|---|-----------|
| <b>Preface.....</b>   | <b>11</b> |
| Conventions.....  | 11        |
| Notes, cautions, and warnings.....                          | 11        |
| Text formatting conventions.....                            | 11        |
| Command syntax conventions.....                             | 12        |
| Documentation and Training.....                             | 12        |
| Training.....   | 12        |
| Getting Help.....   | 12        |
| Subscribing to Service Notifications.....                   | 13        |
| Providing Feedback to Us.....                               | 13        |
| <b>About This Document.....</b>                             | <b>15</b> |
| Supported hardware and software.....                        | 15        |
| Interface module capabilities.....                          | 15        |
| What's new in this document .....                           | 15        |
| <b>Link Aggregation.....</b>                                | <b>17</b> |
| Link aggregation overview.....                              | 17        |
| LAG load sharing.....                                       | 18        |
| Link Aggregation Control Protocol.....                      | 22        |
| LAG distribution process and conditions.....                | 22        |
| Configuring and managing Link Aggregation.....              | 22        |
| <b>Unidirectional Link Detection.....</b>                   | <b>33</b> |
| Unidirectional Link Detection overview.....                 | 33        |
| How UDLD works.....   | 33        |
| UDLD considerations and restrictions.....                   | 34        |
| Configuring UDLD.....                                       | 34        |
| <b>VLANs.....</b>   | <b>37</b> |
| 802.1Q VLAN overview.....                                   | 37        |
| Configuring VLANs.....                                      | 37        |
| Configuring a VLAN.....                                     | 37        |
| Configuring a switchport interface.....                     | 37        |
| Configuring the switchport interface mode.....              | 38        |
| Configuring the switchport access VLAN type.....            | 38        |
| Configuring a VLAN in trunk mode.....                       | 39        |
| Configuring a native VLAN on a trunk port.....              | 39        |
| Enabling VLAN tagging for native traffic.....               | 40        |
| Displaying the status of a switchport interface.....        | 41        |
| Displaying the switchport interface type.....               | 41        |
| Verifying a switchport interface running configuration..... | 42        |
| Displaying VLAN information.....                            | 42        |
| Enabling Layer 3 routing for VLANs.....                     | 43        |
| VLAN statistics.....  | 44        |
| Enabling statistics on a VLAN.....                          | 44        |
| Displaying statistics for VLANs.....                        | 44        |
| Clearing statistics on VLANs.....                           | 45        |

|   |           |
|---|-----------|
| VE route-only mode.....   | 45        |
| Configuring VE route-only mode on a physical port.....            | 46        |
| Configuring VE route-only mode on a LAG port.....                 | 47        |
| Configuring virtual routing interfaces.....                       | 48        |
| DHCP Layer 2 relay agent Option 82 for VLANs.....                 | 49        |
| Overview.....   | 49        |
| Option 82.....  | 49        |
| Topologies and operation.....                                     | 50        |
| Considerations for Layer 2 relay agent.....                       | 52        |
| Configuring DHCP Layer 2 relay agent Option 82.....               | 52        |
| Endpoint tracking.....  | 53        |
| Overview.....   | 53        |
| Additional details and considerations.....                        | 54        |
| RADIUS VSA support.....   | 54        |
| Enabling and disabling endpoint tracking on a port.....           | 55        |
| <b>VXLAN Layer 2 Gateway.....</b>                                 | <b>59</b> |
| VXLAN Layer 2 gateway overview.....                               | 59        |
| VXLAN Layer 2 gateway considerations and limitations.....         | 60        |
| Configuring VXLAN Layer 2 gateway.....                            | 60        |
| VXLAN Layer 2 gateway support for bridge domains.....             | 62        |
| Configuring VXLAN Layer 2 Gateway support for bridge domains..... | 62        |
| VXLAN Layer 2 gateway payload tag processing.....                 | 63        |
| VXLAN Layer 2 support for LVTEP.....                              | 64        |
| LVTEP control plane.....  | 64        |
| LVTEP data plane.....   | 65        |
| Port-based VLAN bundle service.....                               | 68        |
| Configuring VXLAN LVTEP support.....                              | 69        |
| LVTEP support for other features.....                             | 73        |
| Nondefault TPID .....   | 75        |
| Configuring TCAM profiles to support LVTEP.....                   | 78        |
| LVTEP show commands.....  | 79        |
| <b>QoS for VXLAN Layer 2 gateways.....</b>                        | <b>85</b> |
| Configuring QoS for VXLAN Layer 2 gateways.....                   | 85        |
| <b>Multi-Chassis Trunking (MCT).....</b>                          | <b>87</b> |
| MCT Overview.....   | 87        |
| MCT terminology.....  | 88        |
| SLX-OS MCT control plane.....                                     | 88        |
| SLX-OS MCT data plane traffic.....                                | 90        |
| MAC management.....   | 95        |
| Automatic RSVP LSP bring up for MCT.....                          | 98        |
| MCT configuration considerations.....                             | 99        |
| General considerations.....                                       | 99        |
| Peer considerations.....  | 99        |
| VLAN considerations.....  | 99        |
| LACP considerations.....  | 100       |
| LSP considerations.....   | 100       |
| Configuring the BGP EVPN peer.....                                | 101       |
| Configuring MCT.....  | 102       |
| Taking the MCT node offline for maintenance.....                  | 104       |

|   |            |
|---|------------|
| Configuring additional MCT cluster parameters.....                            | 104        |
| Changing the client-isolation mode .....                                      | 104        |
| Changing the designated-forwarder hold timer value.....                       | 105        |
| Moving the traffic from an MCT node to the remote node.....                   | 105        |
| Configuring an auto-generated ESI for a cluster client.....                   | 105        |
| Displaying MCT information.....   | 105        |
| Displaying the cluster information .....                                      | 105        |
| Displaying the cluster client information.....                                | 106        |
| Displaying member VLAN information.....                                       | 106        |
| Displaying and clearing the MAC address table cluster information.....        | 106        |
| VPLS and VLL MCT.....   | 107        |
| Control plane for VPLS or VLL MCT.....  | 108        |
| PW state in VPLS or VLL MCT.....  | 108        |
| VLL-MCT data plane.....   | 109        |
| VPLS-MCT data plane.....  | 110        |
| VPLS MAC management.....  | 112        |
| Configuration considerations and limitations for VPLS and VLL MCT.....        | 114        |
| Configuring MCT for VPLS or VLL.....  | 115        |
| Displaying information related to VPLS and VLL MCT.....                       | 116        |
| Layer 3 routing over MCT.....   | 117        |
| Configuration considerations.....   | 118        |
| Layer 3 MCT VLAN configuration example.....                                   | 118        |
| Layer 3 MCT bridge-domain configuration example.....                          | 119        |
| Using MCT with VRRP and VRRP-E.....   | 121        |
| MCT short path forwarding configuration using VRRP-E example.....             | 121        |
| PE1 configuration.....  | 122        |
| PE2 configuration.....  | 123        |
| MCT use cases.....  | 125        |
| L2 MCT in the data center core.....   | 125        |
| L2 MCT in a data center with a collapsed core and aggregation.....            | 126        |
| <b>Multiple VLAN Registration Protocol (MVRP).....</b>                        | <b>129</b> |
| Multiple VLAN Registration Protocol overview.....                             | 129        |
| MVRP considerations and limitations.....                                      | 129        |
| Enabling MVRP on an Ethernet interface.....                                   | 130        |
| Configuring an edge port.....   | 132        |
| Configuring the VLAN registration mode on the interface.....                  | 133        |
| MVRP over a port channel.....   | 133        |
| Enabling MVRP over a port channel.....  | 133        |
| Configuring the MVRP join, leave, and leave-all timers.....                   | 135        |
| Displaying MVRP configuration information, statistics, and attributes.....    | 136        |
| Clearing MVRP statistics.....   | 138        |
| MVRP with endpoint tracking.....  | 139        |
| MVRP over MCT.....  | 139        |
| MVRP over MCT configuration example.....                                      | 141        |
| <b>Logical Interfaces.....</b>  | <b>147</b> |
| Logical interfaces overview.....  | 147        |
| LIFs and bridge domains.....  | 147        |
| Configuration considerations.....   | 147        |
| Configuring a logical interface on a physical port or port-channel (LAG)..... | 149        |

|   |            |
|---|------------|
| <b>Bridge Domains.....</b>  | <b>151</b> |
| Bridge domain overview.....   | 151        |
| Bridge domain statistics.....   | 151        |
| Configuring a bridge domain.....  | 151        |
| Displaying bridge-domain configuration information.....                         | 152        |
| Enabling statistics on a bridge domain.....                                     | 155        |
| Displaying statistics for logical interfaces in bridge domains.....             | 156        |
| Clearing statistics on bridge domains.....                                      | 157        |
| <b>VPLS and VLL Layer 2 VPN services.....</b>                                   | <b>159</b> |
| VPLS overview.....  | 159        |
| VLL.....  | 162        |
| VPLS service endpoints.....   | 163        |
| Pseudowires.....  | 164        |
| Supported VPLS features.....  | 169        |
| Configuration of VPLS and VLL.....  | 170        |
| QoS treatment in VPLS packet flow.....  | 170        |
| Configuring a PW profile.....   | 171        |
| Attaching a PW profile to a bridge domain.....                                  | 171        |
| Configuring control word for a PW profile.....                                  | 172        |
| Configuring PW control word on a bridge domain.....                             | 173        |
| Configuring flow label for a PW profile.....                                    | 174        |
| Configuring PW flow label on a bridge domain.....                               | 175        |
| Configuring a static MAC address over an endpoint in a VPLS instance.....       | 176        |
| Displaying MAC address information for VPLS bridge domains.....                 | 177        |
| Configuring a VPLS instance.....  | 177        |
| Configuring a VLL instance.....   | 179        |
| Configuration example for VPLS with switching between ACs and network core..... | 181        |
| PE1.....  | 181        |
| PE2.....  | 181        |
| VPLS MAC withdrawal .....   | 182        |
| Enabling VPLS MAC address withdrawal.....                                       | 182        |
| Routing over VPLS.....  | 183        |
| OAR for VEOVPLS.....  | 185        |
| Enabling routing on a VPLS instance.....  | 185        |
| Configuration example for enabling routing over VPLS.....                       | 187        |
| <b>802.1ag Connectivity Fault Management.....</b>                               | <b>189</b> |
| Maintenance Domain (MD).....  | 190        |
| Maintenance Association (MA).....   | 191        |
| Maintenance End Point (MEP).....  | 191        |
| Maintenance Intermediate Point (MIP).....                                       | 191        |
| CFM Hierarchy.....  | 192        |
| Mechanisms of Ethernet IEEE 802.1ag OAM.....                                    | 192        |
| Fault detection (continuity check message).....                                 | 192        |
| Fault verification (Loopback messages).....                                     | 192        |
| Fault isolation (Linktrace messages).....                                       | 192        |
| Enabling or disabling CFM.....  | 192        |
| Creating a Maintenance Domain.....  | 193        |
| Creating and configuring a Maintenance Association.....                         | 193        |
| Displaying CFM configurations.....  | 194        |

# Preface

---

|                                   |    |
|-----------------------------------|----|
| • Conventions.....                | 11 |
| • Documentation and Training..... | 12 |
| • Getting Help.....               | 12 |
| • Providing Feedback to Us.....   | 13 |

This section discusses the conventions used in this guide, ways to provide feedback, additional help, and other Extreme Networks® publications.

## Conventions

This section discusses the conventions used in this guide.

### Notes, cautions, and warnings

Notes, cautions, and warning statements may be used in this document. They are listed in the order of increasing severity of potential hazards.

#### NOTE

A Note provides a tip, guidance, or advice, emphasizes important information, or provides a reference to related information.

#### ATTENTION

An Attention statement indicates a stronger note, for example, to alert you when traffic might be interrupted or the device might reboot.

#### CAUTION

A Caution statement alerts you to situations that can be potentially hazardous to you or cause damage to hardware, firmware, software, or data.

#### DANGER

*A Danger statement indicates conditions or situations that can be potentially lethal or extremely hazardous to you. Safety labels are also attached directly to products to warn of these conditions or situations.*

### Text formatting conventions

Text formatting conventions such as boldface, italic, or Courier font may be used to highlight specific words or phrases.

| Format             | Description  |
|--------------------|--|
| <b>bold text</b>   | Identifies command names.<br>Identifies keywords and operands.<br>Identifies the names of GUI elements.              |
| <i>italic text</i> | Identifies text to enter in the GUI.<br>Identifies emphasis.<br>Identifies variables.<br>Identifies document titles. |

| Format       | Description                         |
|--------------|-------------------------------------|
| Courier font | Identifies CLI output.              |
|              | Identifies command syntax examples. |

## Command syntax conventions

Bold and italic text identify command syntax components. Delimiters and operators define groupings of parameters and their logical relationships.

| Convention         | Description   |
|--------------------|---|
| <b>bold text</b>   | Identifies command names, keywords, and command options.  |
| <i>italic text</i> | Identifies a variable.  |
| [ ]                | Syntax components displayed within square brackets are optional.  |
|                    | Default responses to system prompts are enclosed in square brackets.  |
| { x   y   z }      | A choice of required parameters is enclosed in curly brackets separated by vertical bars. You must select one of the options.   |
| x   y              | A vertical bar separates mutually exclusive elements.   |
| < >                | Nonprinting characters, for example, passwords, are enclosed in angle brackets.   |
| ...                | Repeat the previous element, for example, <i>member[member...]</i> .  |
| \                  | Indicates a "soft" line break in command examples. If a backslash separates two lines of a command input, enter the entire command at the prompt without the backslash. |

## Documentation and Training

To find Extreme Networks product guides, visit our documentation pages at:

|  |   |
|--|---|
| Current Product Documentation  | <a href="http://www.extremenetworks.com/documentation/">www.extremenetworks.com/documentation/</a>  |
| Archived Documentation (for earlier versions and legacy products)    | <a href="http://www.extremenetworks.com/support/documentation-archives/">www.extremenetworks.com/support/documentation-archives/</a>          |
| Release Notes  | <a href="http://www.extremenetworks.com/support/release-notes">www.extremenetworks.com/support/release-notes</a>                              |
| Hardware/Software Compatibility Matrices                             | <a href="https://www.extremenetworks.com/support/compatibility-matrices/">https://www.extremenetworks.com/support/compatibility-matrices/</a> |

## Training

Extreme Networks offers product training courses, both online and in person, as well as specialized certifications. For more information, visit [www.extremenetworks.com/education/](http://www.extremenetworks.com/education/).

## Getting Help

If you require assistance, contact Extreme Networks using one of the following methods:

|                       |  |
|-----------------------|--|
| <b>Extreme Portal</b> | Search the GTAC (Global Technical Assistance Center) knowledge base, manage support cases and service contracts, download software, and obtain product licensing, training, and certifications.  |
| <b>The Hub</b>        | A forum for Extreme Networks customers to connect with one another, answer questions, and share ideas and feedback. This community is monitored by Extreme Networks employees, but is not intended to replace specific guidance from GTAC.         |
| <b>Call GTAC</b>      | For immediate support: 1-800-998-2408 (toll-free in U.S. and Canada) or +1 408-579-2826. For the support phone number in your country, visit: <a href="http://www.extremenetworks.com/support/contact">www.extremenetworks.com/support/contact</a> |

Before contacting Extreme Networks for technical support, have the following information ready:

- Your Extreme Networks service contract number and/or serial numbers for all involved Extreme Networks products
- A description of the failure
- A description of any action(s) already taken to resolve the problem
- A description of your network environment (such as layout, cable type, other relevant environmental information)
- Network load at the time of trouble (if known)
- The device history (for example, if you have returned the device before, or if this is a recurring problem)
- Any related RMA (Return Material Authorization) numbers

## Subscribing to Service Notifications

You can subscribe to email notifications for product and software release announcements, Vulnerability Notices, and Service Notifications.

1. Go to [www.extremenetworks.com/support/service-notification-form](http://www.extremenetworks.com/support/service-notification-form).
2. Complete the form with your information (all fields are required).
3. Select the products for which you would like to receive notifications.

### NOTE

You can modify your product selections or unsubscribe at any time.

4. Click **Submit**.

## Providing Feedback to Us

Quality is our first concern at Extreme Networks, and we have made every effort to ensure the accuracy and completeness of this document. We are always striving to improve our documentation and help you work better, so we want to hear from you! We welcome all feedback but especially want to know about:

- Content errors or confusing or conflicting information.
- Ideas for improvements to our documentation so you can find the information you need faster.
- Broken links or usability issues.

If you would like to provide feedback to the Extreme Networks Information Development team, you can do so in two ways:

- Use our short online feedback form at <https://www.extremenetworks.com/documentation-feedback/>.
- Email us at [documentation@extremenetworks.com](mailto:documentation@extremenetworks.com).

Please provide the publication title, part number, and as much detail as possible, including the topic heading and page number if applicable, as well as your suggestions for improvement.

# About This Document

- Supported hardware and software.....15
- What's new in this document .....15

## Supported hardware and software

In those instances in which procedures or parts of procedures documented here apply to some devices but not to others, this guide identifies exactly which devices are supported and which are not.

Although many different software and hardware configurations are tested and supported by Extreme Networks for the current release, documenting all possible configurations and scenarios is beyond the scope of this document.

The following hardware platforms are supported by this release:

- ExtremeRouting SLX 9850-4
- ExtremeRouting SLX 9850-8
- ExtremeRouting SLX 9640

To obtain information about other releases, refer to the documentation specific to that release.

## Interface module capabilities

The following table lists the supported capabilities for the following SLX 9850 interface modules:

- BR-SLX9850-10Gx72S-M
- BR-SLX9850-100Gx36CQ-M
- BR-SLX9850-10Gx72S-D
- BR-SLX9850-100Gx36CQ-D
- BR-SLX9850-100Gx12CQ-M

TABLE 1 SLX 9850 interface modules capabilities

| Capability                                | Modular interface module  |
|---|---|
| MPLS                                      | Yes   |
| Packet Buffer memory per interface module | 12GB (BR-SLX9850-10Gx72S-M)<br>36GB (BR-SLX9850-100Gx36CQ-M)<br>8GB (BR-SLX9850-10Gx72S-D)<br>24GB (BR-SLX9850-100Gx36CQ-D)<br>8GB (BR-SLX9850-100Gx12CQ-M) |

## What's new in this document

The following table describes new information added to this guide for the SLX-OS 18r.1.00b release.

**TABLE 2** Summary of enhancements in the SLX-OS 18r.1.00b release

| Feature                     | Description   | Described in  |
|-----------------------------|---|---|
| Endpoint tracking (updates) | The endpoint tracking feature minimizes the configuration and management of VLANs on switches in the data center. | <a href="#">Endpoint tracking</a> on page 53                |
| Multi-chassis trunking      | Configuration considerations vary by category: general, peer, VLAN, LSP, and LACP.                                | <a href="#">MCT configuration considerations</a> on page 99 |

The following table describes new information added to this guide for the SLX-OS 18r.1.00 release.

**TABLE 3** Summary of enhancements in the SLX-OS 18r.1.00 release

| Feature                                    | Description   | Described in   |
|--|---|--|
| Endpoint tracking                          | The endpoint tracking feature minimizes the configuration and management of VLANs on switches in the data center.                             | <a href="#">Endpoint tracking</a> on page 53                           |
| Layer 3 routing on an MCT bridge domain    | Layer 3 routing is supported for IPv4 and IPv6 BGP, OSPF, and IS-IS routing protocols on an MCT bridge domain (BD).                           | <a href="#">Layer 3 routing over MCT</a> on page 117                   |
| Multiple VLAN Registration Protocol (MVRP) | MVRP is a Layer 2 protocol that allows the dynamic propagation of VLAN information from device to device                                      | <a href="#">Multiple VLAN Registration Protocol (MVRP)</a> on page 129 |
| Routing over VPLS (VEoVPLS)                | VEoVPLS is enhanced to support <ul style="list-style-type: none"> <li>• OSPF (V2 and V3)</li> <li>• ISIS</li> <li>• VRRP and VRRPE</li> </ul> | <a href="#">Routing over VPLS</a> on page 183                          |
| Loop detection                             | Loop detection for VLAN   | <a href="#">Loop detection for VLAN</a> on page 283                    |

For more information, see the *Release Notes*.

# Link Aggregation

---

- [Link aggregation overview.....](#) 17
- [LAG distribution process and conditions.....](#) 22

## Link aggregation overview

Link aggregation allows you to bundle multiple physical Ethernet links to form a single logical trunk providing enhanced performance and redundancy. The aggregated trunk is referred to as a Link Aggregation Group (LAG). The LAG is viewed as a single link by connected devices, the Spanning Tree Protocol, IEEE 802.1Q VLANs, and so on. When one physical link in the LAG fails, the other links stay up. A small drop in traffic is experienced when the link carrying the traffic fails.

To configure links to form a LAG, the physical links must be of the same speed. Link aggregation can be done by statically configuring the LAG, or by dynamically configuring the LAG using the IEEE 802.1AX Link Aggregation Control Protocol (LACP).

When queuing traffic from multiple input sources to the same output port, all input sources are given the same weight, regardless of whether the input source is a single physical link or a trunk with multiple member links.

### NOTE

The LAG or LAG interface is also referred to as a *port-channel* in the SLX 9850 platform.

The benefits of link aggregation are summarized as follows:

- Increased bandwidth (The logical bandwidth can be dynamically changed as the demand changes.)
- Increased availability
- Load sharing
- Rapid configuration and reconfiguration

Each LAG consists of the following components:

- A MAC address that is different from the MAC addresses of the LAG's individual member links.
- An interface index for each link to identify the link to the neighboring devices.
- An administrative key for each link. Only the links with the same administrative key value can be aggregated into a LAG. On each link configured to use LACP, LACP automatically configures an administrative key value equal to the port-channel identification number.

The SLX 9850 platform supports the following LAG types:

- Static LAG— In static link aggregation, links are added into a LAG without exchanging any control packets between the partner systems. The distribution and collection of frames on static links is determined by the operational status and administrative state of the link.
- Dynamic, standards-based LAG using LACP—Dynamic link aggregation uses LACP to negotiate with links that can be added and removed from a LAG. Typically, two partner systems sharing multiple physical Ethernet links can aggregate a number of those physical links using LACP. LACP creates a LAG on both partner systems and identifies the LAG by the LAG ID. All links with the same administrative key, and all links that are connected to the same partner switch become members of the LAG. LACP continuously exchanges LACPDUs to monitor the health of each member link.

The SLX 9850 platform supports the following trunk type:

- Static and standards-based LAG

The SLX 9850 platform supports the following LAG scalability configuration:

- The **default** profile supports 256 LAGs (64 ports per LAG)
- The **Lag-profile-1** profile supports 512 LAGs (32 ports per LAG)

#### NOTE

The following example enables the lag hardware profile for scaling to 512. The user has to save and reload to activate a new profile. Use the same procedure to revert to the default profile.

```
device# configure terminal
Entering configuration mode terminal
device(config)# hardware
device(config-hardware)# profile lag lag-profile-1
%Warning: To activate the new profile config, please run 'copy running-config startup-config'
followed by 'reload system'.
device(config-hardware)#
```

## LAG load sharing

Extreme devices can be configured for load sharing over a LAG by using the following:

- Hash-based load sharing

### *Hash-based load sharing*

The Extreme device tries to share the traffic load evenly across the ports in LAG group, while ensuring that packets in the flow are not reordered. Individual flows are assigned a LAG index to identify them. An improved hash-based load sharing algorithm has the following enhancements:

- Better distribution
- Support for 32-port LAGs when the maximum number of LAGs in the system is 512.
- Support for 64-port LAGs when the maximum number of LAGs in the system is 256.
- An increased number of fields in the packet header that can be used for load balancing
- Enhanced load sharing in configurations of ECMP with LAGs.

### *Configuring LAG hashing*

To configure symmetric LAG hashing on an SLX 9850 device, complete the following tasks.

1. Define where to start the picking headers for the key generation using the **lag hash hdr-start <fwd |term>** command.
  - **fwd**— start from the header that is used for the forwarding of the packet (inner header). This is the default option.
  - **term**— start from the last terminated header (outer header), that is the header below forwarding header. In the case of switching traffic, there would not be any header below forwarding header, thus hashing will not be visible.
2. Configure the number of headers to be considered for LAG hashing using the **lag hash hdr-count <count>** command. The default value is 1. There can be a maximum of 3 headers based on the first header selected using the command in the previous step.

The following options provide other LAG configurations to achieve specific tasks.

- Configure hash rotate using the **lag hash rotate <rotate-number>** command to provide different options for randomness of hashing. The number can be between 0 and 15. The default value is 3.
- Configure hash normalize by using the **lag hash normalize** command if there is a need to use the same hash in both directions. The normalize option is disabled by default.

- Allow the source port to be included in the hashing configuration using the **lag hash srcport** command. The source port is not used for hashing by default.
- To skip the entire MPLS label stack and pick only the BOS label for hashing, use the **lag hash bos <start | skip>**. The command default is If MPLS header is used for hashing, it will use all labels including BOS label for hashing.
  - start— start from BOS. This is the default option.
  - skip— hash from header next to BOS.
- Enter the **lag hash pwctrlword skip** command to skip password control word in the hashing configuration.
- The following MPLS transit node LSR hashing configuration options are available when using the **lag hash speculate-mpls** command. The default option is using the MPLS labels.
  - enable— Enables Speculative MPLS.
  - inner-eth— Enables inner ethernet header hash for L2VPN.
  - inner-ip-raw— Enables inner IPv4 header hash for L2VPN raw mode.
  - inner-ip-tag— Enables inner IPv4 header hash for L2VPN tag mode.
  - inner-ipv6-raw— Enables inner IPv6 header hash for L2VPN raw mode.
  - inner-ipv6-tag— Enables inner IPv6 header hash for L2VPN tag mode.
- Select the fields to be used for LAG hashing per-header type by entering the **[no] lag hash protocol-type packet-fields-to-be-used-for-hashing** command.
- Select the protocol header type using one of the following commands. By default, all the header parameters are enabled as shown here. You can disable or enable a parameter only one at any given instant.

#### NOTE

Using the **no** form of the following commands will mask a certain field in the configuration and that field will not be used for load-balance hashing.

- Ethernet headers. (By default, all the header parameters are enabled as shown here. You can disable or enable a parameter only one at any given instant.) :
 

```
> [no] load-balance hash ethernet <sa-mac>
> [no] load-balance hash ethernet <da-mac>
> [no] load-balance hash ethernet <etype>
> [no] load-balance hash ethernet <vlan>
```
- IPv4 and L4 headers: `[no] load-balance hash ip < src-ip > <dst-ip > < protocol > < src-l4-port> < dst-l4-port >`
- IPv6 and L4 headers: `[no] load-balance hash ipv6 < ipv6-src-ip > < ipv6-dst-ip> < ipv6-next-hdr> <ipv6-src-l4-port> < ipv6-dst-l4-port>`
- MPLS: `[no] load-balance hash mpls < label1 > <label2> < label3>`

## Load balancing mechanism on different traffic types

The following table provides information about load balancing on different traffic types.

**TABLE 4** Load balancing on different traffic types

| Traffic type                                  | Header field   | Description   |
|---|--|---|
| <b>Layer 2/ Layer 3 packet load balancing</b> | <ul style="list-style-type: none"> <li>• Ethernet DA, SA, Etype, Vlan-id</li> <li>• IPv4/v6 dst IP, src IP</li> <li>• L4 Src-Port, Dst-Port</li> </ul> | <ul style="list-style-type: none"> <li>• Ethernet destination address, source address, ethernet type, VLAN ID load balancing</li> <li>• IPv4/v6 destination address, source address load balancing</li> <li>• Layer 4 source and destination port-based load balancing</li> </ul> |

**TABLE 4** Load balancing on different traffic types (continued)

| Traffic type  | Header field  | Description   |
|---|---|---|
| <b>VPLS/ VLL packet load balancing</b>  | <p>CE to PE router traffic can use the following fields for load-balancing similar to the Layer 2/ Layer 3 traffic)</p> <ul style="list-style-type: none"> <li>Ethernet DA, SA, Etype, Vlan-id</li> <li>IPv4/v6 dst IP, src IP</li> <li>L4 Src-Port, Dst-Port</li> </ul> <p>PE to CE router traffic can use the following fields for load-balancing</p> <ul style="list-style-type: none"> <li>Customer (inner) ethernet DA, SA, Etype, Vlan-id</li> <li>Customer (inner) IPv4/v6 dst IP, Ipv4/Ipv6 src IP, protocol</li> <li>Customer (inner) L4 Src-Port, Dst-Port</li> </ul> | <p>CE to PE router traffic</p> <ul style="list-style-type: none"> <li>Ethernet destination address, source address, ethernet type, VLAN ID load balancing</li> <li>IPv4/v6 destination address, source address load balancing</li> <li>Layer 4 source and destination port-based load balancing</li> </ul> <p>PE to CE router traffic</p> <ul style="list-style-type: none"> <li>Customer ethernet destination and source address, ethernet type, VLAN ID load balancing</li> <li>Customer IPv4/v6 destination address, source address load balancing</li> <li>Customer Layer 4 source and destination port-based load balancing</li> </ul> |
| <b>MPLS LSR load balancing</b> <ul style="list-style-type: none"> <li>Extreme SLX 9850 device provides multiple options to handle different MPLS transit hashing scenarios</li> <li>The hashing options are mutually exclusive. If one option is enabled, the other option will be disabled.</li> </ul> | IP over MPLS traffic going over transit node  | Extreme supports speculate-mpls option as default which speculates the IPv4/IPv6 header after the MPLS labels and use the fields for hashing. This hashing scenario is handled by the <b>lag hash speculate-mpls enable</b> command in the global mode.   |
| <b>L2VPN (VPLS/VLL) traffic</b> <ul style="list-style-type: none"> <li>The hashing options are mutually exclusive. If one option is enabled, the other option will be disabled.</li> </ul>  | L2VPN tagged mode with IPv4 inner payload   | This scenario is handled using the <b>lag hash speculate-mpls inner-ip-tag</b> command in the global mode. Some sections of the IPv4 source and destination address fields are also used for load-balance hashing.  |
|   | L2VPN raw mode with IPv4 inner payload  | This scenario is handled using the <b>lag hash speculate-mpls inner-ip-raw</b> command. Some sections of the IPv4 source and destination address fields are also used for load-balance hashing.   |
|   | L2VPN tagged mode with IPv6 inner payload   | This scenario is handled using the <b>lag hash speculate-mpls inner-ipv6-tag</b> command. Some sections of the IPv6 source and destination address fields are also used for load-balance hashing.   |
|   | L2VPN raw mode with IPv6 inner payload  | This scenario is handled using the <b>lag hash speculate-mpls inner-ipv6-raw</b> command. Some sections of the IPv6 source and destination address fields are also used for load-balance hashing.   |

## Displaying LAG hashing

Use the **show port-channel load-balance** command to display the configured parameters for LAG hashing.

```

device# show port-channel load-balance
Header parameters
  Ethernet Mask: sa-mac da-mac etype vlan
  ip: src-ip dst-ip protocol src-l4-port dst-l4-port
  ipv6: ipv6-src-ip ipv6-dst-ip ipv6-next-hdripv6-src-l4-port ipv6-dst-l4-port
  mpls: label1 label2 label3

```

```

Hash Settings
  hdr-start:FWD, hdr-count:1, bos-start:0, bos-skip:0, skip-cw:0
  normalize:0, rotate:3, include_src_port:0, Disable: L2 0, ipv4 0, ipv6 0, mpls 0

mpls_speculate: Enabled

load-balance-type hash-based

```

## MPLS transit load balancing

A hashing scheme for enhanced load balancing allows MPLS transit load balancing to include inner headers of different packet types in parallel. With this enhanced load balancing scheme, SLX-OS is capable of load balancing the MPLS packets based on the inner headers like Inner source/destination mac address, Inner IPv4 source/destination address, Inner IPv6 source/destination address, Inner L4 port number if the inner header is IPv4.

This hashing scheme is supported only with the "Layer 2 Optimized" Tcam profile and when the feature is enabled by default in this profile. When the **profile tcam layer2-optimised-1** configuration is activated, the "Error: Operation not supported in the current hardware TCAM profile" message is displayed for the following commands as these functionalities are already taken care of by this enhanced hashing scheme:

- lag hash speculate-mpls inner-eth
- lag hash speculate-mpls inner-ip-raw
- lag hash speculate-mpls inner-ip-tag
- lag hash speculate-mpls inner-ipv6-raw
- lag hash speculate-mpls inner-ipv6-tag

## Displaying LAG hashing with "Layer 2 Optimized" Tcam profile

Use the **show port-channel load-balance** command to display the configured parameters for LAG hashing when the **profile tcam layer2-optimised-1** configuration is activated.

```

device# show port-channel load-balance
Header parameters
  Ethernet Mask: sa-mac da-mac etype vlan
  ip: src-ip dst-ip protocol src-l4-port dst-l4-port
  ipv6: ipv6-src-ip ipv6-dst-ip ipv6-next-hdr ipv6-src-l4-port ipv6-dst-l4-port
  mpls: label1 label2 label3

Hash Settings
  hdr-start:FWD, hdr-count:3, bos-start:0, bos-skip:0, skip-cw:0
  normalize:0, rotate:3, include_src_port:0, Disable: L2 0, ipv4 0, ipv6 0, mpls 0

mpls_speculate: Enabled

Inner Header parameters for MPLS packets
  Ethernet Mask: Selective 64 bits from sa-mac da-mac vlan
  ip: src-ip dst-ip src-l4-port dst-l4-port
  ipv6: ipv6-src-ip ipv6-dst-ip

load-balance-type hash-based

```

For comparison, the following displays the **show port-channel load-balance** command output for a non layer 2 optimized profile:

```

device# show port-channel load-balance
Header parameters
  Ethernet Mask: sa-mac da-mac etype vlan
  ip: src-ip dst-ip protocol src-l4-port dst-l4-port
  ipv6: ipv6-src-ip ipv6-dst-ip ipv6-next-hdr ipv6-src-l4-port ipv6-dst-l4-port
  mpls: label1 label2 label3

Hash Settings

```

```

hdr-start:FWD, hdr-count:1, bos-start:0, bos-skip:0, skip-cw:0
normalize:0, rotate:3, include_src_port:0, Disable: L2 0, ipv4 0, ipv6 0, mpls 0

mpls_speculate:Enabled

load-balance-type hash-based

```

## Link Aggregation Control Protocol

Link Aggregation Control Protocol (LACP) is an IEEE 802.1AX standards-based protocol that allows two partner systems to dynamically negotiate attributes of physical links between them to form logical trunks. LACP determines whether a link can be aggregated into a LAG. If a link can be aggregated into a LAG, LACP puts the link into the LAG. All links in a LAG inherit the same administrative characteristics.

LACP operates in two modes:

- *Active mode*— LACP initiates the LACPDU exchange regardless of whether the partner system sends LACPDUs.
- *Passive mode* — LACP responds to Link Aggregation Control Protocol Data Units (LACPDUs) initiated by its partner system but does not initiate the LACPDU exchange.

## LAG distribution process and conditions

The LAG aggregator is associated with the collection and distribution of Ethernet frames. The collection and distribution process is required to guarantee the following:

- Inserting and capturing control PDUs.
- Restricting the traffic of a given conversation to a specific link.
- Load balancing between individual links.
- Handling dynamic changes in LAG membership.

On each port, link aggregation control does the following:

- Maintains configuration information to control port aggregation.
- Exchanges configuration information with other devices to form LAGs.
- Attaches ports to and detaches ports from the aggregator when they join or leave a LAG.
- Enables or disables an aggregator's frame collection and distribution functions.

LAG configuration guidelines:

- Each link in the SLX 9850 hardware can be associated with a LAG; a link cannot be associated with more than one LAG. The process of adding and removing links to and from a LAG is controlled statically or dynamically (through LACP).
- The maximum number of port members that may be assigned to a LAG depends on the LAG profile configuration. By default, the SLX 9850 platform can have a maximum of 256 LAGs with the maximum of 64 ports in each LAG. With the LAG profile 1, SLX 9850 platform can have a maximum of 512 LAGs with the maximum of 32 ports in each LAG.
- Use the **show hardware profile current** command to view the current LAG profile. When the LAG profile is changed from "default" profile to "LAG-PROFILE-1", the device enables LAG scaling up to 512 LAGs.
- Interfaces configured as switchport interfaces cannot be aggregated into a LAG. However, a LAG can be configured as a switchport.

## Configuring and managing Link Aggregation

The following sections discuss working with Link Aggregation on Extreme devices.

## Configuring a new port channel interface

Follow this procedure to create a new port channel interface at the global configuration mode.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
```

2. Enter the **interface port-channel** command to create a new port channel interface at the global configuration level.

```
device(config)# interface port-channel 30
```

### NOTE

The port-channel interface ranges from 1 to 512.

The following example creates a new port channel interface of 30.

```
device# configure terminal
device(config)# interface port-channel 30
```

After creating a new port channel, you can do "no shutdown" or "shutdown" to bring up or down the port-channel as follows.

