>extremeSystemPowerUsageNotification</td>
<td>sysUpTime, sysDescr, extremeSystemPowerUsageValue, extremeSystemPowerUsageUnitMultiplier</td>
<td>Whenever the power usage is increased/decreased by the configured threshold value, then the power usage trap is generated if the trap is enabled.</td>
</tr>
<tr>
<td>extremeImageTable</td>
<td>extremeImageNumber</td>
<td>This table contains image information for all images installed on the device. extremeImageNumber values are not compatible with EW releases. Current image has value 3 instead of 0.</td>
</tr>
<tr>
<td>extremeMajorVersion</td>
<td></td>
<td>This is the first number within the software image version number which consists of 4 numbers separated by a period.</td>
</tr>
<tr>
<td>extremeMinorVersion</td>
<td></td>
<td>This is the second number within the software image version number.</td>
</tr>
<tr>
<td>extremeBuildNumber</td>
<td></td>
<td>This is the fourth number within the software image version number.</td>
</tr>
<tr>
<td>extremeTechnologyReleaseNumber</td>
<td></td>
<td>The technology release version. This value is zero for all but TR releases.</td>

<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>------------------------------</td>
<td>----------------------------------</td>
<td>--------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>extremeSustainingReleaseNumber</td>
<td>The sustaining release number for the ExtremeXOS version.</td>
</tr>
<tr>
<td></td>
<td>extremeBranchRevisionNumber</td>
<td>This is the branch from where the software image was built.</td>
</tr>
<tr>
<td></td>
<td>extremImageType</td>
<td>This is the software image type (for example, ExtremeXOS core, ExtremeXOS module, ExtremeXOS firmware).</td>
</tr>
<tr>
<td></td>
<td>extremImageDescription</td>
<td>Description of image contains image version, including major version, submajor version, minor version, build version, build branch, build-master login, and build date.</td>
</tr>
<tr>
<td></td>
<td>extremePatchVersion</td>
<td>The ExtremeXOS release patch version. This is the third number within the software image version number.</td>
</tr>
<tr>
<td>extremImageFeatureTable</td>
<td>extremImageFeatureEntry</td>
<td>A table containing information about the software features.</td>
</tr>
<tr>
<td></td>
<td>extremImageFeatureNumber</td>
<td>A unique integer identifying the particular software image. This indicates the partition on which the image is loaded: 0—Current partition, 1—Primary partition, 2—Secondary partition.</td>
</tr>
<tr>
<td></td>
<td>extremImageSshCapability</td>
<td>Indicates whether image has SSH capability: 1=nossh—shown by default when the SSH license is not enabled, 2=ssh—shown when the SSH license is enabled.</td>
</tr>
<tr>
<td></td>
<td>extremImageUAACapability</td>
<td>Not supported.</td>
</tr>
<tr>
<td></td>

**EXTREME-TRAP-MIB**

This MIB defines the following Extreme-specific SNMPv1 traps generated by Extreme Networks devices.

<table>
<thead>
<tr>
<th>Trap</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeOverheat</td>
<td>The on-board temperature sensor has reported an overheat condition. The system shuts down until the unit has sufficiently cooled such that operation can begin again. A cold start trap is issued when the unit has come back on line.</td>
</tr>
<tr>
<td>extremeFanfailed</td>
<td>One or more of the cooling fans inside the device has failed. A fanOK trap will be sent once the fan has attained normal operation.</td>
</tr>
<tr>
<td>extremeFanOK</td>
<td>A fan has transitioned out of a failure state and is now operating correctly.</td>
</tr>
<tr>
<td>extremeInvalidLoginAttempt</td>
<td>A user attempted to log into the console or by telnet but was refused access due to an incorrect username or password.</td>
</tr>
<tr>
<td>extremePowerSupplyGood</td>
<td>One or more previously bad sources of power to this agent has come back to life without causing an agent restart.</td>
</tr>
<tr>
<td>extremePowerSupplyFail</td>
<td>One or more sources of power to this agent has failed. Presumably a redundant power-supply has taken over.</td>
</tr>
<tr>
<td>extremeEdpNeighborAdded</td>
<td>This node discovers a new neighbor through EDP.</td>
</tr>
<tr>
<td>extremeEdpNeighborRemoved</td>
<td>No EDP updates are received from this neighbor within the configured timeout period and this neighbor entry is aged out by the device.</td>
</tr>
<tr>
<td>extremeModuleStateChanged</td>
<td>Signifies that the value of the extremeSlotModuleState for the specified extremeSlotNumber has changed. Traps are reported only for significant states.</td>
</tr>
</tbody>
</table>

**EXTREME-TRAPPOLL-MIB**

The following tables, groups, and variables are supported in this MIB.
### Table/Group Supported Variables Comments

| **extremeSmartTrapFlushInstanceTableIndex** | This object acts as a flush control for the `extremeSmartTrapInstanceTable`. Setting this object can flush the matching entries from the `extremeSmartTrapInstanceTable` based on certain rules as defined in the MIB. |
| **extremeSmartTrapRulesTable** | The entries created in the `extremeSmartTrapRulesTable` define the rules that are used to generate Extreme smart traps. The object `extremeSmartTrapRulesDesiredOID` supports OID values whose prefix are among the following: ipAddrTable, ifMauTable, extremeSlotTable, extremeVlanGroup, extremeVirtualGroup, extremeVlanProtocolTable, extremeVlanProtocolVlanTable, extremeVlanOpaqueTable, extremeStpDomainTable, extremeStpPortTable, extremeStpVlanPortTable, pethPsePortTable, extremePethSystem, extremePethPseSlotTable, extremePethPsePortTable |
| **extremeSmartTrapInstanceTable** | `extremeSmartTrapInstanceTable` is a read-only table that stores the information about which variables have changed according to rules defined in the `extremeSmartTrapRulesTable`. |

### EXTREME-V2TRAP-MIB

This MIB defines the following Extreme-specific SNMPv2c traps generated by Extreme Networks devices.

<table>
<thead>
<tr>
<th>Trap</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>extremeHealthCheckFailed</code></td>
<td>CPU HealthCheck has failed.</td>
</tr>
<tr>
<td><code>extremeBgpM2PrefixReachedThreshold</code></td>
<td>This notification is generated when the number of prefixes received over this peer session reaches the threshold limit.</td>
</tr>
<tr>
<td><code>extremeBgpM2PrefixMaxExceeded</code></td>
<td>This notification is generated when the number of prefixes received over this peer session reaches the maximum configured limit.</td>
</tr>
<tr>
<td><code>extremeEapsStateChange</code></td>
<td>Send on master/transit nodes.</td>
</tr>
<tr>
<td><code>extremeEapsFailTimerExpFlagSet</code></td>
<td>This notification is generated when the EAPS domain fail timer expires for the first time, while its state is not in Fail state.</td>
</tr>
<tr>
<td><code>extremeEapsFailTimerExpFlagClear</code></td>
<td>This notification is generated when the EAPS domain fail timer expired flag is cleared.</td>
</tr>
<tr>
<td><code>extremeEapsLinkDownRingComplete</code></td>
<td>If a transit is in link-down state, and it receives a Health-Check-Pdu from the master indicating the ring is complete, there is some problem with the transit switch that has issued this trap message.</td>
</tr>
<tr>
<td><code>extremeEapsLastStatusChangeTime</code></td>
<td>Sent on master/transit nodes. Provides a general indication of a status change using a 10 second timer.</td>
</tr>
<tr>
<td><code>extremeEapsPortStatusChange</code></td>
<td>Sent on master/transit nodes.</td>
</tr>
<tr>
<td><code>extremeEapsConfigChange</code></td>
<td>Sent on master/transit nodes. This trap has a granularity of 30 seconds.</td>
</tr>
<tr>
<td><code>extremeEapsSharedPortStateChange</code></td>
<td>Sent on controller/partner nodes.</td>
</tr>
</tbody>
</table>
These traps are not generated by the ExtremeXOS SNMP agent but by the Ridgeline NMS.

An overheat (return to) normal notification indicates that the on-board temperature sensor has reported a temperature that has returned to within the normal operating range from having been in an overheat (or overcold) condition. The temperature of the unit has sufficiently cooled to be below the maximum (or warmed to be above the minimum) of the normal operating range.

**EXTREME-VLAN-MIB**

The following tables, groups, and variables are supported in this MIB.

**Table/Group** | **Supported Variables** | **Comments**
---|---|---
extremeVirtualGroup | extremeNextAvailableVirtIfIndex | While creating a new row in the extremeVlanIfTable, the value of the object extremeVlanIfDescr must be specified. For all tables in this MIB that contain objects with RowStatus semantics, the only values supported are: {active, createAndGo, destroy}.

extremeVlanIfTable | extremeVlanIfIndex | This is a description of the VLAN interface.

extremeVlanIfDescr | The VLAN interface type.

extremeVlanIfType | Not supported.

extremeVlanIfGlobalIdentifier | The status column for this VLAN interface. This object can be set to: active (1); createAndGo (4); createAndWait (5); destroy (6). The following values may be read: active (1); notInService (2); notReady (3).

extremeVlanIfStatus | Not supported.

extremeVlanIfIgnoreStpFlag | Not supported.

extremeVlanIfIgnoreBpduFlag | Not supported.

extremeVlanIfLoopbackModeFlag | Setting this object to true causes loopback mode to be enabled on this VLAN.

extremeVlanIfVlanId | The VLAN ID of this VLAN.

extremeGlobalMappingTable | Not supported.

extremeVlanEncapsTable | Not supported.
<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeVlanIpTable</td>
<td>All objects</td>
<td>For all tables in this MIB that contain objects with RowStatus semantics, the only values supported are: {active, createAndGo, and destroy}.</td>

<td>Not supported</td>
<td></td>
</tr>
<tr>
<td>extremeVlanProtocolBindingTable</td>
<td>Partial</td>
<td>For all tables in this MIB that contain objects with RowStatus semantics, the only values supported are: {active, createAndGo, and destroy}. New to the ExtremeXOS software: association of a protocol filter and VLAN.</td>
</tr>
<tr>
<td>extremeVlanProtocolVlanTable</td>
<td>Not supported</td>
<td></td>
</tr>
<tr>
<td>extremeVlanProtocolDefTable</td>
<td>Partial</td>
<td>For all tables in this MIB that contain objects with RowStatus semantics, the only values supported are: {active, createAndGo, and destroy}. New to the ExtremeXOS software: This is a new table introduced to add a protocol filter with etype values during creation of the filter itself.</td>
</tr>
<tr>
<td>extremeVlanOpaqueTable</td>
<td>All objects</td>
<td>This is a read only table. For adding ports to a VLAN or deleting ports from a VLAN, use extremeVlanOpaqueControlTable.</td>
</tr>
<tr>
<td>extremeVlanOpaqueControlTable</td>
<td>All objects</td>
<td>For all tables in this MIB that contain objects with RowStatus semantics, the only values supported are: {active, createAndGo, and destroy}. New to the ExtremeXOS software: extremeVlanOpaqueControlTable is a write only table and cannot be used to read. This is used to add/delete ports on a VLAN.</td>
</tr>
<tr>
<td>extremeVlanStackTable</td>
<td>All objects</td>
<td>Not supported.</td>
</tr>
<tr>
<td>extremeVlanL2StatsTable</td>
<td>All objects</td>
<td>Not supported. This table contains per VLAN information about the number of packets sent to the CPU, the number of packets learned, the number of IGMP (Internet Group Management Protocol) control packets snooped and the number of IGMP data packets switched. This is the same information that is available using the CLI command show l2stats.</td>
</tr>
<tr>

</table>
### EXTREME-VM-MIB

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeVMFTPServerTable</td>
<td>extremeVMFTPServerEntry</td>
<td>The type of the FTP server. The backup server is contacted if the primary fails to respond.</td>
</tr>
<tr>
<td></td>
<td>extremeVMFTPServerType</td>
<td>The IP type of IP address.</td>
</tr>
<tr>
<td></td>
<td>extremeVMFTPServer</td>
<td>The IP address of the FTP server used for transferring various management files.</td>
</tr>
<tr>
<td></td>
<td>extremeVMFTPSynchInterval</td>
<td>The time in minutes between automatic synchronization attempts. A value of 0 indicates that automatic synchronizations are not performed. Note that each switch does not perform a synchronization at exactly the time configured, but varies the synchronization interval between 3/4 and 5/4 of the configured interval. This avoids the situation where all switches in a network attempt a synchronization at exactly the same moment. Automatic synchronization is disabled by default, and requests to enable them are rejected until the FTP server information (IPv4 or IPv6 address, username, and password) is configured.</td>
</tr>
<tr>
<td></td>
<td>extremeVMFTPRowStatus</td>
<td>There can only be two entries in this table, one each for primary and secondary FTP servers.</td>
</tr>
<tr>
<td></td>
<td>extremeVMFTPPathName</td>
<td>The FTP server directory name for the policies to be synchronized. A value of ‘/pub’ is used by default.</td>
</tr>
<tr>
<td></td>
<td>extremeVMFTPUsername</td>
<td>A valid username on the FTP server.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>extremeVMFTPPassword</td>
<td>The password associated with the FTP user. This object returns a zero length string when queried.</td>
</tr>
<tr>
<td>extremeVMGeneral</td>
<td>extremeVFTPPolicyDir</td>
<td>The server directory name for the policies to be synchronized. A value of ‘/’ is used by default.</td>
</tr>
<tr>
<td></td>
<td>extremeVMLastSynch</td>
<td>The timestamp of the most recent synchronization attempt.</td>
</tr>
<tr>
<td></td>
<td>extremeVMLastSynchStatus</td>
<td>The result of the most recent synchronization attempt: success (1)—indicates that the synchronization completed successfully, accessDenied (2)—The username and password were not accepted by the server, serverTimeout (3)—Could not establish a file transfer session with the configured server, serverNotConfigured (4)—The server configuration is not complete.</td>
</tr>
<tr>
<td></td>
<td>extremeVMSynchAdminState</td>
<td>Triggers a synchronization cycle on demand. A synchronization automatically downloads new or updated policies as well as delete policies to match those on the server: idle (1) is returned whenever this object is read, synchronizeNow (2) triggers an immediate synchronization, and is reflected in extremeVMSynchOperState. Attempts to set this variable to synchronizeNow (2) are rejected if a synchronization is currently in progress.</td>
</tr>
<tr>
<td></td>
<td>extremeVMSynchOperState</td>
<td>Indicates if a synchronization is in progress, either on-demand or automatic.</td>
</tr>
<tr>
<td></td>
<td>extremeVMTrackingEnabled</td>
<td>The virtual machine (VM) tracking feature is disabled by default and can be enabled using this object.</td>
</tr>
<tr>
<td></td>
<td>extremeVMPortConfigTable</td>
<td>Configures the VM features on each port.</td>
</tr>
<tr>
<td></td>
<td>extremeVMPortConfigEntry</td>
<td>An entry in the table for VM features on each port.</td>
</tr>
<tr>
<td></td>
<td>extremeVMPortConfigIfIndex</td>
<td>The value of ifIndex of a physical port capable of supporting the VM tracking features.</td>
</tr>
<tr>
<td></td>
<td>extremeVMPortConfigVMTrackingEnabled</td>
<td>Enables the VM tracking feature on a port. The VM tracking feature is disabled by default.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>extremeVMVPTable</td>
<td></td>
<td>This table contains port policies contained within this switch. Port policies come in two variants: network and local. Network policies are downloaded from the FTP server; local policies reside only within a single switch.</td>
</tr>
<tr>
<td>extremeVMVPPEntry</td>
<td></td>
<td>An entry in the table of VM policy information of this device. This table is populated with two sets of policies, those downloaded from the policy server and those defined locally on this switch.</td>
</tr>
<tr>
<td>extremeVMVPPType</td>
<td></td>
<td>The type of the port policy. Network port policies are obtained from a central policy store. Local policies are specific to this particular switch.</td>
</tr>
<tr>
<td>extremeVMVPPName</td>
<td></td>
<td>The name of the port VPP. VPP names must be alpha-numeric and must start with an alpha character.</td>
</tr>
<tr>
<td>extremeVMVPPControl</td>
<td></td>
<td>Performs the requested operation on this policy. synchronizeNow (1) downloads a copy of the policy from the FTP server. (Network policies only). This object returns noOperation (2) if read.</td>
</tr>
<tr>
<td>extremeVMVPPRowStatus</td>
<td></td>
<td>Only local VPPs can be created or deleted.</td>
</tr>
<tr>
<td>extremeVMMappingTable</td>
<td></td>
<td>This table contains the mapping of port policies to VM MAC addresses.</td>
</tr>
<tr>
<td>extremeVMMappingEntry</td>
<td></td>
<td>An entry in the table of VM information of this device.</td>
</tr>
<tr>
<td>extremeVMMappingType</td>
<td></td>
<td>The type of mapping for this entry. A local mapping exists only on this specific switch. A network mapping is one obtained through a download of a mapping file.</td>
</tr>
<tr>
<td>extremeVMMappingMAC</td>
<td></td>
<td>The MAC address associated with the VM. Note that a VM can have multiple MAC addresses.</td>
</tr>
<tr>
<td>extremeVMMappingIngressVPPName</td>
<td></td>
<td>The ingress policy associated with the VM/MAC address. Note that this may refer to a policy without a corresponding entry in the extremeVMVPTable if a network policy mapping refers to a non-existent policy. This indicates an error in the policy mapping file that is consulted if network authentication fails. When creating an entry in this table, this name must refer to an existing, valid, local policy. The creation of a mapping to a network policy is not permitted. Those mappings must be created at the central policy server.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------</td>
<td>----------</td>
</tr>
<tr>
<td></td>
<td>extremeVMMappingEgressVPPName</td>
<td>The egress policy associated with the VM/MAC address. Note that this might refer to a policy without a corresponding entry in the extremeVMVPPTable if a network policy mapping refers to a non-existent policy. This indicates an error in the policy mapping file that is consulted if network authentication fails. When creating an entry in this table, this name must refer to an existing, valid, local policy. The creation of a mapping to a network policy is not permitted. Those mappings must be created at the central policy server.</td>
</tr>
<tr>
<td></td>
<td>extremeVMMappingStatus</td>
<td>Indicates the virtual port profile mapping status: vppValid (1)—A VPP mapped to this VM MAC address does not have any policies associated with it (or) all the policies associated with this VPP can be applied (policy validation is success). Policy validation will happen only when this VM MAC is detected. vppMissing (2)—This value is applicable only for network VM if the specified VPP name was missing. vppInvalid (3)—One of the policies mapped to VPP cannot be applied (policy validation failed) because the policy file contains one or more errors that prevent it from being applied. vppNotMaped (4)—The VM does not have any VPP mapped.</td>
</tr>
<tr>
<td></td>
<td>extremeVMMappingRowStatus</td>
<td>Only local policies can be created or deleted.</td>
</tr>
<tr>
<td></td>
<td>extremeVMVPP2PolicyTable</td>
<td>This table contains the mapping of a VPP to individual policies.</td>
</tr>
<tr>
<td></td>
<td>extremeVMVPP2PolicyEntry</td>
<td>An individual mapping of VPP to policy.</td>
</tr>
<tr>
<td></td>
<td>extremeVMVPP2PolicyVPPName</td>
<td>The name of the VPP.</td>
</tr>
<tr>
<td></td>
<td>extremeVMVPP2PolicyPolicyName</td>
<td>The name of the local policy.</td>
</tr>
<tr>
<td></td>
<td>extremeVMVPP2PolicyType</td>
<td>The type of policy.</td>
</tr>
<tr>
<td></td>
<td>extremeVMVPP2PolicyOrder</td>
<td>The order in which this policy is executed.</td>
</tr>
<tr>
<td></td>
<td>extremeVMVPP2PolicyRowStatus</td>
<td>The row status for this mapping.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------</td>
<td>--------------------------------------------------------------------------</td>
</tr>
<tr>
<td>extremeVMDetected</td>
<td>extremeVMDetectedNumber</td>
<td>The number of VMs detected on this switch.</td>
</tr>
<tr>
<td>extremeVMDetectedTable</td>
<td></td>
<td>This table contains the currently detected VMs on this switch.</td>
</tr>
<tr>
<td>extremeVMDetectedEntry</td>
<td></td>
<td>An entry in the table of VM information of this device.</td>
</tr>
<tr>
<td></td>
<td>extremeVMDetectedMAC</td>
<td>The MAC address associated with the VM. Note that a VM can have multiple MAC addresses.</td>
</tr>
<tr>
<td></td>
<td>extremeVMDetectedVMName</td>
<td>The name of the VM. Note that a VM authenticated locally might not have a name.</td>
</tr>
<tr>
<td></td>
<td>extremeVMDetectedIngressVPPName</td>
<td>The name of the policy applied (or attempted to apply) to this VM.</td>
</tr>
<tr>
<td></td>
<td>extremeVMDetectedEgressVPPName</td>
<td>The name of the policy applied (or attempted to apply) to this VM.</td>
</tr>
<tr>
<td></td>
<td>extremeVMDetectedIfIndex</td>
<td>The value of ifIndex on which this VM was detected.</td>
</tr>
<tr>
<td></td>
<td>extremeVMDetectedAdminStatus</td>
<td>The administrative status of the VM authentication. Setting this variable to authenticating (1) will force the re-authentication of the VM. This variable always returns idle (2) when read.</td>
</tr>
<tr>
<td></td>
<td>extremeVMDetectedOperStatus</td>
<td>The authentication status of the VM: authenticating (1)—an authentication is currently in progress; authenticatedNetwork (2)—the VM has been authenticated by a network source; authenticatedLocally (3)—the VM has been authenticated by the local database; denied (4)—the VM was explicitly denied entry; notAuthenticated (5)—the authentication process timed out or was never attempted.</td>
</tr>
<tr>
<td></td>
<td>extremeVMDetectedResultIngress</td>
<td>Indicates the result of a VM entry into the network. Only the two values below will be returned at any point of time: policyApplied (1)—All the ingress policies in the VPP were successfully applied to the port; policyNotApplied (2) - One of the ingress policies in the VPP was not applied to the port. If this value is returned then refer to the extremeVMDetectedIngErrPolicies object for list of failed ingress policies.</td>
</tr>
</tbody>
</table>
Table/Group | Supported Variables | Comments |
--- | --- | --- |
 | extremeVMDetectedResultEgress | Indicates the result of a VM entry into the network. Only the two values below will be returned at any point of time: policyApplied (1) - All the egress policies in the VPP were successfully applied to the port, policyNotApplied (2) - One of the egress policies in the VPP was not applied to the port. If this value is returned then refer to the extremeVMDetectedEgrErrPolicies object for list of failed egress policies. |
 | extremeVMDetectedIngErrPolicies | Displays the list of failed ingress policies. |
 | extremeVMDetectedEgrErrPolicies | Displays the list of failed egress policies. |
 | extremeVMDetectedVPPName | The name of the VPP applied (or attempted to apply) to this VM. |
 | extremeVMDetectedVPPResult | Indicates the result of a VPP associated with a VM MAC: vppMapped (1)—indicates that the named VPP was mapped, vppNotMapped (2)—indicates that the no VPP was mapped, vppInvalid (3)—indicates that the VPP mapped was invalid, vppMissing (4)—indicates that the VPP mapped was missing |
 | extremeVMVPPDetailTable | This table contains the mapping of a VPP to individual policies. |
 | extremeVMVPPDetailEntry | A set of mappings from a VPP to one or more policies. |
 | extremeVMVPPDetailVPPName | The name of the VPP. |
 | extremeVMVPPDetailDirection | The direction in which the policy is applied. |
 | extremeVMVPPDetailType | The type of policy. |
 | extremeVMVPPDetailOrder | The order in which this policy is executed. |
 | extremeVMVPPDetailPolicyName | The name of the local policy |
 | extremeVMVPPDetailRowStatus | The row status for this mapping. |
 | extremeVMVPPSynchType | Indicates the type of policy |