```
device# configuration terminal
device(config)# interface Port-channel 30
2016/10/17-20:31:21, [NSM-1004], 302, M2 | Active | DCE, INFO, SLX, Port-channel 30 is created.
device(config-Port-channel-30)#
device(config-Port-channel-30)# no shutdown
2016/10/17-20:31:26, [NSM-1019], 303, M2 | Active | DCE, INFO, SLX, Interface Port-channel 30 is
administratively up.
device(config-Port-channel-30)#
```

## Deleting a port channel interface

Follow this procedure to delete a port channel interface and all member interfaces from the specified LAG at the global configuration mode.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
```

2. Enter the **no interface port-channel** command to delete an existing port channel interface at the global configuration level.

```
device(config)# no interface port-channel 30
```

### NOTE

The port-channel interface ranges from 1 to 512.

The following example deletes the existing port channel interface 30.

```
device# configure terminal
device(config)# no interface port-channel 30
```

## Adding a member port to a port channel

Follow this procedure to add a port to a specific port channel interface at the interface configuration level. If the port channel is not created, the **channel-group** command creates the port channel and also adds a port to the port channel.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
device(config)#
```

2. Enter the **interface port-channel** command to add a port channel interface at the global configuration level.

```
device(config)# interface port-channel 30
device(conf-Port-channel-30)#
```

3. Configure the **interface ethernet** command to enable the interface.

```
device(conf-Port-channel-30)# interface ethernet 1/5
device(conf-if-eth-1/5)#
```

4. Add a port to the port channel interface as static.

```
device(conf-if-eth-1/5)# channel-group 30 mode on
```

5. Add a port to the port channel interface as a dynamic (using LACP), active or passive mode.

```
device(conf-if-eth-1/5)# channel-group 30 mode active
device(conf-if-eth-1/5)# channel-group 30 mode passive
```

The following example is for a static LAG configuration with the mode ON.

```
device# configure terminal
device(config)# interface port-channel 30
device(conf-Port-channel-30)# interface ethernet 1/5
device(conf-if-eth-1/5)# channel-group 30 mode on
```

The following example adds a port 1/5 to the existing dynamic port channel interface 30 with the mode active.

```
device# configure terminal
device(config)# interface port-channel 30
device(conf-Port-channel-30)# interface ethernet 1/5
device(conf-if-eth-1/5)# channel-group 30 mode active
```

#### NOTE

Run the **no shutdown** command to bring the above interface online.

```
device(conf-if-eth-1/5)# no shutdown
2016/10/18-03:47:15, [NSM-1019], 528, M2 | Active | DCE, INFO, SLX, Interface Ethernet 1/5 is
administratively up.2016/10/18-03:47:15, [NSM-1001], 529, M2 | Active | DCE, INFO, SLX, Interface
Ethernet 1/5 is online.
```

The following example adds a port 1/5 to the existing dynamic port channel interface 30 with the mode passive.

```
device# configure terminal
device(config)# interface port-channel 30
device(conf-Port-channel-30)# interface ethernet 1/5
device(conf-if-eth-1/5)# channel-group 30 mode passive
```

## Deleting a member port from a port channel

Follow this procedure to delete a member port from a port channel interface at the interface configuration level.

Delete a port from the port channel interface.

```
device(conf-if-eth-1/5)# no channel-group
```

The following example deletes a port 1/5 from the existing port channel interface 30.

```
device# configure terminal
device(config)# interface ethernet 1/5
device(conf-if-eth-1/5)# no channel-group
```

## Configuring the minimum number of LAG member links

Follow this procedure to configure the minimum number of LAG member links that should be functional so that the port-channel interface is operationally up.

This configuration allows a port-channel to operate at a certain minimum bandwidth at all times. If the bandwidth of the port-channel drops below the minimum number, then the port-channel is declared operationally DOWN even though it has operationally UP members.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
device(config)#
```

2. Enter the **interface port-channel** command at the global configuration level.

```
device(config)# interface port-channel 30
device(conf-Port-channel-30)#
```

3. Configure the minimum number of LAG member links at the port-channel interface configuration mode.

```
device(conf-Port-channel-30)# minimum-links 5
```

### NOTE

The number of links ranges from 1 to 64. The default minimum links is 1.

The following example sets min-link 5 to the existing port channel interface 30.

```
device# configure terminal
device(config)# interface port-channel 30
device(conf-Port-channel-30)# minimum-links 5
```

## Configuring the LACP system priority

You configure the LACP system priority on each switch running LACP. LACP uses the system priority with the switch MAC address to form the system ID and also during negotiation with other switches.

The system priority value must be a number in the range of 1 through 65535. The higher the number, the lower the priority. The default priority is 32768.

To configure the global LACP system priority, perform the following steps:

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
```

2. Specify the LACP system priority.

```
device(config)# lacp system-priority 25000
```

3. To reset the system priority to the default value.

```
device(config)# no lacp system-priority
```

## Configuring the LACP port priority

Follow this procedure to configure the LACP port priority of a member port of a specific port-channel interface.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
device(config)#
```

2. Enter the **interface port-channel** command to add a port channel interface at the global configuration level.

```
device(config)# interface port-channel 30
device(config-Port-channel-30)#
```

3. Configure the **interface ethernet** command and add the port to the port-channel interface.

```
device(config-Port-channel-30)# interface ethernet 1/5
device(config-if-eth-1/5)# channel-group 30 mode active
```

4. Configure the LACP port priority 12 for the member port.

```
device(config-if-eth-1/5)# lacp port-priority 12
```

### NOTE

The LACP port priority value ranges from 1 to 65535. The default value is 32768.

5. To reset the configured port priority to the default value.

```
device(config-if-eth-1/5)# no lacp port-priority
```

The example sets the port priority as 12.

```
device# configure terminal
device(config)# interface port-channel 30
device(config-Port-channel-30)# interface ethernet 1/5
device(config-if-eth-1/5)# channel-group 30 mode active
device(config-if-eth-1/5)# lacp port-priority 12
```

## Configuring the LACP timeout period

The LACP timeout period indicates how long LACP waits before timing out the neighboring device. The **short** timeout period is 3 seconds and the **long** timeout period is 90 seconds. The default is **long**. The **short** timeout period specifies that the PDU is sent every second and the port waits three times this long (three seconds) before invalidating the information received earlier on this PDU. The **long** timeout period specifies that the PDU is sent once in 30 seconds and the port waits three times this long (90 seconds) before invalidating the information received earlier on this PDU.

To configure the LACP timeout period on an interface, perform the following steps:

1. Enter the **configure terminal** command to access global configuration mode.
2. Enter the **interface** command, specifying the interface type and the slot/port.

```
device(config)# interface ethernet 1/1
```

3. Enter the **no shutdown** command to enable the interface.
4. Specify the LACP timeout short period for the interface.

```
device(config-if-eth 1/1)# lacp timeout short
```

5. Specify the LACP timeout long period for the interface.

```
device(config-if-eth 1/1)# lacp timeout long
```

## Configuring LACP default Up

Follow this procedure to activate an LACP link even in the absence of PDUs.

Consider the following when using the **lacp default-up** command:

- The command is available only if the configured interface is a dynamic member of a port-channel interface.
  - The command is not supported on static LAGs.
  - The command is not supported on port-channel interfaces.
1. Enter the **configure terminal** command to access global configuration mode.
  2. Enter the **interface** command, specifying the interface type and the slot/port.

```
device(config)# interface ethernet 1/1
```

3. Specify LACP default-up for the interface.

```
device(config-if-eth-1/1)# lacp default-up
```

4. Enter the no form of the command to disable the configuration.

```
device(config-if-eth-1/1)# no lacp default-up
```

## LACP PDU forwarding

By default, LACP PDUs received on an interface where LACP is not configured are discarded. For scenarios in which the interface requires LACP PDU packet forwarding, you can configure the device to forward the LACP PDU on the VLAN on which it is received using the **lacp-pdu-forward enable** command in the interface configuration mode or port channel configuration mode.

Since the destination address of the PDU is a multicast MAC, the frame will be flooded on the VLAN. If the VLAN on which the LACP PDU is received is a regular VLAN, the PDU will be flooded on the VLAN. If the VLAN on which the PDU is received is a service delimiter for a bridge domain, the LACP PDU is flooded on the bridge domain accordingly.

LACP PDU forwarding is supported only on physical interfaces and static port channel interfaces. LACP PDUs cannot be forwarded if they are received on a LACP based dynamic port channel. LACP PDU forwarding enabled on a static port channel applies to all the member ports. If LACP is enabled on a port, it overrides the LACP PDU forwarding configuration and the PDUs are trapped in the CPU.

## Configuring LACP PDU forwarding on a port-channel interface

Perform the following steps to configure LACP PDU forwarding on a port-channel interface.

1. Enter the global configuration mode.

```
device# configure terminal
device(config)#
```

2. Enter the **interface port-channel** command to add a port channel interface at the global configuration level.

```
device(config)# interface port-channel 10
device(config-Port-channel-10)#
```

3. Configure LACP PDU forwarding on the port-channel interface.

```
device(conf-Port-channel-10)# lacp-pdu-forward enable
```

LACP PDU forwarding is supported only on static port channel interfaces.

The following example enables LACP forwarding on a port-channel interface.

```
device# configure terminal
device(config)# interface port-channel 10
device(conf-Port-channel-10)# lacp-pdu-forward enable
```

## Configuring LACP PDU forwarding on a physical interface

Perform the following steps to configure LACP PDU forwarding on a physical interface.

1. Enter the global configuration mode.

```
device# configure terminal
device(config)#
```

2. Specify the physical interface on which LACP PDU forwarding needs to be enabled.

```
device(config)# interface ethernet 4/1
device(conf-if-eth-4/1)#
```

3. Configure LACP PDU forwarding on the physical interface.

```
device(conf-if-eth-4/1)# lacp-pdu-forward enable
```

The following example enables LACP forwarding on a port-channel interface.

```
device# configure terminal
device(config)# interface ethernet 4/1
device(conf-if-eth-4/1)# lacp-pdu-forward enable
```

## Displaying port-channel information

Various show commands are used to display information for a specific port-channel interface.

Before displaying the port-channel information, you should have created a port-channel interface in a LAG to generate details.

1. Use the **show port-channel summary** command to display brief information of all port-channels.

```
device# show port-channel summary
Flags:  D - Down          P - Up in port-channel (members)
        U - Up (port-channel)  * - Primary link in port-channel
        S - Switched
        M - Not in use. Min-links not met
=====
Group  Port-channel  Protocol  Member ports
=====
1      Po 1          (D)      None      Eth 2/125 (D)
                        Eth 4/125 (D)
2      Po 2          (D)      None      Eth 2/126 (D)
                        Eth 4/126 (D)
10     Po 10         (U)      LACP      Eth 2/4*  (P)
                        Eth 2/18  (P)
100    Po 100       (U)      None      Eth 2/10* (P)
                        Eth 2/11  (P)
```

2. Use the **show port-channel detail** command to display detailed information of all the port-channels.

```

device# show port-channel detail
Static Aggregator: Po 1
Aggregator type: Standard
Number of Ports: 2
Member ports:
  Eth 2/125
  Eth 4/125

Static Aggregator: Po 2

  Output 0.000000 Mbits/sec, 0 packets/sec, 0.00% of line-rate
Time since last interface status change: 00:29:09

```

## Displaying LACP system-id information

Follow this procedure to display LACP system ID and priority information.

Enter the **show lacp sys-id** command to display LACP information for the system ID and priority.

```

device# show lacp sys-id
System ID: 0x8000,76-8e-f8-0a-98-00

```

## Displaying LACP statistics

Follow this procedure to display LACP statistics for a port-channel interface or for all port-channel interfaces.

Before displaying the LACP port-channel information, it is recommended that you create a port-channel interface in a LAG to generate details.

Enter the **show lacp counters** command to display LACP statistics for a port-channel.

```

device# show lacp counter
Traffic statistics
Port          LACPDUs      Marker      Pckt err    Sent      Recv      Sent      Recv
Sent          Recv
Aggregator Po 3  Eth 1/6      110        0           0          0
0              0

```

## Clearing LACP counter statistics on a LAG

This topic describes how to clear LACP counter statistics on a single LAG.

To clear LACP counter statistics on a LAG, use the following command:

Enter the **clear lacp LAG\_group\_number counters** command to clear the LACP counter statistics for the specified LAG group number.

```
device# clear lacp 42 counters
```

## Clearing LACP counter statistics on all LAG groups

This topic describes how to clear the LACP counter statistics for all LAG groups.

To clear LACP counter statistics on all LAG groups, use the following command:

Enter the **clear lacp counter** command to clear the LACP counter statistics for all LAG groups.

```
device# clear lacp counter
```

## Troubleshooting LACP

To troubleshoot problems with your LACP configuration, use the following troubleshooting tips.

If a standard IEEE 802.1AX-based dynamic trunk is configured on a link and the link is not able to join the LAG, do the following:

- Make sure that both ends of the link are configured as **standard** for the trunk type.
- Make sure that both ends of the link are *not* configured for **passive** mode. They must be configured as **active /active**, **active /passive**, or **passive /active**.
- Make sure that the port-channel interface is in the administrative "up" state by ensuring that the **no shutdown** command was entered on the interface on both ends of the link.
- Make sure that the links that are part of the LAG are connected to the same neighboring switch.
- Make sure that the system ID of the switches connected by the link is unique. You can verify this by entering the **show lacp sys-id** command on both switches.
- Make sure that LACPDUs are being received and transmitted on both ends of the link and that there are no error PDUs. You can verify this by entering the **show lacp counters number** command and looking at the receive mode (rx) and transmit mode (tx) statistics. The statistics should be incrementing and should not be at zero or a fixed value. If the PDU rx count is not incrementing, check the interface for possible CRC errors by entering the **show interface link-name** command on the neighboring switch. If the PDU tx count is not incrementing, check the operational status of the link by entering the **show interface link-name** command and verifying that the interface status is "up."

When a link has problem, the **show port-channel** command displays the following message:

```
Mux machine state: Deskew not OK.
```

If a static trunk is configured on a link and the link is not able to join the LAG, do the following:

- Make sure that both ends of the link are configured as **standard** for trunk type and verify that the mode is "on."
- Make sure that the port-channel interface is in the administrative "up" state by ensuring that the **no shutdown** command was entered on the interface on both ends of the link.

# Unidirectional Link Detection

- [Unidirectional Link Detection overview.....](#) 33
- [Configuring UDLD.....](#) 34

## Unidirectional Link Detection overview

Unidirectional Link Detection (UDLD) monitors a link between two Extreme devices and blocks the ports on both ends of the link if there is a unidirectional failure.

UDLD protocol detects and blocks broken unidirectional links in the network. This is done through the exchange of UDLD protocol data units (PDU) between devices on a physical link. Both ends of the link must support the same proprietary UDLD protocol to detect the unidirectional link condition.

A unidirectional link is assumed when the UDLD stops receiving UDLD PDUs from the other end of the link. The device then blocks the physical link. The physical link will still be up but the line protocol will be down. UDLD PDUs continue to be transmitted and received on the link.

UDLD is disabled by default. To use the UDLD protocol, the protocol must first be enabled globally and then on each individual physical port. When enabled globally and on a physical port, the device starts transmitting UDLD PDUs periodically on the port.

## How UDLD works

The following shows a simple four-switch network in which two paths connect to each switch. STP blocks traffic on as many ports as necessary so that only one operational path exists from the STP root bridge to all nodes in the network.

**FIGURE 1** Four-switch example for UDLD

In the previous figure, STP detects that the port on Switch D that is connected to Switch C should be put into a blocked state. Therefore, no data traffic gets transmitted or received on this port. Data traffic remains blocked as long as Switch D receives bridge protocol data units (BPDUs) from both switches C and B.

If the link between Switch C and Switch D becomes unidirectional (for reasons such as hardware failure or incorrect cabling) in the direction from D to C, Switch D ages out the status that it was receiving BPDUs from Switch C. This eventually causes STP to put the port in a forwarding state, thus allowing all data traffic. This creates a loop for all BUM traffic that enters the network. BUM traffic can go from Switch B to Switch D to Switch C to Switch A, and then back to Switch B.

To prevent this loop from forming, UDLD can be used to detect that the link between Switch C and Switch D has become unidirectional.

## UDLD considerations and restrictions

Note the following for UDLD:

- UDLD is used in conjunction with the Spanning Tree Protocol.
- UDLD runs only on physical ports assigned to a port channel.
- UDLD is supported on directly connected switches only.
- The protocol must be running on both ends of the link.
- The default timeout is 2.5 (2500 ms) seconds.
- Tagged UDLD is not supported.
- The feature is not compatible with Cisco UDLD protocol.
- Extreme uses a proprietary implementation that interoperates with Multi-Service IronWare devices, FastIron devices, and VDX devices.
- The UDLD interface statistics lose some accuracy after a failover.
- Upon executing the **no protocol udld** command, all of the UDLD global and UDLD interface configuration changes will be removed and the protocol will revert back to its initial disabled state. This means that all interfaces that have been enabled for the protocol stops transmitting and receiving UDLD PDUs.

## Configuring UDLD

Complete the following steps to configure basic UDLD on your device.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enable the UDLD protocol and enter protocol UDLD configuration mode.

```
device(config)# protocol udld
```

3. Change the hello interval to 2000 milliseconds.

```
device(config-udld)# hello 20
```

This changes the interval at which UDLD PDUs are transmitted. The default interval, in counts of one hundred milliseconds is 500 ms.

4. Change the timeout multiplier from the default of 5.

```
device(config-udld)# multiplier 8
```

This changes the timeout multiplier value to affect the UDLD PDU timeout interval. The UDLD timeout interval is the product of the hello time interval at the other end of the link and the timeout multiplier value.

When the remote is Multi-Service IronWare or FastIron devices, the timeout equals local hello interval × multiplier value.

5. Return to global configuration mode.

```
device(config-udld)# exit
```

6. Enter interface configuration mode for an port.

```
device(config)# interface ethernet 5/1
```

7. Enable UDLD on the interface.

```
device(config-if-eth-5/1)# udld enable
```

8. Repeat the preceding step for each port on which you wish to enable UDLD.

#### NOTE

When the UDLD protocol is enabled on one end of a link, the timeout period might elapse before the UDLD protocol is enabled on the other end of the link. In this case, the link becomes temporarily blocked. When the UDLD protocol is enabled at the other end of the link and a UDLD PDU is received, UDLD automatically unblocks the link.

9. Return to privileged exec mode.

```
device(config-if-eth-5/1)# end
```

## 10. Verify the configuration.

- Show the UDLD global configuration.

```
device# show udld
UDLD Global Information
  Admin State:      UDLD enabled
  UDLD hello time:  1000 milliseconds
  UDLD timeout:     5000 milliseconds
```

- Show UDLD status for an interface

```
device# show udld interface ethernet 2/6
Global Admin State:  UDLD enabled

UDLD information for Ethernet 2/6
  UDLD Admin State:      Enabled
  Interface Operational State: Bidirectional link
  Remote hello time:     Unknown
  Remote MAC Addr:       0024.3890.0d81
  Local system id:       0x9f01fee0
  Remote system id:      0x24900c00
  Local port :           2/6
  Remote port :          9/2
  Local link id:         0x0
  Remote link id:        0x0
  Last Xmt Seq Num:      43849
  Last Rcv Seq Num:      43880
```

- Show UDLD statistics.

```
device# show udld statistics
UDLD Interface statistics for Ethernet 2/7
  Frames transmitted:    260
  Frames received:       223
  Frames discarded:      0
  Frames with error:     0
  Remote port id changed: 0
  Remote MAC address changed: 0
```

**NOTE**

The **show interface** command also indicates whether UDLD is enabled.

## 11. Save the configuration.

```
device# copy running-config startup-config
```

## UDLD configuration example

```
device# configure terminal
device(config)# protocol udld
device(config-udld)# hello 20
device(config-udld)# multiplier 8
device(config-udld)# exit
device(config)# interface ethernet 5/1
device(config-if-eth-5/1)# udld enable
device(config-if-eth-5/1)# end
device# show udld
device# copy running-config startup-config
```

## 802.1Q VLAN overview

IEEE 802.1Q VLANs provide the capability to overlay the physical network with multiple virtual networks. VLANs allow you to isolate network traffic between virtual networks and reduce the size of administrative and broadcast domains.

A VLAN contains end stations that have a common set of requirements that are independent of physical location. You can group end stations in a VLAN even if they are not physically located in the same LAN segment. VLANs are typically associated with IP subnetworks and all the end stations in a particular IP subnet belong to the same VLAN. Traffic between VLANs must be routed. VLAN membership is configurable on a per-interface basis.

## Configuring VLANs

The following sections discuss working with VLANs on Extreme devices.

### Configuring a VLAN

Follow this procedure to configure a VLAN in the Extreme device at the global configuration level.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
```

2. Enter the **vlan** command to create a topology group at the global configuration level.

```
device(config)# vlan 5
device(config-vlan-5)#
```

#### NOTE

The **no vlan** command removes the existing VLAN instance from the device.

### Configuring a switchport interface

Follow this procedure to configure a switchport interface in the device to send and receive data packets.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
```

2. Enter the **interface ethernet** command to configure the interface mode.

```
device(config)# interface ethernet 0/1
```

3. Enter the **switchport** command to configure a switchport interface.

```
device(conf-if-eth-0/1)# switchport
```

## Configuring the switchport interface mode

Do the following to set the switchport interface as access or trunk. This configuration works only when the interface is set as switchport.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
```

2. Enter the **interface ethernet** command to configure the interface mode.

```
device(config)# interface ethernet 0/1
```

3. Enter the **switchport** command to set the interface as switchport.

```
device(conf-if-eth-0/1)# switchport
```

4. Enter the **switchport mode** command to configure the switchport interface in trunk mode.

```
device(conf-if-eth-0/1)# switchport mode trunk
```

### NOTE

The default mode is access. Enter the **switchport mode access** command to set the mode as *access*.

### NOTE

Before you change the switch port mode from **switchport mode access** with an explicit **switchport access vlan** to **switchport mode trunk-no-default-native**, you must enter the **no switchport** command on the interface level, and then enter the **switchport** command to set the interface as a switchport. Now you can configure the **switchport mode trunk-no-default-native** command.

## Configuring the switchport access VLAN type

Do the following to change the switchport access VLAN type. This configuration works only when the interface is set as switchport.

Ensure that reserved VLANs are not used. Use the **no switchport access vlan** command to set the default VLAN as the access VLAN.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
```

2. Enter the **interface ethernet** command to specify an Ethernet interface.

```
device(config)# interface ethernet 0/1
```

3. Enter the **switchport** command to set the interface as switchport.

```
device(conf-if-eth-0/1)# switchport
```

4. Enter the **switchport access vlan** command to set the mode of the interface to *access* and specify a VLAN.

```
device(conf-if-eth-0/1)# switchport access vlan 10
```

This example sets the mode of a specific port-channel interface to *trunk*.

```
device# configure terminal
device(config)# interface port-channel 35
device(config-port-channel-35)# switchport mode trunk
```

## Configuring a VLAN in trunk mode

Do the following to add or remove VLANs on a Layer 2 interface in trunk mode. The configuration is also used to configure the VLANs to send and receive data packets.

Ensure that reserved VLANs are not used.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
```

2. Enter the **interface ethernet** command to specify an Ethernet interface.

```
device(config)# interface ethernet 0/1
```

3. Enter the **switchport** command to set the interface as switchport.

```
device(conf-if-eth-0/1)# switchport
```

4. Enter the **switchport trunk allowed vlan** command to set the mode of the interface to *trunk* and add a VLAN.

```
device(conf-if-eth-0/1)# switchport trunk allowed vlan add 5
```

The example sets the mode of the Ethernet interface to *trunk*.

```
device# configure terminal
device(config)# interface ethernet 0/1
device(conf-if-eth-0/1)# switchport mode trunk
```

The example sets the mode of a port-channel interface to *trunk* and allows all VLANs.

```
device# configure terminal
device(config)# interface port-channel 35
device(config-Port-channel-35)# switchport trunk allowed vlan all
```

## Configuring a native VLAN on a trunk port

Do the following to set native VLAN characteristics on a trunk port for classifying the untagged traffic data packets.

Ensure that reserved VLANs are not used.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
device(config)#
```

2. Enter the **interface ethernet** command to configure the interface mode.

```
device(config)# interface ethernet 0/1
```

3. Enter the **switchport** command to set the interface as switchport.

```
device(conf-if-eth-0/1)# switchport
```

4. Enter the **switchport trunk native-vlan** command to set native VLAN characteristics to *access* and specify a VLAN.

```
device(conf-if-eth-0/1)# switchport trunk native-vlan 300
```

This example removes the configured native VLAN on the Ethernet interface.

```
device# configure terminal
device(config)# interface ethernet 0/1
device(conf-if-eth-0/1)# no switchport trunk native-vlan 300
```

## Enabling VLAN tagging for native traffic

Do the following to enable tagging for native traffic on a specific interface.

Ensure that reserved VLANs are not used.

The following table describes the acceptable frame types, as well as system behavior, for tagged native VLAN, untagged native VLAN, and no native VLAN.

**TABLE 5** Acceptable frame types and system behavior for native VLANs

|                                      | Tagged native VLAN  | Untagged native VLAN  | No native VLAN                          |
|--------------------------------------|---|---|---|
| <b>Configuration</b>                 | switchport trunk tag native-vlan (Default) and Globally: <b>vlan dot1q tag native</b> | no switchport trunk tag native-vlan or Global config: <b>no vlan dot1q tag native</b> | switchport mode trunk-no-default-native |
| <b>Acceptable frame type</b>         | VLAN-tagged only  | All (tagged and untagged)   | VLAN-tagged only                        |
| <b>Receive untagged</b>              | Drop  | Forward/flood in native VLAN  | Drop                                    |
| <b>Receive tagged on native VLAN</b> | Forward/flood in native VLAN  | Forward/flood in native VLAN  | Drop                                    |
| <b>Transmit on native VLAN</b>       | Tagged with native VLAN   | Untagged packet   | Will not forward on native VLAN         |

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
```

2. Enter the **interface ethernet** command to configure the interface mode.

```
device(config)# interface ethernet 0/1
```

3. Enter the **switchport** command to set the interface as switchport.

```
device(conf-if-eth-0/1)# switchport
```

4. Enter the **switchport trunk tag native-vlan** command to enable tagging for native traffic data VLAN characteristics on a specific interface.

```
device(conf-if-eth-0/1)# switchport trunk tag native-vlan
```

This example enables tagging for native traffic data on a specific Ethernet interface.

```
device# configure terminal
device(config)# interface ethernet 0/1
device(conf-if-eth-0/1)# switchport trunk tag native-vlan
```

This example disables the native VLAN tagging on a port-channel.

```
device# configure terminal
device(config)# interface port-channel 35
device(config-Port-channel-35)# no switchport trunk tag native
```

## Displaying the status of a switchport interface

Do the following to display detailed Layer 2 information for all switchport interfaces.

Enter the **show interface switchport** to display the detailed Layer 2 information for all interfaces.

```
device# show interface switchport
Interface name      : Eth 0/1
Switchport mode    : access
Ingress filter      : enable
Acceptable frame types : all
Default Vlan       : 1
Active Vlans        : 1
Inactive Vlans      : -
Interface name      : Port-channel 5
Switchport mode    : access
Ingress filter      : enable
Acceptable frame types : all
Default Vlan       : 1
Active Vlans        : 1
```

## Displaying the switchport interface type

Do the following to display detailed Layer 2 information for a specific interface.

Enter the **show interface switchport** to display the detailed Layer 2 information for a specific interface.

```
device# show interface ethernet 0/1 switchport
Interface name      : ethernet 0/1
Switchport mode    : trunk
Fcoeport enabled    : no
Ingress filter      : enable
Acceptable frame types : vlan-tagged only
Native Vlan        : 1
Active Vlans        : 1,5-10
Inactive Vlans      : -
```

The example displays the detailed Layer 2 information for a port-channel interface.

```
device# show interface port-channel 5 switchport
Interface name      : Port-channel 5
Switchport mode    : access
Fcoeport enabled    : no
Ingress filter      : enable
Acceptable frame types : vlan-untagged only
Default Vlan       : 1
Active Vlans        : 1
Inactive Vlans      : -
```

## Verifying a switchport interface running configuration

Do the following to display the running configuration information for the Layer 2 properties for a specific interface.

Enter the **show running-config interface** to display the running configuration information for a specific interface.

```
device# show running-config interface ethernet 0/1 switchport
interface interface Eth 0/1
switchport
switchport mode trunk
switchport trunk allowed vlan add 5-10
switchport trunk tag native-vlan
```

This example displays the running configuration information for a port-channel interface.

```
device# show running-config interface port-channel 5 switchport
interface Port-channel 5
switchport
switchport mode access
switchport access vlan 1
```

## Displaying VLAN information

Do the following to display information about a specific VLAN.

1. Enter the **show vlan** to display information about VLAN 1.

```
device# show vlan 1
VLAN Name State Ports
(u)-Untagged, (t)-Tagged
(c)-Converged
=====
1 default ACTIVE Eth 0/1(t) Eth 0/4(t) Eth 0/5(t) Eth 0/8(t)
```

2. Enter the **show vlan detail** command to display detailed information.

```
device# show vlan det
VLAN: 1, Name: default
Admin state: ACTIVE, Config status: Static
Number of interfaces: 7
    Eth 0/4, tagged, Static
    Eth 0/3, tagged, Static
    Eth 0/2, tagged, Static
    Eth 0/8, tagged, Static
    Eth 0/6, tagged, Static
    Eth 0/9, untagged, Static
    Po 20, tagged, Static
VLAN: 10, Name: VLAN0010
Admin state: ACTIVE, Config status: Static
Number of interfaces: 3
    Eth 0/3, tagged, Static
    Eth 0/2, tagged, Static
    Eth 0/4, tagged, Static
    Po 20, tagged, Static
VLAN: 11, Name: VLAN0011
Admin state: ACTIVE, Config status: Static
Number of interfaces: 3
    Eth 0/3, tagged, Static
    Eth 0/2, tagged, Static
    Eth 0/4, tagged, Dynamic (MVRP)
VLAN: 12, Name: VLAN0012
Admin state: ACTIVE, Config status: Dynamic (MVRP)
Number of interfaces: 1
    Eth 0/4, tagged, Dynamic (MVRP)
VLAN: 13, Name: VLAN0013
Admin state: ACTIVE, Config status: Dynamic (EP tracking)
Number of interfaces: 1
    Eth 0/6, tagged, Dynamic (EP tracking)
VLAN: 14, Name: VLAN0014
Admin state: INACTIVE(member port down), Config status: Static
Number of interfaces: 1
    Eth 0/8, tagged, Static
```

## Enabling Layer 3 routing for VLANs

Do the following to enable Layer 3 routing on a VLAN.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Create a VLAN.

```
device(config)# vlan 200
```

3. Create a virtual Ethernet (VE), assign an IP address and mask, and enable the interface.

```
device(config)# interface ve 200
device(config-Ve-200)# ip address 10.2.2.1/24
device(config-Ve-200)# no shutdown
```

A VE interface can exist without a VLAN configuration, but it must be provisioned in the VLAN in order to be used.

4. Enter the **router-interface** command and specify the VLAN.

```
device(config-vlan-200)# router-interface ve 200
```

# VLAN statistics

Devices gather statistics for all ports and port channels on configured VLANs.

Use the **statistics** command in the VLAN configuration mode to enable statistics on a VLAN.

## NOTE

Statistics has to be manually enabled for a specific VLAN, since it is not enabled by default for VLANs.

Please note that:

- The statistics reported are not real-time statistics since they depend upon the load on the system.
- Statistics has to be manually enabled for a specific VLAN. This ensures better utilization of the statistics resources in the hardware.
- Statistics for VLANs with VE interfaces consider only the switched frames. Packets which are routed into or out of the VE interface are not counted.
- Enabling statistics on a VLAN has a heavy impact on the data traffic.

## Enabling statistics on a VLAN

Follow this procedure to enable statistics on a VLAN.

1. Enter the global configuration mode.

```
device# configure terminal
```

2. Enter the **vlan** command to specify a VLAN for statistics collection.

```
device(config)# vlan 5
device(config-vlan-5)#
```

3. Enter the **statistics** command to enable statistics for all ports and port channels on configured VLANs.

```
device(config-vlan-5)# statistics
```

## NOTE

Use the **no statistics** command to disable statistics on VLANs.

```
device(config-vlan-5)# no statistics
```

## Displaying statistics for VLANs

Do the following to display statistics information for VLANs.

Enter the **show statistics vlan** command to view the statistics for all ports and port channels on all configured VLANs.

```
device# show statistics vlan
```

```
Vlan 10 Statistics
Interface      RxPkts      RxBytes      TxPkts      TxBytes
eth 0/1        821729      821729      95940360    95940360
eth 0/2        884484      885855      95969584    95484555
po 1           8884        8855        9684        9955

Vlan 20 Statistics
```

```

Interface      RxPkts      RxBytes      TxPkts      TxBytes
eth 0/6        821729      821729      95940360    95940360
eth 0/21       8884        8855        9684        9955
po 2           884484      885855      95969584    95484555

```

**TABLE 6** Output descriptions of the show statistics vlan command

| Field     | Description  |
|-----------|--|
| Interface | The interface whose counter statistics are displayed.      |
| RxPkts    | The number of packets received at the specified port.      |
| RxBytes   | The number of bytes received at the specified port.        |
| TxPkts    | The number of packets transmitted from the specified port. |
| TxBytes   | The number of bytes transmitted from the specified port.   |

## Displaying VLAN statistics for a specific VLAN

Enter the **show statistics vlan** *vlan ID* command to view the statistics for a specific VLAN. Here *vlan ID* is the specific VLAN ID.

```
device# show statistics vlan 10
```

```

Vlan 10 Statistics
Interface      RxPkts      RxBytes      TxPkts      TxBytes
eth 0/1        821729      821729      95940360    95940360
eth 0/2        884484      885855      95969584    95484555
po 1           8884        8855        9684        9955

```

## Clearing statistics on VLANs

Follow the procedure to clear statistics' information for VLANs.

Enter the **clear statistics vlan** command to clear the statistics for all ports and port channels on all configured VLANs.

```
device# clear statistics vlan
```

## Clearing statistics for a specific VLAN

Enter the **clear statistics vlan** *vlan ID* command to clear the statistics for a specific VLAN. Here *vlan ID* is the specific VLAN ID.

```
device# clear statistics vlan 10
```

# VE route-only mode

By default, physical ports and port-channels (LAG ports) support both Layer 2 switching and Layer 3 routing. VE route-only mode enables these ports to act exclusively as a Layer 3 virtual Ethernet (VE) interface, dropping all ingress packets that require Layer 2 switching.

The MAC learning of dropped packets is not affected by this feature. ARP requests (broadcast), LACP, and BPDU packet processing are also not affected. The following table lists the effects of this mode on a variety of features.

**TABLE 7** Effects of VE route-only mode on features

| Feature                     | Ingress port as route-only port (incoming frames) | Egress port as route-only port (outgoing frames) |
|-----------------------------|---|--|
| Packets requiring switching | Drop, learn MAC address                           | Forwarded/switched                               |
| Packets requiring routing   | Forwarded   | Forwarded  |

**TABLE 7** Effects of VE route-only mode on features (continued)

| Feature          | Ingress port as route-only port (incoming frames) | Egress port as route-only port (outgoing frames) |
|------------------|---|--|
| ARP requests     | Trapped/punted, ARP response generated            | Forwarded  |
| LACP packets     | Trapped/punted and processed                      | Forwarded  |
| STP/BPDU packets | Trapped/punted and processed                      | Forwarded  |

Note the following considerations and limitations:

- Egress packets through a port configured as route-only are transmitted irrespective of whether they are switched or routed.
- This feature is enabled on the active management module (MM), and is available on the other MM after a failover.
- The number of TCAM entries required for this feature depends on the maximum number of physical ports. On a there are approximately 40 physical ports per PPE , and a maximum of 512 LAG ports for the entire system. Therefore the maximum number of TCAM entries for route-only support is 40. These entries are available on all TCAM profiles.

## Configuring VE route-only mode on a physical port

Do the following to configure VE route-only mode on a physical port.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Create a VLAN.

```
device(config)# vlan 100
```

3. Specify an Ethernet interface.

```
device(config)# interface ethernet 1/2
```

4. Enter the **switchport** command to configure Layer 2 characteristics.

```
device(conf-if-eth-1/2)# switchport
```

5. Specify trunk mode.

```
device(conf-if-eth-1/2)# switchport mode trunk
```

6. Tag the port to a VLAN.

```
device(conf-if-eth-1/2)# switchport mode trunk allowed vlan add 100
```

7. Enter the **route-only** command to enable Layer 3 routing exclusively on the port.

```
device(conf-if-eth-1/2)# route-only
```

Use the **no route-only** command to revert to default Layer 2 and Layer 3 behavior.

8. Enable the interface and exit to global configuration mode.

```
device(conf-if-eth-1/2)# no shutdown
device(conf-if-eth-1/2)# exit
```

## 9. Verify the Ethernet configuration.

```
device(conf-if-eth-1/2)# do show running-cocnfig interface ethernet 1/2
switchport
switchport mode trunk
switchport trunk allowed vlan add 100
route only
no shutdown
```

## 10. Verify the port statistics for switching packets dropped.

```
device(conf-if-eth-1/2)# do show interface ethernet 1/2
Ethernet 1/2 is up, line protocol is up (connected)
Hardware is Ethernet, address is 768e.f80a.033c
Current address is 768e.f80a.033c
...
Rate info:
Input 0.001008 Mbits/sec, 0 packets/sec, 0.00% of line-rate
Output 0.000252 Mbits/sec, 0 packets/sec, 0.00% of line-rate
Route-Only Packets Dropped: 17
Time since last interface status change: 21:35:41
```

## 11. Enter virtual Ethernet (VE) configuration mode and specify the VLAN.

```
device(config)# interface ve 100
```

## 12. Assign an IP address and mask and enable the interface.

```
device(config-Ve-100)# ip address 10.2.2.2/24
device(config-Ve-100)# no shutdown
```

## 13. Confirm the VE configuration.

```
device(config-Ve-100)# do show running-config interface ve 100
interface Ve 100
ip proxy-arp
ip address 10.2.2.2/24
no shutdown
```

## Configuring VE route-only mode on a LAG port

Do the following to configure VE route-only mode on a LAG (port-channel) port.

## 1. Enter global configuration mode.

```
device# configure terminal
```

## 2. Create a VLAN.

```
device(config)# vlan 100
```

## 3. Specify a port-channel interface.

```
device# configure terminal
device(config)# interface port-channel 1
```

4. Enter the **switchport** command to configure Layer 2 characteristics.

```
device(config-Port-channel-1)# switchport
```

5. Specify trunk mode.

```
device(config-Port-channel-1)# switchport mode trunk
```

6. Tag the port to a VLAN.

```
device(config-Port-channel-1)# switchport trunk allowed vlan add 100
```

7. Enable tagging on native VLAN traffic.

```
device(config-Port-channel-1)# switchport trunk tag native-vlan
```

8. Enter the **route-only** command to enable Layer 3 routing exclusively on the port.

```
device(config-Port-channel-1)# route-only
```

Use the **no route-only** command to revert to default Layer 2 and Layer 3 behavior.

9. Enable the interface and exit to global configuration mode.

```
device(config-Port-channel-1)# no shutdown
device(config-Port-channel-1)# exit
```

10. Verify the port-channel configuration.

```
device(config-Port-channel-1)# do show running-config interface port-channel 1
interface Port-channel 1
switchport
switchport mode trunk
switchport trunk allowed vlan add 100,200
switchport trunk tag native-vlan
route-only
no shutdown
```

11. Enter virtual Ethernet (VE) configuration mode and specify the VLAN.

```
device(config)# interface ve 100
```

12. Assign an IP address and mask and enable the interface.

```
device(config-Ve-100)# ip address 10.2.2.2/24
device(config-Ve-100)# no shutdown
```

13. Verify the VE configuration.

```
device(config-Ve-100)# do show running interface ve 100
interface Ve 100
ip proxy-arp
ip address 10.2.2.2/24
no shutdown
```

## Configuring virtual routing interfaces

The Extreme device sends Layer 3 traffic at Layer 2 within a protocol-based VLAN. However, Layer 3 traffic from one protocol-based VLAN to another must be routed. If you want the device to be able to send Layer 3 traffic from one protocol-based VLAN to another on the same device, you must configure a virtual routing interface on each protocol-based VLAN, then configure routing parameters on the virtual routing interfaces.

A *virtual routing interface* is a logical routing interface that the Extreme device uses to route Layer 3 protocol traffic between protocol-based VLANs. It is a logical port on which you can configure Layer 3 routing parameters.

For example, to enable a Extreme device to route IP traffic from one IP protocol VLAN to another, you must configure a virtual routing interface on each IP protocol VLAN, then configure the appropriate IP routing parameters on each of the virtual routing interfaces.

To attach a router interface to a VLAN, using the **router-interface** command:

```
device# configure terminal
device(config)# vlan 2
device(config-vlan-2)# router-interface ve 2
```

#### NOTE

Only one router VE interface can be mapped to a VLAN. The VLAN ID and the VE ID need not be the same.

Use the **no router interface ve** command to remove the router VE interface.

## DHCP Layer 2 relay agent Option 82 for VLANs

This feature supports DHCP Relay Agent Information Option 82 for Layer 2 on VLANs.

#### NOTE

For a discussion of this feature for Layer 3, refer to the "DHCPv4" chapter in the *Extreme SLX-OS Layer 3 Configuration Guide*.

## Overview

It is advantageous to have DHCP relay agent support when DHCP clients and servers are not on the same subnet. DHCP broadcast requests are relayed by the DHCP relay agent to the DHCP server. The DHCP replies are unicasted to the DHCP relay agent, which in turn relays them back to the DHCP client.

For Layer 3, relay agents populate the GIADDR (global IP address) field and also append the "Relay Agent Information" option. DHCP servers use this option for assigning the IP address and other parameters.

In some network configurations that have Layer 2 devices between the DHCP client and the DHCP relay agent, it is better to have Layer 2 relay agents running on Layer 2 devices. This places the agents in a better position to append the Relay Agent Information option because they are closer to the DHCP clients. These agents also broadcast the DHCP messages. (A Layer 3 relay agent, on the other hand, relays the information to the DHCP server.)

## Option 82

When this Layer 2 feature is enabled on a VLAN, the Option 82 information is inserted by the Layer 2 relay agent before the DHCP messages are broadcasted further. This information allows the DHCP server to select an IP address or other parameter. The DHCP server echos Option 82 in the reply packets. The DHCP Layer 2 relay agent validates and removes Option 82 and sends the response to the DHCP client.

The format of Option 82 is shown in the following table.

**TABLE 8** Option 82 format

| Code | Len | Agent Information Field |    |    |    |     |    |
|------|-----|-------------------------|----|----|----|-----|----|
| 82   | N   | i1                      | i2 | i3 | i4 | ... | iN |

#### NOTE

The length *N* represents the total number of octets in the Agent Information Field. The Agent Information field consists of a sequence of SubOpt/Length/Value tuples for each suboption.

The following table lists the circuit ID suboptions that are added by the relay agent.

**TABLE 9** Circuit ID suboptions

| Suboption type<br>(1 byte) | Length<br>(1 byte) | VLAN ID <string><br>(4 bytes) | IF-description string<br>(4 bytes) |
|----------------------------|--------------------|-------------------------------|------------------------------------|
| 2                          | 68                 |                               |                                    |

**NOTE**

The circuit ID is a combination of the VLAN ID and the interface description string. If the interface description is not configured, the default string "Extreme" is used in the circuit ID.

The following table lists the remote ID suboptions that are added by the relay agent.

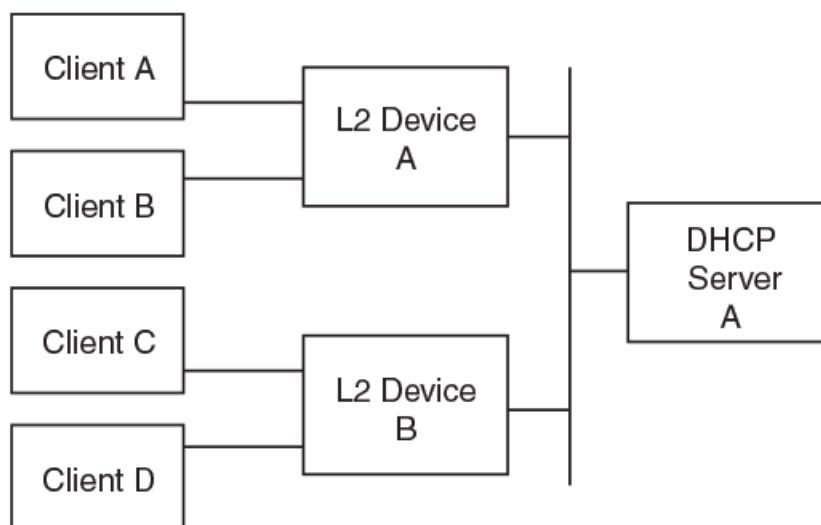

**TABLE 10** Remote ID suboptions

| Suboption type<br>(1 byte) | Length<br>(1 byte) | VLAN ID<br>(2 bytes) | MAC address<br>(6 bytes) |
|----------------------------|--------------------|----------------------|--------------------------|
| 2                          | 8                  |                      |                          |

## Topologies and operation

The following figure illustrates a single DHCP server and clients on the same subnet.

**FIGURE 2** Single DHCP server and clients on same subnet

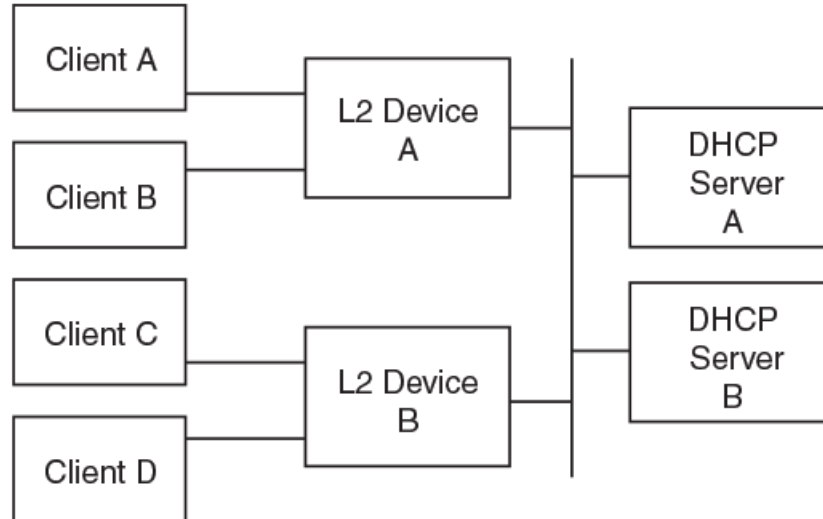

Note the following considerations for the above scenario:

- The Layer 2 relay agent (on the Layer 2 device) appends Option 82 information to a DHCP message received from the client and broadcasts the message to all other ports. The Option 82 information contains the remote ID suboption and the circuit ID suboption.
- The Layer 2 relay agent does not set the GIADDR field.
- The DHCP server echoes the Relay Agent Information option in the response message.

- The Layer 2 relay agent uses the Relay Agent Information option to find out whether it had appended Option 82 to the request message.
- The Layer 2 relay agent removes Option 82 from the packet received from the DHCP server after this option is validated, and then it forwards the message to the interface identified by the Relay Agent Information option.

The following figure illustrates multiple DHCP servers and clients on the same subnet.

**FIGURE 3** Multiple DHCP servers and clients on the same subnet

Note the following considerations for the above scenario:

- The Layer 2 relay agent receives multiple responses (from all the servers).
- The processing of DHCP messages in the Layer 2 relay agent remains the same as in the scenario above.

The following figure illustrates a DHCP server on another subnet with clients and one Layer 3 relay agent.

**FIGURE 4** DHCP server on another subnet with clients and one Layer 3 relay agent

Note the following considerations for the above scenario:

- The Layer 3 relay agent receives the message relayed by the Layer 2 relay agent. It finds that the message already contains a Relay Agent Information option. The Layer 3 relay agent populates the GIADDR field as appropriate and relays the message to the DHCP server.
- The DHCP server processes the message and unicasts the response to the Layer 3 relay agent on the address specified in the GIADDR field.
- The L3 relay agent processes the response from the server and identifies the outgoing interface. It resets the GIADDR field and broadcasts the message on the identified outgoing interface.

## Considerations for Layer 2 relay agent

Note the following:

- All client interfaces are treated as untrusted interfaces.
- There are no separate configurations for the suboptions. Enabling Option 82 for this feature enables the automatic insertion of both the circuit ID and remote ID suboptions.

## Configuring DHCP Layer 2 relay agent Option 82

This task enables, verifies, and disables DHCP Relay Agent Information Option 82 for Layer 2 on VLANs.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Specify a VLAN and enter VLAN configuration mode.

```
device(config)# vlan 10
```

3. Enter the **t2 relay agent information option** command.

```
device(config-vlan-10)# l2 relay agent information option
DHCP L2 Relay Agent Information Option is enabled.
```

4. To verify the running configuration on the VLAN, enter the **show running-config** command and specify the VLAN.

```
device# show running-config vlan 10
vlan 10
ip dhcp relay information option
```

5. To verify the configuration on the switch, enter the **show ip dhcp relay option** command.

```
device# show ip dhcp relay option
```

| Interface | Circuit-ID            | Remote-ID        |
|-----------|-----------------------|------------------|
| -----     | -----                 | -----            |
| eth0/1    | 0201630080Extreme     | 000a0027f8c744e4 |
| eth0/2    | 0201630081EdgeDevices | 00140027f8c744e5 |
| po1000    | 0201630082Clusters    | 004b0027f8c744e9 |
| ve10      | 0201630097Extreme     | 00640027f8c744f1 |

You can use the **interface** keyword in the above command to specify an interface.

6. To disable this feature, enter the **no t2 relay agent information option** command.

```
device(config-vlan-10)# no l2 relay agent information option
DHCP L2 Relay Agent Information Option is disabled.
```

## Endpoint tracking

The endpoint tracking feature minimizes the configuration and management of VLANs on switches in the data center, by means of MAC authentication using RADIUS protocol.

### Overview

#### NOTE

This feature is supported only on the SLX 9850 and SLX 9540.

Statically provisioning VLANs in a data center network has the following drawbacks:

- Managing VLANs on top-of-rack (TOR) switches is tedious for the administrator.
- Having VLANs provisioned ahead of time increases the size of the active topology for control protocols such as STP and RSTP, increasing convergence times.
- Flood (unknown unicast, broadcast) traffic can unnecessarily eat up bandwidth on the TOR-to-EOR (end of row) links.
- For the case when the virtual machine (VM) sends or receives tagged traffic, flood traffic can consume CPU cycles on every server that is connected to the network.
- The dynamic VLAN feature allows SLX-OS to create, prune, and open VLANs on the switch dynamically as they are needed by the VMs. This enables the VLAN to follow the VM as it migrates between servers in the data center.

This feature provides the following to remedy the above drawbacks:

- Association of MAC addresses to specific VLANs.
- Once a MAC address is authorized and the VLAN is not already provisioned on the switch, the dynamic (1) creation of the VLAN to which this MAC is associated, (2) configuration of the tag, and (3) addition of the feature-enabled port on which the MAC was detected.

- Once the last MAC address using the VLAN is deleted or aged out, deletion of the VLAN and associated resources on the switch.

The endpoint tracking feature also authorizes the VM. When a VM (and MAC address) is authorized, SLX-OS dynamically creates the VLAN that is required for the VM to send traffic. If a VM shuts down or is moved, its VLAN is pruned to preserve bandwidth. In this way the network responds to changes in the VM network.

## Additional details and considerations

Note the following:

- The user enables or disables this feature on a Layer 2 port (switchport), by means of the **endpoint-tracking enable** command. This feature is also supported on LAG and MCT ports.
- SLX-OS communicates with a RADIUS server or XMC-NAC (Extreme Management Center Network Access Control) for MAC authentication information, which can map a MAC address to a VLAN. RADIUS VLAN assignment triggers the creation of the VLAN and the port VLAN membership. SLX-OS expects MAC-to-VLAN binding information from RADIUS. VNI (VXLAN Network Identifier) assignment is not supported.
- The maximum number of authenticated or nonauthenticated MAC addresses supported for each endpoint-tracking-enabled port is 8000 per system.
- Port VLAN membership is local to SLX-OS. The removal of port VLAN membership or the deletion of the VLAN is not propagated to the RADIUS server.
- On an access port, if RADIUS does not provide MAC-to-VLAN mapping, SLX-OS assigns a default VLAN. Only the first RADIUS VLAN assignment is honored, and subsequent MAC addresses cannot override the existing assignment.
- For VMs sending tagged traffic, if the RADIUS authentication response does not have a VLAN assignment for the MAC, SLX-OS creates the VLAN (assuming the VLAN does not already exist) with the received packet's tag and adds the port to the VLAN as tagged. Dynamically created VLANs are not saved across reboots, and therefore are not part of the running configuration.
- When a port becomes part of a VLAN dynamically, this is not reflected in the running configuration of the interface.
- In reauthentication, RADIUS sends two attributes as part of a Change of Authorization (CoA) request (a CoA is an unsolicited message from RADIUS to the switch to trigger an authentication-related action): (1) Calling-station-id, a value field that holds the MAC being authenticated, and VSA, a vendor-specific attribute value field that holds commands and parameters for commands. RADIUS matches the outstanding requests response by means of a CoA identifier.

## RADIUS VSA support

This feature supports the following VSA format.

**TABLE 11** VSA format

|                    |        |                               |            |
|--------------------|--------|-------------------------------|------------|
| Type (26)          | Length | Vendor ID (Extreme Vendor ID) |            |
| Vendor ID (cont'd) |        | Sub-attr (Sub-type)           | Sub-length |
| Value              |        |                               |            |

The VSA fields are as follows.

**TABLE 12** VSA fields

| Field | Description  |
|-------|--|
| Type  | 8-bit field. Always 26 as it represents a VSA attribute. |

**TABLE 12** VSA fields (continued)

| Field               | Description  |
|---------------------|--|
| Length              | 8-bit field. Length of entire attribute, including type and length fields.                 |
| Vendor ID           | 4 octets, encoding the Extreme Vendor ID.  |
| Sub-attr (Sub-type) | 8-bit field, indicating class of command.  |
| Sub-length          | 8-bit field. Length of the Sub-attr (attribute), including sub-type and sub-length fields. |
| Value               | A string, integer, or IP address based on Sub-type   |

As a RADIUS Access response, only one VSA attribute is provided, for Egress-vlan. The Egress-vlan VSA format has sub-type 216 and a value field of type integer. The format is shown below.

**TABLE 13** Egress-vlan VSA format

|                    |        |                               |            |
|--------------------|--------|-------------------------------|------------|
| Type (26)          | Length | Vendor ID (Extreme Vendor ID) |            |
| Vendor ID (cont'd) |        | Sub-type (216)                | Sub-length |
| egress VLAN_ID     |        |                               |            |

**NOTE**

Both Cisco and Extreme Networks Vendor IDs are supported for the above.

For MAC reauthentication, RADIUS sends a Change of Authorization (CoA) of Code 43 with the VSA. This has a sub-type of 1 and the Value field is the string "subscriber:command=reauthenticate". The format is shown below.

**TABLE 14** MAC reauthentication format

|                                   |        |                               |            |
|-----------------------------------|--------|-------------------------------|------------|
| Type (26)                         | Length | Vendor ID (Extreme Vendor ID) |            |
| Vendor ID (cont'd)                |        | Sub-type (1)                  | Sub-length |
| subscriber:command=reauthenticate |        |                               |            |

**NOTE**

Both Cisco and Extreme Networks Vendor IDs are supported for the above.

## Enabling and disabling endpoint tracking on a port

This feature is enabled on a per-port basis, on a port in Layer 2 mode (switchport). This section provides additional details and illustrates the configuration.

**NOTE**

For configuration details, refer to the "VLANs" chapter in this guide.

### Endpoint tracking on an access port

When endpoint tracking is enabled on an access port, initial MAC learning occurs on the default VLAN and after authentication if there is RADIUS VLAN assignment. Note the following:

- If RADIUS assigns the VLAN, the VLAN is created if it does not exist. The Layer 2 forwarding entry is added with the RADIUS-assigned VLAN.
- If RADIUS does not assign the VLAN, the Layer 2 forwarding entry is added with the default VLAN.

The following illustrates the use of the **endpoint-tracking enable** command in switchport access mode (the default).

```
device: configure terminal
device(config)# interface ethernet 0/1
device(conf-if-eth-0/1)# switchport
device(conf-if-eth-0/1)# endpoint-tracking enable
```

## Endpoint tracking on a trunk port

On a trunk port, packets are always tagged. To allow any tagged traffic on the port, ingress VLAN filtering is disabled in the forwarding plane when endpoint tracking is enabled. As a result, all the tagged packets are trapped to the CPU as a Layer 2 learning event, which is later authenticated by RADIUS. A MAC learning event that is generated has wire tag information as part of the VLAN information. After authentication, a RADIUS-assigned dynamic VLAN is added for egress forwarding on the port.

The following illustrates the use of the **endpoint-tracking enable** command in switchport trunk mode.

```
device: configure terminal
device(config)# interface ethernet 0/1
device(conf-if-eth-0/1)# switchport
device(conf-if-eth-0/1)# switchport mode trunk
device(conf-if-eth-0/1)# endpoint-tracking enable
```

By default, reauthentication for each session on the port is disabled. However, you can optionally set a timer value for reauthentication, by means of the **endpoint-tracking timeout reauth-period** command, as in the following example.

```
device(conf-if-eth-0/1)# endpoint-tracking timeout reauth-period 86400
```

Once endpoint tracking is enabled on a trunk port, the following occurs:

1. The source MAC lookup fails to find a matching entry in hardware and the packet is sent to the CPU for Layer 2 learning with a tag in place of the IVID.
2. When received by the CPU, the wire tag information is stored as a VLAN, and the MAC address is sent for authentication.
3. If authentication is successful and the RADIUS VLAN assignment matches the wire tag, or if there is no VLAN assignment from RADIUS, VLAN creation is triggered and the egress VIF is set for the port to allow forwarding and flooding.

## Verifying configurations

A variety of **show** commands are available to verify the configuration of endpoint tracking, as described in the following table.

**TABLE 15** Endpoint tracking show commands

| Command   | Description  |
|---|--|
| <b>show mac-address-table endpoint-tracking authenticated</b>                   | Displays authenticated MAC addresses that are learned on all ports that are enabled for endpoint tracking.         |
| <b>show mac-address-table endpoint-tracking authentication-failed</b>           | Displays nonauthenticated MAC addresses that are learned on all ports that are enabled for endpoint tracking.      |
| <b>show mac-address-table endpoint-tracking authenticated interface</b>         | Displays authenticated MAC addresses that are learned on a specific port that is enabled for endpoint tracking.    |
| <b>show mac-address-table endpoint-tracking authentication-failed interface</b> | Displays nonauthenticated MAC addresses that are learned on a specific port that is enabled for endpoint tracking. |
| <b>show vlan detail</b>   | Displays detailed VLAN information.  |

Examples are shown below respectively for these commands.

**show mac-address-table endpoint-tracking authenticated**

```
device# show mac-address-table endpoint-tracking authenticated
VlanId/BDId  Mac-address      Type      State (R-Radius,F-FailOpen)  Ports
100 (V)      0001.0100.0001  Dynamic   Authenticated(R)             Eth 0/5
```

**show mac-address-table endpoint-tracking authenticated interface**

```
device# show mac-address-table endpoint-tracking authenticated interface ethernet 0/5
VlanId/BDId  Mac-address      Type      State      Ports
100 (V)      0001.0100.0001  Dynamic   Authenticated  Eth 0/5
```

**show mac-address-table endpoint-tracking authentication-failed**

```
device# show mac-address-table endpoint-tracking authenticated interface ethernet 0/5
VlanId/BDId  Mac-address      Type      State (R-Radius,F-FailOpen)  Ports
100 (V)      0001.0100.0001  Dynamic   Authenticated(R)             Eth 0/5
```

**show mac-address-table endpoint-tracking authenticated-failed interface**

```
device# show mac-address-table endpoint-tracking authentication-failed interface ethernet 0/5
VlanId/BDId  Mac-address      Type      State      Ports
100 (V)      0001.0100.0001  Dynamic   Pending     Eth 0/5
100 (V)      0001.0100.0002  Dynamic   Failed      Eth 0/5
```

**show vlan detail**

```
device# show vlan detail
VLAN: 10, Name: VLAN0010
Admin State: ACTIVE, Config status: Dynamic (Endpoint Tracking)
Number of interfaces: 6
  Eth 1/6: tagged, trunk, dynamic (EP tracking)
  Eth 1/10: tagged, trunk, dynamic (EP tracking)
  Eth 1/11: tagged, trunk, dynamic (MVRP)
  Eth 1/12: untagged, access, dynamic (MVRP)
  Tu 61441: tagged, trunk, dynamic(BGP-EVPN), vni : 10010
  Tu 61442: tagged, trunk, static, vni : 10010
```

## VM MAC aging and flush

When a VMs MAC address is deleted because of aging or a flush operation, if it is the last MAC on the port, SLX-OS removes the port from the VLAN and checks to see if the VLAN is associated with other ports. If there are no other associations, the VLAN is also deleted.

## Interoperation with MVRP

In the case of statically configured VLANs, a dynamically created VLAN also triggers Multiple VLAN Registration Protocol (MVRP) registration if MVRP is configured on the endpoint-tracking-enabled port.

## MAC reauthentication

MAC reauthentication lets the RADIUS server send unsolicited messages to SLX-OS, to relearn the MAC address of the VM. Note the following:

- SLX-OS stores the CoA request identifier and uses the same identifier in the response (ACK/NAK).
- A RADIUS reauthentication request without calling-station-id is returned with a NAK.
- A RADIUS reauthentication request with a calling-station-id that is not present in the switch is returned with a NAK.
- A RADIUS request with a different vendor-id is silently ignored by the switch.
- Duplicate CoA messages are rejected at the switch.

- Re-authentication can be achieved by means of either a CoA or a Disconnect message. In the case of a CoA message, the VM is not removed and traffic is not disrupted during re-authentication. In the case of a Disconnect message, the VM is removed from the switch. When new traffic from the VM is relearned, authentication is triggered, and traffic is disrupted.

## MCT support

A VLAN that is created dynamically on one MCT peer node is communicated to other peer node. Similarly, if a cluster client edge port (CCEP) port becomes part of a VLAN dynamically on one MCT peer node, this is communicated to the other peer node. The receiving MCT peer node, depending on the message, creates a dynamic VLAN or dynamic port VLAN membership.

The dynamic deletion of a VLAN or port VLAN membership is triggered by the last local MAC deletion. In addition, similar to the addition case, this information is also communicated to the peer.

### NOTE

If MVRP is enabled on an MCT node, you must configure the interface enabled for endpoint tracking with MVRP applicant mode as non-participant through the **mvrp applicant-mode non-participant** command in interface configuration mode. Refer to [MVRP with endpoint tracking](#) on page 139 in this document. Also, if you observe an MVRP flap, configure MVRP timers to higher values on the ICL interfaces. For details, refer to the **timer** command.

## Static and MVRP VLAN dependency

A statically configured VLAN has a higher precedence over a dynamically created VLAN. Note the following:

- If a dynamically created VLAN is configured as static as well, removing the static VLAN also removes the dynamic VLAN information from the system.
- If a dynamically created port/VLAN membership is configured as static as well, removing the static port/VLAN membership also removes the dynamic port/VLAN membership from the system.
- If a VLAN has MVRP dependency, then dynamic pruning of the VLAN through endpoint-tracking action does not occur.

## Static VLAN dependency

A statically configured VLAN has a higher precedence over a dynamically created VLAN. Note the following:

- If a dynamically created VLAN is configured as static as well, removing the static VLAN also removes the dynamic VLAN information from the system.
- If a dynamically created port/VLAN membership is configured as static as well, removing the static port/VLAN membership also removes the dynamic port/VLAN membership from the system.

# VXLAN Layer 2 Gateway

- [VXLAN Layer 2 gateway overview.....59](#)
- [VXLAN Layer 2 gateway considerations and limitations.....60](#)
- [Configuring VXLAN Layer 2 gateway.....60](#)
- [VXLAN Layer 2 gateway support for bridge domains.....62](#)
- [VXLAN Layer 2 support for LVTEP.....64](#)

## VXLAN Layer 2 gateway overview

SLX-OS devices can act as a Layer 2 gateway.  
The following figure illustrates an example Layer 2 gateway topology.

FIGURE 5 Layer 2 gateway topology

| Device             | IP address | Mapping              |
|--------------------|------------|----------------------|
| 1: SLX 9850 series | 1.1.1.1    | VNI 5000 < > VLAN 10 |
| 2: VDX 6740 series | 2.2.2.2    | VNI 5000 < > VLAN 20 |
| 3: SLX 9540 series | 3.3.3.3    | VNI 5000 < > VLAN 5  |

VLANs on each node are extended through common Virtual Network Instance (VNI) 5000. The MAC addresses of local hosts are learned on access points, and MAC addresses are learned on VXLAN tunnels. A split-horizon topology is supported. All nodes participating in the VLAN must be connected through VXLAN tunnels, because there is no tunnel-to-tunnel flooding of broadcast, unknown unicast, and multicast (BUM) traffic.

In this topology, Devices 1, 2, and 3 are VXLAN Layer 2 gateway devices. On Device 3, tunnel 1 and tunnel 2 are mapped to VLAN 5. VLAN 5 has two hosts, MAC 3 and MAC 4. Device 3 is connected to two other hosts, Device 1 and Device 2, which connect to hosts MAC 1 and MAC 2, respectively, through VXLAN tunnels 1 and 2, respectively. If MAC 3 needs to establish traffic to MAC 1, initially there will be BUM flooding and upon a response from MAC 1, MAC 1 is learned through tunnel 1. Subsequent traffic goes directly from MAC 3 to Device 1 on tunnel 1. Traffic in the reverse direction comes from Device 1, is decapsulated, and goes to MAC 3.

## VXLAN Layer 2 gateway considerations and limitations

Note the following considerations and limitations for VXLAN Layer 2 gateway.

- A maximum of 512 tunnels are supported.
- A maximum of 8 ECMP paths are supported.
- Layer 2 snooping is not supported.
- VRRPe source IP addresses and EVPN Multi-Chassis Trunks (MCTs) are not supported.
- QoS, TTL, and MTU values are not configurable. The MTU is based on the IP interface MTU. If a packet is bigger than the IP interface MTU minus the VXLAN header, the packet is dropped. The default TTL value is 255. The default QoS value is 0, which is applied to the DSCP field of the IP header.
- VXLAN tunnels have the standard UDP header encapsulated with the standard defined value of 4789. This value is not configurable. SLX-OS expects VXLAN tunnel packets to be received with this value.
- Only the VXLAN extended TCAM profile is supported.
- VXLAN tunnels are not supported when the counter profile 1 or 4 is configured. These profiles do not allocate hardware resources for TX statistics, which is needed for VXLAN tunnels.
- Only static VXLAN tunnels with regular VTEPs are supported; logical VTEP tunnels are not supported.
- The tunnel TX bytes statistics do not account for the outer VLAN header size.
- When BUM packets received on the tunnel are flooded, split horizon drops the packets to the same tunnel. However, the TX Statistics counter on that tunnel increments.

## Configuring VXLAN Layer 2 gateway

Follow these steps to configure a VXLAN Layer 2 gateway.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enter the **overlay-gateway** command, specify the name of a gateway, and enter VXLAN overlay gateway configuration mode.

```
device(config)# overlay-gateway GW1
```

3. Enter the **type** command and specify **layer2-extension**.

```
device(config-overlay-gw-GW1)# type layer2-extension
```

4. Enter the **map vlan vni** command and specify **l2-extension**.

```
device(config-overlay-gw-GW1)# map vlan 5 vni 5000
```

5. Enter the **map bridge-domain** command and specify a bridge domain and VNI.

```
device(config-overlay-gw-GW1)# map bridge-domain 1 vni 2000
```

6. Enter the **ip interface** command and specify a loopback ID.

```
device(config-overlay-gw-GW1)# ip interface loopback 1
```

7. Enter the **site** command, specify a site name, and enter VXLAN overlay gateway site configuration mode.

```
device(config-overlay-gw-GW1)# site mysitel
```

This mode configures a VXLAN tunnel to the site node. Only regular VTEPs are supported; logical VTEPs are not supported.

8. Enter the **ip address** command and specify an IP address.

```
device(config-overlay-gw-GW1-site-mysitel)# ip address 1.1.1.1
```

9. Enter the **extend vlan add** command and specify a VLAN.

```
device(config-overlay-gw-GW1-site-mysitel)# extend vlan add 5
```

10. Enter the **extend bridge-domain add** command and specify a bridge domain.

```
device(config-overlay-gw-GW1-site-mysitel)# extend bridge-domain add 1
```

11. Enter the **activate** command to activate the site.

```
device(config-overlay-gw-GW1-site-mysitel)# activate
```

12. In privileged EXEC mode, enter the **show overlay-gateway** command to confirm the gateway configuration.

```
device# show overlay-gateway
Overlay Gateway "GW1", ID 1,
Admin state up
IP address 3.3.3.3 (loopback 1), Vrfdefault-vrf
Number of tunnels 1
Packet count: RX 17909 TX 1247
Byte count : RX (500125) TX 356626
```

13. In privileged EXEC mode, enter the **show tunnel** command to confirm the tunnel configuration.

```
device# show tunnel 61441
Tunnel 61441, mode VXLAN
Ifindex 0x7c00f001, Admin state up, Operstate up
Source IP 3.3.3.3, Vrf: default-vrf
Destination IP 1.1.1.1
Active next hops on node 1:
IP: 4.4.4.5, Vrf: default-vrf
Egress L3 port: Ve45, Outer SMAC: 609c.9f5a.4415
Outer DMAC: 609c.9f5a.0015, ctag: 0
BUM forwarder: yes
```

14. In privileged EXEC mode, enter the **show vlan** command to confirm the VLAN configuration.

```
device# show vlan 5
VLAN          Name          State          Ports          Classification
(R)-RSPAN
=====
5              VLAN05        ACTIVE         Eth 2/1(t)     =====
                  Eth 2/5(t)     Eth 2/5(t)
                  tu61441 vni5000
```

15. In privileged EXEC mode, enter the **show mac-address-table** command to confirm the MAC configuration.

```
device# show mac-address-table
VlanId/BDId    Mac-address      Type      State      Ports/LIF/PW
35 (V)         609c.9f5a.5b15   Dynamic   Active     Po 35
45 (V)         609c.9f5a.4415   Dynamic   Active     Po 45
5 (V)          0000.0400.0011   Dynamic   Active     tu61441
5 (V)          0000.0500.0011   Dynamic   Active     Eth 0/5
5 (V)          0000.0400.0011   Dynamic   Active     tu61441
5 (V)          0000.0500.0011   Dynamic   Active     Eth 0/5
Total MAC addresses : 6
device#
```

## VXLAN Layer 2 gateway support for bridge domains

An SLX-OS device provides VXLAN Layer 2 gateway support for bridge domains in addition to supporting Layer 2 VLANs. VXLAN gateway support to bridge domains allows a maximum of 4 K bridge domain Virtual Network Interface (VNI) mappings along with a maximum of 4 K VLAN VNI mappings, for a total of 8 K mappings.

Since a bridge domain supports different port and VLAN endpoints, all of its traffic can be extended to a remote node through one VNI.

Also, VXLAN gateway support to bridge domains enables VLAN translation of traffic on both sides of the network. The local VLANs can use different VLAN tags on either side of the network and map to the same VNI.

### NOTE

Only point-to-multipoint bridge domains are supported to extend over VXLAN tunnels. Point-to-point bridge domains are not supported.

You can extend the bridge domain under a site configuration. You can configure the bridge domain to VNI mapping automatically with auto mode where the bridge domain to the VNI is mapped implicitly. For example, VLANs 1 through 4096 are mapped to VNI 1 through 4090, respectively, and the bridge domain 1 is mapped to 4097. You can also configure the bridge domain to a VNI map manually, similarly to that of a VLAN.

### NOTE

The default tagging mode for a bridge domain is raw mode.

## Configuring VXLAN Layer 2 Gateway support for bridge domains

Before performing this configuration, configure a point-to-multipoint bridge domain.

Follow these steps configure a VXLAN Layer 2 gateway to support bridge domains.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Create a VXLAN overlay gateway and access the overlay gateway configuration mode.

```
device(config)# overlay-gateway gateway1
device(config-overlay-gw-gateway1)#
```

3. Configure the Layer 2 type extension.

```
device(config-overlay-gw-gateway1)# type layer2-extension
```

- Specify a loopback interface.

```
device(config-overlay-gw-gateway1)# ip interface loopback 1
```

- Enable the mapping of a bridge domain to a VNI.

```
device(config-overlay-gw-gateway1)# map bridge-domain 1 vni 999
```

- Create a remote Layer 2 extension site in a VXLAN overlay gateway and access site configuration mode.

```
device(config-overlay-gw-gateway1)# site bd1
```

- Specify the destination IPv4 address of a tunnel.

```
device(config-site-bd1)# ip address 10.67.67.1
```

- Configure a bridge domain for the tunnel to the site.

```
device(config-site-bd1)# extend bridge-domain add 1
```

- Exit site configuration mode.

```
device(config-site-bd1)# exit
```

- Activate the gateway.

```
device(config-overlay-gateway-gateway1)# activate
```

The following summarizes the configuration example.