The following traps can be generated.

<table>
<thead>
<tr>
<th>Trap</th>
<th>Notification Objects</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremeVMNotificationPrefix</td>

</table>

## MIB Support Details

The following sections describe the MIB support provided by the ExtremeXOS SNMP agent residing on Extreme Networks devices running ExtremeXOS:

Where applicable, these sections note how the implementation differs from the standards, or from the private MIBs.

**Note**

Only entries for the default VR are supported.

ExtremeXOS software supports only the following “Row status” in the MIBs:

- Create and Go
- Active
- Destroy

The standard MIBs are described in the following sections.

### IEEE 802.1AB (LLDP-MIB)

All tables and variables of this MIB are supported.

### IEEE 802.1AB (LLDP-EXT-DOT1-MIB)

All tables and variables of this MIB are supported.

### IEEE 802.1AB (LLDP-EXT-DOT3-MIB)

All tables and variables of this MIB are supported.

### IEEE 802.1AG (CFM MIB)

This MIB contains objects for the 802.1ag protocol.

The following tables, groups, and variables are supported in this MIB.
<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>dot1agCfmMdTable</td>
<td>dot1agCfmMdIndex</td>
<td>The index to the Maintenance Domain (MD) table.</td>

Supported Standards, Protocols, and MIBs
### IEEE8021-PAE-MIB

This MIB contains objects for the 802.1X protocol draft D10 of the 802.1X standard.

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>dot1agCfmFaultAlarm</td>
<td>dot1agCfmMepHighestPrDefect</td>
<td>A MEP has a persistent defect condition. A notification (fault alarm) is sent to the management entity with the OID of the MEP that has detected the fault. The management entity receiving the notification can identify the system from the network source address of the notification, and can identify the MEP reporting the defect by the indices in the OID of the dot1agCfmMepHighestPrDefect variable in the notification: dot1agCfmMdIndex—Also the index of the MEPs.MD table entry (dot1agCfmMdTable), dot1agCfmMaIndex—Also an index (with the MD table index) of the MEP's MA network table entry (dot1agCfmMaNetTable), and (with the MD table index and component ID) of the MEP's MA component table entry, dot1agCfmMepIdentifier—MEP Identifier and final index into the MEP table (dot1agCfmMepTable).</td>
</tr>

**SNMPv3 MIBs**

The ExtremeXOS SNMP stack fully supports the SNMPv3 protocol and therefore implements the MIBs in the SNMPv3 RFCs.

Specifically, the MIBs in following RFCs are fully supported:

- RFC 2576—Coexistence between Version 1, Version 2, and Version 3 of the Internet-standard Network Management Framework
- RFC 3410—Introduction and Applicability Statements for Internet-Standard Management Framework
- RFC 3412—Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)
- RFC 3414—User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3)
- RFC 3415—View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)
RFC 1213 (MIB-II)

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>System group scalars</td>
<td>All objects</td>
<td>The sysServices object always returns the value 79.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> The allowed character set is A-Z, a-z, 0-9, +,-,_,:;()/&quot; for sysName, sysLocation, sysContact.</td>
</tr>
<tr>
<td>Interfaces group</td>
<td></td>
<td>Supported as per RFC 2233.</td>
</tr>
<tr>
<td>IP Group scalars</td>
<td>All objects</td>
<td></td>
</tr>
<tr>
<td>ipAddrTable</td>
<td>All objects</td>
<td></td>
</tr>
<tr>
<td>ipRouteTable</td>
<td>All objects</td>
<td>Supported as read only. Routes are indexed by prefix only.</td>
</tr>
<tr>
<td>ipNetToMediaTable</td>
<td>All objects</td>
<td>context support is available for the ipNetToMediaTable in MIB-2. In order to retrieve entries in various VRs for ipNetToMediaTable in MIB-2, VRs can be mentioned as contexts. For example, to get the entries in VR-Mgmt, the following net-snmp query needs to be used: snmpwalk -v3 -n &quot;VR-Mgmt&quot; -u &lt;v3username&gt; -a md5 -a &lt;v3user-authentication password&gt; &lt;deviceIpAddress/Hostname&gt; ipNetToMediaTable. Here -n has the context value of &quot;VR-Mgmt&quot;. If no context is specified in the SNMP query, then only the entries in the VR-Default are shown.</td>
</tr>
<tr>
<td>ICMP group</td>
<td>All objects</td>
<td></td>
</tr>
<tr>
<td>TCP group scalars</td>
<td>All objects</td>
<td></td>
</tr>
<tr>
<td>tcpConnTable</td>
<td>All objects</td>
<td></td>
</tr>
<tr>
<td>UDP group scalars</td>
<td>All objects</td>
<td></td>
</tr>
<tr>
<td>udpTable</td>
<td>All objects</td>
<td></td>
</tr>
<tr>
<td>EGP Group</td>
<td>Not supported</td>
<td></td>
</tr>
<tr>
<td>SNMP Group</td>
<td>All objects</td>
<td></td>
</tr>
<tr>
<td>At group</td>
<td>All objects</td>
<td>Supported as read only.</td>
</tr>
</tbody>
</table>

RFC 1215

This MIB defines an SMI for SNMPv1 traps, and some traps themselves.

Of these, the following are supported.

<table>
<thead>
<tr>
<th>Traps</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>coldStart</td>
<td></td>
</tr>
<tr>
<td>warmStart</td>
<td></td>
</tr>
</tbody>
</table>
The authentication failure trap will have additional extreme proprietary varbinds
(extremeAuthFailSrcAddr, extremeAuthFailSrcAddressType, extremeAuthFailSrcAddress, extremeAuthFailSrcAddressVrName)

The BRIDGE-MIB has been augmented with draft-ietf-bridge-rstpmib-03.txt for 802.1w support.

Supported Standards, Protocols, and MIBs

**Traps** | **Comments**
--- | ---
authenticationFailure | The authentication failure trap will have additional extreme proprietary varbinds (extremeAuthFailSrcAddr, extremeAuthFailSrcAddressType, extremeAuthFailSrcAddress, extremeAuthFailSrcAddressVrName)
linkDown | 
linkUp | 

**RFC 1493 (BRIDGE-MIB) and draft-ietf-bridge-rstpmib-03.txt**

The BRIDGE-MIB has been augmented with draft-ietf-bridge-rstpmib-03.txt for 802.1w support.

Objects below that are defined in the latter are marked as such.

**Table/Group** | **Supported Variables** | **Comments**
--- | --- | ---
dot1dBase group scalars | dot1dBaseBridgeAddress | This object returns the number of ports in STP domain s0, not the total number of ports on the switch.
dot1dBaseNumPorts | 
dot1dBaseType | 

dot1dBasePortTable | dot1dBasePort | dot1dBasePort is supported and returns the port number.
dot1dBasePortIfIndex | dot1dBasePortIfIndex is supported.
dot1dBasePortCircuit | dot1dBasePortCircuit always has the value {0 0} since there is a one to one correspondence between a physical port and its ifIndex.
dot1dBasePortMtuExceededDiscards | dot1dBasePortMtuExceededDiscards is supported and value can be checked if packets exceed MTU configured on particular ports.

dot1dStp group scalars | dot1dStpProtocolSpecification | Values for these objects will be returned for the STP domain s0 only. For other domains, see the EXTREME-STPEXTENSIONS-MIB.
dot1dStpPriority | 
dot1dStpTimeSinceTopologyChange | 
dot1dStpTopChanges | 
dot1dStpDesignatedRoot | 
dot1dStpRootCost | 
dot1dStpRootPort | 
dot1dStpMaxAge | 
dot1dStpHelloTime | 
dot1dStpHoldTime | 
dot1dStpForwardDelay | 
dot1dStpBridgeMaxAge | 
dot1dStpBridgeHelloTime | 
dot1dStpBridgeForwardDelay |

**RFC 4363 (P-BRIDGE-MIB)**

The following tables, groups, and variables are supported in this MIB.
### Supported Variables

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>dot1dPortCapabilitiesTable</td>
<td>dot1dDeviceCapabilities.</td>
<td>A table that contains capabilities information about every port that is associated with this bridge. Read-only.</td>
</tr>
<tr>
<td>dot1dDeviceCapabilities</td>
<td>Bit 0 (dot1dExtendedFilteringServices)</td>
<td>Denotes the multicast address filtering capability by GMRP. ExtremeXOS does not support this, and returns 0 always.</td>
</tr>
<tr>
<td></td>
<td>Bit 1 (dot1dTrafficClasses)</td>
<td>Denotes switch capability on user priority mapping for multiple traffic classes. ExtremeXOS supports this, and always returns 1.</td>
</tr>
<tr>
<td></td>
<td>Bit 2 (dot1qStaticEntryIndividualPort)</td>
<td>Denotes switch capability on Static unicast/multicast address support for all/particular port. ExtremeXOS does not support this, and returns 0 always.</td>
</tr>
<tr>
<td></td>
<td>Bit 3 (dot1qIVLCapable)</td>
<td>Denotes switch capability on Independent VLAN Learning (IVL). ExtremeXOS supports this, and always returns 1.</td>
</tr>
<tr>
<td></td>
<td>Bit 4 (dot1qSVLCapable)</td>
<td>Denotes switch capability on Shared VLAN Learning (SVL). ExtremeXOS does not support this, and returns 0 always.</td>
</tr>
<tr>
<td></td>
<td>Bit 5 (dot1qHybridCapable)</td>
<td>Denotes switch capability to support both IVL and SVL. ExtremeXOS does not support this, and returns 0 always.</td>
</tr>
<tr>
<td></td>
<td>Bit 6 (dot1qConfigurablePvidTagging)</td>
<td>Denotes whether the switch supports the ability to override the default PVID setting and its egress status (VLAN-Tagged or Untagged) on each port. ExtremeXOS supports this, and always returns 1.</td>
</tr>
<tr>
<td></td>
<td>Bit 7 (dot1dLocalVlanCapable)</td>
<td>Denotes whether the switch supports multiple local vlans. ExtremeXOS supports this, and always returns 1.</td>
</tr>
<tr>
<td>dot1dPortDefaultUserPriority</td>
<td></td>
<td>The default ingress User Priority for this port. This only has effect on media, such as Ethernet, that do not support native User Priority. The value of this object MUST be retained across reinitializations of the management system. Read-write access.</td>
</tr>
</tbody>
</table>

**RFC 4363 (Q-BRIDGE-MIB)**

The following tables, groups, and variables are supported in this MIB.
<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC 4363</td>
<td>dot1qVlanVersionNumber</td>

<tr>
<td>dataSourceDapsTable</td>
<td>dataSourceCapsObject</td>
<td>Defines an object that can be a SMON data source or a source or a destination for a port copy operation.</td>
</tr>
<tr>
<td></td>
<td>dataSourceRmonCaps</td>
<td>General attributes of the specified dataSource. Note that these are static attributes, which SHOULD NOT be adjusted because of current resources or configuration.</td>
</tr>
<tr>
<td></td>
<td>dataSourceCopyCaps</td>
<td>PortCopy function capabilities of the specified dataSource. Note that these are static capabilities, which SHOULD NOT be adjusted because of current resources or configuration.</td>
</tr>
<tr>
<td></td>
<td>dataSourceCapsIfIndex</td>
<td>This object contains the ifIndex value of the ifEntry associated with this smonDataSource. The agent MUST create ‘propVirtual’ ifEntries for each dataSourceCapsEntry of type VLAN or entPhysicalEntry.</td>
</tr>
<tr>
<td>portCopyConfigTable</td>
<td>portCopySource</td>
<td>The ifIndex of the source which has all packets redirected to the destination as defined by portCopyDest.</td>
</tr>
<tr>
<td></td>
<td>portCopyDest</td>
<td>Defines the ifIndex destination for the copy operation.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------</td>
<td>----------</td>
</tr>
<tr>
<td></td>
<td>portCopyDestDropEvents</td>
<td>The total number of events in which port copy packets were dropped by the switch at the destination port due to lack of resources. Note that this number is not necessarily the number of packets dropped; it is just the number of times this condition has been detected. A single dropped event counter is maintained for each portCopyDest. Thus all instances associated with a given portCopyDest will have the same portCopyDestDropEvents value. The value for this field is “0” (zero) due to hardware limitation.</td>
</tr>
<tr>
<td></td>
<td>portCopyDirection</td>
<td>This object affects the way traffic is copied from a switch source port, for the indicated port copy operation. If this object has the value copyRxOnly (1), then only traffic received on the indicated source port will be copied to the indicated destination port. If this object has the value copyTxOnly (2), then only traffic transmitted out the indicated source port will be copied to the indicated destination port. If this object has the value copyBoth (3), then all traffic received or transmitted on the indicated source port will be copied to the indicated destination port. The creation and deletion of instances of this object is controlled by the portCopyRowStatus object. Note that there is no guarantee that changes in the value of this object performed while the associated portCopyRowStatus object is equal to active will not cause traffic discontinuities in the packet.</td>
</tr>
<tr>
<td></td>
<td>portCopyStatus</td>
<td>Defines the status of the port copy entry. In order to configure a source to destination portCopy relationship, both source and destination interfaces MUST be present as an ifEntry in the ifTable and their respective ifAdminStatus and ifOperStatus values must be equal to up (1). If the value of any of those two objects changes after the portCopyEntry is activated, portCopyStatus transitions to notReady (3). The capability of an interface to be source or destination of a port copy operation is described by the copySourcePort (0) and copyDestPort (1) bits in dataSourceCopyCaps. Those bits should be appropriately set by the agent, in order to allow for a portCopyEntry to be created.</td>
</tr>

<tr>
<td></td>
<td></td>
<td>Read-only.</td>
</tr>
</tbody>
</table>

**entPhySensorType**

The `entPhySensorType` object is an integer that defines the sensor as one of the following types:

- Value
### Sensor Types

<table>
<thead>
<tr>
<th>Value</th>
<th>Sensor Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Other</td>
</tr>
<tr>
<td>2</td>
<td>Unknown</td>
</tr>
<tr>
<td>3</td>
<td>voltsAC</td>
</tr>
<tr>
<td>4</td>
<td>voltsDC</td>
</tr>
<tr>
<td>5</td>
<td>Amperes</td>
</tr>
<tr>
<td>6</td>
<td>Watts</td>
</tr>
<tr>
<td>7</td>
<td>Hertz</td>
</tr>
<tr>
<td>8</td>
<td>Celsius</td>
</tr>
<tr>
<td>9</td>
<td>percentRH</td>
</tr>
<tr>
<td>10</td>
<td>Rpm</td>
</tr>
<tr>
<td>11</td>
<td>Cmm</td>
</tr>
<tr>
<td>12</td>
<td>thruthvalue</td>
</tr>
</tbody>
</table>

The following sensor types are used for the digital diagnostic monitoring data.

<table>
<thead>
<tr>
<th>Sensor</th>
<th>Sensor Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Temperature</td>
<td>Celsius</td>
</tr>
<tr>
<td>VCC</td>
<td>voltsDC</td>
</tr>
<tr>
<td>Tx Bias Current</td>
<td>Amperes</td>
</tr>
<tr>
<td>Rx Power</td>
<td>Watts</td>
</tr>
<tr>
<td>Tx Power</td>
<td>Watts</td>
</tr>
</tbody>
</table>

Power measurements may be represented as decibels (dB). If this is the case, the sensor type is defined as "other" and the units of measurement are determined using `entPhySensorUnitsDisplay`.

#### `entPhySensorScale`

The `entPhySensorScale` object is an integer that defines the scale of the sensor as one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Sensor Scale</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Yocto</td>
</tr>
<tr>
<td>2</td>
<td>Zepto</td>
</tr>
<tr>
<td>3</td>
<td>Atto</td>
</tr>
<tr>
<td>4</td>
<td>femto</td>
</tr>
<tr>
<td>5</td>
<td>Pico</td>
</tr>
<tr>
<td>6</td>
<td>nano</td>
</tr>
<tr>
<td>7</td>
<td>micro</td>
</tr>
<tr>
<td>8</td>
<td>milli</td>
</tr>
</tbody>
</table>
Value | Sensor Scale
--- | ---
9 | units
10 | Kilo
11 | mega
12 | giga
13 | tera
14 | Exa
15 | peta
16 | zetta
17 | yotta

*entPhySensorPrecision*

This object defines the sensor precision range.

A value in the range 1 to 9, represents the number of decimal places in the fractional part of an associated *entPhySensorValue* fixed-point number. A value in the range -8 to -1, represents the number of accurate digits in the associated *entPhySensorValue* fixed-point number. The value zero indicates the associated *entPhySensorValue* object is not a fixed-point number.

*entPhySensorValue*

The *entPhySensorValue* object is the value of the sensor.

*entPhySensorOperStatus*

The *entPhySensorOperStatus* object is an integer that defines the operating status of the sensor as one of the following.

<table>
<thead>
<tr>
<th>Value</th>
<th>Sensor Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Ok</td>
</tr>
<tr>
<td>2</td>
<td>Unavailable</td>
</tr>
<tr>
<td>3</td>
<td>Nonoperational</td>
</tr>
</tbody>
</table>

Ports without a populated transceiver or one that is unreachable due to i2c bus errors, etc. are designated “nonoperational”. Ports populated with a transceiver that does not support digital diagnostic monitoring are designated “unavailable.”

*entPhySensorUnitsDisplay*

The *entPhySensorUnitsDisplay* object is a textual description of the data units that should be used in the display of *entPhySensorValue*.

*entPhySensorValueTimeStamp*

The *entPhySensorValueTimeStamp* object is the value of sysUpTime at the time the status and/or value of this sensor were last obtained.
entPhySensorValueUpdateRate

The entPhySensorValueUpdateRate object is an indication of the frequency that the agent updates the associated entPhySensorValue object, represented in milliseconds.

RFC 3621 (PoE-MIB)

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>

RFC-4133 (ENTITY MIB)

For RFC-4133, the entityPhysicalGroup contains a single table, entityPhysicalTable, to identify physical system components. The following table lists the objects that are supported.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>entPhysicalIndex</td>
<td>The arbitrarily assigned index for the table</td>
<td>Not-accessible</td>
</tr>
<tr>
<td>entPhysicalDescr</td>
<td>Text description of the sensor.</td>
<td>Read-only</td>
</tr>
<tr>
<td>entPhysicalVendorType</td>
<td>Specified OID used to identify enterprise-wide type/version/model.</td>
<td>Read-only</td>
</tr>
<tr>
<td>entPhysicalContainedIn</td>
<td>The entPhysicalIndex of the parent device. For SFP sensors, this is the corresponding port index.</td>
<td>Read-only</td>
</tr>
<tr>
<td>entPhysicalClass</td>
<td>Integer that defines the general device type. SFP sensors are of class &quot;sensor (8)&quot;.</td>
<td>Read-only</td>
</tr>
<tr>
<td>entPhysicalParentRelPos</td>
<td>Relative position of the parent device.</td>
<td>Read-only</td>
</tr>
<tr>
<td>entPhysicaModuleName</td>
<td>Text String of the model information stored in the SFP/QSFP.</td>
<td>Read-only</td>
</tr>
<tr>
<td>entPhysicalSerialNum</td>
<td>Text String of the serial number information stored in the SFP/QSFP.</td>
<td>Read-only</td>
</tr>
<tr>
<td>entPhysicalMfgName</td>
<td>Manufacture Name of the SFP/QSFP, “Extreme Networks”.</td>
<td>Read-only</td>
</tr>
</tbody>
</table>

RFC 5601 (PW-STD-MIB)

The following tables, groups, and variables are supported in this MIB.