```
device# configure terminal
device(config)# overlay-gateway gateway1
device(config-overlay-gw-gateway1)# type layer2-extension
device(config-overlay-gw-gateway1)# ip interface loopback 1
device(config-overlay-gw-gateway1)# map bridge-domain 1 vni 999
device(config-overlay-gw-gateway1)# site bd1
device(config-site-bd1)# ip address 10.67.67.1
device(config-site-bd1)# extend bridge-domain add 1
device(config-site-bd1)# exit
device(config-overlay-gateway-gateway1)# activate
```

## VXLAN Layer 2 gateway payload tag processing

An SLX-OS device provides the following modes for the processing of the payload tag that is received on the attachment-circuit packets:

- VXLAN RFC-compliant mode
- Enhanced payload tag transport mode

### *VXLAN RFC-compliant mode*

In RFC-compliant mode, the VLAN tag in a packet is not carried in the packet and must be stripped at the ingress device before the VXLAN encapsulated packet is sent into the network.

To configure RFC-compliant mode, configure the bridge domain in raw mode as shown in the following example.

```
pw-profile test
vc-mode raw

bridge-domain 10 p2mp
pw-profile test
```

Then extend the bridge domain in the overlay gateway, as shown in the following example.

```
overlay-gateway gateway1
type layer2-extension
ip interface loopback 1
map bridge-domain 10 vni 999
site vcs1
ip address 10.67.67.1
extend bridge-domain add 10
```

#### NOTE

An SLX-OS device supports RFC-compliant mode with the bridge domain-based VXLAN service only.

## Enhanced payload tag transport mode

In enhanced payload tag transport mode, one VLAN tag from the traffic is carried as part of the VXLAN encapsulated packet as an inner payload tag. This tag can carry the PCP value to include the priority information and also can interoperate with other devices. This tag is removed in the remote device capable of this behavior.

#### NOTE

This mode does not interoperate with RFC-compliant mode.

This mode is supported for VLAN-based VXLAN service and bridge domain-based VXLAN service with tag mode.

To configure enhanced payload tag transport mode, configure the bridge domain in tagging mode as shown in the following example.

```
pw-profile test
vc-mode tag

bridge-domain 10 p2mp
pw-profile test
```

Then extend the bridge domain in the overlay gateway, as shown in the following example.

```
overlay-gateway gateway1
type layer2-extension
ip interface Loopback 1
map bridge-domain 10 vni 999
site vcs1
ip address 10.67.67.1
extend bridge-domain add 10
```

# VXLAN Layer 2 support for LVTEP

This section details support for a logical VXLAN tunnel end point (LVTEP) at Layer 2.

## LVTEP control plane

In a BGP EVPN deployment, each node in an LVTEP pair is an independent BGP speaker.

The BGP session between the cluster peers must be configured with an encapsulation of MPLS. The BGP session with the remote peers must be configured with an encapsulation of VXLAN.

The LVTEP control plane uses MCT Control Plane Designated Forwarder Election among the cluster peers. BGP VXLAN tunnels that are discovered automatically are treated as cluster client end points (CCEPs).

The following table shows Ethernet Segment Identifier (ESI) values for the VXLAN tunnels.

**TABLE 16** ESI values for VXLAN tunnels

| Parameter                    | Value   |
|------------------------------|---------|
| ESI type                     | 0       |
| Destination IP address (DIP) | 4 bytes |
| Source IP address (SIP)      | 4 bytes |

The ESI label is allocated globally for the LVTEP and is the same for all LVTEP tunnels. The tunnel operational status that is used for LVTEP tunnels is the same as that used for cluster clients.

For BGP EVPN deployment, MAC addresses that are learned on the LVTEP VXLAN tunnels are not synchronized between the cluster peers. However, for static LVTEP, the data-plane MAC addresses that are learned on the CCEPs of the LVTEP tunnel are synchronized between the cluster peers.

#### NOTE

LVTEP is supported only with the TCAM profile VxlanExtended, as configured by the **profile tcam vxlan-ext** command in hardware configuration mode. It is not supported in other TCAM profiles.

All the **show** commands that apply to MCT clients also apply to tunnel cluster clients.

## LVTEP data plane

This section presents the details of the LVTEP data plane, including a basic topology, packet formats, and support for various deployment scenarios.

### Example topology

The following figure illustrates a basic LVTEP topology for the data plane, with cluster nodes supporting remote peers and client end points (CEPs) and cluster client end points (CCEPs).

FIGURE 6 LVTEP topology

Packet formats

The following tables describe the supporting packet formats.

TABLE 17 VXLAN encapsulation

|                  |                 |            |              |                   |
|------------------|-----------------|------------|--------------|-------------------|
| Outer MAC header | Outer IP header | UDP header | VXLAN header | Original L2 frame |
|------------------|-----------------|------------|--------------|-------------------|

The preceding packet format is used between the remote peers for both unicast and BUM traffic.

TABLE 18 Pseudowire emulation (PWE) Multi-Chassis Trunk (MCT) unicast encapsulation

|                  |                   |                    |                   |
|------------------|-------------------|--------------------|-------------------|
| Outer MAC header | MPLS tunnel label | EVPN unicast label | Original L2 frame |
|------------------|-------------------|--------------------|-------------------|

The preceding packet format is used between the cluster peers for unicast traffic.

TABLE 19 PWE MCT multicast encapsulation without ESI label

|                  |                   |                      |                   |
|------------------|-------------------|----------------------|-------------------|
| Outer MAC header | MPLS tunnel label | EVPN multicast label | Original L2 frame |
|------------------|-------------------|----------------------|-------------------|

The above packet format is used between the cluster peers for BUM traffic when the traffic is received on the CEP interface.

TABLE 20 PWE MCT multicast encapsulation with ESI label

|                  |                   |                      |           |                   |
|------------------|-------------------|----------------------|-----------|-------------------|
| Outer MAC header | MPLS tunnel label | EVPN multicast label | ESI label | Original L2 frame |
|------------------|-------------------|----------------------|-----------|-------------------|

The above packet format is used between the cluster peers for BUM traffic when the traffic is received on the CCEP Interface. This applies to both the Layer 2 CCEP interface or the tunnel CCEP interface. The ESI label distinguishes whether the interface is a Layer 2 CCEP interface or a tunnel CCEP interface.

#### NOTE

For PWE (unicast/multicast) encapsulation, the MPLS tunnel label is present if and only if the peers are not directly connected over an ICL link and there is an MPLS transit router between them. For directly connected ICL peers, there is only the EVPN unicast/multicast encapsulation, with or without an ESI label, and there is no MPLS tunnel label.

### *Dynamic cluster configuration support*

When the cluster is dynamically changed from "Deploy" to "No Deploy" and conversely, the LVTEP tunnel CCEP is accordingly converted to a single VTEP and conversely.

When one or both cluster nodes are configured with "No Deploy" of the cluster configuration, the traffic behavior becomes undeterministic. Recovery scenarios are presented here.

#### **Deploy to No Deploy**

Do the following to recover from this error scenario:

1. Deactivate the overlay gateway on both cluster nodes.
2. Undeploy (or remove) the cluster configuration on both the cluster nodes.
3. Change the loopback address on both the cluster nodes to be different from the LVTEP loopback address.
4. Activate the overlay gateway on both the cluster nodes.

#### **No Deploy to Deploy**

Do the following to recover from this error scenario:

1. Deactivate the overlay gateway on both the cluster nodes.
2. Change the loopback address on both the cluster nodes to a common LVTEP loopback address that is different from the previous loopback address.
3. Deploy (or configure) a cluster on both the cluster nodes.
4. Activate the overlay gateway on both the cluster nodes.

### *Deployment scenario 1: BGP session and tunnel down, remote peers*

For a BGP EVPN deployment, the MAC addresses learned on the LVTEP tunnel CCEP are flushed. Traffic destined to a remote VXLAN tunnel, although the tunnel may be up on the cluster node, is still flooded on the corresponding VLAN/BD. This behavior differs from that for the Layer 2 CCEP, where traffic is forwarded to the cluster node with the PWE unicast label. The primary reason for this behavior is that the MAC addresses are not synced between the cluster nodes (they are learned on the LVTEP tunnel CCEP).

For the static LVTEP, the behavior is the same as that for the Layer 2 CCEP, where the MAC addresses are synced between the cluster peers. When a BGP session or tunnel down event occurs, the MAC addresses point to the corresponding MCT EVPN PWE and are forwarded to the cluster peer; they are not flooded on the corresponding VLAN/BD.

### *Deployment scenario 2: BGP session and PW down, cluster peers*

The client isolation mode should be configured as loose on both the cluster nodes. This ensures that when the ICL link goes down, the traffic comes from the remote peer.

**NOTE**

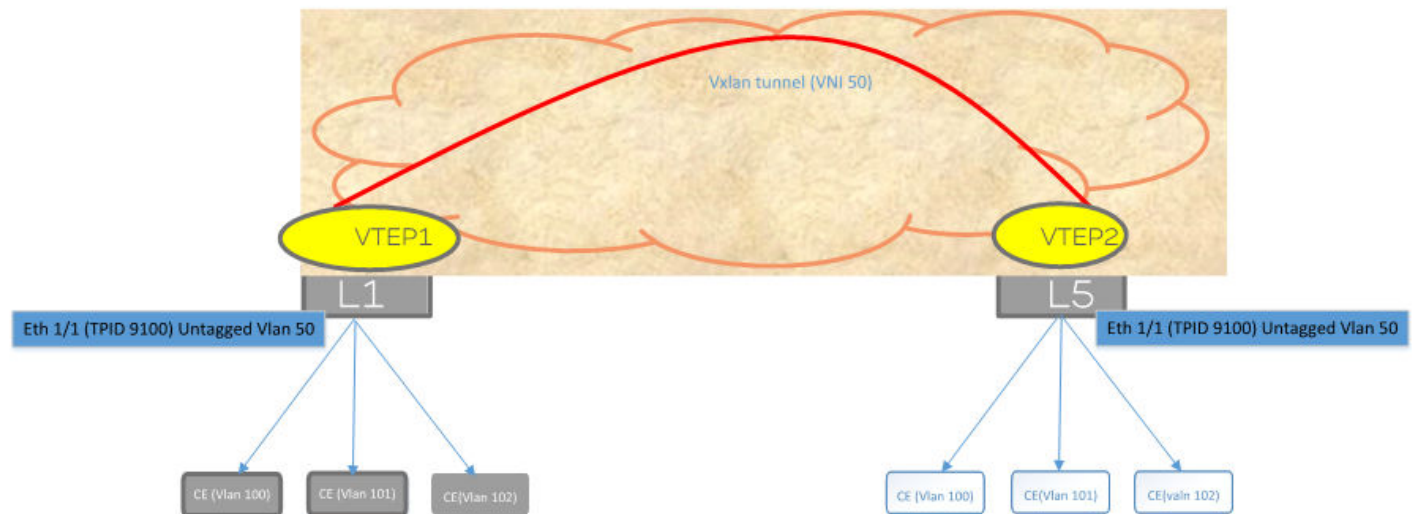

This behavior differs from that for a Layer 2 CCEP and EVPN MPLS, where the nodes operate in loose/strict mode when the ICL link goes down.

## Port-based VLAN bundle service

Multiple customer VLANs can be bundled in a single EVI instance.

The attachment circuit (AC) port is configured with a tag protocol identifier (TPID) that is different from that of the incoming traffic; the port is also configured with an untagged VLAN. All the traffic coming in on this port is treated as untagged traffic. The following figure illustrates this topology.

**FIGURE 7** Port-based VLAN bundle service

The untagged VLAN configured on the AC port is extended through the EVPN. All the traffic arriving on this untagged VLAN is bundled with a single Virtual Network Identifier (VNI). The MAC addresses are learned on the untagged VLAN that is configured on that port, irrespective of the VLAN tag of the incoming packet. As all the traffic on this port is mapped to a single flooding domain, MAC addresses on this VLAN must be unique.

The following example illustrates a configuration with a VLAN on an Ethernet port.

```
device(conf-if-eth-1/1) # switchport
device(conf-if-eth-1/1) # switchport mode access
device(conf-if-eth-1/1) # switchport access vlan 200
device(conf-if-eth-1/1) # tag-type 9100
```

The following example illustrates a configuration with a bridge domain (BD) logical interface (LIF) on an Ethernet port.

```
device(conf-if-eth-1/1) # switchport
device(conf-if-eth-1/1) # switchport mode trunk-no-default-native
device(conf-if-eth-1/1) # logical-interface ethernet 1/1.1 untagged vlan 200
device(conf-if-eth-1/1) # tag-type 9100
```

## Configuring VXLAN LVTEP support

This task configures VXLAN LVTEP support, which includes TCAM profile, loopback, VLAN, Ethernet, and bridge domain (BD), overlay gateway, and MCT cluster configurations.

Configure the appropriate TCAM profile for this feature. Refer to [Configuring TCAM profiles to support LVTEP](#) on page 78.

1. Configure multiple loopback interfaces to support BGP neighbor address-family and the LVTEP IP address.

- a) Enter global configuration mode.

```
device# configure terminal
```

- b) In global configuration mode, specify a loopback port number.

```
device(config)# interface loopback 1
```

- c) Configure a loopback interface with OSPF area 0 and an IP address, and enable the interface to support BGP neighbor address-family.

```
device(config-Loopback-1)# ip ospf area 0
device(config-Loopback-1)# ip address 6.6.100.6/32
device(config-Loopback-1)# no shutdown
```

- d) Configure a second loopback interface to support the LVTEP IP address.

```
interface Loopback 2
ip ospf area 0
ip address 6.7.100.67/32
no shutdown
```

The same address is used for both nodes in the cluster.

2. In global configuration mode, create two VLANs to support a pair of logical interfaces (LIFs) and BDs.

```
device(config)# vlan 11-12
```

## 3. Configure the LIFs and BDs.

- a) Specify an Ethernet interface.

```
device(config)# interface ethernet 0/5
```

- b) Configure the parent interface as switchport.

```
device(conf-if-eth-0/5)# switchport
```

- c) Specify trunk mode.

```
device(conf-if-eth-0/5)# switchport mode trunk
```

- d) Enable the interface.

```
device(conf-if-eth-0/5)# no shutdown
```

- e) Specify a service instance and enter LIF configuration mode.

```
device(conf-if-eth-0/5)# logical-interface ethernet 0/5.1
```

- f) Specify an interface and create a dual-tagged (inner VLAN) VLAN.

```
device(conf-if-eth-lif-0/5.1)# vlan 10 inner-vlan 1
```

The VLAN in the LIF configuration is for VLAN tag classification. This example shows a dual-tagged LIF being configured. The expected packet that enters through this port must be dual-tagged, without VLAN 10 and the inner VLAN 1, in order to be classified as a packet received for this LIF.

- g) (Optional) By default, the administrative state of the LIF is "no shutdown." To remove the port from participating in any data traffic without having to shut down the physical interface, enter the
- no**
- form of the
- shutdown (LIF)**
- command.

```
device(conf-if-eth-lif-0/5.1)# no shutdown
```

- h) Repeat Step 3e through Step 3g for the second logical interface, and specify a second inner VLAN.

```
logical-interface ethernet 0/5.2
  vlan 10 inner-vlan 2
```

#### 4. Create and configure a BD.

##### a) Create BD 1.

```
device(config)# bridge-domain 1 p2mp
```

By default, the bridge-domain service type is point-to-multipoint (**p2mp**).

##### b) Bind the logical interfaces for attachment circuit (AC) endpoints to the BD.

```
device(config-bridge-domain-1)# logical-interface ethernet 0/5.1
```

Logical interfaces representing BD endpoints must be created before they can be bound to a BD. For further information, refer to *Logical Interfaces*.

##### c) Ensure that local switching is enabled for BD 1.

```
device(config-bridge-domain-1)# local-switching
```

Local switching is enabled by default.

##### d) Enable the dropping of Layer 2 bridge protocol data units (BPDUs) for BD 1.

```
device(config-bridge-domain-1)# bpdu-drop-enable
```

A default pseudowire (PW) profile is automatically configured, with the following defaults:

```
Vc_mode = RAW Mode
mtu = 1500
mtu_enforce = NO
pw_profile_control_word = 0
pw_profile_flow_label = 0
```

##### e) Repeat the above BD configuration for the second BD, as in the following example.

```
bridge-domain 2 p2mp
 logical-interface ethernet 0/5.2
 pw-profile default
 bpdu-drop-enable
 local-switching
```

#### 5. Configure an overlay gateway.

##### a) In global configuration mode, specify a gateway.

```
device(config)# overlay-gateway gw1
```

##### b) Specify the type as Layer 2 extension.

```
device(config-overlay-gw-gw1)# type layer-2-extension
```

##### c) Specify the LVTEP loopback interface.

```
device(config-overlay-gw-gw1)# ip interface loopback 2
```

##### d) Configure the automatic mapping of VLANs/BDs to Virtual Network Identifiers (VNIs).

```
device(config-overlay-gw-gw1)# map vni auto
```

##### e) Activate the gateway.

```
device(config-overlay-gw-gw1)# activate
```

6. In global configuration mode, enable EVPN configuration mode and configure the EVPN instance.

- a) Enter default EVPN configuration mode.

```
device(config)# evpn
```

Default mode is the only available mode.

- b) Enable the auto-generation of the import and export route-target community attributes for the default EVPN instance.

```
device(config-evpn-default)# route-target both auto
```

- c) Enable the auto-generation of a route distinguisher (RD) for the default EVPN instance.

```
device(config-evpn-default)# rd auto
```

- d) Add the BDs to the default EVPN instance.

```
device(config-evpn-default)# bridge-domain add 1-2
```

- e) Add the VLANs to the default EVPN instance.

```
device(config-evpn-default)# vlan add 11-12
```

7. Configure the cluster.

- a) In global configuration mode, specify an MCT cluster name and cluster ID (in this example, "c1" and "1", respectively) to enable cluster configuration mode.

```
device(config)# cluster c1 1
```

- b) Ensure that client-isolation loose mode is enabled.

```
device(config-cluster-1)# client-isolation-loose
```

By default, the node with the lower peer IP address is set to the client-isolation mode of loose. Note that loose mode is recommended for LVTEP. This mode ensures that both cluster nodes forward traffic received from the remote peer when the ICL link is down. Without this default configuration, one node becomes loose and one becomes strict (as a result of the peer IP address configuration). The node that becomes strict is not able to forward traffic to the CCEP, because the CCEP links are shut down.

- c) Specify a virtual Ethernet (VE) interface through which to reach the MCT cluster peer.

```
device(config-cluster-1)# peer-interface ve 2
```

- d) Specify the IP address of the MCT cluster peer.

```
device(config-cluster-1)# peer 7.7.100.7
```

- e) Deploy the cluster.

```
device(config-cluster-1)# deploy
```

- f) Exit to Privileged EXEC mode.

8. In Privileged EXEC mode, enter the **cluster management** command and specify a cluster.

```
device# cluster management 2
```

The cluster ID for each node in the cluster must be unique.

9. Configure BGP routing with neighbor and address-family attributes.

- a) In global configuration mode, enable BGP routing and enter BGP router configuration mode.

```
device(config)# router bgp
```

- b) Specify the autonomous system number (ASN) for the AS in which the remote neighbor resides.

```
device(config-bgp-router)# neighbor 7.7.100.7 remote-as 100
```

- c) Configure the BGP device to communicate with a neighbor through a specified interface, in this case loopback 1.

```
device(config-bgp-router)# neighbor 7.7.100.7 update-source loopback 1
```

- d) Repeat the above two substeps for the other peer address, as in the following example.

```
neighbor 8.8.100.8 remote-as 100
neighbor 8.8.100.8 update-source loopback 1
```

- e) Enable IPv4 and IPv6 unicast address-family.

```
device(config-bgp-router)# address-family ipv4 unicast
device(config-bgp-router)# address-family ipv6 unicast
```

10. Enable the L2VPN address-family configuration mode to configure a variety of BGP EVPN options.

- a) Enable L2VPN address-family configuration mode and enter BGP EVPN configuration mode.

```
device(config-bgp-router)# address-family l2vpn evpn
```

- b) Specify VXLAN encapsulation for the first peer.

```
device(config-bgp-evpn)# neighbor 8.8.100.8 encapsulation vxlan
```

- c) Enable the exchange of information with BGP neighbors and peer groups.

```
device(config-bgp-evpn)# neighbor 8.8.100.8 activate
```

- d) Repeat the above two substeps for the other peer. Then, activate the EVPN peer, as in the following example.

```
neighbor 7.7.100.7 activate
```

11. Repeat the above steps for the other node in the cluster, with modifications as appropriate.

## LVTEP support for other features

This section details how LVTEP supports other features.

### AC LIF

AC LIFs of type untagged, single tagged, and double tagged are supported.

### Layer 2 ACLs

Layer 2 end points (leaf) support Layer 2 ACLs.

## Rate limiting

Layer 2 end points (leaf) do not support rate limiting.

## QoS

QoS behavior is similar to that for a single VTEP gateway. Details are listed in the following tables for DiffServ tunneling uniform and pipe modes in an overlay network.

**TABLE 21** QoS behavior for DiffServ tunneling uniform mode

| Traffic type               | VXLAN origination   | VXLAN tunnel termination   |
|----------------------------|---|--|
| VLAN cases (untagged)      | DSCP 0 and TTL 255 are sent on the tunnel header.   | NA   |
| VLAN cases (tagged)        | Priority Code Point (PCP) is mapped to IP DCSP of VXLAN tunnel and TTL is set to 255.                 | DSCP is remapped to PCP of L2 traffic.   |
| BD (raw, single tagged)    | PCP of VLAN is mapped to DSCP and TTL is set to 255.  | DCSP is remapped to PCP of VLAN.   |
| BD (raw, double tagged)    | PCP of outer VLAN is mapped to DSCP and TTL is set to 255.  | DCSP is remapped to PCP of both inner and outer VLAN. Original PCP inner VLAN is not retained. |
| BD (raw, untagged)         | DSCP 0 and TTL 255 are sent on the tunnel header  | NA   |
| BD (tagged, single tagged) | PCP is mapped to DSCP and TTL is set to 255   | DSCP is remapped to PCP of L2 traffic.   |
| BD (tagged, double tagged) | Outer VLAN PCP is mapped to DSCP and TTL is 255 Inner VLAN header is carried with original PCP.       | DSCP is remapped to PCP of outer VLAN and Inner VLAN of L2 traffic.                            |
| BD (tagged, untagged)      | DSCP 0 and TTL 255 are sent on the tunnel header. Dummy VLAN is added: VLAN ID is BD ID and PCP is 0. | NA   |

**TABLE 22** QoS behavior for DiffServ tunneling pipe mode

| Traffic type               | VXLAN origination   | VXLAN tunnel termination  |
|----------------------------|---|---|
| VLAN cases (untagged)      | DSCP 0 and TTL 255 are sent on the tunnel header.   | NA  |
| VLAN cases (tagged)        | DSCP 0 and TTL 255 are sent on the tunnel header.   | PCP value is set to 0 as inner VLAN is not carried.                               |
| BD (raw, single tagged)    | DSCP 0 and TTL 255 are sent on the tunnel header.   | PCP value is set to 0 as inner VLAN is not carried.                               |
| BD (raw, double tagged)    | DSCP 0 and TTL 255 are sent on the tunnel header.   | PCP value is set to 0 as inner VLAN is not carried. PCP is cleared for both tags. |
| BD (raw, untagged)         | DSCP 0 and TTL 255 are sent on the tunnel header.   | NA  |
| BD (tagged, single tagged) | DSCP 0 and TTL 255 are sent on the tunnel header. VLAN is carried and PCP is carried.                 | PCP value is set to zero.   |
| BD (tagged, double tagged) | DSCP 0 and TTL 255 are sent on the tunnel header. Inner VLAN is carried and PCP is carried.           | PCP value is set to zero.   |
| BD (tagged, untagged)      | DSCP 0 and TTL 255 are sent on the tunnel header. Dummy VLAN is added: VLAN ID is BD ID and PCP is 0. | NA  |

## MTU

MTU behavior is similar to that for a single VTEP gateway.

## Inner packet tag behavior

Inner packet tag behavior is similar to that for a single VTEP gateway.

The following table summarizes this behavior for VLANs and BDs.

**TABLE 23** Inner packet tag behavior for VLANs and BDs

| VLAN/BD Configuration | Inner packet tag behavior        | Remarks   |
|-----------------------|----------------------------------|---|
| VLAN                  | Inner packet is always untagged. |   |
| BD raw mode           | Inner packet is always untagged. | This is RFC-compliant behavior.   |
| BD tagged mode        | Inner packet is always tagged.   | This mode can be used if a tag must always be sent in the inner packet. |

## Statistics

The LVTEP tunnel CCEP supports statistics. For BUM traffic, although the traffic is suppressed (through split horizon), it is still accounted for as part of the statistics. This behavior is the same as existing single VTEP behavior.

## Nondefault TPID

The Tag Protocol Identifier (TPID) is a 16-bit field that identifies the frame as an IEEE 802.1Q-tagged frame. The TPID is set to the default value of 0x8100, but the user can change this value.

The TPID field is located at the same position as the EtherType/length field in untagged frames, and is thus used to distinguish the frame from untagged frames. If you require support for dual tagging or provider backbone bridge (PBB), the outer TPID of the packet must be configured to a value different from the default.

The raw pass-through support for an untagged LIF requires you to configure the interface TPID to a value that allows it to treat all traffic received on that port as untagged. You can configure the TPID on port and LAG interfaces.

### ATTENTION

When the tag type is changed on interface, the interface is brought down first, causing all learned MAC addresses to be flushed.

High availability (HA) MM failover supports the TPID feature. The TPID configuration is automatically synchronized to the standby module if a standby MM is installed on an SLX-OS device.

## Hardware limitations

The TPID feature has the following limitations:

- **Tagging:** The TPID configuration is supported for an outer tag. If dual-tagging needs to be supported on the interface, the inner tag must be 0x8100.
- **TPID:** Up to four TPIDs are supported system-wide. One is used by default (TPID = 0x8100) and cannot be changed.
- **LSP FRR:** Hardware support for LSP FRR is available only for TPID 0x8100. If you require a label switched path with fast reroute (LSP FRR) configuration, note that none of the routable interfaces (whether a router port or a LIF of a VE) can have any nondefault TPID configuration, because FRR always assumes that the link layer has the default TPID of 0x8100.

- **OpenFlow:** If OpenFlow is enabled while the default TCAM profile is used, then no TPID can be configured. This restriction is also enforced in the opposite direction; if any port has TPID configured, then OpenFlow cannot be enabled while the default profile is used.

**NOTE**

The LSP FRR limitation is for any tag-type configured in the device. You can configure either FRR or tag-type on any interface in the device, as in the following example.

```
device(config-router-mpls-lsp-to-avalanche-1)# frr
%Error: Not allowed, when a non-default TPID (tag-type) is configured on any port-channel or physical
interfaces.
device(config-router-mpls-lsp-to-avalanche-1)#
```

## Configuring a nondefault TPID

Perform the following steps to configure a nondefault TPID. The interface can be a port or a port-channel (LAG).

1. Do the following to configure a nondefault TPID on an Ethernet interface.

- a) Enter global configuration mode.

```
device# configuration terminal
```

- b) Enter interface configuration mode and specify an Ethernet interface.

```
device(config)# interface ethernet 1/1
```

- c) Use the **tag-type** command to configure the TPID.

```
device(config-if-eth-1/1)# tag-type 0x9100
```

By default, all interfaces in the system have default TPID value of 0x8100.

- d) Enter the **show interface ethernet** command to confirm the configuration.

```
device# show interface ethernet 1/1
Ethernet 1/1 is up, line protocol is up (connected)
Hardware is Ethernet, address is 609c.9f5f.5005
  Current address is 609c.9f5f.5005
Pluggable media present
Interface index (ifindex) is 203431936
MTU 1548 bytes
10G Interface
LineSpeed Actual      : 1000 Mbit
LineSpeed Configured : Auto, Duplex: Full
Tag-type: 0x9100
Priority Tag disable
Forward LACP PDU: Disable
Route Only: Disabled
Last clearing of show interface counters: 23:12:47
Queueing strategy: fifo
Receive Statistics:
  0 packets, 0 bytes
  Unicasts: 0, Multicasts: 0, Broadcasts: 0
  64-byte pkts: 0, Over 64-byte pkts: 0, Over 127-byte pkts: 0
  Over 255-byte pkts: 0, Over 511-byte pkts: 0, Over 1023-byte pkts: 0
  Over 1518-byte pkts(Jumbo): 0
  Runt: 0, Jabbers: 0, CRC: 0, Overruns: 0
  Errors: 0, Discards: 0
Transmit Statistics:
  0 packets, 0 bytes
  Unicasts: 0, Multicasts: 0, Broadcasts: 0
  Underruns: 0
  Errors: 0, Discards: 0
Rate info:
  Input 0.000000 Mbits/sec, 0 packets/sec, 0.00% of line-rate
  Output 0.000000 Mbits/sec, 0 packets/sec, 0.00% of line-rate
Route-Only Packets Dropped: 0
Time since last interface status change: 23:12:45
```

- e) To revert to the default TPID value, enter the **no tag-type** command.

```
device(config-if-eth-1/1)# no tag-type
```

You can achieve the same result by configuring a tag-type of 0x8100.

2. Do the following to configure a nondefault TPID on a port-channel interface.

- a) Enter global configuration mode.

```
device# configuration terminal
```

- b) Enter interface configuration mode and specify a port-channel interface.

```
device(config)# interface port-channel 20
```

- c) Use the **tag-type** command to configure the TPID.

```
device(config-Port-channel-20)# tag-type 0x88a8
```

By default, all interfaces in the system have default TPID value of 0x8100.

- d) Enter the **show interface port-channel** command to confirm the configuration.

```
device# show interface port-channel 20
Port-channel 20 is up, line protocol is up
Hardware is AGGREGATE, address is 609c.9f5c.ac07
Current address is 609c.9f5c.ac07
Interface index (ifindex) is 671088660 (0x28000014)
Minimum number of links to bring Port-channel up is 1
MTU 1548 bytes
LineSpeed Actual      : 300000 Mbit
Allowed Member Speed  : 100000 Mbit

Route-Only Packets Dropped: 0
Time since last interface status change: 1d23h59m
```

## Configuring TCAM profiles to support LVTEP

LVTEP configurations require a hardware TCAM profile that supports VXLAN, as illustrated in this task.

### ATTENTION

This profile must be applied to all LVTEP configurations in this chapter.

1. Enter global configuration mode and enter the **hardware** command.

```
device# configure terminal
device(config)# hardware
```

2. In hardware configuration mode, enter the **profile tcam** command and specify **vxlan-ext**.

```
device(config-hardware)# profile tcam vxlan-ext
```

3. Save the running configuration to the startup configuration.

```
device# copy running-config startup config
```

4. Reboot the device.

## LVTEP show commands

The following **show** commands are helpful in diagnosing a variety of LVTEP configurations.

### Cluster show commands

#### *show cluster*

```
device# show cluster 1
Cluster c1 1
=====
Cluster State: Deployed
Client Isolation Mode: Loose
DF Hold Time: 3
Configured Member Vlan Range: 11-12
Active Member Vlan Range: 11-12
Configured Member BD Range: 1-2
Active Member BD Range: 1-2
No. of Peers: 1
No. of Clients: 1

Peer Info:
=====
Peer IP: 7.7.100.7, State: Up
Peer Interface: Ethernet 0/50
ICL Tunnel Type: MPLS, State: Up

Client Info:
=====
Name          Id          ESI          Interface          Local/Remote State
-----
tu61441       513         0:0:8:8:64:8:6:7:64:43  Tunnel 61441      Up / Up
```

#### *show cluster client*

```
device# show cluster 1 client 513
Client Info:
=====
Client: tu61441, client-id: 513, Deployed, State: Up
Interface: Tunnel 61441
Vlans: 11-12
Bridge Domains: 1-2
Number of DF Vlans : 0
Elected DF for vlans :
Number of DF Bridge Domains : 0
Elected DF for Bridge Domains :
```

## MCT show commands

### show cluster management

```
device# show cluster management
```

```
Total Number of Nodes in Cluster : 2
```

| Node-Id | Switch MAC          | IP Address | Status       |
|---------|---------------------|------------|--------------|
| 1       | 60:9C:9F:5A:44:14   | 4.4.100.4  | Connected    |
| 2       | >60:9C:9F:5A:00:14* | 5.5.100.5  | Co-ordinator |

Please note that 5.5.100.5 (Node-id 2) is this node, 4.4.100.4 (Node-id 1) is remote node

## BGP show commands

### show bgp evpn routes type ethernet-segment detail

```
device# show bgp evpn routes type ethernet-segment detail
```

```
Total number of BGP EVPN Ethernet Segment Routes : 2
```

```

# QoS for VXLAN Layer 2 gateways

SLX-OS VXLAN Layer 2 gateways can support QoS.

A VXLAN L2 gateway can interconnect tenants in the same subnet through the VXLAN configuration. The following figure illustrates a simple use case where a packet is sent from VM1. If it is a BUM packet, Leaf-A floods through the packet to all the VTEPs in the same VXLAN segment, until the MAC table at Leaf-A is populated with corresponding entries through mechanisms such as EVPN. Meanwhile, the known unicast packet is forwarded in unicast mode to the corresponding VTEP only. At Leaf-A, the Traffic Class/802.1p marking of the tenant frame determines the DSCP of the added IP header, and the IP header is followed by the VXLAN header. At terminating leaf nodes, the DSCP of the IP header is ignored and the Traffic Class/802.1p marking of the tenant frame is thereby exposed, and the original tenant frame is used to determine the QoS policy for switching the frame to the destination VM.

FIGURE 8 VXLAN L2 gateway interconnection of tenants in the same subnet

## Configuring QoS for VXLAN Layer 2 gateways

Enter the **qos-ttl-mode uniform** command to set the QoS type mode to uniform, which is the default, when configuring the VXLAN L2 gateway. For example, enter the following commands when configuring the gateway for the ingress (tunneling) side of packet forwarding:

```
device# configure terminal
device(config)# overlay-gateway gateway_L2
device(config-overlay-gw-gateway_L2)# type layer2-extension
device(config-overlay-gw-gateway_L2)# ip interface loopback 1
device(config-overlay-gw-gateway_L2)# qos-ttl-mode uniform
```

```
device(config-overlay-gw-gateway_L2)# map vni auto  
device(config-overlay-gw-gateway_L2)# activate
```

**NOTE**

For information about QoS configuration on VXLAN L3 gateways and on VLAN L2 and L3 gateway interconnections, refer to "QoS for VXLAN Layer 3 gateways" and "QoS for VXLAN Layer 2 and Layer 3 gateway interconnections".

## MCT Overview

Multi-Chassis Trunking (MCT) is trunking that initiates at a single MCT-unaware server or switch and terminates at two MCT-aware switches. MCT allows the links to the two MCT-aware switches to appear to a downstream device as if they are coming from a single device on a single Link Aggregation (LAG) trunk interface or physical port.

### NOTE

The SLX-OS device does not support Layer 2 protocols over MCT. You must provide a loop-free topology.

### NOTE

MCT does not support any variant of Spanning Tree Protocol (STP). STP is disabled by default and must not be enabled with MCT.

In a datacenter network environment, LAG trunks provide link level redundancy and increased capacity. However, they do not provide switch-level redundancy. If the switch connected to the LAG trunk fails, the entire trunk loses network connectivity.

With MCT, member links of the LAG trunk are connected to two MCT-aware devices. A configuration between the devices enable data flow and control messages between them to establish a logical Inter-Chassis Link (ICL). In this model, if one MCT device fails, a data path remains through the other device.

SLX-OS Layer 2 MCT is based on RFC 7432 (BGP Ethernet VPN). The MP-BGP EVPN extension is the control plane on the SLX-OS device to perform both MAC synchronization and cluster management. MAC synchronization between the MCT peers synchronizes the MAC tables between the MCT nodes for node resiliency and faster convergence.

For the data plane, the SLX-OS device supports the MPLS forwarding mechanism to leverage MPLS LER functionality.

SLX-OS MCT provides Layer 3 protocol support for IPv4 and IPv6 BGP, OSPF, and IS-IS through a VLAN or bridge domain VE interface. The VE over MCT interface MAC address is synchronized to the MCT peer through BGP by using an EVPN MAC route.

SLX-OS supports MCT over VPLS or VLL Layer 2 VPN services, Multicast, or IPv4 or IPv6 Virtual Routing Redundancy Protocol (VRRP) and VRRP Extended (VRRP-E). For more information on Multicast over MCT, see the *Extreme SLX-OS IP Multicast Configuration Guide*.