All tables and variables of this MIB are supported as read only. The comments here are abbreviated versions of the description in the RFC documentation.
<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwTable</td>
<td>pwIndex</td>
<td>A unique index for the conceptual row identifying a PW within this table.</td>
</tr>
<tr>
<td></td>
<td>pwPeerAddr</td>
<td>This object contains the value of the peer node address of the PW/PE maintenance protocol entity. This object should contain a value of all zeroes if not applicable (pwPeerAddrType is 'unknown').</td>
</tr>
<tr>
<td></td>
<td>pwID</td>
<td>Pseudowire identifier. If the pwOwner object is pwIldFecSignaling or l2tpControlProtocol, then this object is signaled in the outgoing PW ID field within the Virtual Circuit FEC Element. For other values of pwOwner, this object is not signaled and it can be set to zero.</td>
</tr>
<tr>
<td></td>
<td>pwLocalCapabAdvert</td>
<td>If a maintenance protocol is used, it indicates the capabilities the local node will advertise to the peer.</td>
</tr>
<tr>
<td></td>
<td>pwRemoteGroupID</td>
<td>This object is obtained from the Group ID field as received through the maintenance protocol used for PW setup. Value of zero is reported if not used. Value of 0xFFFFFFFF is used if the object is yet to be defined by the PW maintenance protocol.</td>
</tr>
<tr>
<td></td>
<td>pwOutboundLabel</td>
<td>The PW label used in the outbound direction (i.e., toward the PSN). It might be set manually if pwOwner is 'manual'; otherwise, it is set automatically.</td>
</tr>
<tr>
<td></td>
<td>pwInboundLabel</td>
<td>The PW label used in the inbound direction (i.e., packets received from the PSN). It may be set manually if pwOwner is 'manual'; otherwise, it is set automatically.</td>
</tr>
<tr>
<td></td>
<td>pwCreateTime</td>
<td>The value of sysUpTime at the time this PW was created.</td>
</tr>
<tr>
<td></td>
<td>pwUpTime</td>
<td>Specifies the time since last change of pwOperStatus to Up (1).</td>
</tr>
<tr>
<td></td>
<td>pwLastChange</td>
<td>The value of sysUpTime at the time the PW entered its current operational state. If the current state was entered prior to the last re-initialization of the local network management subsystem, then this object contains a zero value.</td>
</tr>
<tr>
<td></td>
<td>pwAdminStatus</td>
<td>The desired operational status of this PW. This object can be set at any time.</td>
</tr>
<tr>
<td></td>
<td>pwOperStatus</td>
<td>This object indicates the operational status of the PW; it does not reflect the status of the Customer Edge (CE) bound interface.</td>
</tr>
<tr>
<td></td>
<td>pwLocalStatus</td>
<td>Indicates the status of the PW in the local node.</td>
</tr>
<tr>
<td></td>
<td>pwRemoteStatus</td>
<td>Indicates the status of the PW as was advertised by the remote.</td>
</tr>
<tr>
<td></td>
<td>pwRowStatus</td>
<td>For creating, modifying, and deleting this row. This object can be changed at any time.</td>
</tr>
</tbody>
</table>
Table/Group Supported Variables Comments
---

pwOamEnable This variable indicates if OAM is enabled for this PW. It can be changed at any time.

pwIndexMappingTable All objects This table enables the reverse mapping of the unique PWid parameters [peer IP, PW type, and PW ID] and the pwIndex. The table is not applicable for PWs created manually or by using the generalized FEC.

**RFC 5602 (PW-MPLS-STD-MIB)**

The following tables, groups, and variables are supported in this MIB.

All tables and variables of this MIB are supported as read only. The comments here are abbreviated versions of the description in the RFC documentation.

Table/Group Supported Variables Comments
---
pwMplsTable pwIndex This table controls MPLS-specific parameters when the PW is going to be carried over MPLS PSN.
pwMplsMplsType This object is set by the operator to indicate the outer tunnel types, if existing.
pwMplsTtl This object is set by the operator to indicate the PW TTL value to be used on the PW shim label.
pwMplsLocalLdpId The LDP identifier of the LDP entity that creates this PW in the local node.
pwMplsLocalLdpEntityIndex The local node LDP Entity Index of the LDP entity creating this PW.
pwMplsPeerLdpId The peer LDP identifier of the LDP session. This object should return the value zero if LDP is not used or if the value is not yet known.
pwMplsOutboundTable All objects This table reports and configures the current outbound MPLS tunnels (i.e., toward the PSN) or the physical interface in the case of a PW label only that carries the PW traffic. It also reports the current outer tunnel and LSP that forward the PW traffic.

**RFC 5603 (PW-ENET-STD-MIB)**

The following tables, groups, and variables are supported in this MIB.

All tables and variables of this MIB are supported as read only. The comments here are abbreviated versions of the description in the RFC documentation.
<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>

<td>pwIndex</td>
<td>This table contains the index to the Ethernet tables associated with this Ethernet PW, the VLAN configuration, and the VLAN mode.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>pwEnetPwInstance</td>
<td>If multiple rows are mapped to the same PW, this index is used to uniquely identify the individual row.</td>
</tr>
<tr>
<td></td>
<td>pwEnetPwVlan</td>
<td>This object defines the (service-delimiting) VLAN field value on the PW.</td>
</tr>
<tr>
<td></td>
<td>pwEnetVlanMode</td>
<td>This object indicates the mode of VLAN handling between the port or the virtual port associated with the PW and the PW encapsulation.</td>
</tr>
<tr>
<td></td>
<td>pwEnetPortVlan</td>
<td>This object defines if the mapping between the original port (physical port or VPLS virtual port) to the PW is VLAN based or not.</td>
</tr>
<tr>
<td></td>
<td>pwEnetPortIfIndex</td>
<td>This object is used to specify the ifIndex of the Ethernet port associated with this PW for point-to-point Ethernet service, or the ifIndex of the virtual interface of the VPLS instance associated with the PW if the service is VPLS.</td>
</tr>
<tr>
<td></td>
<td>pwEnetRowStatus</td>
<td>This object enables creating, deleting, and modifying this row.</td>
</tr>
</tbody>
</table>

**RFC 5643**

A subset of the traps in RFC 5643 are supported.

**RFC 6933 (ENTITY-MIB)**

The following tables, groups, and variables are supported in this MIB.

<table>
<thead>
<tr>
<th>Table/Group</th>
<th>Supported Variables</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>entityPhysicalTable</td>
<td>entPhysicalIndex</td>
<td>The index for this entry.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalDescr</td>
<td>A textual description of physical entity. This object should contain a string that identifies the manufacturer’s name for the physical entity and should be set to a distinct value for each version or model of the physical entity.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------</td>
<td>----------</td>
</tr>
<tr>
<td></td>
<td>entPhysicalVendorType</td>
<td>An indication of the vendor-specific hardware type of the physical entity. Note that this is different from the definition of MIB-II's sysObjectID. An agent should set this object to an enterprise-specific registration identifier value indicating the specific equipment type in detail. The associated instance of entPhysicalClass is used to indicate the general type of hardware device. If no vendor-specific registration identifier exists for this physical entity, or the value is unknown by this agent, then the value { 0 0 } is returned.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalContainedIn</td>
<td>The value of entPhysicalIndex for the physical entity that 'contains' this physical entity. A value of zero indicates this physical entity is not contained in any other physical entity. Note that the set of 'containment' relationships define a strict hierarchy; that is, recursion is not allowed. In the event that a physical entity is contained by more than one physical entity (e.g., double-wide modules), this object should identify the containing entity with the lowest value of entPhysicalIndex.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalClass</td>
<td>An indication of the general hardware type of the physical entity. An agent should set this object to the standard enumeration value that most accurately indicates the general class of the physical entity, or the primary class if there is more than one entity. If no appropriate standard registration identifier exists for this physical entity, then the value 'other(1)' is returned. If the value is unknown by this agent, then the value 'unknown(2)' is returned.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalParentRelPos</td>
<td>An indication of the relative position of this 'child' component among all its 'sibling' components. Sibling components are defined as entPhysicalEntries that share the same instance values of each of the entPhysicalContainedIn and entPhysicalClass objects.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------</td>
<td>----------</td>
</tr>
<tr>
<td></td>
<td>entPhysicalName</td>
<td>The textual name of the physical entity. The value of this object should be the name of the component as assigned by the local device and should be suitable for use in commands entered at the device’s ‘console’. This might be a text name (e.g., ‘console’) or a simple component number (e.g., port or module number, such as ‘1’), depending on the physical component naming syntax of the device. If there is no local name, or if this object is otherwise not applicable, then this object contains a zero-length string. Note that the value of entPhysicalName for two physical entities will be the same in the event that the console interface does not distinguish between them, e.g., slot-1 and the card in slot-1.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalHardwareRev</td>
<td>The vendor-specific hardware revision string for the physical entity. The preferred value is the hardware revision identifier actually printed on the component itself (if present). Note that if revision information is stored internally in a non-printable (e.g., binary) format, then the agent must convert such information to a printable format in an implementation-specific manner. If no specific hardware revision string is associated with the physical component, or if this information is unknown to the agent, then this object will contain a zero-length string.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalFirmwareRev</td>
<td>The vendor-specific firmware revision string for the physical entity. Note that if revision information is stored internally in a non-printable (e.g., binary) format, then the agent must convert such information to a printable format in an implementation-specific manner. If no specific firmware programs are associated with the physical component, or if this information is unknown to the agent, then this object will contain a zero-length string.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalSoftwareRev</td>
<td>The vendor-specific software revision string for the physical entity. Note that if revision information is stored internally in a non-printable (e.g., binary) format, then the agent must convert such information to a printable format in an implementation-specific manner. If no specific software programs are associated with the physical component, or if this information is unknown to the agent, then this object will contain a zero-length string.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>entPhysicalSerialNum</td>
<td>The vendor-specific serial number string for the physical entity. The preferred value is the serial number string actually printed on the component itself (if present). On the first instantiation of a physical entity, the value of entPhysicalSerialNum associated with that entity is set to the correct vendor-assigned serial number, if this information is available to the agent. If a serial number is unknown or non-existent, the entPhysicalSerialNum will be set to a zero-length string instead. Note that implementations that can correctly identify the serial numbers of all installed physical entities do not need to provide write access to the entPhysicalSerialNum object. Agents that cannot provide non-volatile storage for the entPhysicalSerialNum strings are not required to implement write access for this object. Not every physical component will have a serial number, or even need one. Physical entities for which the associated value of the entPhysicalIsFRU object is equal to 'false(2)' (e.g., the repeater ports within a repeater module) do not need their own unique serial numbers. An agent does not have to provide write access for such entities and may return a zero-length string. If write access is implemented for an instance of entPhysicalSerialNum and a value is written into the instance, the agent must retain the supplied value in the entPhysicalSerialNum instance (associated with the same physical entity) for as long as that entity remains instantiated. This includes instantiations across all re-initializations/reboots of the network management system, including those resulting in a change of the physical entity’s entPhysicalIndex value.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalMfgName</td>
<td>The name of the manufacturer of this physical component. The preferred value is the manufacturer name string actually printed on the component itself (if present). Note that comparisons between instances of the entPhysicalModelName, entPhysicalFirmwareRev, entPhysicalSoftwareRev, and the entPhysicalSerialNum objects are only meaningful amongst entPhysicalEntries with the same value of entPhysicalMfgName. If the manufacturer name string associated with the physical component is unknown to the agent, then this object will contain a zero-length string.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>entPhysicalmodelName</td>
<td>The vendor-specific model name identifier string associated with this physical component. The preferred value is the customer-visible part number, which may be printed on the component itself. If the model name string associated with the physical component is unknown to the agent, then this object will contain a zero-length string.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalAlias</td>
<td>Not supported.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalAssetID</td>
<td>Not supported.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalIsFRU</td>
<td>This object indicates whether or not this physical entity is considered a 'field replaceable unit' by the vendor. If this object contains the value 'true(1)', then this entPhysicalEntry identifies a field replaceable unit. For all entPhysicalEntries that represent components permanently contained within a field replaceable unit, the value 'false(2)' should be returned for this object.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalMfgDate</td>
<td>This object contains the date of manufacturing of the managed entity. If the manufacturing date is unknown or not supported, the object is not instantiated. The special value '0000000000000000'H may also be returned in this case.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalUris</td>
<td>This object contains identification information about the physical entity. The object contains URIs; therefore, the syntax of this object must conform to RFC 3986. Multiple URIs may be present and are separated by white space characters. Leading and trailing white space characters are ignored. If no URI identification information is known about the physical entity, the object is not instantiated. A zero-length octet string may also be returned in this case.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> This object has read-write permission, but is implemented with read-only mode. Write operation is not supported.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalUUID</td>
<td>This object contains identification information about the physical entity. The object contains a Universally Unique Identifier, the syntax of this object must conform to RFC 4122, Section 4.1. A zero-length octet string is returned if no UUID information is known.</td>
</tr>
<tr>
<td>Table/Group</td>
<td>Supported Variables</td>
<td>Comments</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------</td>
<td>----------</td>
</tr>
<tr>
<td></td>
<td>entAliasMappingIdentifier</td>
<td>The value of this object identifies a particular conceptual row associated with the indicated entPhysicalIndex and entLogicalIndex pair. Because only physical ports are modeled in this table, only entries that represent interfaces or ports are allowed. If an ifEntry exists on behalf of a particular physical port, then this object should identify the associated ifEntry. For repeater ports, the appropriate row in the 'rptrPortGroupTable' should be identified instead.</td>
</tr>
<tr>
<td></td>
<td>entPhysicalChildIndex</td>
<td>The value of entPhysicalIndex for the contained physical entity.</td>
</tr>
<tr>
<td></td>
<td>entConfigChange</td>
<td>An entConfigChange notification is generated when the value of entLastChangeTime changes. It can be utilized by an NMS to trigger logical/physical entity table maintenance polls. An agent should not generate more than one entConfigChange notification-event in a given time interval (five seconds is the suggested default). A notification-event is the transmission of a single trap or inform PDU to a list of notification destinations. If additional configuration changes occur within the throttling period, then notification-events for these changes should be suppressed by the agent until the current throttling period expires. At the end of a throttling period, one notification-event should be generated if any configuration changes occurred since the start of the throttling period. In such a case, another throttling period is started right away. An NMS should periodically check the value of entLastChangeTime to detect any missed entConfigChange notification-events.</td>
</tr>
<tr>
<td>entityGeneral</td>
<td>entLastChangeTime</td>
<td>The value of sysUpTime at the time a conceptual row is created, modified, or deleted in any of these tables: - entPhysicalTable - entLogicalTable - entLPMappingTable - entAliasMappingTable - entPhysicalContainsTable</td>
</tr>
</tbody>
</table>

**VPLS-MIB (draft-ietf-l2vpn-vpls-mib-02.txt)**

Glossary

AAA
Authentication, Authorization, and Accounting is a system in IP-based networking to control which computer resources specific users can access and to keep track of the activity of specific users over the network.

ACL
An Access Control List is a mechanism for filtering packets at the hardware level. Packets can be classified by characteristics such as the source or destination MAC, IP address, IP type, or QoS queue. Once classified, the packets can be forwarded, counted, queued, or dropped.

ad hoc mode
An 802.11 networking framework in which devices or stations communicate directly with each other, without the use of an AP.

ARP
Address Resolution Protocol is part of the TCP/IP suite used to dynamically associate a device’s physical address (MAC address) with its logical address (IP address). The system broadcasts an ARP request, containing the IP address, and the device with that IP address sends back its MAC address so that traffic can be transmitted.

AS
In OSPF, an Autonomous System is a connected segment of a network topology that consists of a collection of subnetworks (with hosts attached) interconnected by a set of routes. The subnetworks and the routers are expected to be under the control of a single administration. Within an AS, routers may use one or more interior routing protocols and sometimes several sets of metrics. An AS is expected to present to other autonomous systems an appearance of a coherent interior routing plan and a consistent picture of the destinations reachable through the AS. An AS is identified by a unique 16-bit number.

ATM
Asynchronous Transmission Mode is a start/stop transmission in which each character is preceded by a start signal and followed by one or more stop signals. A variable time interval can exist between characters. ATM is the preferred technology for the transfer of images.

BGP
Border Gateway Protocol is a router protocol in the IP suite designed to exchange network reachability information with BGP systems in other autonomous systems. You use a fully meshed configuration with BGP.

BGP provides routing updates that include a network number, a list of ASs that the routing information passed through, and a list of other path attributes. BGP works with cost metrics to choose the best available path; it sends updated router information only when one host has detected a change, and only the affected part of the routing table is sent.

BGP communicates within one AS using Interior BGP (IBGP) because BGP does not work well with IGP. Thus the routers inside the AS maintain two routing tables: one for the IGP and one for IBGP. BGP uses exterior BGP (EBGP) between different autonomous systems.
BPDU
In STP, a Bridge Protocol Data Unit is a packet that initiates communication between devices. BPDU packets contain information on ports, addresses, priorities, and costs and they ensure that the data ends up where it was intended to go. BPDU messages are exchanged across bridges to detect loops in a network topology. The loops are then removed by shutting down selected bridge interfaces and placing redundant switch ports in a backup, or blocked, state.

bridge
In conventional networking terms, bridging is a Layer 2 function that passes frames between two network segments; these segments have a common network layer address. The bridged frames pass only to those segments connected at a Layer 2 level, which is called a broadcast domain (or VLAN). You must use Layer 3 routing to pass frames between broadcast domains (VLANs).

In wireless technology, bridging refers to forwarding and receiving data between radio interfaces on APs or between clients on the same radio. So, bridged traffic can be forwarded from one AP to another AP without having to pass through the switch on the wired network.

BSS
Basic Service Set is a wireless topology consisting of one access point connected to a wired network and a set of wireless devices. Also called an infrastructure network. See also IBSS (Independent Basic Service Set).

CCM
In CFM, Connectivity Check Messages are frames transmitted periodically by a MEP to ensure connectivity across the maintenance entities to which the transmitting MEP belongs. The CCMs contain a unique ID for the specified domain. Because a failure to receive a CCM indicates a connectivity fault in the network, CCMs proactively check for network connectivity.

CEP
Customer Edge Port, also known as Selective Q-in-Q or C-tagged Service Interface, is a role that is configured in software as a CEP VMAN port, and connects a VMAN to specific CVLANs based on the CVLAN CVID. The CNP role, which is configured as an untagged VMAN port, connects a VMAN to all other port traffic that is not already mapped to the port CEP role.

CFM
Connectivity Fault Management allows an ISP to proactively detect faults in the network for each customer service instance individually and separately. CFM comprises capabilities for detecting, verifying, and isolating connectivity failures in virtual bridged LANs.

Chalet
Chalet is a web-based user interface for setting up and viewing information about a switch, removing the need to enter common commands individually in the CLI.

CHAP
Challenge-Handshake Authentication Protocol is one of the two main authentication protocols used to verify a user’s name and password for PPP Internet connections. CHAP is more secure because it performs a three-way handshake during the initial link establishment between the home and remote machines. It can also repeat the authentication anytime after the link has been established.
**CIST root port**

In an NSTO environment, the port on the CIST regional root bridge that connects to the CIST root bridge is the CIST root port. The CIST root port is the master port for all MSTIs in that MSTP region, and it is the only port that connects the entire region to the CIST root bridge.

**CLI**

Command Line Interface. The CLI provides an environment to issue commands to monitor and manage switches and wireless appliances.

**CoS**

Class of Service specifies the service level for the classified traffic type.

**Data Center Connect**

DCC, formerly known as DCM (Data Center Manager), is a data center fabric management and automation tool that improves the efficiency of managing a large virtual and physical network. DCC provides an integrated view of the server, storage, and networking operations, removing the need to use multiple tools and management systems. DCC automates VM assignment, allocates appropriate network resources, and applies individual policies to various data objects in the switching fabric (reducing VM sprawl). Learn more about DCC at [http://www.extremenetworks.com/product/data-center-connect/](http://www.extremenetworks.com/product/data-center-connect/).

**DCB**

Data Center Bridging is a set of IEEE 802.1Q extensions to standard Ethernet, that provide an operational framework for unifying Local Area Networks (LAN), Storage Area Networks (SAN) and Inter-Process Communication (IPC) traffic between switches and endpoints onto a single transport layer.

**DHCP**

Dynamic Host Configuration Protocol allows network administrators to centrally manage and automate the assignment of IP addresses on the corporate network. DHCP sends a new IP address when a computer is plugged into a different place in the network. The protocol supports static or dynamic IP addresses and can dynamically reconfigure networks in which there are more computers than there are available IP addresses.

**DoS attack**

Denial of Service attacks occur when a critical network or computing resource is overwhelmed so that legitimate requests for service cannot succeed. In its simplest form, a DoS attack is indistinguishable from normal heavy traffic. ExtremeXOS software has configurable parameters that allow you to defeat DoS attacks.

**DSCP**

Differentiated Services Code Point is a field in the header of IP packets that is used for packet classification purposes.

**DSSS**

Direct-Sequence Spread Spectrum is a transmission technology used in Local Area Wireless Network (LAWN) transmissions where a data signal at the sending station is combined with a higher data rate bit sequence, or chipping code, that divides the user data according to a spreading ratio. The chipping code is a redundant bit pattern for each bit that is transmitted, which increases the signal's resistance to
interference. If one or more bits in the pattern are damaged during transmission, the original data can be recovered due to the redundancy of the transmission. (Compare with FHSS (Frequency-Hopping Spread Spectrum).)

**EAP-TLS/EAP-TTLS**

EAP-TLS Extensible Authentication Protocol - Transport Layer Security. A general protocol for authentication that also supports multiple authentication methods, such as token cards, Kerberos, one-time passwords, certificates, public key authentication and smart cards.

IEEE 802.1x specifies how EAP should be encapsulated in LAN frames.

In wireless communications using EAP, a user requests connection to a WLAN through an access point, which then requests the identity of the user and transmits that identity to an authentication server such as RADIUS. The server asks the access point for proof of identity, which the access point gets from the user and then sends back to the server to complete the authentication.