## MCT terminology

Before implementing MCT in your network, you must understand some key terms and definitions.

|  |   |
|--|---|
| <i>MCT peer devices</i>  | A pair of SLX-OS device configured as peers. The LAG interface is spread across two MCT peer devices and acts as the single logical endpoint to the MCT client.   |
| <p><b>NOTE</b><br/>MCT is supported across the same chassis type only; for example, SLX-9850 &lt;---&gt; SLX-9850.</p> |   |
| <i>MCT client</i>  | The MCT client is the device that connects with the MCT peer devices. It can be a switch or an endpoint server host in the single-level MCT topology or another pair of MCT switches in a multi-tier MCT topology.  |
| <i>MP-BGP EVPN extension</i>   | The control plane for Layer 2 MCT on the SLX-OS device.   |
| <i>MCT Cluster Client Edge Port (CCEP)</i>   | A port on one of the MCT peer devices that is a member of the LAG interface to the MCT client. To have a running MCT instance, at least one Link Aggregation Interface is needed with a member port on each peer device. While there is a LAG on the client device, CCEP on the MCT device can be a LAG or a physical port. |
| <i>MCT Cluster Edge Port (CEP)</i>   | A port on MCT peer device that a member of a MCT VLAN and is not a Cluster Client Edge Port.  |
| <i>MCT VLANs</i>   | VLANs on which MCT clients are operating. These VLANs are explicitly configured in the MCT configuration.   |

## SLX-OS MCT control plane

Multiprotocol-BGP (MP-BGP) EVPN extension, as specified in RFC 7432, is used as the SLX-OS MCT control plane.

The control plane consist of the following components:

- EVPN instance—Mapped to a Layer 2 VLAN that the RFC refers to the VLAN-Based service interface.
- Ethernet segment ID (ESI)—10-byte integer that uniquely identifies the set of links connecting MCT PEs to the client CE. SLX-OS MCT supports both dynamic and static LAG between MCT PE and CE and uses ESI type 0 that is encoded as follows:
  - 1-byte ESI type = 0
  - 9-byte ESI value = user input through the SLX-OS **esi** command

When the client interface is a port channel and LACP is running on the port channel, MCT supports an automatically generated ESI value, as defined in RFC 7432. This ESI is encoded as type 1, as follows:

- 1-byte ESI type = 1
- 9-byte ESI value = 6-byte LACP system MAC address of the client followed by the 2-byte LACP port key, and then a 1-byte 0x00
- MP-BGP route distinguisher (RD)—Encoded using RD type 1 as defined in RFC 4364 that consists of the following subfields:
  - 4-byte administrator subfield that is set with the 4-byte router ID
  - 2-byte assigned number subfield that is encoded with the all zeros for the Ethernet segment (ES) route, client ID for the Ethernet Auto-Discovery route, and EVPN ID (VLAN ID) for MAC and multicast routes.
- MP-BGP EVPN capability—When a BGP session is brought up to a MCT peer, BGP indicates to the peer that it is EVPN capable using BGP capability advertisement with the following information:
  - Capability code = 1 (MP-BGP)
  - AFI = 25 (L2VPN)
  - SAFI = 70 (EVPN)

If a BGP session already existed to the same peer, the existing BGP session is flapped to allow the advertisement of the EVPN capability.

- MP-BGP EVPN route types—Includes Ethernet Auto-Discovery (A-D), MAC/IP Advertisement, Inclusive Multicast Ethernet Tag, and Ethernet Segment routes.

- MPLS Label Assignment—Statically assigned label ranges for ESI label, EVPN unicast label and EVPN BUM label.
  - The ESI label is generated based on the start ESI label value plus the client ID.
  - EVPN unicast or BUM label is generated based on the start unicast or BUM label plus the VLAN ID.
- Designated forwarder—A PE in a set of multi-homing PEs connected to the same Ethernet segment that is elected for sending BUM traffic to a client for a VLAN ID on an Ethernet segment.

SLX-OS MCT operates in dual-homing mode.

## MP-BGP EVPN Routes

RFC 7432 defines EVPN Network Layer Reachability Information (NLRI) with the format as shown in the following figure:

FIGURE 9 EVPN NLRI format

|                                |
|--------------------------------|
| Route Type (1 octet)           |
| Length (1 octet)               |
| Route Type specific (variable) |

SLX-OS MCT supports the following route types.

TABLE 24 SLX-OS MCT route types

| Route type | Route name   | SLX-OS usage  |
|------------|--|---|
| 1          | Ethernet Auto-Discovery (for each Ethernet Segment only) | <p>Mass MAC address withdraw and Designated forwarder election.</p> <p>The PE can advertise multiple Ethernet A-D routes for each deployed client interface. Each A-D route has a maximum of 128 route targets (RTs).</p> <p>When the client interface goes down, the PE withdraws the Ethernet A-D route which is served as a trigger for the remote PE to remove all MAC addresses learned over the affected client interface instead of withdrawing an individual MAC address.</p>   |
| 2          | MAC/IP Advertisement                                     | <p>MAC synchronization of the MAC addresses between two MCT peers.</p> <p>Type 2 MAC/IP routes are also referred as ARP and Neighbor Discovery (ARP/ND) routes. ARP/ND addresses that are learned on the VLAN or bridge domain are automatically exported into BGP. Then BGP advertises the ARP routes to all of its EVPN peers. ARP/ND resolution is dependent on the MAC address. ARP/ND entries for Virtual IP and IP address configured on VE interfaces are automatically advertised.</p> <p>For more information on a Type 2 route, refer to <i>Extreme SLX-OS Layer 3 Routing Configuration Guide</i>.</p> |
| 3          | Inclusive Multicast Ethernet Tag                         | Advertisement of ingress replication usage and multicast label expected for each EVPN instance when receiving BUM traffic.  |
| 4          | Ethernet Segment (ES)                                    | <p>Designated forwarder election.</p> <p>The ES route is used to update the remote peer when the MCT client is deployed and undeployed.</p> <p>The ES route is used as an acknowledgment (ACK) mechanism to handle the client interface up scenario. The ACK ensures that the DF election does not occur on the node where the interface comes up until the A-D routes are processed by the remote peer.</p>  |

**TABLE 24** SLX-OS MCT route types (continued)

| Route type | Route name      | SLX-OS usage  |
|------------|-----------------|---|
| 5          | IP Prefix route | <p>This route is an extension to RFC 7432 described in the IETF draft, "draftietf-bess-evpn-prefix-advertisement." It is used to support advertisement of IP prefix routes. This route exchanges IPv4 and IPv6 routes in the overlay network. Prefix route exchange is supported over BGP-EVPN encapsulation and peering on the MPLS data plane.</p> <p>For more information on Type 5 route, refer to <i>Extreme SLX-OS Layer 3 Routing Configuration Guide</i>.</p> |

### Designated forwarder election

Designated forwarder election is triggered in the following scenarios:

- A client is deployed locally or remotely.
- BGP session comes up.
- CCEP goes up or down.

To elect a designated forwarder (DF) for a VLAN ID on an Ethernet segment, each PE exchanges its router IP address with its multi-homing PEs through the Ethernet Segment route. The following algorithm uses the IP address to select the DF.

1. Upon the discovery of a new ES, a PE advertises the ES route and waits a default of three seconds for its peer to advertise the ES route.
2. When the timer expires, the PE builds a sorted list of PE IP addresses including its own address connected to the same ES.
3. The PE with the ordinal number that equals  $(V \bmod N)$  is elected the DF. V is the VLAN ID and N is the number of PEs.
4. When the ES link fails, the PE withdraws its ES route which triggers the selection process to select a new DF. When a PE node failure occurs, DF election is also triggered when the PE is up and down.

#### NOTE

DF election is triggered only after the client is deployed on both MCT devices.

## SLX-OS MCT data plane traffic

For the discussion of the MCT data plane traffic, refer to the following topology diagram and configuration.

FIGURE 10 EVPN MPLS forwarding topology

- Cluster VLAN 1000 is configured on both PE1 and PE2.
- Cluster VLAN 1000 has client interface e1/1 and e1/2 that belong to ESI 100 and 200 respectively and a cluster end point on e1/3.
- PE1 is elected as Designated Forwarder (DF) for VLAN 1000 for both ESI 100 and 200.
- VLAN 1000 is mapped to VSI/EVPN instance 1000.

Unicast traffic sent between CE1 and CE\_A or CE\_B follows normal L2 forwarding.

### Forwarding unicast traffic between PEs

To send unicast traffic received over a CEP or CCEPs on PE1 to the remote PE2, PE1 pushes an previously-received PE2 EVPN label. The following figure shows the packet encapsulation.

**FIGURE 11** EVPN unicast forwarding between cluster PEs

For an SLX-OS device, it advertises one label for all the MACs learned within a bridge domain.

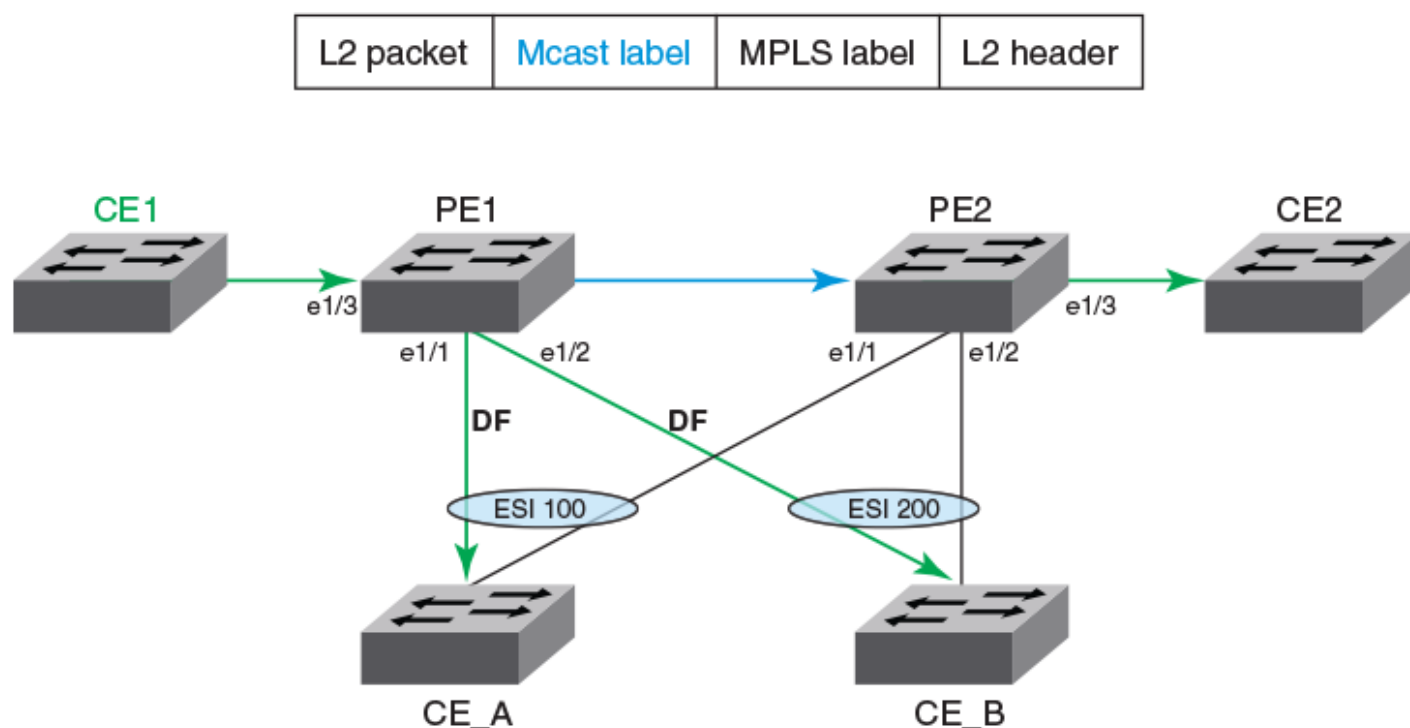

#### NOTE

This traffic forwarding is also applicable for MCT VPLS and MCT VLL. For MCT VLL, there are no CEP ports. There is no EVPN label. Only the MPLS label is involved for communication between cluster peers. For each bridge domain, the forwarding rules are defined based on the DF role.

### *Flooding traffic received from a CEP*

For unicast traffic received over a CEP that PE1 needs to flood on VLAN 1000, PE1 sends a copy to e1/1, e1/2, and to PE2. The copy sent on e1/1 and e1/2 has basic L2 encapsulation as in the case of a normal L2 VLAN. The copy sent to PE2 has a multicast label previously received from PE2 encapsulated as shown in the following figure.

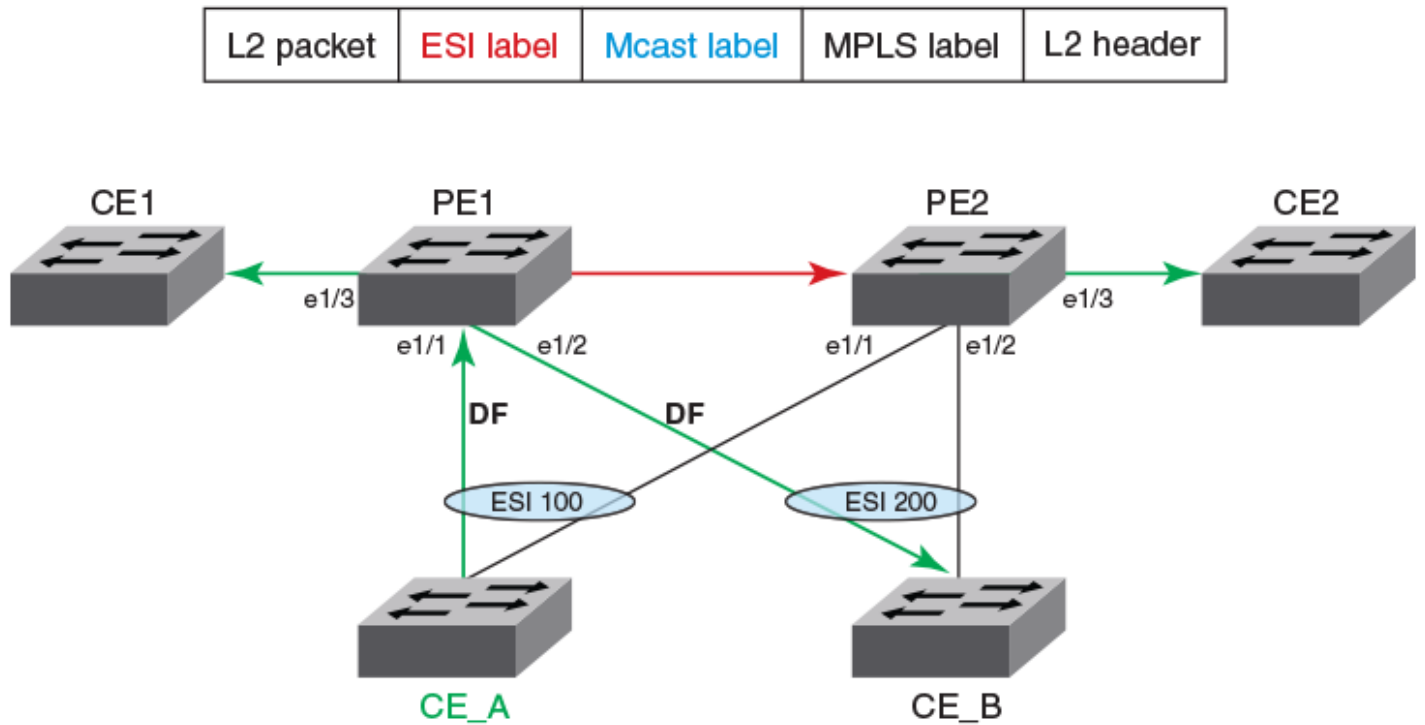

FIGURE 12 EVPN BUM forwarding between cluster PEs

For SLX-OS device, it advertises one multicast label for each EVPN instance.

### *Flooding traffic received from CCEP*

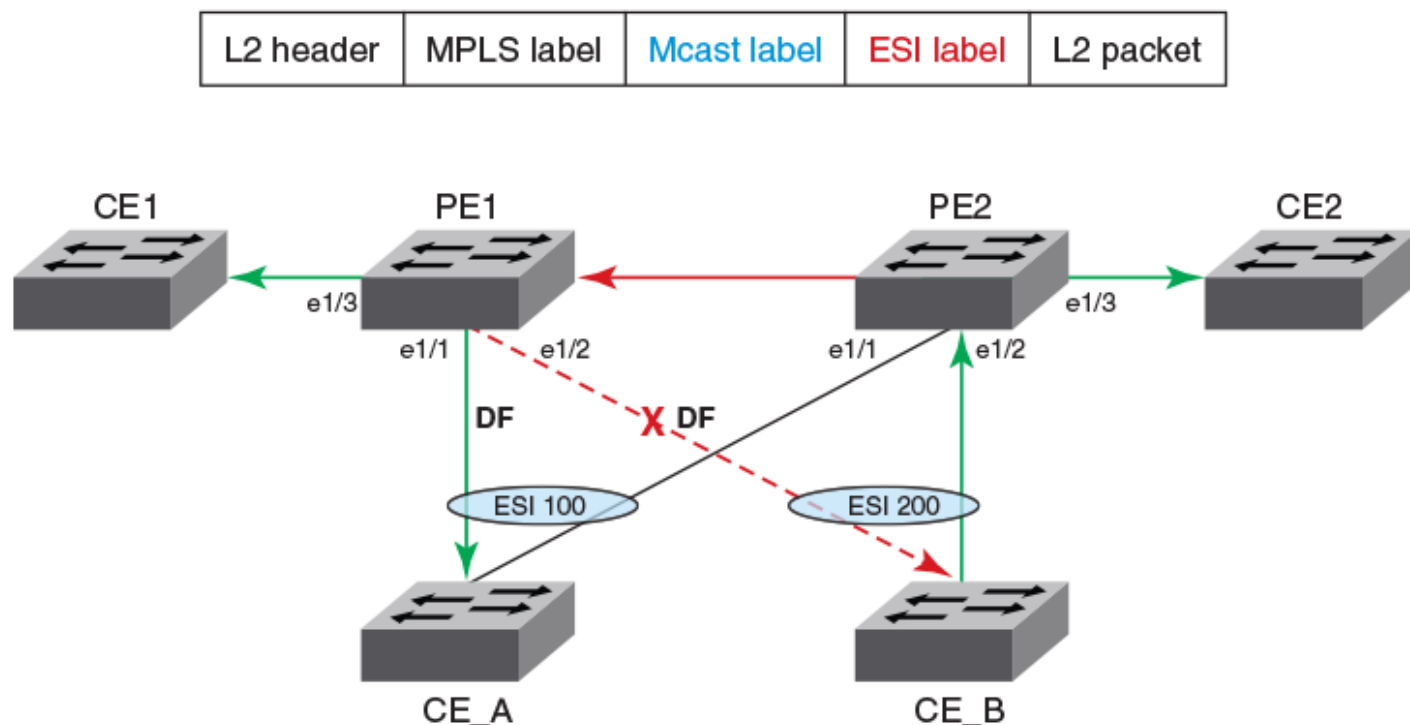

For traffic received over a CCEP from CE\_A on PE1 to be flooded to remote PE2, PE1 must push previously received multicast and ESI labels from PE2. The following figure shows the packet encapsulation.

**FIGURE 13** EVPN source port suppression based on DF election

Since source port suppression is based on the DF election result, PE2 suppresses copies to be sent to CE\_A and CE\_B because e1/1 and e1/2 are not elected as DF for ESI 100 and 200 respectively.

In the following figure, source port suppression is done based on the ESI label carried in the packet itself.

FIGURE 14 EVPN source port suppression based on the ESI label

For traffic received from CE\_B on PE2 that is flooded to PE1, PE1 sends a copy to CE1 and CE\_A on e1/1. However, it suppresses a copy to be sent to CE\_B. The suppression is done because the copy received from PE2 carried an ESI label that PE1 previously advertised to PE2 for ESI 200.

## MAC management

Each MAC entry maintains information about all the owners of the MAC entry who learned and advertised it. The information about each owner is maintained in the form of the MAC database (MDB).

A MDB entry contains peer and client information with the cost. A local MAC entry has cost 0 and MAC addresses learned from an MCT peer has a cost of 1. The MDB entry with the lowest cost is chosen as the filtering database (FDB).

In MCT topologies, MAC addresses can be learned either on local CCEP or CEP interfaces, or from the remote MCT node. If the same MAC is learned from both MCT nodes, then MAC entries learned locally have higher priority than the one learned from the remote peer.

For remote MAC addresses, aging is disabled, and they can only be deleted when delete notifications are received from the remote node that advertised it before for learning.

The following terminologies are associated with MCT MAC entries.

- Dynamic—MAC addresses learned locally as EVPN on CEP ports
- EVPN—MAC addresses learned on remote CEP ports
- Cluster Client Local (CCL)—MAC addresses learned locally on a client interface
- Cluster Client Remote (CCR)—MAC addresses learned on a remote client interface

## Static MAC handling

Configuration of static MAC entries is allowed over MCT enabled VLANs and CEP and CCEP interfaces.

The MCT static MAC addresses configured on a local node are advertised to remote MCT node for learning. While advertising the MAC using the BGP MAC advertisement route, it uses the MAC mobility extended-community route to identify the MAC as static using the sticky MAC field. On the remote node, when MAC advertisement is received for a static MAC address, the sticky MAC information is saved along with the MAC entry.

When an MCT static MAC address is deleted, a BGP MAC withdrawal route is sent to the remote peer to delete the MAC entry from its database.

When a CEP interface is down and if any static MAC entries are present, MAC Delete messages are sent to the remote node to flush the entries.

When a CCEP interface is down and if any static MAC entries are associated with the client, the MAC addresses are moved to point to the remote MCT peer. The MAC addresses are moved back to the CCEP when the interface comes back up.

On a local MCT node, when a cluster is UP and you configure a static MAC on a CEP or CCEP interface, the node synchronizes the MAC address to the remote MCT node. The remote node processes the MAC address and adds it to the FDB. On the remote MCT node, you can configure the same MAC as the static MAC address for the client 1 CCEP interface since it is configured on the same client CCEP interface. No additional static MAC configurations on the remote node are required since the same MAC are already part of the local MCT node.

When the cluster is down on the local and remote MCT nodes, both nodes are independent as clusters that can be independently configured with the static MAC addresses for the CEP or CCEP interface. However, when the cluster is brought up, the static MAC addresses are synchronized from both nodes and the addresses on the remote node are rejected since the local configuration takes precedence. The misconfiguration remains until you correct it.

## MAC learning

MAC learning over CEP interfaces is like basic Layer 2 learning and the EVPN MAC advertisement route is sent to the cluster peer to synchronize the learned MAC address. MAC learning over CCEP interfaces is two-step process in which the MAC entry is added into the MDB first. The best MAC entry is chosen and installed into the FDB and the EVPN MAC advertisement route is sent to the cluster peer for synchronization of the learned MAC address.

The following rules are used for MAC learning:

- If a static MAC address is configured on the CEP port, it is learned as the Static and the EVPN MAC advertisement route message is sent to the peer. In this case, the ESI is set to NULL. On the peer MCT node, the EVPN MAC address programmed on the cluster peer is static towards the MCT peer.
- If a static MAC address is configured on the CCEP port, an EVPN MAC advertisement route is sent to the peer. In this case, the MAC entry is associated with the ESI of the MCT client. The peer MCT node programs the MAC address as static over the local CCEP interface.
- Dynamic MAC learning from the CEP is similar to basic Layer 2 MAC learning. An EVPN MAC advertisement route is sent to the peer. In this case, the ESI is set to invalid or NULL. On the peer MCT node, the EVPN MAC address programmed on the cluster peer is static towards the MCT peer.
- Dynamic MAC learning from the CCEP occurs as a CCL MAC. An EVPN MAC advertisement route is sent to the peer. In this case, the MAC entry is associated with the ESI of the cluster client. The peer MCT node programs the MAC address as static over the local CCEP interface.

## MAC aging rules

The following rules are defined for MAC aging:

- The local MAC age over CEP interface is similar to the Layer 2 MAC age. After the local MAC delete, an EVPN MAC withdrawal route is sent to the MCT peer.
- The local MAC age over CCEP interface is considered aged only if all MCT nodes age out the entry. When the MAC that ages on one of the MCT node local MDB is deleted, if the remote MDB present MAC is reprogrammed as the CCR, else the MAC is removed from the local FDB, an EVPN MAC withdrawal route is sent to MCT peer.
- The remote MAC addresses of the EVPN and CCR that are learned through the EVPN MAC advertisement route does not age out. They can only be removed by the EVPN MAC withdraw messages from the peer.

## MAC movement

A MAC address is considered to be moved when the same MAC address is received on a different interface with same VLAN. In MCT, a MAC movement is allowed on both local and remote nodes.

The following table describes the allowed MAC movements in MCT.

**TABLE 25** MCT MAC movement

| MAC movement scenario  | Behavior   |
|--|--|
| Local dynamic MAC move from CEP1 to the CEP2 edge interface on MCT1.                                     | On local node MCT1, the MAC address is updated to point to the new CEP2 interface.<br>There is no MAC route update required to the remote MCT node. As on the remote node, the MAC always point towards the MCT peer for all EVPN MAC addresses.   |
| Local dynamic MAC move from CEP1 edge interface to the CCEP1 client interface on MCT1.                   | On local node MCT1, the MAC address is updated to point to the new client interface CCEP1.<br>A MAC update route is sent with the new ESI of client 1.<br>The remote node updates the MAC address to point to the CCEP of client 1.  |
| CCEP1 interface (client 1) to CCEP2 interface (client 2) on MCT1.  | On local node MCT1, the MAC address is updated to point to the new client interface CCEP2.<br>A MAC update is sent with the new ESI of client 2 to the remote node.<br>The remote node updates the MAC address to point to the CCEP of client 2.   |
| Local dynamic MAC move from CCEP1 interface (client 1) to CEP1 edge interface on MCT1.                   | On local node MCT1, the MAC address is updated to point to the new edge interface CEP1.<br>A MAC update is sent with the new ESI 0 to the remote node.<br>The remote node MCT2 updates the MAC address pointing to the MCT1 node.  |
| For a MAC learned on a CEP port locally (MCT1). Dynamic MAC move to a CEP port on the remote node (MCT2) | On the MCT2 node for the EVPN MAC learned from MCT1, it is considered as a MAC move when it is learned on a CEP port. The MAC is updated as local on MCT2 and now points to the Dynamic on the CEP port on MCT2 instead of pointing to MCT1 node<br>MCT2 sends an updated MAC to MCT1. MCT1 updates the MAC as remote and points to the MCT2 .   |
| For a MAC learned on a CEP port locally (MCT1). Dynamic MAC move to CCEP1 on MCT2.                       | On the MCT2 node for the EVPN MAC learned from MCT1, it is considered as a MAC move when the same MAC is learned on a CCEP1 port. The MAC is updated as CCL on MCT2 and now points to the local CCEP1 port on MCT2 instead of pointing to the MCT1 node.<br>MCT2 sends a CCL MAC updated to MCT1. MCT1 updates the MAC as CCR and point to the CCEP1 port.                               |
| For a MAC CCL learned on a CCEP1 port locally (MCT1). Dynamic MAC move to CCEP2 on remote MCT2 node.     | On the MCT2 node for the CCR MAC learned from MCT1 for client 1, it is considered as a MAC move when the same MAC is learned on client 2 over the CCEP2 port. The MAC is updated as CCL on MCT2 and now points to the local CCEP2 port on MCT2 instead of pointing to CCEP1.<br>From MCT2, it sends a CCL MAC updated to MCT1. MCT1 updates the MAC as CCR and points to the CCEP2 port. |

**TABLE 25** MCT MAC movement (continued)

| MAC movement scenario   | Behavior   |
|---|--|
| For a MAC CCL learned on a CCEP1 port locally (MCT1). Dynamic MAC move to CEP port on remote MCT2 node. | On the MCT2 node for the CCR MAC learned from MCT1 for client1, it is considered as a MAC move when the same MAC is learned on the CEP port. The MAC is updated as Dynamic on MCT2 and points to the local CEP port on MCT2 instead of pointing to CCEP1. From MCT2, it sends the EVPN MAC updated to MCT1. MCT1 updates the MAC as EVPN and points to the MCT2. |

## MAC address deletion

The following rules are defined for MAC address deletion. Note that every deletion triggers the MAC resolution algorithm and reprograms the MAC entry if required.

- If the CEP interface is down, MAC addresses are deleted locally and individual MAC deletion messages are sent to the peer.
- If the CCEP local port is down and the remote CCEP is down, MAC addresses are deleted locally and the ESI withdraw message is sent to the MCT peer instead of sending individual MAC delete messages.
- If the CCEP local port is down and the remote CCEP is up, all local MAC addresses are moved to point to the remote MCT peer including the static MAC addresses associated with the CCEP.
- When the client entry is undeployed, all MAC addresses are deleted locally, and the ESI withdraw message is sent to the MCT peer to delete all associated client MAC addresses.

## Automatic RSVP LSP bring up for MCT

The automatic bring up of an RSVP LSP for MCT functionality allows MPLS to automatically create and delete an RSVP LSP when you deploy or undeploy the MCT cluster with a peer-interface configuration. This functionality handles MM failover and the MPLS process restart for automatically-created LSPs.

### NOTE

This LSP is a non-CSPF LSP.

## Automatic LSP creation

When you deploy the MCT cluster, MPLS receives the cluster peer interface and a peer address for the LSP creation. The peer interface can be any Layer 3 interface (physical or VE). The peer address is the peer router ID.

Upon receiving the cluster deploy update, MPLS is enabled on the peer interface and the RSVP LSP is created with a default template with a unique auto-generated name, *MCT\_peer-ipaddr\_peer-interface-index*. A random number suffix is generated if this name is already in use in the user configurations. You can see the LSP by using the **show mpls lsp** command.

## Automatic LSP deletion

When the cluster is undeployed, MCT updates the MPLS daemon to delete the automatically-created RSVP LSP. Then the MPLS daemon deletes the corresponding LSP. MPLS is disabled on the peer interface if it is not MPLS enabled from the CLI configuration.

# MCT configuration considerations

## General considerations

- MCT Peers need to run the same version of SLX-OS.
- When the primary physical interface is also an MCT cluster client interface, logical interfaces that belong to that primary interface cannot be in the same MCT bridge domain (BD).
- MCT does not support any variant of Spanning Tree Protocol (STP) on ICL links, cluster client ports, or any VLAN that is part of the cluster. STP is disabled by default.

### NOTE

If you enable STP on MCT nodes, each node acts as an independent (not interconnected) STP switch. This situation results in STP state flap at the node connected to the CCEP port, because it receives two different Bridge Protocol Data Units (BPDU) on that CCEP port

- SLX-OS supports dynamic and static LAG between the MCT PE and CE.
- SLX-OS uses Ethernet segment identifier (ESI) type 0 (static LAG) and type 1 (dynamic LAG). Consider the following for ESI type 0:
  - Configure the 9-byte ESI value that is used to form a globally unique 10-byte integer ESI.
  - Configure the same 9-byte ESI value for each client on both MCT devices.
- SLX MCT configurations (Layer 2 or Layer 3) do not require the Advance Feature license.

## Peer considerations

- For both MCT peers, the MCT peer address must match the peer's BGP router ID (loopback address).
- You must configure the same client ID on both MCT peers for the link or CCEP that is connected to the same client.
- Layer 3 connectivity should allow a BGP session to be established between MCT peers.
- SLX MCT peers must be physically connected to each other.
- You must configure and activate a BGP EVPN neighbor as the peer interface.
- (Required) Prevent native VLAN traffic from going across the ICL by disabling the default native VLAN on the ICL trunk port between the MCT peers. To prevent native VLAN traffic, use the **switchport mode trunk-no-default-native** command from interface configuration mode. For example:

```
device(conf-if-eth-0/17) # switchport mode trunk-no-default-native
```

- MCT MPLS interfaces are automatically created when you configure MCT without the use of router MPLS. By design, automatically created MCT MPLS interfaces do not offer FRR (fast reroute) protection, because it is difficult to remove the FRR configuration from outside of MPLS.

### NOTE

You need an Advance Feature license if you want to enable FRR for non-MCT paths

## VLAN considerations

- To avoid traffic looping, consider these guidelines:
  - Overlay EVPN VLANs or BDs must not be natively configured on the peer interface (underlay interface).

- If you use a VE as a peer interface, use the corresponding VLAN for underlay alone and do not extend it into the EVPN domain.
- The peer interface is in a separate control VLAN that is not used for MCT members
- If you configure an MCT port channel for multiple VLAN or VE interfaces, use static routes instead of OSPF ECMP.
  - For example, you have two VE interfaces, VE 10 (an MCT VLAN) and VE 20 (a non-MCT VLAN). When OSPF is configured on the interfaces, the route to the BGP router-id (or MCT) peer address is through the interfaces. If you then configure BGP BFD and BGP EVPN sessions between the MCT peers for faster recovery, BFD flaps continuously. Flapping occurs because OSPF does per-packet load balancing of BGP BFD packets, which are not reassembled properly.
  - As a best practice, configure a static route for MCT peers through the MCT VLAN (VE 10 in this example). A static route has a lower administrative distance than OSPF and places only one route in the routing table.

## LACP considerations

- When the client interface is a port channel on which LACP is running, MCT supports an automatically generated ESI value, as defined in RFC 7432.
- To ensure that two MCT peers send the same system ID and key but a different port ID to each client, you must configure the same cluster ID and client ID on both nodes. The system ID is derived by appending a cluster ID to the MCT base system ID, which is a device-defined value.

```
System ID = mct_base_system_id (0180.c200) + cluster_id
```

- The LACP fields have the following settings:

```
Key = MCT_LACP_KEY_BASE (3000) + client_ID
```

```
Port ID (16-bit unique value) =  
5-bit (slot value) + 8-bit (port value + 3-bit) (MCT position offset)
```

## LSP considerations

LSP is automatically created when a cluster is deployed. No user configuration is required.

- The SLX-OS device uses the peer interface to set up the MPLS data path automatically. The LSP is the outgoing peer interface and has an MCT prefix when it is displayed by the **show mpls lsp** command.
- The configured peer interface must be the best next hop to reach the MCT peer. If not, the automatically created LSP fails to come up.
- The automatically created LSP can co-exist with other explicit MPLS configurations. You can configure more LDPs and RSVP LSPs, but not with the same name as the automatically created LSP.
- When co-existence occurs on the device:
  - As part of the MCT cluster configuration, the MPLS daemon automatically creates and signals the RSVP LSP with the default template and a unique auto-generated name.
  - If you create an MCT LSP with the same name as an existing LSP, then the MCT LSP is created with a similar name but with a different number suffix to make it unique. For example: `MCT_20.21.22.23_9876543_123456`.
  - You cannot create an LSP with same name as an existing MCT LSP. The attempted configuration is rejected with an error message.
  - When the router port or the VE interface is MPLS-enabled from the MCT configuration, you cannot disable the router port or the VE interface. The configuration to disable the router port or the VE interface from the CLI is rejected with an error message.

- You can disable MPLS with the **no router mpls** command. Upon command execution, the automatically created LSP and the MPLS-enabled peer-interface configuration are disabled and re-enabled.
- An automatically created LSP is restricted to using the configured MCT peer interface as its next hop connection to the MCT peer. The IGP shortest path between the two peers must match the configured MCT peer interface. Otherwise, the LSP remains operationally down.
  - For example, suppose there are two paths between the MCT peers, eth 1/1 and eth 1/2, and the node configuration for the two peers is symmetrical. Furthermore, the user has configured eth 1/1 as the MCT peer interface.
  - If the IGP SPF path between the two peers uses eth 1/1 as the next hop link, then the LSP becomes operational and uses eth 1/1 as the next hop interface. If the IGP cost of eth 1/1 increases such that eth 1/2 is selected by the IGP SPF calculation, then the LSP remains operationally down.
  - You can use eth 1/2 as a normal MPLS interface. Do not use eth 1/1 (which is the MCT interface) for normal MPLS purposes.

## Configuring the BGP EVPN peer

Create a BGP EVPN address family to configure and activate the cluster EVPN peer. This configuration is associated with the MCT cluster peer configuration.

Before configuring a BGP EVPN peer, ensure you configure a loopback interface.

You also create an EVPN instance to add the bridge domains and VLANs associated with the MCT cluster.

1. In privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Enable BGP routing.

```
device(config-terminal)# router bgp
```

3. Configure the EVPN peer with the autonomous system number (ASN).

```
device(config-bgp-router)# neighbor 10.1.1.1 remote-as 100
```

4. Configure the EVPN peer through the loopback interface.

```
device(config-bgp-router)# neighbor 10.1.1.1 update-source loopback 1
```

5. Enter EVPN address family configuration mode

```
device(config-bgp-router)# address-family l2vpn evpn
```

6. Activate the EVPN peer.

```
device(config-bgp-evpn)# neighbor 10.1.1.1 activate
```

7. Access global configuration mode.

```
device(config-bgp-router)# exit
```

8. Access EVPN configuration mode.

```
device(config)# evpn myinstance
```

9. Configure the bridge domains.

```
device(config-evpn-myinstance)# bridge-domain add 1-2000,4000-4096
```

For more information on the bridge domain configuration, see the Bridge Domain chapter.