EAP-TLS provides for certificate-based and mutual authentication of the client and the network. It relies on client-side and server-side certificates to perform authentication and can be used to dynamically generate user-based and session-based WEP keys.

EAP-TTLS (Tunneled Transport Layer Security) is an extension of EAP-TLS to provide certificate-based, mutual authentication of the client and network through an encrypted tunnel, as well as to generate dynamic, per-user, per-session WEP keys. Unlike EAP-TLS, EAP-TTLS requires only server-side certificates.

(See also **PEAP (Protected Extensible Authentication Protocol)**.)

**EAPS**

Extreme Automatic Protection Switching is an Extreme Networks-proprietary version of the Ethernet Automatic Protection Switching protocol that prevents looping Layer 2 of the network. This feature is discussed in RFC 3619.

**ECMP**

Equal Cost Multi Paths is a routing algorithm that distributes network traffic across multiple high-bandwidth OSPF, BPG, IS-IS, and static routes to increase performance. The Extreme Networks implementation supports multiple equal cost paths between points and divides traffic evenly among the available paths.

**edge safeguard**

Loop prevention and detection on an edge port configured for RSTP. Configuring edge safeguard on RSTP edge ports can prevent accidental or deliberate misconfigurations (loops) resulting from connecting two edge ports together or from connecting a hub or other non-STP switch to an edge port. Edge safeguard also limits the impact of broadcast storms that might occur on edge ports. This advanced loop prevention mechanism improves network resiliency but does not interfere with the rapid convergence of edge ports.

**EDP**

Extreme Discovery Protocol is a protocol used to gather topology information about neighboring Extreme Networks switches.

**ELRP**
Extreme Loop Recovery Protocol is an Extreme Networks-proprietary protocol that allows you to detect Layer 2 loops.

**ERPS**

Ethernet Ring Protection Switching provides fast protection and recovery switching for Ethernet traffic in a ring topology. It also ensures that the Ethernet layer remains loop-free. It is defined in ITU/T G.8032.

**ESRP**

Extreme Standby Router Protocol is an Extreme Networks-proprietary protocol that provides redundant Layer 2 and routing services to users.

**ESRP group**

An ESRP group runs multiple instances of ESRP within the same VLAN (or broadcast domain). To provide redundancy at each tier, use a pair of ESRP switches on the group. See [ESRP (Extreme Standby Router Protocol)](#).

**event**

Any type of occurrence on a switch that could generate a log message or require an action. For more, see [syslog](#).

**Extreme Access Control**

EAC, formerly NAC™, featuring both physical and virtual appliances, is a pre- and post-connect solution for wired and wireless LAN and VPN users. Using Identity and Access appliances and/or Identity and Access Virtual Appliance with the Extreme Management Center software, you can ensure only the right users have access to the right information from the right place at the right time. EAC is tightly integrated with the Intrusion Prevention System (IPS) and Security Information and Event Manager (SIEM) to deliver best-in-class post-connect access control. Learn more about EAC at [http://www.extremenetworks.com/product/extreme-access-control/](http://www.extremenetworks.com/product/extreme-access-control/).

**Extreme Application Analytics**

EAA, formerly Purview™, is a network powered application analytics and optimization solution that captures and analyzes context-based application traffic to deliver meaningful intelligence about applications, users, locations, and devices. EAA provides data to show how applications are being used. This can be used to better understand customer behavior on the network, identify the level of user engagement, and assure business application delivery to optimize the user experience. The software also provides visibility into network and application performance allowing IT to pinpoint and resolve performance issues in the infrastructure whether they are caused by the network, application, or server. Learn more about EAA at [http://www.extremenetworks.com/product/extremeanalytics/](http://www.extremenetworks.com/product/extremeanalytics/).

**Extreme Management Center**

Extreme Management Center (Management Center), formerly Netsight™, is a web-based control interface that provides centralized visibility into your network. Management Center reaches beyond ports, VLANs, and SSIDs and provides detailed control of individual users, applications, and protocols. When coupled with wireless and Identity & Access Management products, Management Center becomes the central location for monitoring and managing all the components in the infrastructure. Learn more about Management Center at [http://www.extremenetworks.com/product/management-center/](http://www.extremenetworks.com/product/management-center/).

**ExtremeCloud**
ExtremeCloud is a cloud-based network management Software as a Service (SaaS) tool. ExtremeCloud allows you to manage users, wired and wireless devices, and applications on corporate and guest networks. You can control the user experience with smarter edges – including managing QoS, call admission control, secure access policies, rate limiting, multicast, filtering, and traffic forwarding, all from an intuitive web interface. Learn more about ExtremeCloud at http://www.extremenetworks.com/product/extremecloud/.

ExtremeSwitching

ExtremeSwitching is the family of products comprising different switch types: Modular (X8 and 8000 series [formerly BlackDiamond] and S and K series switches); Stackable (X-series and A, B, C, and 7100 series switches); Standalone (SSA, X430, and D, 200, 800, and ISW series); and Mobile Backhaul (E4G). Learn more about ExtremeSwitching at http://www.extremenetworks.com/products/switching-routing/.

ExtremeWireless

ExtremeWireless products and solutions offer high-density WiFi access, connecting your organization with employees, partners, and customers everywhere they go. The family of wireless products and solutions includes APs, wireless appliances, and software. Learn more about ExtremeWireless at http://www.extremenetworks.com/products/wireless/.

ExtremeXOS

ExtremeXOS, a modular switch operating system, is designed from the ground up to meet the needs of large cloud and private data centers, service providers, converged enterprise edge networks, and everything in between. Based on a resilient architecture and protocols, ExtremeXOS supports network virtualization and standards-based SDN capabilities like VXLAN gateway, OpenFlow, and OpenStack Cloud orchestration. ExtremeXOS also supports comprehensive role-based policy. Learn more about ExtremeXOS at http://www.extremenetworks.com/product/extremexos-network-operating-system/.

FDB

The switch maintains a database of all MAC address received on all of its ports and uses this information to decide whether a frame should be forwarded or filtered. Each forwarding database (FDB) entry consists of the MAC address of the sending device, an identifier for the port on which the frame was received, and an identifier for the VLAN to which the device belongs. Frames destined for devices that are not currently in the FDB are flooded to all members of the VLAN. For some types of entries, you configure the time it takes for the specific entry to age out of the FDB.

FHSS

Frequency-Hopping Spread Spectrum is a transmission technology used in Local Area Wireless Network (LAWN) transmissions where the data signal is modulated with a narrowband carrier signal that 'hops' in a random but predictable sequence from frequency to frequency as a function of time over a wide band of frequencies. This technique reduces interference. If synchronized properly, a single logical channel is maintained. (Compare with DSSS (Direct-Sequence Spread Spectrum).)

gratuitous ARP

When a host sends an ARP request to resolve its own IP address, it is called gratuitous ARP.

IBSS

An IBSS is the 802.11 term for an ad hoc network. See ad hoc mode.

ICMP

Glossary

ExtremeXOS® User Guide for version 22.6

1864
Internet Control Message Protocol is the part of the TCP/IP protocol that allows generation of error messages, test packets, and operating messages. For example, the ping command allows you to send ICMP echo messages to a remote IP device to test for connectivity. ICMP also supports traceroute, which identifies intermediate hops between a given source and destination.

**IGMP**

Hosts use Internet Group Management Protocol to inform local routers of their membership in multicast groups. Multicasting allows one computer on the Internet to send content to multiple other computers that have identified themselves as interested in receiving the originating computer’s content. When all hosts leave a group, the router no longer forwards packets that arrive for the multicast group.

**IGP**

Interior Gateway Protocol refers to any protocol used to exchange routing information within an AS. Examples of Internet IGPs include RIP and OSPF.

**JSON**

JavaScript Object Notation is a lightweight data-interchange format. Like XML, it can be used to transmit dynamic data between web servers and applications. It uses human-readable text that consists of one or more attribute–value pairs.

**LAG**

A Link Aggregation Group is the logical high-bandwidth link that results from grouping multiple network links in link aggregation (or load sharing). You can configure static LAGs or dynamic LAGs (using the LACP).

**LLDP**

Link Layer Discovery Protocol conforms to IEEE 802.1ab and is a neighbor discovery protocol. Each LLDP-enabled device transmits information to its neighbors, including chassis and port identification, system name and description, VLAN names, and other selected networking information. The protocol also specifies timing intervals in order to ensure current information is being transmitted and received.

**LSA**

A Link State Advertisement is a broadcast packet used by link state protocols, such as OSPF. The LSA contains information about neighbors and path costs and is used by the receiving router to maintain a routing table.

**LSDB**

In OSPF, a Link State Database is a database of information about the link state of the network. Two neighboring routers consider themselves to be adjacent only if their LSDBs are synchronized. All routing information is exchanged only between adjacent routers.

**MD5**

Message-Digest algorithm is a hash function that is commonly used to generate a 128-bit hash value. It was designed by Ron Rivest in 1991. MD5 is officially defined in RFC 1321 - The MD5 Message-Digest Algorithm.

**MEP**

In MEP, a Maintenance End Point is an end point for a single domain, or maintenance association. The MEP may be either an UP MEP or a DOWN MEP.
MIB
Management Information Bases make up a database of information (for example, traffic statistics and port settings) that the switch makes available to network management systems. MIB names identify objects that can be managed in a network and contain information about the objects. MIBs provide a means to configure a network device and obtain network statistics gathered by the device. Standard, minimal MIBs have been defined, and vendors often have private enterprise MIBs.

MIC
Message Integrity Check (or Code), also called ‘Michael’, is part of WPA and TKIP. The MIC is an additional 8-byte code inserted before the standard 4-byte ICV appended in by standard WEP to the 802.11 message. This greatly increases the difficulty in carrying out forgery attacks. Both integrity check mechanisms are calculated by the receiver and compared against the values sent by the sender in the frame. If the values match, there is assurance that the message has not been tampered with.

MLAG
The Multi-switch Link Aggregation Group feature allows users to combine ports on two switches to form a single logical connection to another network device. The other network device can be either a server or a switch that is separately configured with a regular LAG (or appropriate server port teaming) to form the port aggregation.

MPLS
Multiprotocol Label Switching speeds up network traffic. When forwarding packets, the Layer 2 (Switching) label is used to avoid complex destination lookups in the routing table. MPLS uses Label Switched Paths (LSPs) to establish the network path. The packet will be labeled so that service providers can decide the best way to keep traffic flowing. The Multiprotocol Label Switching Transport Profile (MPLS-TP) extensions to MPLS are designed to meet service provider requirements and are used as a network layer technology in transport networks. MPLS-TP gives service providers a reliable packet-based technology that is based on circuit-based transport networking. MPLS-TP is expected to be a low cost level 2 technology (if the limited profile is implemented in isolation) that will provide QoS, end-to-end OAM and protection switching.

MSDP
Multicast Source Discovery Protocol is used to connect multiple multicast routing domains. MSDP advertises multicast sources across Protocol Independent Multicast-Sparse Mode (PIM-SM) multicast domains or Rendezvous Points (RPs). In turn, these RPs run MSDP over TCP to discover multicast sources in other domains.

MSTI
Multiple Spanning Tree Instances control the topology inside an MSTP region. An MSTI is a spanning tree domain that operates within a region and is bounded by that region; and MSTI does not exchange BPDUs or send notifications to other regions. You can map multiple VLANs to an MSTI; however, each VLAN can belong to only one MSTI. You can configure up to 64 MSTIs in an MSTP region.

MSTP
Multiple Spanning Tree Protocol, based on IEEE 802.1Q-2003 (formerly known as IEEE 892.1s), allows you to bundle multiple VLANs into one STP topology, which also provides enhanced loop protection and better scaling. MSTP uses RSTP as the converging algorithm and is compatible with legacy STP protocols.
**NetLogin**
Network login provides extra security to the network by assigning addresses only to those users who are properly authenticated. You can use web-based, MAC-based, or IEEE 802.1X-based authentication with network login. The two modes of operation are campus mode and ISP mode.

**netmask**
A netmask is a string of 0s and 1s that mask, or screen out, the network part of an IP address, so that only the host computer part of the address remains. A frequently-used netmask is 255.255.255.0, used for a Class C subnet (one with up to 255 host computers). The ".0" in the netmask allows the specific host computer address to be visible.

**OSPF**
An interior gateway routing protocol for TCP/IP networks, Open Shortest Path First uses a link state routing algorithm that calculates routes for packets based on a number of factors, including least hops, speed of transmission lines, and congestion delays. You can also configure certain cost metrics for the algorithm. This protocol is more efficient and scalable than vector-distance routing protocols. OSPF features include least-cost routing, ECMP routing, and load balancing. Although OSPF requires CPU power and memory space, it results in smaller, less frequent router table updates throughout the network. This protocol is more efficient and scalable than vector-distance routing protocols.

**OSPFv3**
Open Shortest Path First version 3 is one of the routing protocols used with IPV6 and is similar to OSPF.

**PEAP**
Protected Extensible Authentication Protocol is an IETF draft standard to authenticate wireless LAN clients without requiring them to have certificates. In PEAP authentication, first the user authenticates the authentication server, then the authentication server authenticates the user. If the first phase is successful, the user is then authenticated over the SSL tunnel created in phase one using EAP-Generic Token Card (EAP-GTC) or Microsoft Challenged Handshake Protocol Version 2 (MSCHAP V2). (See also EAP-TLS/EAP-TTLS.)

**PoE**
The Power over Ethernet standard (IEEE 802.3af) defines how power can be provided to network devices over existing Ethernet connections, eliminating the need for additional external power supplies.

**QoS**
Quality of Service is a technique that is used to manage network resources and guarantee a bandwidth relationship between individual applications or protocols. A communications network transports a multitude of applications and data, including high-quality video and delay-sensitive data such as real-time voice. Networks must provide secure, predictable, measurable, and sometimes guaranteed services. Achieving the required QoS becomes the secret to a successful end-to-end business solution.

**RADIUS**
RADIUS is a client/server protocol and software that enables remote access servers to communicate with a central server to authenticate dial-in users and authorize their access to the requested system or service. RADIUS allows a company to maintain user profiles in a central database that all remote servers can share. It provides better security, allowing a company to set up a policy that can be applied at a single administered network point. With RADIUS, you can track usage for billing and for keeping network statistics.
rate limiting
In QoS, rate limiting is the process of restricting traffic to a peak rate (PR).

rate shaping
In QoS, rate shaping is the process of reshaping traffic throughput to give preference to higher priority traffic or to buffer traffic until forwarding resources become available.

RIP
This IGP vector-distance routing protocol is part of the TCP/IP suite and maintains tables of all known destinations and the number of hops required to reach each. Using Routing Information Protocol, routers periodically exchange entire routing tables. RIP is suitable for use only as an IGP.

RIPng
Routing Information Protocol Next Generation is one of the routing protocols used with IPv6 and is similar to RIP.

RSTP
Rapid Spanning Tree Protocol, described in IEEE 802.1w, is an enhanced version of STP that provides faster convergence. The Extreme Networks implementation of RSTP allows seamless interoperability with legacy STP.

segment
In Ethernet networks, a section of a network that is bounded by bridges, routers, or switches. Dividing a LAN segment into multiple smaller segments is one of the most common ways of increasing available bandwidth on the LAN.

SNMP
Simple Network Management Protocol is a standard that uses a common software agent to remotely monitor and set network configuration and runtime parameters. SNMP operates in a multivendor environment, and the agent uses MIBs, which define what information is available from any manageable network device. You can also set traps using SNMP, which send notifications of network events to the system log.

SNTP
Simple Network Time Protocol is used to synchronize the system clocks throughout the network. An extension of NTP, SNTP can usually operate with a single server and allows for IPv6 addressing.

SSL
Secure Socket Layer is a protocol for transmitting private documents using the Internet. SSL works by using a public key to encrypt data that is transferred over the SSL connection. SSL uses the public-and-private key encryption system, which includes the use of a digital certificate. SSL is used for other applications than SSH, for example, OpenFlow.

STP
Spanning Tree Protocol, defined in IEEE 802.1d, used to eliminate redundant data paths and to increase network efficiency. STP allows a network to have a topology that contains physical loops; it operates in bridges and switches. STP opens certain paths to create a tree topology, thereby preventing packets from looping endlessly on the network. To establish path redundancy, STP creates a tree that spans all of the switches in an extended network, forcing redundant paths into a standby, or blocked, state.
STP allows only one active path at a time between any two network devices (this prevents the loops) but establishes the redundant links as a backup if the initial link should fail. If STP costs change, or if one network segment in the STP becomes unreachable, the spanning tree algorithm reconfigures the STP topology and re-establishes the link by activating the standby path.

**STPD**

Spanning Tree Domain is an STP instance that contains one or more VLANs. The switch can run multiple STPDs, and each STPD has its own root bridge and active path. In the Extreme Networks implementation of STPD, each domain has a carrier VLAN (for carrying STP information) and one or more protected VLANs (for carrying the data).

**syslog**

A protocol used for the transmission of event notification messages across networks, originally developed on the University of California Berkeley Software Distribution (BSD) TCP/IP system implementations, and now embedded in many other operating systems and networked devices. A device generates messages, a relay receives and forwards the messages, and a collector (a syslog server) receives the messages without relaying them. syslog uses the UDP as its underlying transport layer mechanism. The UDP port that has been assigned to syslog is 514. (RFC 3164)

**TLV**

An LLDP frame that can contain multiple pieces of information. Each piece is known as a Type Length Value.

**UDP**

User Datagram Protocol is an efficient but unreliable, connectionless protocol that is layered over IP (as is TCP). Application programs must supplement the protocol to provide error processing and retransmitting data. UDP is an OSI Layer 4 protocol.

**virtual router**

In the Extreme Networks implementations, virtual routers allow a single physical switch to be split into multiple virtual routers. Each virtual router has its own IP address and maintains a separate logical forwarding table. Each virtual router also serves as a configuration domain. The identity of the virtual router you are working in currently displays in the prompt line of the CLI. The virtual routers discussed in relation to Extreme Networks switches themselves are not the same as the virtual router in VRRP.

In VRRP, the virtual router is identified by a virtual router (VRID) and an IP address. A router running VRRP can participate in one or more virtual routers. The VRRP virtual router spans more than one physical router, which allows multiple routers to provide redundant services to users.

**VLAN**

The term VLAN is used to refer to a collection of devices that communicate as if they are on the same physical LAN. Any set of ports (including all ports on the switch) is considered a VLAN. LAN segments are not restricted by the hardware that physically connects them. The segments are defined by flexible user groups you create with the CLI.

**VMAN**

In ExtremeXOS software, Virtual MANs are a bi-directional virtual data connection that creates a private path through the public network. One VMAN is completely isolated from other VMANs; the encapsulation allows the VMAN traffic to be switched over Layer 2 infrastructure. You implement VMAN
using an additional 892.1Q tag and a configurable EtherType; this feature is also known as Q-in-Q switching.

**VR-Control**
This virtual router is part of the embedded system in Extreme Networks switches. VR-Control is used for internal communications between all the modules and subsystems in the switch. It has no ports, and you cannot assign any ports to it. It also cannot be associated with VLANs or routing protocols. (Referred to as VR-1 in earlier ExtremeXOS software versions.)

**VR-Default**
This virtual router is part of the embedded system in Extreme Networks switches. VR-Default is the default VR on the system. All data ports in the switch are assigned to this VR by default; you can add and delete ports from this VR. Likewise, VR-Default contains the default VLAN. Although you cannot delete the default VLAN from VR-Default, you can add and delete any user-created VLANs. One instance of each routing protocol is spawned for this VR, and they cannot be deleted. (Referred to as VR-2 in earlier ExtremeXOS software versions.)

**VR-Mgmt**
This virtual router is part of the embedded system in Extreme Networks switches. VR-Mgmt enables remote management stations to access the switch through Telnet, SSH, or SNMP sessions; and it owns the management port. The management port cannot be deleted from this VR, and no other ports can be added. The Mgmt VLAN is created VR-Mgmt, and it cannot be deleted; you cannot add or delete any other VLANs or any routing protocols to this VR. (Referred to as VR-0 in earlier ExtremeXOS software versions.)

**VRRP**
The Virtual Router Redundancy Protocol specifies an election protocol that dynamically assigns responsibility for a virtual router to one of the VRRP routers on a LAN. The VRRP router controlling the IP address(es) associated with a virtual router is called the master router, and forwards packets sent to these IP addresses. The election process provides dynamic failover in the forwarding responsibility should the master router become unavailable. In case the master router fails, the virtual IP address is mapped to a backup router’s IP address; this backup becomes the master router. This allows any of the virtual router IP addresses on the LAN to be used as the default first-hop router by end-hosts. The advantage gained from using VRRP is a higher availability default path without requiring configuration of dynamic routing or router discovery protocols on every host. VRRP is defined in RFC 2338.

**VXLAN**
VXLAN is a network virtualization technology that leverages existing Layer 3 infrastructures to create tenant overlay networks. VXLAN addresses the requirements of a multi-tenant data center network infrastructure by:
- Increasing virtual network scalability to 16 million instances. This allows for tenant VLAN (Virtual LAN) isolation whereby multiple tenants can manage their own VLAN/VMAN and MAC address spaces.
- Adding an encapsulation that effectively hides VM MAC addresses from the physical network that results in physical networking devices to have smaller MAC and IP table sizes.
- Allowing for Layer 2 adjacency across IP networks by which DC network operators protect their investment in their current infrastructure. Additionally operators can distribute traffic loads across links efficiently using Layer 3 ECMP.
**WLAN**

Wireless Local Area Network.

**XNV**

Extreme Network Virtualization is an ExtremeXOS feature that enables the software to support VM port movement, port configuration, and inventory on network switches.