10. Configure the VLANs.

```
device(config-evpn-myinstance)# vlan add 1-2000
```

11. Enable auto-generation of a route distinguisher (RD) for this EVPN instance.

```
device(config-evpn-myinstance)# rd auto
```

12. Enable the auto-generation of the import and export route-target community attributes and ignore the autonomous system (AS) number.

```
device(config-evpn-myinstance)# route-target both auto ignore-as
```

The following example shows the steps in the previous configuration.

```
device# configure terminal
device(config-terminal)# router bgp
device(config-bgp-router)# neighbor 10.1.1.1 remote-as 100
device(config-bgp-router)# neighbor 10.1.1.1 update-source loopback 1
device(config-bgp-router)# address-family l2vpn evpn
device(config-bgp-evpn)# neighbor 10.1.1.1 activate
device(config-bgp-router)# exit
device(config)# evpn myinstance
device(config-evpn-myinstance)# bridge-domain add 1-2000,4000-4096
device(config-evpn-myinstance)# vlan add 1-2000
device(config-evpn-myinstance)# rd auto
device(config-evpn-myinstance)# route-target both auto ignore-as
```

## Configuring MCT

Configure the local and remote MCT cluster and cluster clients.

Before configuring MCT, ensure that the following configurations exist:

- Layer 3 interface for the cluster peer interface
- VLANs and bridge domains under an EVPN configuration to function as the MCT members
- Port channel for Link Aggregation or an Ethernet interface as a client interface
- Disable the default native VLAN on the trunk port between the MCT peers by using the interface configuration mode **switchport mode trunk-no-default-native** command. For example:

```
device(conf-if-eth-0/17)# switchport mode trunk-no-default-native
```

### NOTE

The peer interface is in a separate VLAN that is not an MCT member. Do not configure VLANs and bridge domains configured under EVPN on the trunk port between the MCT peers.

Perform the following steps.

1. In privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Create a cluster on the device.

```
device (config)# cluster MCT1 1
```

3. Configure the peer IP address.

```
device(config-cluster-1)# peer 10.1.1.1
```

The peer IP address must be the remote peer's router ID. This address corresponds with the neighbor in BGP EVPN address family configuration for the peer.

4. Configure the peer interface.

```
device(config-cluster-1)# peer-interface Ve 10
```

The peer interface should be a valid Layer 3 interface. You should configure the peer interface before deploying the configuration.

5. Deploy the cluster.

```
device(config-cluster-1)# deploy
```

The MPLS LSP is created when the cluster is deployed and is removed when the cluster is undeployed.

6. Create the client for the cluster and access cluster client configuration mode.

```
device(config-cluster-1)# client MCT1-client 200
```

On both MCT nodes, you must configure the same client ID.

7. Configure the interface to the cluster client instance.

```
device(config-cluster-client-200)# client-interface port-channel 3
```

The port channel specifies the LAG ID.

The client interface can also be a physical interface, for example:

```
device(config-cluster-client-200)# client-interface Ethernet 2/5
```

The client interface cannot be added under multiple client entries.

8. Set the 9-octet Ethernet Segment ID (ESI) value which is used to uniquely identify the cluster client.

```
device(config-cluster-client-200)# esi 00.a1.b2.c3.d4.e5.f6.89.00
```

You must configure the same value on both MCT nodes to create the MCT client LAG.

The ESI cannot be added under multiple client entries.

9. Deploy the cluster client.

```
device(config-cluster-client-200)# deploy
```

10. After configuring the local MCT cluster and client, configure the remote MCT cluster and client.

The following example is the steps in the previous configuration.

```
device# configure terminal
device (config)# cluster MCT1 1
device(config-cluster-1)# peer 10.1.1.1
device(config-cluster-1)# peer-interface Ve 10
device(config-cluster-1)# deploy
device(config-cluster-1)# client MCT1-client 200
device(config-cluster-client-200)# client-interface port-channel 3
device(config-cluster-client-200)# esi 00.a1.b2.c3.d4.e5.f6.89.00
device(config-cluster-client-200)# deploy
```

## Taking the MCT node offline for maintenance

If you need to take an MCT device offline for maintenance or an upgrade, perform the following steps to minimize traffic loss.

1. Verify that the MCT node that is peer to the node being taken offline is in loose client-isolation mode.

```
device# show cluster 1
Cluster MCT1 1
=====
Cluster State: Deploy
Client Interfaces Shutdown: FALSE
Client Isolation Mode: Strict
DF Hold Time: 3
Configured Member Vlan Range: 2, 4-7
Active Member Vlan Range: 2, 4-7
...
```

2. If the peer node is in strict client-isolation mode, configure it to loose mode.

```
device(config)# cluster MCT1 1
device(config-cluster-1)# client-isolation loose
```

3. Disable the MCT clients from the MCT node that you will take offline, as shown in the following example.

```
device(config)# cluster MCT1 1
device(config-cluster-1)# client-interfaces-shutdown
```

4. Isolate the MCT node that you will take offline from the core of the network by shutting down all uplink interfaces.

### NOTE

Do not write the configuration changes made in the previous steps to the startup-configuration file.

To bring the MCT node back online, perform one of the following actions.

- If you upgraded or downgraded the device, select the **coldboot** option under the firmware download menu.
- For any other reason, execute the **reload system** command. Since the changed configuration was not saved, the reload reverts the configuration changes that had taken the MCT node offline.

## Configuring additional MCT cluster parameters

The SLX-OS device has additional cluster commands with default values. You can change the parameters for these commands in cluster configuration mode.

### Changing the client-isolation mode

Isolation mode defines the action to be taken when the BGP control session goes down between the MCT nodes while the cluster is in deployed state. When the client-isolation mode is strict, the client interface will be shutdown.

By default, client-isolation mode is based on the peer IP address. The node with the lower peer IP address is set to the client-isolation mode of loose, while the node with the higher peer IP address is set to the client-isolation mode of strict. You can override this behavior by configuring strict client-isolation mode on both nodes.

Use the **client-isolation strict** command to configure the strict mode on both nodes, as shown in the following example.

```
device(config-cluster-1)# client-isolation strict
```

Use the **client-isolation loose** command to configure the loose mode on both nodes, as shown in the following example.

```
device(config-cluster-1)# client-isolation loose
```

## Changing the designated-forwarder hold timer value

Upon expiration of the designated-forwarder hold timer, the reelection of the designated forwarder is considered.

By default, the hold time is three seconds. Use the **designated-forwarder-hold-time** command to change the time in seconds from 1 to 60 seconds, as shown in the following example.

```
device(config-cluster-1)# designated-forwarder-hold-time 35
```

## Moving the traffic from an MCT node to the remote node

Use the **client-interfaces-shutdown** command to move all the traffic on the node to the remote MCT node by disabling the local client interfaces administratively, as shown in the following example.

```
device(config-cluster-1)# client-interfaces-shutdown
```

## Configuring an auto-generated ESI for a cluster client

When a client interface is a port channel and LACP is running on the port channel, you can configure an automatically generated ESI value, as defined in RFC 7432 on the cluster client.

The following example shows how to configure an auto-generated ESI for the cluster client.

```
device(config)# cluster MCT1 1
device(config-cluster-1)# client MCT1-client 200
device(config-cluster-client-200)# esi auto lacp
```

## Displaying MCT information

You can display detailed MCT information and related MCT MAC addresses.

To display the EVPN neighbor information, use **show ip bgp neighbors** command. This information includes the peer configured for the EVPN address family, the undeployed MCT cluster, and the negotiation of the EVPN address family.

## Displaying the cluster information

The following example shows the information of the cluster on the SLX-OS device.

```
device# show cluster 1

Cluster MCT1 1
=====
Cluster State: Deploy
Client Interfaces Shutdown: FALSE
Client Isolation Mode: Loose
DF Hold Time: 3
Configured Member Vlan Range: 2, 4-7
Active Member Vlan Range: 2, 4-7

Peer Info:
-----
```

```
Peer IP: 10.1.1.1, State: Up
Peer Interface: Ve 20
ICL Tunnel Type: MPLS, State: Up
```

#### Client Info:

| Name    | Id  | ESI                     | Interface      | Local/Remote State |
|---------|-----|-------------------------|----------------|--------------------|
| access1 | 100 | 0:11:22:33:80:0:0:0:0:0 | Ethernet 1/8   | Up/UP              |
| access2 | 200 | 0:11:22:33:81:0:0:0:0:0 | Port-Channel 3 | Dep/UnDep          |
| access3 | 300 | 0:11:22:33:82:0:0:0:0:0 | Eth 2/3        | Up/Down            |

#### NOTE

When you delete an IP router ID that is used as the neighbor ID and IP address on an MCT peer, the **show cluster** command on the MCT peer devices displays inconsistent cluster states.

## Displaying the cluster client information

The following example displays all client information for cluster 1.

```
device# show cluster 1 client
Client Info:
-----
Name      Id      Label(Lo/Re)  Interface      Local/Remote State
access1   100     NA/ 798721    Ethernet 1/8    UnDep/Dep
access2   200     798722/798722 Port-Channel 3  Up/UP
access3   300     798723/798723 Ethernet 2/3     Down/Up
```

The following example displays client 100 information for cluster 10.

```
device# show cluster 10 client 100
Client Info:
-----
Client: access1, client-id: 100, Deployed, State: Up
Interface: Ethernet 1/8
Vlans : 1-10, 100
Elected DF for vlans: 2, 4, 8, 10, 100
```

## Displaying member VLAN information

The following example displays the member VLAN information for the cluster.

```
device# show cluster member vlan
VLAN-ID    Mcast-label(Lo/Re)  Unicast-label(Lo/Re)  Forwarding State
101        817253 / 817253     800869 / 800869      Up
102        817254 / 817254     800870 / 800870      Up
103        817255 / 817255     800871 / 800871      Up
104        817256 / 817256     800872 / 800872      Up
105        817257 / 817257     800873 / 800873      Up
106        817258 / 817258     800874 / 800874      Up
```

## Displaying and clearing the MAC address table cluster information

The following example shows how to display the MCT cluster information in the MAC address table.

```
device# show mac-address-table cluster 1
Vlan/BD'Id Mac-address  Type      State  Ports
100 (V)    0010.a111.aaaa  CCL       Active ETH3/1
100 (V)    0010.a111.aa22  Static-CCL Active ETH3/1
100 (V)    0010.a111.bbbb  CCR       Active ETH3/1
200 (V)    003d.a111.1111  Dynamic   Active Eth 1/1
200 (V)    003d.a111.1122  Static    Active Eth 1/1
200 (V)    003d.a111.3333  EVPN      Active 10.2.2.2
200 (V)    003d.a111.3322  EVPN-Static Active 10.2.2.2
```

The MAC Type for an MCT cluster displays the following information:

- The MAC address over the CEP AC endpoints or the VPLS PW are learned and treated as EVPN local MAC addresses over a singled-homed edge node. These local addresses are learned as EVPN and displayed as Dynamic. Corresponding MAC addresses synchronized to the remote MCT node are displayed as EVPN. The EVPN MAC addresses are programmed pointing to the MCT PW.
- For the client MAC behavior, MAC addresses are learned as CCL on the local MCT node and CCR on the remote MCT node pointing to the CCEP interface.
- The VPLS MCT MAC on active PWs are learned as Dynamic and the corresponding MAC addresses are learned as EVPN on remote MCT node.
- Static MAC addresses configured on CEP AC endpoints are learned as Static. The corresponding remote MAC addresses are learned as EVPN-Sticky in the remote node.
- For static MAC addresses over client interfaces, Static-CCL and CCR are displayed.

You can also view the MAC entries for a specific client.

### *Clearing the MCT cluster MAC table entries*

You can clear all cluster entries from the MAC address table or the entries for a specified client. The following example clears the MAC entries for client 3 of cluster 1.

```
device# clear mac-address-table cluster 1 client 3
```

Only the local MAC entries are deleted from the current node. Individual MAC withdrawal flush messages are sent through the EVPN. However, BGP still batches multiple routes to the remote node.

When the remote MCT peer receives the MAC withdrawal message, it only deletes the remote MAC entry. To clear MAC addresses on both nodes, you must issue **clear mac-address-table** commands on both MCT nodes.

## VPLS and VLL MCT

VPLS and VLL MCT are used for data center interconnection in which SLX-OS MCT acts as a data center gateway to connect to another data center through either the VPLS or VLL WAN connection.

### NOTE

For more information on VPLS and VLL, refer to the "VPLS and VLL Layer 2 VPN services" chapter.

For VPLS MCT, a point-to-multipoint (p2mp) bridge domain is added to the MCT cluster. For VLL MCT, a point-to-point (p2p) bridge domain is added to the MCT cluster. The VPLS or VLL horizon is added as a pseudowire (PW) client.

VLL MCT supports PW redundancy. At any point of time, one active-active PW path exists to reach the destination. The node on which the PW is active is called the active node. The endpoint traffic coming from the standby node traverses through the MCT PW session to the active node for that instance and the active MCT node takes care of the forwarding to the remote VPLS or VLL peer.

### NOTE

For SLX-OS, the MCT cluster requires both nodes to be on SLX-OS devices. However, an SLX-OS MCT cluster that connects to a Extreme MLX cluster through VPLS or VLL is supported.

## Control plane for VPLS or VLL MCT

As with Layer 2 MCT, VPLS or VLL MCT uses MP-BGP EVPN for the control plane. However, an Ethernet segment ID (ESI) controls all pseudowires (PWs) and is encoded the same as the Layer 2 CCEP ESI. This ESI is called the PW horizon ESI.

The bridge domain is mapped to an EVPN instance. For each BD, the default EVPN ID is the BD ID plus 4,096. A user configured EVPN ID is not supported. The EVPN ID for the VLAN is the VLAN ID.

For VPLS or VLL MCT, the physical and LAG CCEP operate in active/active multi-homing mode. However, the PW operates in active/standby mode.

The designated forwarder (DF) state of the PW ESI represents the active PW node state for a VPLS or VLL instance. The DF election process for the PW ESI is the same as the Layer 2 ESI process. However, for VLL MCT in the following dynamic cases, VLL does not change its role and is driven through the PW horizon client.

- If the local endpoint is down, the remote endpoint is up.
- If the active-active PW is down on the active node, the active-active PW is up on the standby node.

### PW redundancy for VLL MCT

PW redundancy for VLL MCT allows the quick failover of traffic to the backup PWs. To support active and standby PWs to remote PEs, the Preferential status bit in the PW status TLV is exchanged to indicate whether the PW forwarding is active or standby.

Status TLV support is enabled through a VLL instance if one of the following is true.

- VLL is configured with two remote peers.
- The VLL endpoint is a MCT client CCEP port.

To support PW redundancy, configure two VLL peers under one VLL instance. One PW is for each VLL peer. Among these PWs, an active-active PW is selected and used for traffic flow to the remote side. An active-active PW is selected based on the local and remote PW redundancy preferences. A remote PW redundancy preference is received by the PW status TLV. When the bit is set, it indicates PW forwarding standby. When the bit is cleared, it indicates PW forwarding active.

## PW state in VPLS or VLL MCT

The PW state in VPLS or VLL MCT is controlled by two entities. The MCT module controls its MCT state. The PW remote peer provides its PW redundancy state. Together, they decide the operational (forwarding) state of the PW. The following table shows the PW state decisions.

| MCT state | PW remote state | Operational state | PW signaling state |
|-----------|-----------------|-------------------|--------------------|
| DF        | Active          | Active            | Active             |
| DF        | Standby         | Standby           | Active             |
| Non-DF    | Any             | Standby           | Standby            |

When the PW is in active operational state, the data plane objects (such as LIF or MGID, or cross-connect for VLL) is created and be programmed into the hardware. When the PW is in standby operational state, the data plane is programmed as if this PW is down.

#### NOTE

The SLX-OS PW state table is the same as the Extreme NetIron VPLS-MCT or VLL-MCT PW state table to ensure compatibility when facing an MLX MCT cluster over a VPLS or VLL connection.

## VLL-MCT data plane

A topology for VLL MCT is provided in the following figure. Two MCT clusters face each other and four PWs connect the clusters.

### NOTE

This topology is for only one BD. Since the DF state is selected per BD, another BD can use a different PE as the active node.

FIGURE 15 VLL MCT topology

When VLL MCT is activated, only one PW is operationally active between the MCT clusters, as represented by the solid line. The standby PWs are represented by the dotted lines.

The ICL link between the MCT nodes is a BGP EVPN connection. It is not a spoke PW.

### NOTE

VLL MCT does not use MAC learning. BUM traffic handling is not required. It uses cross-connect instead of VSI. VLL MCT does not use the EVPN label.

## Steady state traffic

Based on the previous figure, the steady state traffic is as follows:

CE1->PE1->**PW2**->PE4->CE2

CE1->PE2->ICL[Split Horizon PW or ICL]->PE1->**PW2**->PE4->CE2

## Client Link down protection

When the client link (CL1) is down, the device does not change the MCT status for this VLL. Traffic from the client will be received on CL2 to PE2 and forwarded using EVPN PW from PE2 to PE1. The traffic flow from the client is as follows:

CE1 -> PE2 -> [Split Horizon PW or ICL] -> PE1 -> **PW2** -> PE4 -> CE2

### Active MCT Node protection

VLL MCT provides protection when one PE node has a failure including a software or hardware failure, or a power down. In the case when the active MCT node (PE1) is down, the standby MCT node acts as active and uses corresponding PWs for the traffic flow from the client. The traffic flow from the client is as follows:

CE1 -> PE2 -> **PW4** -> PE4 -> CE2

#### NOTE

For active-active PW link protection when the PW redundancy status changes, the device relies on the MPLS configuration. There should not be a case where PW2 is down and PW4 is up. The MPLS configuration ensure that both PW2 and PW4 are UP or DOWN. When PW2 is not active-active due to a role change on PE4, PW1 will become active-active.

## VPLS-MCT data plane

The main case topology for VPLS MCT is provided in the following figure. Two MCT clusters face each other and four PWs connect the clusters.

#### NOTE

This topology is for only one BD. Since the DF state is selected per BD, another BD can use a different PE as the active node.

When VPLS MCT is activated, only one PW is operationally active between the MCT clusters, as represented by the solid line. The standby PWs are represented by the dotted lines.

The ICL link between the MCT nodes is a BGP EVPN connection. It is not a spoke PW.

### VPLS MCT BUM traffic

The following figure illustrates how a BUM packet that starts from host 4 travels through the VPLS-MCT network to reach hosts 1, 2, and 3.

### VPLS-MCT PE node protection

VPLS MCT provides protection when one PE node has a failure, including a software or hardware failure, or a power-down event. When the active PE fails in MCT, the standby PE becomes the active PE and all PWs on this node transit into MCT active state.

The following figure shows the BUM packet flow after an MCT PE switch-over event.

## NOTE

VPLS MCT does not support PW link protection.

## VPLS MAC management

In VPLS-MCT topologies, MAC addresses can be learned either on local PW or from the remote MCT node. The same MAC can be learned from either locally or remotely but not from both MCT nodes.

For MCT remote MAC addresses, aging is disabled, and they can only be deleted when delete notifications are received from the remote MCT node that advertised it before for learning.

The following terminologies are associated with MCT MAC entries.

- Dynamic—MAC addresses learned locally as EVPN on CEP ports
- EVPN—MAC addresses learned on remote CEP ports
- Cluster Client Local (CCL)—MAC addresses learned locally on a client interface
- Cluster Client Remote (CCR)—MAC addresses learned on a remote client interface

VPLS MAC addresses that are learned locally are classified as Dynamic, and the corresponding VPLS MAC addresses that are learned remotely are classified as EVPN.

## Static MAC handling

Static MAC configuration over the local VPLS endpoints is supported. Static MAC pointing to the PW that is established with the remote VPLS PE is not supported.

## MAC learning

MAC addresses learned from the PW on the active PE triggers EVPN MAC synchronization message that are sent to the peer. The PW ESI is used in this MAC route. VPLS CR MAC addresses point to the active MCT node since no local forwarding path on the standby PE traffic is expected to be switched by the active MCT node.

## MAC aging

When the VPLS MAC ages on the active node, the MAC address is locally flushed and the EVPN MAC withdrawal route is sent to remote MCT node to flush the MAC.

## VPLS MAC movement

A MAC address is considered to be moved when the same MAC address is received on a different interface with same VLAN. In MCT, a MAC movement is allowed on both local and remote nodes.

The following table describes the allowed VPLS MAC movements in MCT.

| MAC movement scenario   | Behavior  |
|---|---|
| Local dynamic MAC move from PW A to PW B on MCT1.   | On local node MCT1, the MAC address is updated to point to the new PW interface.<br><br>There is no MAC route update required to the remote MCT node. As on the remote node, the MAC always point towards the MCT peer for all VPLS addresses.  |
| Local dynamic MAC move from PW to the Layer 2 CCEP1 client interface on MCT1.                             | On local node MCT1, the MAC address is updated to point to the new client interface CCEP1.<br><br>A MAC update route is sent with the new ESI of client 1.<br><br>The remote node updates the MAC address to point to the CCEP of client 1.   |
| For a MAC learned on a PW locally (MCT1). Dynamic MAC move to CCEP1 on MCT2.                              | On the MCT2 node for the EVPN MAC learned from MCT1, it is considered as a MAC move when the same mac is learned on a CCEP1 port. The MAC is updated as CCL on MCT2 and now points to the local CCEP1 port on MCT2 instead of pointing to the MCT1 (PW) node.<br><br>MCT2 sends a CCL MAC update to MCT1. MCT1 updates the MAC as CCR and points to the CCEP1 port. |
| For a MAC CCL learned on a CCEP1 port locally (MCT1). Dynamic MAC move to the PW on the remote MCT2 node. | On the MCT2 node for the CCR MAC learned from MCT1 for client 1, it is considered as a MAC move when the same MAC is learned on the PW. The MAC is updated as the Dynamic on MCT2 and now points to the PW on MCT2 instead of pointing to CCEP1.<br><br>From MCT2, it sends a Dynamic MAC update to MCT1. MCT1 updates the MAC to point to MCT2.                    |
| Local dynamic MAC move from PW (MCT1) to CEP1 client interface on MCT1.                                   | On local node MCT1, the MAC address is updated to point to the new interface CEP1.<br><br>A MAC advertise route is sent with ESI 0 to the remote MCT node.<br><br>The remote node MCT2 updates the MAC address to point to the MCT1 node.   |
| For a MAC learned as EVPN on a PW locally (MCT1). Dynamic MAC move to CEP on MCT2.                        | On the MCT2 node for the EVPN MAC learned from MCT1, it is considered as a MAC move when the same mac is learned on the CEP port. The MAC is updated as Dynamic on MCT2 and points to the local CEP1 port.<br><br>From MCT2, it sends a Dynamic MAC updated to MCT1. MCT1 updates the MAC as EVPN and points to the MCT2 node.                                      |

| MAC movement scenario  | Behavior  |
|--|---|
| For a MAC learned as EVPN on a CEP1 port locally (MCT1). Dynamic MAC move to PW on remote MCT2 node. | <p>On MCT2 node for the EVPN MAC learned from MCT1 for CEP, it will be considered as a MAC move when the same mac is learned on the PW. The MAC is updated as Dynamic on MCT2 and now points to the PW on MCT2.</p> <p>MCT2 sends a Dynamic MAC updated to MCT1 with the ESI of the PW client, MCT1 now should updated the MAC point to the MCT2.</p> |

## MAC address deletion

The following rules are defined for MAC address deletion. Every MAC deletion triggers the MAC resolution algorithm and reprograms the MAC entry if required.

- If a PW is down, MAC addresses flushed locally and individual MAC deletion messages are sent to the MCT Peer. This is similar to the Layer 2 CEP port-down handling.
- If PW client is undeploy on MCT 1, only one MAC withdraw message is send to MCT 2.  
All MAC addresses tagged to the PW client are flushed.
- If MCT 2 detects that MCT 1 is down or if the EVPN session is down, all VPLS MAC addresses that are learned from MCT 1 are flushed.

## Configuration considerations and limitations for VPLS and VLL MCT

- RSVP graceful restart (GR) is not supported during HA failover. Hitless HA failover is not supported when a VPLS/VLL PW uses RSVP for underlying tunnels.
- Hitless ISSU is not supported. Before starting ISSU, issue the **client-interface shutdown** command on the PE where the ISSU is planned to gracefully move the traffic to the MCT peer. Similarly, use the **force-standby** or **no deploy** command for the PW CCEP before starting ISSU.
- Routing over EVPN is not supported.
- Statistics are not supported.
- For VPLS MCT, consider the following:
  - Configuring a cluster peer as a BD peer impacts data traffic.
  - You can use the **client-interfaces-shutdown** command to shutdown traffic on one node before a software upgrade. After you issue this command, all PWs are put into standby mode.
  - Client-interface shutdown brings down all CCEP interfaces and the BGP session. Other nodes attempt client-isolation logic after the BGP session is down, and you may see the Strict behavior.
  - Logical-interface shutdown brings down the admin state of the CCEP LIF interface if the parent port is an MCT client interface and does not trigger a DF re-election.
  - Protection for a PW link failure is not supported. Active forwarding paths does not occur between the nodes.
- For VLL MCT, consider the following:
  - Cross-connect is used instead of VSI.
  - MAC learning is not required.
  - BUM traffic handling is not required.
  - The MCT role does not depends upon endpoint as well as the PW redundancy status.

## Configuring MCT for VPLS or VLL

Configuration of VPLS or VLL for MCT requires the adding of member bridge domains to the MCT cluster and a PW client.

- Before configuring VPLS MCT, configure a point-to-multipoint (p2mp) bridge domain.
- Before configuring VLL MCT, configure a point-to-point (p2p) bridge domain.

For information on configuring VLL or VPLS bridge domains, refer to the "VPLS and VLL Layer 2 VPN services" chapter.

Create an EVPN instance to add the bridge domains and VLANs associated with the MCT cluster. For information on creating the BGP peer, refer to [Configuring the BGP EVPN peer](#) on page 101.

For information on configuring the MCT cluster and client, refer to [Configuring MCT](#) on page 102. Their full configuration is provided in the example after the steps.

Perform the following steps to configure MCT for VPLS or VLL.

1. In privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Access the cluster on the device.

```
device (config)# cluster MCT1 1
```

3. Create the PW client for the cluster and access PW cluster client configuration mode.

```
device(config-cluster-1)# client-pw
```

Only one instance of the PW client represents all VPLS or VLL PWs over all bridge domains.

4. Set the 9-octet Ethernet Segment ID (ESI) value which is used to uniquely identify the PW client.

```
device(config-cluster-client-pw)# esi 01:02:03:04:05:06:07:08:0a
```

You must configure the same value on both MCT nodes.

The ESI cannot be added under multiple client entries.

5. Deploy the PW client.

```
device(config-cluster-client-pw)# deploy
```

6. After configuring the local MCT cluster and PW client, configure the remote MCT cluster and PW client.

The following example is the steps in the previous configuration with the additional configuration of the MCT cluster and client.

```
device# configure terminal
device (config)# cluster MCT1 1
device(config-cluster-1)# peer 10.1.1.1
device(config-cluster-1)# peer-interface Ve 10
device(config-cluster-1)# deploy
device(config-cluster-1)# client MCT1-client 200
device(config-cluster-client-200)# client-interface port-channel 3
device(config-cluster-client-200)# esi 00.a1.b2.c3.d4.e5.f6.89.00
device(config-cluster-client-200)# deploy
device(config-cluster-1)# client-pw
device(config-cluster-client-pw)# esi 01:02:03:04:05:06:07:08:0a
device(config-cluster-client-pw)# deploy
```

## Displaying information related to VPLS and VLL MCT

The following examples display PW client and bridge domain information for VPLS and VLL MCT.

### Displaying PW client information on an MCT cluster

The following example displays the configuration and state information of the PW client on the MCT cluster.

```
device# show cluster 1
Cluster c1 1
=====
Cluster State: Deployed
Client Isolation Mode: Loose
DF Hold Time: 3
Configured Member Vlan Range: 100-101
Active Member Vlan Range: 100-101
Configured Member BD Range: 1000-1001
Active Member BD Range: 1000-1001
No. of Peers: 1
No. of Clients: 2

Peer Info:
=====
Peer IP: 10.38.38.38, State: Up
Peer Interface: Ethernet 3/1
ICL Tunnel Type: MPLS, State: Up

Client Info:
=====

```

## Displaying MAC address information for a VPLS bridge domain on an MCT cluster

The following example displays the MAC address table for bridge domain of an MCT cluster.

```

device# show mac-address-table bridge-domain
Vlan/BDId  Mac-address  Type           State      Ports/LIF/PeerIp
100(B)     001b.ed0b.ae00 Dynamic        Active     2.2.2.2
100(B)     0230.0774.0aac Dynamic-CCL    Active     eth 1/2
100(B)     0230.0774.0aac CCR            Active     po100
200(B)     003d.ed0b.ae00 Dynamic-CCL    Active     3.3.3.3
200(B)     0230.0774.0aac Dynamic-CCL    Active     3.3.3.3

```

The following example displays all the MAC addresses learned from other VPLS PE nodes over MCT bridge domains.

```

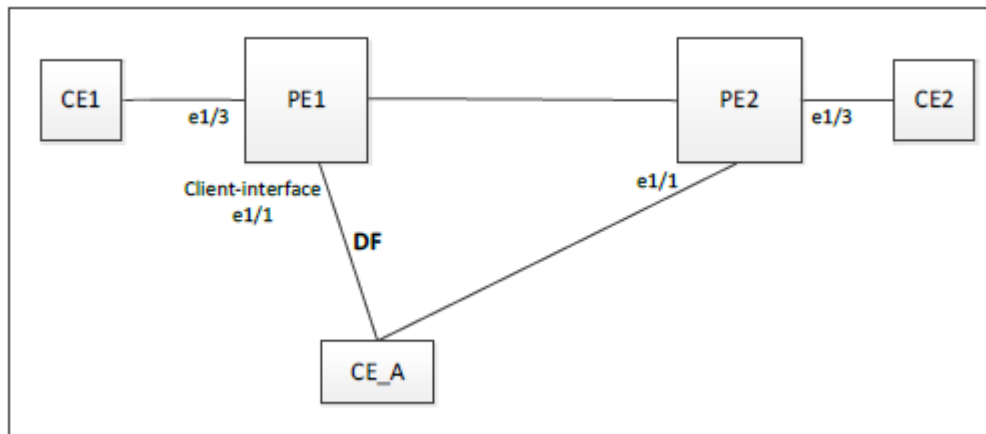

device# show mac-address-table bridge-domain
Vlan/BDId  Mac-address  Type           State      Ports/LIF/PeerIp
100(B)     001b.ed0b.ae00 Dynamic-CCL    Active     2.2.2.2

```

## Layer 3 routing over MCT

Layer 3 routing is supported for IPv4 and IPv6 BGP, OSPF, and IS-IS routing protocols on an MCT VLAN or bridge domain (BD). All local and remote Layer 3 devices appear logically on the same VLAN or BD.

The following diagram is the Layer 3 MCT data plane.

All devices are on the same VE and receive protocol Hello packets. Over the ICL link, the following packets are flooded:

- Hello and multicast packets from PE1 and PE2
- ARP and ND6 packets

Any two devices have direct Layer 3 communications.

- IP traffic is sent to the DA MAC of the target IP address or next-hop IP address.
- Traffic from CE\_A to PE1 or CE1 might be sent through the PE2 link first, and switched by PE2 over the ICL link.

## Configuration considerations

You must first create the VE interface for the MCT VLAN or bridge domain on the MCT pair.

Enabling L3 protocols is the same as enabling them on a VE interface.

For routes learned over Layer 3 protocols, the next-hop IP address is usually the peer IP address and not necessarily the MCT router address.

To bind the VE interface to an MCT VLAN or bridge domain, use the **router-interface ve** command under VLAN or bridge-domain configuration mode, respectively. The following example shows how to bind VE 200 to bridge domain 2.

```

device# configure terminal
device(config)# bridge-domain 2
device(config-bridge-domain-2)# router-interface ve 200
  
```

### NOTE

MPLS cannot be enabled for a VE over an MCT VLAN interface.

## Layer 3 MCT VLAN configuration example

The following configuration example shows how to enable OSPFv2 and OSPFv3 protocols on PE1, PE2, and CE\_A over VE 200 for the MCT member VLAN 2.

PE1:

```

router ospf
  area 0

ipv6 router ospf
  area 0
  
```

```

vlan 2
  router-interface Ve 200

interface Ve 200
  ipv6 address 2001::1/64
  ip address 10.2.2.1/24

  ip ospf area 0
  ipv6 ospf area 0
  !
  no shutdown
  !

```

PE2:

```

router ospf
  area 0

ipv6 router ospf
  area 0

vlan 2
  router-interface Ve 200

interface Ve 200
  ipv6 address 2001::2/64
  ip address 10.2.2.2/24

  ip ospf area 0
  ipv6 ospf area 0
  !
  no shutdown
  !

```

CE\_A:

```

router ospf
  area 0

ipv6 router ospf
  area 0

vlan 2
  router-interface Ve 200

interface Ve 200
  ipv6 address 2001::10/64
  ip address 10.2.2.10/24

  ip ospf area 0
  ipv6 ospf area 0
  !
  no shutdown
  !

```

## Layer 3 MCT bridge-domain configuration example

The following configuration example shows how to enable OSPFv2 and OSPFv3 protocols on PE1, PE2, and CE\_A over VE 200 for the MCT member bridge-domain 2.

PE1:

```

router ospf
  area 0

ipv6 router ospf
  area 0

```

```

interface Ve 200
  ipv6 address 2001::1/64
  ip address 10.2.2.1/24

bridge-domain 2 p2mp
  router-interface Ve200
  logical-interface ethernet 0/1.2
  pw-profile default
  bpdu-drop-enable
  local-switching
!
  ip ospf area 0
  ipv6 ospf area 0
!
  no shutdown
!

```

PE2:

```

router ospf
  area 0

ipv6 router ospf
  area 0

interface Ve 200
  ipv6 address 2001::2/64
  ip address 10.2.2.2/24

bridge-domain 2 p2mp
  router-interface Ve200
  logical-interface ethernet 0/1.2
  pw-profile default
  bpdu-drop-enable
  local-switching
!
  ip ospf area 0
  ipv6 ospf area 0
!
  no shutdown
!

```

CE\_A:

```

router ospf
  area 0

ipv6 router ospf
  area 0

interface Ve 200
  ipv6 address 2001::10/64
  ip address 10.2.2.10/24

bridge-domain 2 p2mp
  router-interface Ve200
  logical-interface ethernet 0/1.2
  pw-profile default
  bpdu-drop-enable
  local-switching
!
  ip ospf area 0
  ipv6 ospf area 0
!
  no shutdown
!

```

## Using MCT with VRRP and VRRP-E

Standard VRRP and VRRP-E configuration commands, VMAC generation login, and scaling numbers apply when used with MCT. VRRP advertisement packets are exchanged through the MCT ICL.

The MCT device that acts as the Virtual Routing Redundancy Protocol (VRRP) and VRRP Extended (VRRP-E) backup router performs as a Layer 2 switch to pass the packets to the VRRP or VRRP-E master router for forwarding. Through MAC synchronization, the VRRP or VRRP-E backup router learns the virtual MAC (VMAC) on the Inter-Chassis Link (ICL) represented by the MPLS cloud in the diagram. The data traffic and control traffic both pass through the ICL MPLS cloud link from the backup router. If VRRP-E short path forwarding is enabled, the backup router can forward the packets directly, instead of sending them to the master.

### NOTE

Short path forwarding is only supported on VRRP-E.

In the diagram below, when an ARP request from the S1 switch device is sent through the direct link to the VRRP or VRRP-E backup router (PE2), a broadcast packet is sent to the VRRP/E master router (PE1) for processing through the ICL. When the ARP request is received by the PE1 device, PE1 sends a reply through the direct link to S1. If the ARP reply was received before the MAC address for the MCT on S1 is learned, the reply packet may be flooded to both the Customer Client Edge Port (CCEP) ports and ICL ports.

Using VRRP or VRRP-E, data traffic received from a client device on a backup router is Layer 2 switched to the master device. If VRRP-E short path forwarding is enabled, traffic received on the backup device may be forwarded by the backup if the route to the destination device is shorter than through the master device.

## MCT short path forwarding configuration using VRRP-E example

In this example configuration, we are assuming that MCT is using the VRRP-E short path forwarding. When short path forwarding is enabled, packets from either the E1 or E2 devices with a destination of the E4 device can be routed through the PE 2 device which is a VRRP-E backup device. Short path forwarding is designed for load-balancing and allows packets to use the shortest path, and in this case, PE2 is directly connected to E4 so the packets will travel through PE2.

**FIGURE 16** MCT short path forwarding

## PE1 configuration

The following example configures the OSPF, BGP, and MPLS protocols with cluster configuration for MCT for the PE1 router in the diagram. A VRRP-E priority value of 110 (higher than the device at PE2) allows the PE1 device to assume the role of VRRP-E master.

```
ip router-id 10.19.19.19
router ospf
 area 0

interface Loopback 200
 no shutdown
 ip ospf area 0
 ip address 10.19.19.19/32

router bgp
 local-as 100
```

## MCT use cases

An L2 MCT solution can be deployed at the access, aggregation, and the core of the data center. However, SLX-OS device is targeted for the data center core.

### L2 MCT in the data center core

The following diagram shows a typical 3-tier data center where access and aggregation layers are running Layer 2 and the core is running Layer 2 and Layer 3. The access and aggregation can be standalone Extreme switches or any other third party switches.

FIGURE 17 Typical 3-tier data center

Another variation of this use case is when the aggregation layer is a virtual cluster of switches which is transparent to SLX-OS devices in the core layer.

**FIGURE 18** L2 MCT in the data center core connecting to a VCS

## L2 MCT in a data center with a collapsed core and aggregation

The following diagram describes a scenario where VCS fabric of VDX 8870 switches is deployed at the access layer. With the availability of 10G and 40G interface, access switches can connect directly to the core without the need to have a separate aggregation layer.

FIGURE 19 L2 MCT with collapsed core and aggregation

## Multiple VLAN Registration Protocol overview

Multiple VLAN Registration Protocol (MVRP) is a Layer 2 protocol that allows the dynamic propagation of VLAN information from device to device. With MVRP, you manually configure an MVRP-aware access device with all the desired VLANs for the network, and all other MVRP-aware devices on the network learn these VLANs dynamically. By automatically providing VLAN ID consistency across the network, MVRP reduces the chances of errors in VLAN configuration.

An MVRP-aware device can exchange VLAN configuration information with other MVRP-aware devices, prune unnecessary broadcast and unknown unicast traffic, and dynamically create and manage VLANs on the devices. These devices form a reachability tree that is a subset of an active topology. To avoid any information loop, the forwarding ports of base spanning tree form the active topology.

### NOTE

It is not mandatory to enable any of the STP variants before configuring MVRP if the topology is already Layer 2 loop free where MVRP can still function effectively.

MVRP on the device propagates the configured VLANs to all MVRP participants to declare it over their respective MVRP-enabled ports. The device initiates a join event information which is placed inside an MVRP data unit (MVRPDU). The MVRPDU is transmitted as untagged Ethernet frame and is sent out as an advertisement through all ports wherever a declaration is made. The advertisement is transmitted only when the port's spanning tree state is forwarding.

Similarly, if a VLAN is removed from a port, MVRP on the device propagates a leave event to all MVRP participants which removes the registration and declaration for the VLAN and then sends out a leave message over their respective MVRP enabled ports. The receiving node mimics this behavior and, through this method, the removal of the VLAN configuration is communicated to the entire topology.

VLAN registration occurs only on ports of intermediate nodes where the MVRP advertisement is received. Each registration acts as a pointer towards the source of the VLAN declaration. If the VLAN configuration on a device changes, MVRP automatically changes the VLAN configurations of the affected devices. Using VLAN pruning, MVRP avoids unnecessary flooding and provides solution for better resource utilization and bandwidth conservation.

## MVRP considerations and limitations

- You can enable MVRP only on interfaces configured as switchport in both trunk and access modes.

- The interface must be configured in 'switchport access mode' only on the edge ports of the SLX-OS device where MVRP selects statically configured VLANs for propagation. The interfaces connecting the devices on the SLX devices should be only configured in 'switchport trunk mode' where MVRP dynamically configures the VLANs. MVRPDUs received on ports configured in access mode are dropped; VLANs are neither learned nor propagated.
- MVRP can be learned for all allowed configurable VLANs, up to 4090 VLANs in number.
- MVRP can be enabled on all physical and PO interfaces without any CLI restrictions.
- A maximum of 2k dynamic VLANs are supported on each MVRP-enabled interface. However, the MVRP timer values require adjustment to less aggressive values based on the number of MVRP-enabled interfaces, VLANs to be learned dynamically on each associated interface, load on the system, and the topology.

If MVRP is scaled to an extent with the default timer settings that are too aggressive, the device may become unresponsive and severe performance impact could occur. Extreme recommends that you increase the MVRP timer values to values that are less aggressive for effective MVRP operation.

- If you manually configure a VLAN that is currently a dynamically-learned VLAN, the VLAN is converted to the Static type and the device initiates an appropriate Syslog message. Though the VLAN is Static in type, its member switch ports are of the Dynamic type (dynamically learned).

If you configure a Static VLAN on a MVRP-enabled dynamically-learned switch port, the ports are configured to the Static type and the device initiates an appropriate Syslog message.

You cannot delete a Static VLAN with Dynamic ports through the CLI until all Dynamic ports are converted to Static.

- The device supports MVRP in compliance to the 802.1ak standard along with the following:
  - Hitless Failover (i.e., HA)
  - GVRP objects in the Dot1q Bridge MIB (Only SNMP Read operations are supported)
  - Interoperability with ExtremeRouting MLX Series, ExtremeRouting CER Series, and ExtremeSwitching CES Series devices
- The device also supports the following Layer 2 features with MVRP:
  - Spanning Tree Protocol (STP)
  - Rapid Spanning Tree Protocol (RSTP)
  - Common Internal Spanning Tree (CIST)
  - Multi Chassis Trunking (MCT)
  - Endpoint tracking (EP)
- The following features are not supported with MVRP:
  - PVST and PVST+
  - RPVST and RPVST+
  - MSTIs for MSTP
  - MVRP over any ring protocols
  - MVRP with topology groups

## Enabling MVRP on an Ethernet interface

Perform the following steps to enable MVRP on an Ethernet interface.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Add a VLAN on a device that will be added to the interface.

```
device(config)# vlan 10
```

This command accesses VLAN configuration mode.

```
device(config-vlan-10)#
```

3. Access global configuration mode.

```
device(config-vlan-10)# exit
```

4. Enable MVRP globally on the device.

```
device(config)# protocol mvrp
```

This command accesses MVRP configuration mode.

```
device(config-mvrp)#
```

5. Access global configuration mode.

```
device(config-mvrp)# exit
```

6. Configure an Ethernet interface and access interface configuration mode.

```
device(config)# interface ethernet 1/1
```

7. Place the interface in Layer 2 mode.

```
device(conf-if-eth-1/1)# switchport
```

8. Set the Layer 2 interface as trunk.

```
device(conf-if-eth-1/1)# switchport mode trunk
```

Trunk mode makes the port linkable to other switches and routers.

9. Add the VLAN to the interface as tagged.

```
device(conf-if-eth-1/1)# switchport trunk allowed vlan add 10
```

10. Enable MVRP on the interface.

```
device(conf-if-eth-1/1)# mvrp enable
```

11. Enable the interface.

```
device(conf-if-eth-1/1)# no shutdown
```

12. Display the MVRP status of the configuration.

```
device(conf-if-eth-1/1)# do show mvrp
```

```
-----
Total configured mvrp ports      :      1
Global Status                    :      Enabled
Join-timer(in centiseconds)     :      20
Leave-timer(in centiseconds)     :      100
Leaveall-timer(in centiseconds)  :      1000
-----
MVRP Port(s): ethe 1/1
```

The following example provides the steps in the previous configuration.

```
device# configure terminal
device(config)# vlan 10
device(config-vlan-10)# exit
device(config)# protocol mvrp
device(config-mvrp)# exit
device(config)# interface ethernet 1/1
device(conf-if-eth-1/1)# switchport
device(conf-if-eth-1/1)# switchport mode trunk
device(conf-if-eth-1/1)# switchport trunk allowed vlan add 10
device(conf-if-eth-1/1)# mvrp enable
device(conf-if-eth-1/1)# no shutdown
device(conf-if-eth-1/1)# do show mvrp
```

```
-----
Total configured mvrp ports      :      1
Global Status                    :      Enabled
Join-timer(in centiseconds)     :      20
Leave-timer(in centiseconds)     :      100
Leaveall-timer(in centiseconds)  :      1000
-----
```

```
MVRP Port(s): ethe 1/1
```

## Configuring an edge port

To ensure that the MVRPDU is not exchanged on the edge port, set the applicant state as non-participant on the port.

This procedure assumes that MVRP is enabled on the device.

Perform the following steps.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Configure an Ethernet interface and access interface configuration mode.

```
device(config)# interface ethernet 1/1
```

3. Enable MVRP on the interface.

```
device(conf-if-eth-1/1)# mvrp enable
```

4. Configure the applicant mode of the interface to non-participant.

```
device(conf-if-eth-1/1)# mvrp applicant-mode non-participant
```

The default applicant mode setting for this command is normal-participant.

The following example are the steps in the previous configuration.

```
device# configure terminal
device(config)# interface ethernet 1/1
device(conf-if-eth-1/1)# mvrp enable
device(conf-if-eth-1/1)# mvrp applicant-mode non-participant
```

# Configuring the VLAN registration mode on the interface

By default, the registration mode for an MVRP-enabled interface is set to Normal. For a static VLAN configuration, the registration mode is automatically set to Fixed. To prune the advertisement propagation and deregistration of a dynamic VLAN on an MVRP-enabled interface port, you can register the VLAN as Forbidden.

This procedure assumes that MVRP is enabled on the device.

## NOTE

You cannot configure a static VLAN as forbidden. If a VLAN is configured in the forbidden list and then it is configured as a static VLAN on the device, this VLAN is implicitly removed from the forbidden list.

Perform the following steps.

1. In privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Configure an Ethernet interface and access interface configuration mode.

```
device(config)# interface ethernet 1/9
```

3. Enable MVRP on the interface.

```
device(config-if-eth-1/9)# mvrp enable
```

4. Register the VLAN on the forbidden list.

```
device(config-if-eth-1/9)# mvrp registration-mode forbidden vlan add 10
```

You can also provide a range of VLANs.

The following example are the steps in the previous configuration.

```
device# configure terminal
device(config)# interface ethernet 1/9
device(config-if-eth-1/9)# mvrp enable
device(config-if-eth-1/9)# mvrp registration-mode forbidden vlan add 10
```

## MVRP over a port channel

You can enable MVRP on a port channel configured in either static or dynamic mode. When MVRP is enabled, it runs on the port-channel interface which determines its MAP context but not on individual member ports of the port-channel interface. MVRP derives its port state from the STP state of the port-channel interface for its advertising decisions.

## Enabling MVRP over a port channel

Perform the following steps to enable MVRP over a port channel.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Enable MVRP globally on the device.

```
device(config)# protocol mvrp
```

This command accesses MVRP configuration mode.

```
device(config-mvrp)#
```

3. Access global configuration mode.

```
device(config-mvrp)# exit
```

4. Configure an Ethernet interface.

```
device(config)# interface ethernet 1/1,2
```

This command accesses interface configuration mode.

```
device(conf-if-eth-1/1,2)#
```

5. Enable static link aggregation on the interface.

```
device(conf-if-eth-1/1,2)# channel-group 10 mode on
```

6. Enable the interface.

```
device(conf-if-eth-1/1,2)# no shutdown
```

7. Access global configuration mode.

```
device(conf-if-eth-1/1,2)# exit
```

8. Configure the port-channel interface and access port-channel configuration mode.

```
device(config)# interface Port-channel 10
```

9. Enable the port channel in Layer 2 mode.

```
device(config-Port-channel-10)# switchport
```

10. Set trunk mode on the port channel.

```
device(config-Port-channel-10)# switchport mode trunk
```

11. Enable MVRP on the port channel.

```
device(config-Port-channel-10)# mvrp enable
```

12. Enable the port channel.

```
device(config-Port-channel-10)# no shutdown
```

13. Display the MVRP status of the configuration.

```
device(config-Port-channel-10)# do show mvrp
```

```
-----
Total configured mvrp ports      :      1
Global Status                    :      Enabled
Join-timer(in centiseconds)     :      20
Leave-timer(in centiseconds)     :      100
Leaveall-timer(in centiseconds)  :     1000
-----
```

```
MVRP Port(s): Po 10
```

The following example provides the steps in the previous configuration.

```
device# configure terminal
device(config)# protocol mvrp
device(config-mvrp)# exit
device(config)# interface ethernet 1/1,2
device(conf-if-eth-1/1,2)# channel-group 10 mode on
device(conf-if-eth-1/1,2)# no shutdown
device(conf-if-eth-1/1,2)# exit
device(config)# interface Port-channel 10
device(config-Port-channel-10)# switchport
device(config-Port-channel-10)# switchport mode trunk
device(config-Port-channel-10)# mvrp enable
device(config-Port-channel-10)# no shutdown
device(config-Port-channel-10)# do show mvrp
```

```
-----
Total configured mvrp ports      :      1
Global Status                    :      Enabled

```

```
MVRP Port(s): Po 10
```

## Configuring the MVRP join, leave, and leave-all timers

By default, the MVRP join, leave, and leave-all timer have the following settings.

- The join timer default setting is 20 centiseconds (cs).
- The leave timer default setting is 100 cs. The leave timer setting must be greater than or equal to twice the join timer setting plus 30 centiseconds.
- The leave-all timer default setting is 1000 cs. The leave-all timer setting must be a minimum of three times the value of the leave timer setting.

You can configure global timer settings or settings for each interface that overrides the global timer settings. If the network radius is large or the expected system load is higher normally, Extreme recommends that you change the timer values to higher numbers as appropriate for the MVRP operation to reduce the MVRP PDU exchanges and processing by the NSM.

1. In privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. To set the global timer settings, access MVRP configuration mode.

```
device(config)# protocol mvrp
```

3. Set the global MVRP join, leave and leave-all timers values that will be applied implicitly on all the MVRP-enabled interfaces.

```
device(config-mvrp)# timer join 40 leave 200 leave-all 2000
```

In this step, the join timer is set to 40 centiseconds (cs), the leave timer is set to 200 cs, and the leave-all timer is set to 2000 cs.

4. Access global configuration mode.

```
device(config-mvrp)# exit
```

- To set the timers for an individual interface, access the configuration mode for the interface.

```
device(config)# interface ethernet 1/1
```

This step is for an Ethernet interface. You can also change the settings for a port-channel interface.

- Configure the timers for the interface.

```
device(conf-if-eth-1/1)# timer join 50 leave 300 leave-all 3000
device(conf-if-eth-1/1)#
```

The following example provides the steps for setting the MVRP timers globally and for an interface.

```
device# configure terminal
device(config)# protocol mvrp
device(config-mvrp)# timer join 40 leave 200 leave-all 2000
device(config-mvrp)# exit
device(config)# interface ethernet 1/1
device(conf-if-eth-1/1)# timer join 50 leave 300 leave-all 3000
device(conf-if-eth-1/1)#
```

## Displaying MVRP configuration information, statistics, and attributes

You can display the following MVRP information:

- Global and specified interface configuration information
- Interface statistics
- Attributes for all interfaces, a specified interface, or a specified VLAN

## Displaying the global MVRP information on the device

To display the global MVRP information on the device including configured ports, global enable status, and timer settings, use the **show mvrp** command.

```
device# show mvrp
-----
Total configured mvrp ports      : 5
Global Status                    : Enabled
Join-timer(in centiseconds)     : 20
Leave-timer(in centiseconds)     : 100
Leaveall-timer(in centiseconds)  : 1000
-----
MVRP Port(s): eth1/1, eth1/5, eth1/7, eth1/9, po11
```

## Displaying the MVRP information for an Ethernet or port-channel interface

To display the MVRP information for an Ethernet or port-channel interface, use the **show mvrp interface** command. This information includes the MVRP status, timer and applicant-mode settings, and information about registered, declared, and forbidden VLANs.

```
device# show mvrp interface ethernet 1/1
-----
MVRP Status                : Enabled
Join-timer(in centiseconds) : 20
Leave-timer(in centiseconds) : 100
Leaveall-timer(in centiseconds) : 1000
P2p                        : Yes
Applicant Mode              : normal-participant
-----
Registered Vlan(s)         : 1 to 60 77 100 to 500 999
Declared Vlan(s)           : 1 to 60 77 100 to 500 999
Forbidden Vlan(s)          : 10
-----
```

## Displaying the MVRP statistics for an Ethernet or port-channel interface

To display the statistics for received and transmitted MVRPDU messages on the interfaces, use the **show mvrp statistics** command.

The following example displays the statistics for all interfaces.

```
device# show mvrp statistics
Port : eth1/1
-----
Message type                Transmitted  Received
-----
New                          0          0
In                           0         1809
Join In                      1816         0
Join Empty                   1788         0
Empty                        0         771
Leave                         99          0
Leave-all                    264         512
-----
Total PDUs                   1827         1293
-----
Port-channel : Po100
-----
Message type                Transmitted  Received
-----
New                          0           2
In                           693          0
Join In                      1800         1777
Join Empty                   0         1956
Empty                        396          0
Leave                         0           96
Leave-all                    369         346
-----
Total PDUs                   1807         1799
-----
```

## Displaying MVRP attributes

To display attributes for all or specific MVRP-enabled Ethernet or port-channel interfaces including the port and VLAN states, use the **show mvrp attributes** command.

The following example displays MVRP attributes for all interfaces.

```
device# show mvrp attributes
Port : eth2/17    State : Disabled
-----
VLAN      Registrar      Registrar      Applicant
         State          Mgmt           State
-----
Port : eth2/5    State : Forwarding
-----
VLAN      Registrar      Registrar      Applicant
         State          Mgmt           State
-----
1         In           Fixed          Quiet Active
5         Empty        Normal         Quiet Active
10        In           Fixed          Quiet Active
Port : po10     State : Forwarding
-----
VLAN      Registrar      Registrar      Applicant
         State          Mgmt           State
-----
1         In           Fixed          Quiet Active
5         In           Normal         Very Anxious Observer
10        Empty        Normal         Quiet Active
```

The following example displays MVRP attributes for a specified interface.

```
device# show mvrp attributes interface ethernet 2/5
Port : eth2/5    State : Forwarding
-----
VLAN      Registrar      Registrar      Applicant
         State          Mgmt           State
-----
1         In           Fixed          Quiet Active
5         Empty        Normal         Quiet Active
10        In           Fixed          Quiet Active
```

The following example displays MVRP attributes for a specified VLAN.

```
device# show mvrp attributes vlan 10
-----
PORT  VLAN      Registrar      Registrar      Applicant
      State          Mgmt           State
-----
eth2/5 10      In           Fixed          Quiet Active
po10   10      Empty        Normal         Quiet Active
```

## Clearing MVRP statistics

To clear MVRP statistics displayed by the **show mvrp statistics** command, use the **clear mvrp statistics** command. You can use this command for either an interface or all interfaces.

- The following example clears statistics for all the MVRP-enabled interfaces.

```
device# clear mvrp statistics
```

- The following example clears the MVRP statistics for an interface.

```
device# clear mvrp statistics interface ethernet 1/1
```

## MVRP with endpoint tracking

The device supports the advertising of VLANs assigned by the RADIUS server as a part of endpoint tracking by MVRP over MVRP-enabled ports. For more information about endpoint tracking, refer to [Endpoint tracking](#) on page 53 in the VLANs chapter.

- The deployment of MVRP and endpoint tracking is similar to MVRP configured on edge ports.
- MVRP and endpoint tracking are supported together in MCT deployments.
- MVRP and endpoint tracking work as independent features or can work together.
- MVRP will advertise the endpoint tracking VLANs, similar to static VLANs.
- MVRP state machines treat the endpoint tracking VLANs the same way as a static VLANs with regards to its FSM states.
- The dynamic VLANs assigned by endpoint tracking and by MVRP can have an impact on each other similar to CLI driven static VLANs with MVRP VLANs. The dynamic VLANs assigned by endpoint tracking are displayed in operational **show** commands for MVRP, same as in the case of static VLANs. In case of conflict, the following rules apply:
  - The static VLAN has the highest precedence, followed by the endpoint tracking VLAN and MVRP VLANs.
  - When endpoint tracking creates a VLAN and MVRP also tries to create a dynamic VLAN with the same VLAN ID in the system, MVRP recognizes that an endpoint tracking-enabled VLAN already exists and adds ports dynamically to it; as in case of a static VLAN.
  - If the RADIUS server deletes the endpoint tracking VLAN, the system deletes the VLAN and, if required, MVRP reprograms it to ensure that it is cleaned up across the network and no false instances remains for this VLAN.
  - When MVRP withdraws a VLAN, it has no impact on the endpoint tracking created VLAN, similar to a static VLAN.

### NOTE

If MVRP is enabled on an MCT node, you must configure the interface enabled for endpoint tracking with MVRP applicant mode as non-participant through the **mvrp applicant-mode non-participant** command in interface configuration mode. Refer to [Endpoint tracking](#) on page 53 in this document. Also, if you observe an MVRP flap, configure MVRP timers to higher values on the ICL interfaces. For details, refer to the **timer** command.

The following example is the configuration of endpoint tracking with MVRP.

```
interface Ethernet 4/15
  switchport
  switchport mode trunk
  switchport trunk tag native-vlan
  endpoint-tracking enable
  mvrp enable
  mvrp applicant-mode non-participant
  no shutdown
!
```

## MVRP over MCT

This device supports MVRP over MCT. Multi-Chassis Trunking (MCT) is trunking that initiates at a single MCT-unaware server or switch and terminates at two MCT-aware switches. MCT allows the links to the two MCT-aware switches to appear to a downstream device as if they are coming from a single device on a single Link Aggregation (LAG) trunk interface or physical port.

With MCT, member links of the LAG trunk are connected to two MCT-aware devices. A configuration between the devices enable data flow and control messages between them to establish a logical Inter-Chassis Link (ICL). In this model, if one MCT device fails, a data path remains through the other device. The following figure shows switch level redundancy provided by MCT between MCT clients through MCT peers.

FIGURE 20 MVRP over MCT example

For more information on MCT and terminology, refer to the MCT chapter.

Consider the example, as shown in the previous figure, where Layer 2 Switch-1 and Layer 2 Switch-2 are CCEP clients and Layer 2 Switch-3 and Layer 2 Switch-4 are CEP clients. SLX-1 and SLX-2 are MCT peers with Ethernet port 1/3 on them being the ICL interfaces and PO 6 on them being the CCEP interfaces.

When MVRP over MCT is implemented on the device and the CCEP client is connected to both MCT peers registered through LAG, MVRP applies the dynamic VLANs on both MCT devices for the CCEP client interfaces. Also, the MVRPDU is propagated onto other MVRP-enabled interfaces except the ICL interface to avoid the formation of a loop. The MVRPDU transmission to the CCEP clients is performed by either of the two MCT peers based on the master derived from the BGP loopback IP.

In the case of the CEP client, the connected interface in the MCT device is with the MVRP dynamic VLANs advertised by the CEP client and the peer MCT device has the same dynamic VLANs replicated. The BGP EVPN pseudowire automatically handles the data traffic on the ICL when the VLAN is configured on both MCT peers this way.

Common Transport Protocol (CTP) communicates between MCT peers and carries MVRPDUs to ensure that the MCT peers configured with MVRP dynamic VLANs do not form a loop and dynamic VLANs are not added to the ICL interface.

## MVRP over MCT configuration example

The following list summarizes the recommended MVRP over MCT configuration. After which, the configuration examples for SLX-1 and SLX-2 are provided in their entirety.

1. Ensure that the MCT cluster configuration is completed and the cluster is up.
2. The following VLAN configuration is for communications on the ICL link.

```
vlan 2
router-interface Ve 2
!
```

3. The following VLAN 4089 configuration is a predefined VLAN to be configured on either MCT peers' corresponding CCEP interface to ensure that the cluster client is always up. Each CCEP interface must be associated with a unique VLAN.

```
vlan 4089
!
```

4. The following EVPN configuration defines the VLANs on each of the cluster peers for the data path to work seamlessly for the configured VLANs on either node. Extreme recommends that you define VLANs 1 through 2K (the maximum VLANs supported for MVRP) under the EVPN configuration on both cluster peers for seamless data traffic flow on the ICL link. VLAN 4089, associated with the CCEP interface, also needs to be part of the EVPN configuration.

```
evpn default
route-target both auto ignore-as
rd auto
vlan add 3-2000,4089-4090
!
```

5. MVRP must be enabled globally. Global timers must be configured to the following values on the cluster nodes.

```
protocol mvrp
timer join 20 leave 300 leave-all 3000
```

6. MVRP must be enabled on the ICL interface (physical or port-channel interface) and the following MVRP timer values are configured on it for MVRP to work seamlessly on the ICL link.

### NOTE

The recommended timer values on the ICL link must be a minimum of 20 centiseconds (cs) for the join timer, 2000 cs for the leave timer, and 6000 cs for the leave-all timer. The reason for this recommendation is that multiple CEP and CCEP clients would be connected to either MCT nodes. Only one leave timer would be associated with an interface for all VLANs advertised by the CEP and CCEP clients. Configuring a shorter leave timer would mean a faster timeout for the dynamic VLANs which would trigger a leave timer expiry on the ICL link. Frequent leave timer expiry in the ICL link would result in MVRP protocol flaps and VLAN synchronization issues. This is best avoided by configuring the recommended timer values.

If the End-Point tracking feature is enabled with MVRP on MCT peers, the recommended timer values on the ICL link must be minimum of a minimum of 20 cs for the join timer, 5000 cs for the leave timer, and 15000 cs for the leave-all timer.

If a forbidden VLAN list is configured on the CEP or EP interface, the VLANs are not honored for this interface to avoid traffic flow for the forbidden VLAN for the CEP or EP client. But the VLANs may be propagated to the other MVRP-enabled ports since other connected CEP or EP clients may be interested in advertising a particular VLAN through MVRP over the ICL.

```
interface Ethernet 1/3
switchport
switchport mode trunk
```

```

switchport trunk allowed vlan add 2
switchport trunk tag native-vlan
mvrp enable
mvrp timer join 20 leave 2000 leave-all 6000
no shutdown
!

```

7. MVRP must be enabled on the corresponding CCEP port-channel interface and the unique VLAN 4089 needs to be associated with the CCEP interface on either cluster nodes.

#### NOTE

The **mvrp enable** configuration must always be present on the corresponding CCEP interfaces on both MCT devices. Configuring it on one MCT peer and not on the other one can cause instability in the network.

If a forbidden VLAN list is configured on an CCEP interface on an MCT device, the corresponding CCEP interface on the other MCT device should have the same configuration.

```

interface Ethernet 1/1
channel-group 5 mode on type standard
no shutdown
!
!
interface Port-channel 5
switchport
switchport mode trunk
switchport trunk allowed vlan add 4089
switchport trunk tag native-vlan
mvrp enable
no shutdown
!

```

8. MVRP must be enabled on the required CEP interfaces (physical or port-channel interface).

```

interface Ethernet 1/13
switchport
switchport mode trunk
switchport trunk tag native-vlan
mvrp enable
no shutdown
!

```

#### NOTE

On the client devices acting as access switches, the MVRP timer values can remain at the MVRP default timer values. You must ensure that timer values on the client devices are less than the global timers configured on the MCT peers to avoid MVRP protocol flaps.

In summary, the recommended MVRP timer values are as follows:

- For global MVRP timers on MCT peers, the recommended values are join 20, leave 300 and leave-all 3000 (in centiseconds).
- For MCT ICL link, the recommended values are a minimum of 20 centiseconds (cs) for the join timer, 2000 cs for the leave timer and 6000 cs for the leave-all timer.

If the endpoint tracking feature is operating with MVRP, then the recommended timer values on the ICL interface are a minimum of 20 cs for the join timer, 5000 cs for the leave timer, and 15000 cs for the leave-all timer.

- For all the other clients connected to the MCT peers, the recommended values are the default timer values.

The following examples provide the recommended configuration for SLX-1 and SLX-2.

## SLX-1 configuration example

```

vlan 1
!

# Logical Interfaces

---

- [Logical interfaces overview](#).....147
- [Configuring a logical interface on a physical port or port-channel \(LAG\)](#)..... 149

## Logical interfaces overview

A logical interface (LIF) serves the purpose of abstracting a forwarding interface in a very generic way, making it possible to capture the underlying physical characteristics of a forwarding interface.

This feature facilitates the support of future forwarding technologies without the need to modify code design in various software components.

A forwarding interface is also known as "main interface." It can be a physical port, a port-channel (Link Aggregation Group, or LAG), a pseudowire (PW), a tunnel, and so on. A logical interface can also be thought of as a subinterface configuration on top of a main interface.

### NOTE

Currently the only LIFs that require explicit user configuration are attachment circuit (AC) LIFs.

## LIFs and bridge domains

A Layer 2 application for LIFs is for bridge domains (BDs). A BD is an infrastructure that supports the implementation of different switching technologies; it is essentially a generic broadcast/forwarding domain that is not tied to a specific transport technology. Bridge domains support a wide range of service endpoints, including regular Layer 2 endpoints and Layer 2 endpoints over Layer 3 technologies. Logical interfaces representing BD endpoints must be created before they can be bound to a BD. For more information and configuration details, refer to the [Bridge Domains](#) on page 151 chapter in this guide.

## Configuration considerations

The following are some common rules to consider in configuring logical interfaces:

- By default, when the LIF is created it is configured as "no shutdown."
- By default, when the LIF is created, it is "tagged" unless it is explicitly configured with the "untagged" option.
- Allowed LIF service instance ID ranges are from 1 through 12288.
- An LIF service instance ID has no correlation to the VLAN ID of the LIF.
- Each physical/LAG-based LIF must have an associated VLAN configured or else it will not be usable when the user attempts to add it to a service (such as VPLS, Layer 2). Such a configuration request to add the LIF to a service will be rejected.
- Once the LIF is associated with a Layer 2 service, its VLAN value cannot be changed or deleted unless it is first removed from the associated service. In case the LIF is not yet associated to a service, the user is free to remove the VLAN configuration or change the VLAN assignment.
- The **no** option to the **logical-interface** command can be applied at any time.
- The "untagged" configuration is allowed for only one LIF under the same physical port or LAG. If one LIF is already configured as untagged, all subsequent attempts on the same physical port or LAG are rejected.
- Once the "untagged" option is selected, it will only have one VLAN as the next classification option. There is no dual-tag support for the untagged case.

- In order to configure an untagged LIF, the main interface must be configured as "switchport mode trunk-no-default-native". If it is configured set to regular trunk mode, the native VLAN is already associated with a regular Layer 2 VLAN LIF and no explicit untagged LIF can be configured on that interface.
- Once the LIF is associated with a service (Layer 2) such as a bridge domain, its "untagged/tagged" configuration cannot be changed. The service instance or its current VLAN classification must be deleted by the user first and then added back with the proper "untagged/tagged" option.
- VLANs 4091 through 4095 are reserved VLANs and these should not be used as the VLAN ID for either the inner or outer VLAN of the LIF.
- The VLAN specified under the LIF ensures that such a VLAN is not already configured under the **switchport** command for a regular Layer 2 allowed VLAN.

If the interface is already configured as "switchport access," then it is not allowed to be configured with LIF. The reverse condition is also not allowed: the interface cannot be changed to mode access if a LIF is still configured under the main interface.

# Configuring a logical interface on a physical port or port-channel (LAG)

This task configures a logical interface on a physical (Ethernet) port and a port-channel (Link Aggregation Group, or LAG) interface.

Refer to the Usage Guidelines for the **logical-interface** command for complete details.

1. Do the following to configure a logical interface on an Ethernet port.

- a) Enter global configuration mode.

```
device# configure terminal
```

- b) Specify an Ethernet interface.

```
device(config)# interface ethernet 2/6
```

- c) Enter the **switchport** command to configure the parent interface as switchport.

```
device(config-if-eth-2/6)# switchport
```

- d) Enter the **switchport mode trunk-no-default-native** command to enable an explicit untagged LIF to be configured.

```
device(config-if-eth-2/6)# switchport mode trunk-no-default-native
```

- e) Enable the interface.

```
device(config-if-eth-2/6)# no shutdown
```

- f) Enter the **logical-interface** command, specify a service instance, and enter LIF configuration mode.

```
device(config-if-eth-2/6)# logical-interface ethernet 2/6.120
```

- g) (Optional) Enter the **name** command to facilitate the management of the LIF.

```
device(config-if-eth-lif-2/6.120)# name myLIF120
```

- h) Enter the **vlan** command with the **inner-vlan** option to specify an interface and create dual-tag VLANs.

```
device(config-if-eth-lif-2/6.120)# vlan 120 inner-vlan 200
```

- i) Alternatively, enter the **untagged vlan** command to specify that the LIF is to receive untagged packets.

```
device(config-if-eth-lif-2/6.120)# untagged vlan 120
```

See the Usage Guidelines for the **vlan (LIF)** command.

- j) (Optional) By default, the administrative state of the LIF is "no shutdown." To remove the port from participating in any data traffic without having to shut down the physical interface, enter the **no** form of the **shutdown (LIF)** command.

```
device(config-if-eth-lif-2/6.120)# no shutdown
```

- k) (Optional) For convenience, you can also enter up to two options in a single command line, as in the following examples.

```
device(config-if-eth-2/6)# logical-interface ethernet 2/6.120 name myLIF120
```

```
device(config-if-eth-2/6)# logical-interface ethernet 2/6.120 vlan 120
```

2. To configure a port-channel, configure the basic LIF parameters and options as in Step 1.
  - a) Specify a port-channel, set its mode to "trunk-no-default-native," and specify a logical interface service instance.

```
device(config)# interface port-channel 10
device(config-port-channel-10)# switchport mode trunk-no-default-native
device(config-port-channel-10)# logical-interface port-channel 10.3
device(config-if-po-lif-10.3)#
```

- b) Repeat additional substeps in Step 1 as appropriate.

# Bridge Domains

## Bridge domain overview

Bridge domain is an infrastructure that supports the implementation of different switching technologies.

A bridge domain is a generic broadcast domain that is not tied to a specific transport technology. Bridge domains support a wide range of service endpoints including regular L2 endpoints and L2 endpoints over L3 technologies.

Bridge domains switch packets between a range of different endpoint types; for example, attachment circuit (AC) endpoints, Virtual Private LAN Service (VPLS) endpoints, Virtual Leased Line (VLL) endpoints, and tunnel endpoints.

The following are examples of bridge-domain capable services:

- VPLS—with multiple AC endpoints and pseudowire (PW) logical interfaces (LIFs)
- Local VPLS—with multiple AC endpoints
- VLL—with one AC endpoint and one PW endpoint
- VLL—with two AC endpoints

A bridge domain that is created for a VPLS application is also referred to as a VPLS instance.

## Bridge domain statistics

Devices gather statistics for all the logical interfaces and peers in bridge domains.

Statistics must be manually enabled for a specific bridge domain, since statistics for bridge domains are not enabled by default.

Use the **statistics** command in bridge domain configuration mode to enable statistics on a bridge domain.

### NOTE

- The statistics reported are not real-time statistics since they depend upon the load on the system.
- Enabling statistics on a bridge domain has a heavy impact on data traffic.
- For optimum utilization of the statistics resources in the hardware, statistics on a bridge domain are not enabled by default.

## Configuring a bridge domain

Bridge domains are configured independently of the different switching technologies that they support.

Before configuring a bridge domain, configure any logical interface that is to be bound to the bridge domain. Logical interfaces that represent bridge-domain endpoints must be created before they are bound to a bridge domain. For further information on configuration of logical interfaces, refer to *Logical Interfaces*.

There is an example at the end of this task that shows all the configuration steps in order.

Perform the following task to configure a bridge domain.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Create a bridge domain.

```
device(config)# bridge-domain 5 p2p
```

By default, the bridge-domain service type is multipoint (**p2mp**). In this example, bridge domain 5 is configured as a point-to-point service (**p2p**).

3. **NOTE**

Logical interfaces representing bridge-domain endpoints must be created before they can be bound to a bridge domain. For further information, refer to *Logical Interfaces*.

Bind the logical interfaces for attachment circuit endpoints to the bridge domain.

```
device(config-bridge-domain-5)# logical-interface ethernet 1/6.400
```

In this example, Ethernet logical interface 1/6.400 is bound to bridge domain 5.

4. Repeat Step 4 to bind other logical interfaces for attachment circuit endpoints to the bridge domain.

```
device(config-bridge-domain-5)# logical-interface port-channel 2.200
```

In this example, port channel logical interface 2.200 is bound to bridge domain 5.

5. (Optional) Enable local switching for bridge domain 5.

```
device(config-bridge-domain-5)# local-switching
```

By default, local switching is enabled.

6. (Optional) Enable dropping L2 bridge protocol data units (BPDUs) for bridge domain 5.

```
device(config-bridge-domain-5)# bpdu-drop-enable
```

The following example creates bridge domain 5. It binds ethernet and port-channel logical interfaces to the bridge domain. It configures local switching, and enables dropping of L2 BPDUs.

```
device# configure terminal
device(config)# bridge-domain 5
device(config-bridge-domain-5)# logical-interface ethernet 1/6.400
device(config-bridge-domain-5)# logical-interface port-channel 2.200
device(config-bridge-domain-5)# local-switching
device(config-bridge-domain-5)# bpdu-drop-enable
```

## Displaying bridge-domain configuration information

Various show commands can be used to display bridge-domain configuration information.

- Enter the **show bridge-domain** command to display information about all configured bridge domains.

```
device# show bridge-domain
```

```
Total Number of bridge-domains: 3

```

## Enabling statistics on a bridge domain

Statistics may be enabled for a specific bridge domain.

### NOTE

By default statistics are disabled on bridge domains. After enablement, statistics should be disabled when no longer needed because the collection of statistical information has a heavy impact on data traffic.

1. Enter the global configuration mode.

```
device# configure terminal
```

2. Enter the **bridge-domain** command to create a bridge domain at the global configuration level.

```
device(config)# bridge-domain 3
```

3. Enter the **statistics** command to enable statistics for all the logical interfaces and peers in the bridge domain.

```
device(config-bridge-domain-3)# statistics
```

#### NOTE

When statistics are no longer needed, use the **no statistics** command to disable statistics on the bridge domain.

The following example shows how to enable statistics on bridge domain 3.

```
device# configure terminal
device(config)# bridge-domain 3
device(config-bridge-domain-3)# statistics
```

The following example shows how to disable statistics on bridge domain 3.

```
device# configure terminal
device(config)# bridge-domain 3
device(config-bridge-domain-3)# no statistics
```

## Displaying statistics for logical interfaces in bridge domains

Various commands can be used to display statistical information for bridge domains.

- Enter the **show statistics bridge-domain** command to display statistics for all logical interfaces and peers on all configured bridge domains.

```
device# show statistics bridge-domain
```

#### Bridge Domain 1 Statistics

| Interface    | RxPkts | RxBytes  | TxPkts   | TxBytes |
|--------------|--------|----------|----------|---------|
| eth 1/1.100  | 821729 | 95940360 | 95940360 |         |
| eth 1/21.200 | 884484 | 95969584 | 95484555 |         |
| po 1.300     | 8884   | 9684     | 9955     |         |

#### Bridge Domain 20 Statistics

| Interface    | RxPkts | RxBytes  | TxPkts   | TxBytes |
|--------------|--------|----------|----------|---------|
| eth 1/6.400  | 821729 | 95940360 | 95940360 |         |
| eth 1/21.100 | 8884   | 9684     | 9955     |         |
| po 2.40      | 884484 | 95969584 | 95484555 |         |

- Enter the **show statistics bridge-domain** command specifying a bridge-domain ID to view the statistics for a specific bridge domain. The following example displays statistics for bridge-domain ID 1.

```
device# show statistics bridge-domain 1
```

#### Bridge Domain 1 Statistics

| Interface    | RxPkts | RxBytes  | TxPkts   | TxBytes |
|--------------|--------|----------|----------|---------|
| eth 1/1.100  | 821729 | 95940360 | 95940360 |         |
| eth 1/21.200 | 884484 | 95969584 | 95484555 |         |
| po 1.300     | 8884   | 9684     | 9955     |         |

# Clearing statistics on bridge domains

Statistical information can be cleared for all bridge domains or for a specific bridge domain.

- Enter the **clear statistics bridge-domain** command to clear statistics for all logical interfaces and peers on all configured bridge domains.

```
device# clear statistics bridge-domain
```

- Enter the **clear statistics bridge-domain** command specifying the bridge-domain ID to clear the statistics for a specific bridge domain. The following example shows how to clear statistics for bridge domain ID 1.

```
device# clear statistics bridge-domain 1
```

## VPLS overview

Virtual Private LAN Service (VPLS) is a Layer 2 Virtual Private Network (L2 VPN) architecture that provides multipoint Ethernet LAN services.

VPLS provides transparent LAN services across provider edge (PE) devices using Internet Protocol (IP) or Multiprotocol Label Switching (MPLS) as the transport technology.

Because it emulates LAN switching, VPLS is considered to be a L2 service that operates over Layer 3 (L3) clouds.

VPLS provides point-to-multipoint (p2mp) functionality while VLL is a special type of VPLS deployment that performs point-to-point (p2p) switching.

VLL is a special type of VPLS deployment that performs point-to-point switching.

The following figure shows a VPLS topology in which switched packets traverse a network.

**FIGURE 21** VPLS topology with switching between attachment circuits (ACs) and network core

AC1 and AC2 represent L2 connectivity between customer edge (CE) and provider edge (PE) devices.

Pseudowire is a circuit emulation infrastructure that extends L2 connectivity from CE1 to CE2 by way of PE1 and PE2. The tunnel is typically a L3 tunnel on which a L2 circuit is emulated.

In the case of a packet flowing from CE1 to CE2, the packet enters PE1 from CE1 after the forwarding database (FDB) is used to determine the destination MAC address. Then, a virtual connection (VC) label is imposed prior to encapsulation with the tunnel forwarding information, and the packet is sent out onto the wire towards the network core.

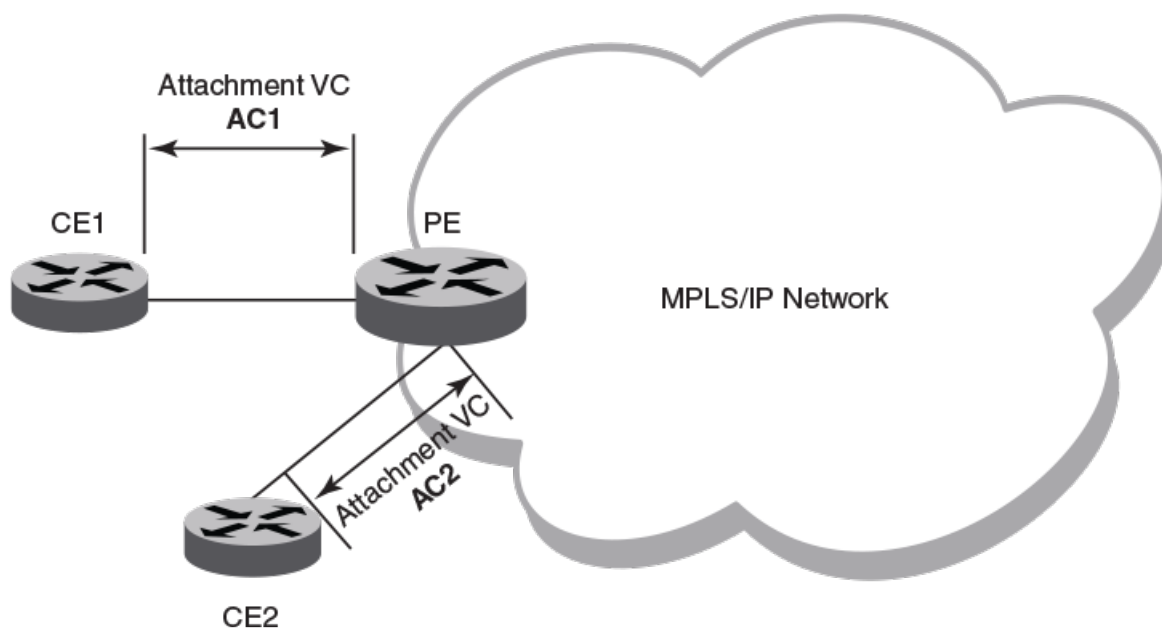

Essentially, the topology in the preceding figure shows a L2 VPN enabling the transport of L2 traffic between two or more native Ethernet networks through an underlying Multiprotocol Label Switching (MPLS) provider network. Customer edge (CE) is the last mile and provider edge (PE) is the first mile node for packets transported towards the provider network. The provider intermediary network is an emulated switch (LAN) or wire (LINE) to the CE. The attachment circuit (AC) represents the logical link between the CE and PE.

An AC may be a port, IEEE 802.1q or IEEE 802.1ad (QinQ) for Ethernet VPNs. A pseudowire (PW) or emulated wire is used as a transport mechanism to tunnel frames between PEs. A PW is characterized by a circuit identifier, which identifies the destination PE.

MPLS tunnels and paths are established by using routing protocols. PW circuits are established by using signaling.

The following figure shows a VPLS topology where switching occurs between two local AC endpoints. This implementation of VPLS does not use VC labels or a pseudowire.

**FIGURE 22** VPLS topology with local switching

The following figure shows a common VPLS deployment; an enterprise LAN service. The CE devices represent customer edge devices while the PE devices represent provider edge devices.

FIGURE 23 Enterprise LAN service (VPLS)

## VLL

Virtual Leased Line (VLL) is a Layer 2 Virtual Private Network (L2 VPN) architecture that provides point-to-point Ethernet line or Virtual Private Wire Services (VPWS).

A VLL instance is a special type of VPLS deployment.

VLL provides point-to-point (p2p) connectivity between two access networks or endpoints. Typically, a VLL is used to connect two sites that are geographically apart.

The following figure depicts an enterprise VLL service.

**FIGURE 24** Enterprise leased line service (VLL)

CE1 and CE2 are the customer edge devices in geographically separate sites.

Pseudowire (PW) is a circuit emulation infrastructure that extends L2 connectivity from CE1 to CE2 by way of PE1 and PE2. The tunnel is typically a L3 tunnel on which a L2 circuit is emulated.

## VPLS service endpoints

VPLS supports two types of service-endpoints for VPLS and VLL.

Service endpoints can be categorized as:

- AC endpoints
- PW endpoints

An AC endpoint is a L2 link between a PE device and a CE device. The AC endpoint can be an untagged port, or a tagged port with one or more VLANs. AC endpoints with different VLAN tags can be configured in a single VPLS instance.

A VLL instance interconnects two AC endpoints through a pseudowire, while a VPLS instance forms a full mesh interconnection between multiple AC endpoints through multiple PWs.

The following endpoints are supported:

- port-vlan
- port-vlan-vlan
- PW

Both regular port and port-channel interfaces can be used to form port-vlan, untagged port-vlan, and port-vlan-vlan endpoints.

VPLS service endpoints are represented by logical interfaces (LIFs). By using LIFs, features that apply to regular interfaces, such as QoS, can be applied to VPLS service endpoints.

## Local switching

The forwarding behavior of AC endpoints in a VPLS instance is controlled by the switching-mode configuration for local endpoints.

When local switching is enabled, traffic is switched and flooded among AC endpoints in addition to between ACs and PWs. When local switching is disabled, the flooding between AC endpoints is suppressed.

When an unknown unicast packet is received on an AC endpoint and local switching is enabled, the packet is flooded to all other AC endpoints and PW endpoints in the VPLS instance. When local switching is disabled, the unknown packet is only flooded to the PW endpoints in the domain.

Regardless of the local switching configuration, an unknown unicast packet that is received on a PW endpoint is flooded to all AC endpoints.

By default, local switching is enabled.

In a VPLS instance that does not have a PW peer and where all endpoints are AC endpoints (Local VPLS), local switching must be enabled.

To avoid receipt of traffic with different VLAN tags on local endpoints, it is recommended that local switching is disabled in a bridge domain where the PW profile is configured with the VC mode option of **raw-passthrough**. Raw passthrough mode is designed to forward packets between two VPLS peer devices and is not intended for use with local switching.

## Pseudowires

A pseudowire (PW) is a virtual circuit (VC) formed between two provider edge (PE) devices that connects peering Virtual Private LAN Services (VPLS) PE nodes.

An Ethernet pseudowire is logically viewed as an L2 nexthop (VC label) that is reachable through an L3 nexthop (LDP label).

The frames from an AC endpoint packet are sent through an ingress pseudowire interface (which abstracts the transport path and packet encapsulations) towards the remote PE. An egress pseudowire interface then abstracts the packet received from a remote PE and hands it over to the corresponding AC end-point.

A pseudowire interface is unidirectional.

PWs support the following underlying MPLS tunnels:

- LDP – Single Path LSP
- RSVP – Single Path LSP
- RSVP – Pri/Sec (Act LSP)
- RSVP – Pri/Sec (Pas LSP)
- FRR: Adaptive LSP (Make Before Break)
- FRR: Protected & detour (1:1)

PWs do not support the following underlying MPLS tunnels:

- FRR: Protected & Bypass (N:1)
- LDP – Multipath LSP (ECMP)
- LDP over RSVP

## Pseudowire operation

The pseudowire setup process establishes the reachability of VPLS bridge domain endpoints across an IP or MPLS cloud.

A pseudowire is operational when the following conditions are met:

- VC signaling is established.
- The L3 reachability of the PW peer is resolved.
- At least one AC endpoint within the bridge domain is up.

A pseudowire is non-operational when the following conditions are met:

- No logical interface is configured for the VPLS instance.
- All AC endpoints are non-operational.

## Supported pseudowire features

Pseudowires (PWs) support the following features for each configured PW:

- LSP Load Balancing—Load balancing across a maximum of 16 underlying MPLS tunnels.
- Assigned LSP—A maximum of 32 LSPs can be assigned.
- Specific COS—The underlying MPLS tunnel with the closest CoS value is selected for the transport
- Raw, raw-passthrough, or tagged mode—Can be configured by way of the PW profile that is associated with the bridge domain.
- MTU and MTU check—Can be configured by way of the PW profile that is associated with the bridge domain.
- Uniform and pipe mode for QoS
- Statistics—Egress and ingress statistics are supported but must be enabled in the bridge-domain configuration by using the **statistics** command

## Unsupported pseudowire features

Pseudowires (PWs) do not support the following features:

- Auto-discovery of peers
- PW redundancy
- Static PW peers
- VC MAC withdraw
- Status TLV update
- VEOVPLS
- OAM
- Multicast snooping
- Extended counters
- High availability—Process restart
- High availability—ISSU

## VLAN tag manipulation (vc-mode) on pseudowires

The virtual connection (VC) mode configuration for a pseudowire (PW) profile determines how VLAN tags are manipulated when a packet is received or transmitted on the PW.

The following table describes VC modes that are supported on PWs.

**TABLE 27** VC modes supported on pseudowires

| VC mode         | Description  |
|-----------------|--|
| Raw             | At VC label imposition, when a tagged packet is received on a tagged AC endpoint, the VLAN tag is removed before it is sent out on the wire. When an untagged packet is received on an untagged AC endpoint it is encapsulated as is and sent out on the wire.   |
| Raw-passthrough | Enables interoperability with third-party devices. When a packet that is destined for a remote peer is received on either a tagged or untagged AC endpoint, it is encapsulated in an MPLS header and sent on to the MPLS cloud without adding or removing VLAN tags. When a packet that is destined for a local endpoint is received on either a tagged or untagged AC endpoint, the MPLS header is removed before sending it on to the local endpoint; VLAN tags in the original packet are not changed in any way. |
| Tagged          | At VC label imposition, when a tagged packet is received on a tagged AC endpoint, the packet is encapsulated as is and sent out on the wire. When a packet is from a dual-tagged AC endpoint, the outer VLAN tag is removed and only the inner VLAN TAG is sent out on the wire. When an untagged packet is received on an untagged AC endpoint, a dummy tag is added and it is sent out on the wire.  |

The VC mode is agreed by PE peer devices during the pseudowire signaling process.

A single VPLS instance can have a mixture of tagged and untagged endpoints.

When the VC mode is changed on a device, the PWs are torn down and re-established except in the cases of a change from raw to raw-passthrough or a change from raw-passthrough to raw. The traffic impact is minimal (because PWs are not torn down and re-established) when the VC mode is changed from raw to raw-passthrough (or vice versa).

VC mode is configured by specifying the **vc-mode** option for the **pw-profile** command.

#### NOTE

When a pseudowire profile is attached to a bridge domain, on which routing is enabled (by using the **router-interface** command), you are not allowed to change the pseudowire profile **vc-mode** configuration to **raw**.

## PW statistics

Pseudowire (PW) statistics are supported for both the ingress (packet going out over the PW) and egress (packet received on the VC-Label of the PW) provider edge (PE) devices.

PW statistics are enabled or disabled per bridge domain and apply to all the PWs that are part of the bridge domain. The logical interfaces for inbound and outbound statistics are shared resources. Hence, the corresponding PW is operational only when these hardware resources are available.

PW statistics are configured using the **statistics** command in bridge domain configuration mode. For further information about enabling statistics on a bridge domain, refer to *Bridge Domains*.

## Pseudowire control word and flow label

Pseudowire (PW) control word and flow label improve PW traffic flow over a Multi-Protocol Label Switched (MPLS) packet switched network (PSN).

- PW control word supports optimal transport of Ethernet Protocol Data Units (PDUs) over an MPLS PSN.
- PW flow label supports improved load balancing of PW traffic over an MPLS PSN.

## PW control word

To ensure that a PW operates correctly over an MPLS PSN, the PW traffic is normally transported over a single network path, even when equal-cost multiple-paths (ECMPs) exist between the ingress and egress PW provider edge (PE) devices. Transporting PW traffic over a single network prevents misordered packet delivery to the egress PE device.

Because the standard MPLS label stack does not contain an explicit protocol identifier, label switching routers (LSRs) in ECMP implementations may examine the first nibble after the MPLS label stack to determine if a labeled packet is an IP packet. When the source MAC address of an Ethernet frame that is carried over a PW (without a control word present) begins with 0x4 or 0x6, it could be mistaken for an IPv4 or IPv6 packet. Depending on the configuration and topology of the MPLS network, this misinterpretation could lead to a situation in which all packets for a specific PW do not follow the same path and may increase out-of-order frames on the specific PW, or cause packets to follow a different path than actual traffic.

PW control word (RFC 4385) enables all packets for a specific PW to follow the same path over an MPLS PSN.

The following figure shows the format of the PW control word.

**FIGURE 25** PW control word format

The first 4 bits are set to 0 to indicate PW data and distinguish a PW packet from an IP packet. The next 12 bits are reserved.

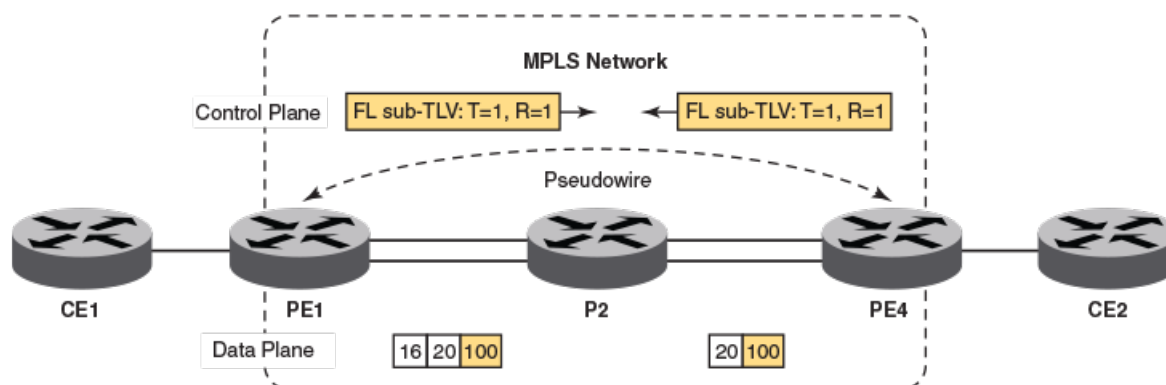

The last 16 bits carry a PW-specific sequence number that guarantees ordered frame delivery. A sequence number value of 0 indicates that the sequence number check algorithm is not used.

#### NOTE

PW control word is a nonconfigurable, global system value.

The following figure shows the operation of PW control word in a PW over MPLS network configuration.

**FIGURE 26** PW over MPLS

- The ingress device (PE1) initiates the PW setup, including the capability to transmit and receive PW control word by using the new interface parameter TLV.
- The egress device (PE4) signals a control word-handling capability.
- When PE1 receives traffic from the customer edge device (CE1), it pushes the label stack onto the traffic control word and forwards the packet to P2.
- P2 uses the field immediately after the bottom of the MPLS label stack to identify the payload as non-IP, IPv4 or IPv6 and forwards the packet to PE4.
- PE4 receives the packet with two labels; the PW label, which identifies the PW, and PW control word, which is discarded without processing.

Pseudowire (PW) control word is configured by enabling control word for either a PW profile or for PW-related devices in a bridge domain. To enable control word for a PW profile, use the **control-word** command in PW profile configuration mode. To enable control word for PW-related devices in a bridge domain, use the **peer** command in bridge domain configuration mode.

## PW flow label

Some PWs transport high volumes of traffic that comprise multiple separate traffic flows (for example, all packets for the same source-destination pair for a Transport Control Protocol [TCP] connection is a specific traffic flow).

To avoid latency and jitter, it is important that packets for a specific traffic flow are mapped to the same links along the path to the egress device.

PWs that carry multiple traffic flows require only the preservation of packet ordering in the context of an individual traffic flow and do not require the preservation of packet order for all traffic carried on the PW.

In normal cases, routers use source and destination IP addresses, protocol type, and TCP or UDP port numbers as keys in a load-balancing algorithm to find the appropriate outgoing interface. In MPLS networks, deep packet inspection may be needed for LSRs to identify such keys.

PW flow label is a mechanism that supports load balancing in an MPLS network, without the need for deep packet inspection by LSRs.

The PW flow label is added to the bottom of the label stack, by the ingress LSR (which has complete information about the packet) before it pushes the label stack. Transit LSRs can use the entire label stack (including the flow label) as a key for a load-balancing algorithm.

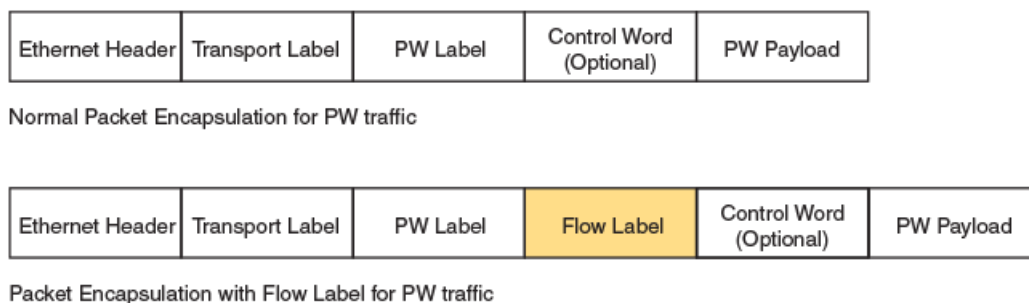

The PW flow label allows PWs to leverage the availability of, for example, equal-cost multiple-path (ECMP) between LSRs in an MPLS PSN. The ingress PE device maps individual traffic flows within a PW to the same flow label. Label Distribution Protocol (LDP) uses the PW flow label to map packets for a specific traffic flow to the same links along the path and to ensure that packets for the specific traffic flow follow the same path over the MPLS PSN. The PW flow label is discarded at the egress PE device.

### NOTE

PW flow label load balancing is not supported when the incoming packet contains more than three labels.

The following figure shows packet encapsulation when flow label is enabled for PW traffic.

**FIGURE 27** PW flow label

PW flow label is not a reserved value (that is, in the range from 0 through 15). To prevent any processing of flow label at the egress LSR, the TTL value of the flow label is set to 0.

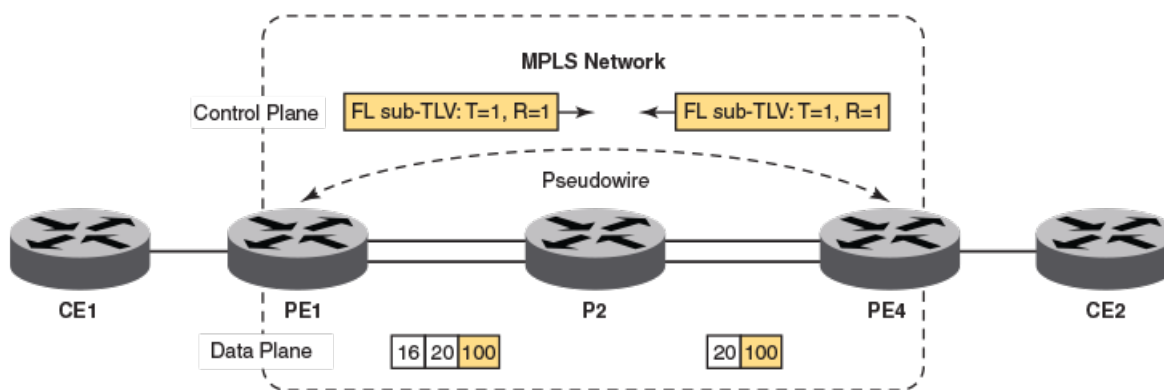

### NOTE

PW flow label is not signaled between PE routers. The flow label is generated locally and pushed to the bottom of the stack by the ingress LSR.

The following figure, which shows a PW over MPLS network configuration, describes the operation of PW flow label.

FIGURE 28 PW over MPLS

- The ingress device (PE1) initiates the PW setup, including the capability to transmit and receive PW flow label by using the new interface parameter TLV.
- The egress device (PE4) signals a flow label-handling capability.
- When PE1 receives traffic from the customer edge router, it uses a hash algorithm based on the keys (destination MAC address, source MAC address, and so on) to generate a flow label. It then pushes the label stack onto the flow label (S=1, TTL=0) and forwards the packet to P2.
- The P2 router uses the bottom label from the stack to ensure that a particular traffic flow (packets for a specific source-destination pair) follows the same path through transit routers.
- PE4 receives the packet with two labels with the top label being the PW label, which is used to identify the pseudowire, and the flow label, which is discarded without processing.

#### NOTE

When load balancing is based only on PW flow label, the transit device (P2) must be configured to include the bottom-of-stack (BOS) label by using the **lag hash bos start** command.

Pseudowire (PW) flow label is configured either by enabling flow label either for a PW profile or the bridge domain to which the PW is attached.

Pseudowire (PW) flow label is configured by enabling flow label for either a PW profile or PW-related devices in a bridge domain. To enable flow label for a PW profile, use the **flow-label** command in PW profile configuration mode. To enable flow label for PW-related devices in a bridge domain, use the **peer** command in bridge domain configuration mode.

## Supported VPLS features

The following VPLS features are supported:

- Local VPLS (without PWs)
- VPLS—untagged, single-tagged, and dual-tagged endpoints
- Flooding of L2 BPDUs in VPLS
- VPLS tagged, raw, and raw-passthrough modes for virtual circuits
- Dynamic LAG support for VPLS endpoints
- VPLS MTU enforcement

- VPLS static MAC address support for AC endpoints
- VPLS over Multi-Chassis Trunking (MCT)
- Virtual Ethernet (VE) over VPLS

## Configuration of VPLS and VLL

Configuration of a VPLS or VLL instance includes configuring a bridge-domain, configuring a virtual connection (VC) identifier, configuring logical interfaces for attachment circuit (AC) endpoints, and configuring peer IP addresses.

To configure a VPLS or VLL instance, you must complete the following tasks:

- Configure a bridge domain.
- Configure a VC identifier.
- Configure logical interfaces for AC endpoints.
- (Optional) Configure a pseudowire (PW) profile.
- Configure peer IP addresses. Configuring peer IP addresses creates PW endpoints.

### NOTE

VPLS (or VLL) configuration is separate from the underlying IP or MPLS configuration. MPLS tunnels need to be brought up separately. For further information about the configuration of MPLS tunnels, refer to the *Extreme SLX-OS MPLS Configuration Guide* for the SLX 9850 Router.

## QoS treatment in VPLS packet flow

There are default behaviors for Quality of Service (QoS) propagation in VPLS forwarding on PE routers.

On the ingress label-edge router (LER), the final EXP value for the VC label is not dependant on the CoS value in the VC-peer configuration.

By default, for traffic flowing from a CE device to a PE device, 3 bits of the PCP field from the incoming Ethernet frame header are extracted and mapped to an internal CoS value by way of an ingress CoS map. This internal value is then mapped to an outgoing CoS value by way of an egress CoS map. The outgoing CoS value is then inserted into the EXP field in the outgoing VC label. When incoming traffic does not have VLAN tag, the default PCP value that is configured on a port is used.

In the case of traffic received from the network core side, by default the EXP field from the incoming VC label is mapped to an internal CoS value by way of an ingress CoS map. This internal value is then mapped to an outgoing CoS value by way of an egress CoS map. The outgoing CoS value is then inserted into the PCP field in the Ethernet frame header going out to the CE device.

On the egress LER, the CoS value for the VC-peer configuration is not dependant on the final EXP value for the VC label.

The following table shows ingress and egress behavior for different global, tunnel and PW configuration combinations.

**TABLE 28** Ingress and Egress LER behavior

| Global  | Tunnel | PW     | AC to PW (per path) | PW to AC (per PW) |
|---------|--------|--------|---------------------|-------------------|
| Uniform | No CoS | No CoS | Uniform             | Uniform           |
| Uniform | CoS    | No CoS | Pipe                | Uniform           |
| Uniform | No CoS | CoS    | Uniform             | Pipe              |
| Uniform | CoS    | CoS    | Pipe                | Pipe              |
| Pipe    | No CoS | No CoS | Pipe                | Pipe              |
| Pipe    | CoS    | No CoS | Pipe                | Pipe              |

**TABLE 28** Ingress and Egress LER behavior (continued)

| Global | Tunnel | PW  | AC to PW (per path) | PW to AC (per PW) |
|--------|--------|-----|---------------------|-------------------|
| Pipe   | No CoS | CoS | Pipe                | Pipe              |
| Pipe   | CoS    | CoS | Pipe                | Pipe              |

## Configuring a PW profile

A pseudowire (PW) emulates a point-to-point connection over a packet-switching network. PW profile configuration defines PW attributes. After configuration, a PW profile must be attached to a bridge domain.

A pseudowire profile can be shared across multiple bridge domains. Complete the following task to configure a PW profile.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Create a PW profile and enter configuration mode for the profile.

```
device(config)# pw-profile pw_example
```

3. Configure the virtual connection mode for the profile.

```
device(config-pw-pw_example)# vc-mode tag
```

In this example, tag mode is configured for the PW profile, pw\_example.

4. Configure a maximum transmission unit (MTU) of 1300 for the PW profile.

```
device(config-pw-pw_example)# mtu 1300
```

5. Enforce an MTU check during PW signaling.

```
device(config-pw-pw_example)# mtu-enforce true
```

The following example creates a PW profile named pw\_example and configures attributes for the profile.

```
device# configure terminal
device(config)# pw-profile pw_example
device(config-pw-pw_example)# vc-mode tag
device(config-pw-pw_example)# mtu 1300
device(config-pw-pw_example)# mtu-enforce true
```

## Attaching a PW profile to a bridge domain

A pseudowire (PW) profile is applied by attaching it to a bridge domain.

Before it is attached to a bridge domain, the PW profile must be configured.

Perform the following task to attach a PW profile to a bridge domain.

1. From privileged EXEC mode, enter the global configuration mode.

```
device# configure terminal
```

2. Enter bridge domain configuration mode.

```
device(config)# bridge-domain 501
```

3. Configure a PW profile for the bridge domain.

```
device(config-bridge-domain-501)# pw-profile pw_example
```

4. Return to privileged EXEC mode.

```
device(config-bridge-domain-501)# end
```

5. Verify the configuration.

```
device# show bridge-domain 501

Bridge-domain 501
-----
Bridge-domain Type: MP , VC-ID: 501
Number of configured end-points: 2 , Number of Active end-points: 2

```

The following example shows how to attach a PW profile named pw\_example to bridge domain 501.

```
device# configure terminal
device(config)# bridge-domain 501
device(config-bridge-domain-501)# pw-profile pw_example
```

## Configuring control word for a PW profile

Configuring control word for a pseudowire (PW) profile enables all PW packets to follow the same path over an MPLS network.

Before completing the following task, the PW profile on which control word is to be enabled must be configured. An example is provided at the end of this task that shows all the steps in order.

PW control word configuration enables all packets for a specific PW to follow the same path over the MPLS network supporting, for example, the optimal transport of Ethernet Protocol Data Units (PDUs) over the network.

Perform the following task to configure PW control word for a PW profile.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Enter PW profile configuration mode

```
device(config)# pw-profile pw_example
```

3. Enable control word for the PW profile.

```
device(config-pw-profile-pw_example)# control-word
```

#### NOTE

When control word is enabled for a previously configured PW, control word capabilities between PE devices are activated only after LDP neighbors are cleared by using the **clear mpls ldp neighbor** command. For further information on clearing LDP neighbors, refer to *Extreme SLX-OS MPLS Configuration Guide*.

The following example shows how to configure a PW profile and enable control word for the profile. It then shows how to attach the PW profile to a bridge domain.

```
device# device# configure terminal
device(config)# pw-profile pw_example
device(config-pw-pw_example)# vc-mode tag
device(config-pw-pw_example)# mtu 1300
device(config-pw-pw_example)# mtu-enforce true
device(config-pw-pw_example)# control-word
device(config-pw-pw_example)# exit
!
device(config)# bridge-domain 502
device(config-bridge-domain-502)# pw-profile pw_example
```

## Configuring PW control word on a bridge domain

Configuring control word for pseudowire-related peer devices in a bridge domain enables all pseudowire (PW) packets to follow the same path over an MPLS network.

Before completing the following task, the relevant bridge domain must be configured. An example is provided at the end of this task that shows all the steps in order.

PW control word configuration enables all packets for a specific PW to follow the same path over the MPLS network supporting, for example, the optimal transport of Ethernet Protocol Data Units (PDUs) over the network.

Perform the following task to configure PW control word for a peer device in a bridge domain.

1. Enable control word for the PW profile.

```
device# configure terminal
```

- a) From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

- b) Enter bridge domain configuration mode. The following example shows how to enter configuration mode for bridge domain 502.

```
device(config)# bridge-domain 502
```

- c) Enable control word for a PW-related peer device (10.9.9.9) that is configured on the bridge domain.

```
device(config-bridge-domain-502)# peer 10.9.9.9 control-word
```

2. Return to privileged EXEC mode.

```
device(config-pw-profile-pw_example)# end
```

### 3. Verify the configuration.

```
show bridge-domain 502

Bridge-domain 502
-----
Bridge-domain Type: MP, VC-ID: 502 MCT Enabled: FALSE
Number of configured end-points: 3, Number of Active end-points: 1

```

The following example shows how to configure a bridge domain on which control word is enabled for a PW-related peer.

```
device(config)# bridge-domain 502
device(config-bridge-domain-502)# vc-id 8
device(config-bridge-domain-502)# logical-interface ethernet 1/5.15
device(config-bridge-domain-502)# logical-interface port-channel 2.200
device(config-bridge-domain-502)# peer 10.9.9.9 load-balance control-word
device(config-bridge-domain-502)# peer 10.12.12.12 control-word
device(config-bridge-domain-502)# peer 10.12.12.12 lsp lsp1 lsp2
device(config-bridge-domain-502)# local-switching
device(config-bridge-domain-502)# bpdu-drop-enable
device(config-bridge-domain-502)#
device(config-pw-pw_example)# exit
```

## Configuring flow label for a PW profile

Configuring flow label for a pseudowire (PW) profile improves load balancing of PW traffic over an MPLS network.

Before completing the following task, the PW profile on which flow label is to be enabled must be configured. An example is provided at the end of this task that shows all the steps in order.

Flow label configuration improves load balancing of PW traffic over an MPLS network, particularly in the context of PWs that transport high volumes of traffic that are comprised of multiple individual traffic flows (for example, the same source-destination pair for a Transport Control Protocol (TCP) connection is an individual traffic flow).

Perform the following task to configure flow label for a PW profile.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Enter PW profile configuration mode.

```
device(config)# pw-profile pw_example
```

3. Enable flow label for the PW profile.

```
device(config-pw-profile-pw_example)# flow-label
```

The following example shows how to configure a PW profile and enable flow label on the profile. It then shows how to attach the PW profile to a bridge domain.

```
device# device# configure terminal
device(config)# pw-profile pw_example
device(config-pw-pw_example)# vc-mode tag
device(config-pw-pw_example)# mtu 1300
device(config-pw-pw_example)# mtu-enforce true
device(config-pw-pw_example)# flow-label
device(config-pw-pw_example)# exit

device(config)# bridge-domain 5
device(config-bridge-domain-5)# pw-profile pw_example
```

## Configuring PW flow label on a bridge domain

Configuring flow label for pseudowire-related peer devices in a bridge domain improves load balancing of pseudowire (PW) traffic over an MPLS network.

Prior to completing the following task, the bridge domain on which flow label is to be enabled must be configured. There is an example at the end of this task that shows all the steps in order.

Flow label configuration improves load balancing of PW traffic over an MPLS network, particularly in the context of PWs that transport high volumes of traffic that are comprised of multiple individual traffic flows (for example, the same source-destination pair for a Transport Control Protocol (TCP) connection is an individual traffic flow).

Perform the following task to configure PW flow label on a bridge domain.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Enter bridge domain configuration mode. The following example shows how to enter configuration mode for bridge domain 502.

```
device(config)# bridge-domain 502
```

3. Enable flow label for the PW-related peer devices that are configured on the bridge domain.

```
device(config-bridge-domain-502)# peer 10.9.9.9 flow-label
```

## 4. Verify the configuration.

```
show bridge-domain 502

Bridge-domain 502
-----
Bridge-domain Type: MP, VC-ID: 502 MCT Enabled: FALSE
Number of configured end-points: 3, Number of Active end-points: 1
VE if-indx: 0, Local switching: TRUE, bpdu-drop-enable: TRUE
MAC Withdrawal: Disabled
PW-profile: default, mac-limit: 0
VLAN: 502, Tagged ports: 1(1 up), Un-tagged ports: 0 (0 up)
Tagged Ports: eth0/5.502
Un-tagged Ports:
Total VPLS peers: 2 (0 Operational):

device(config-pw-pw_example)# exit
```

## Configuring a static MAC address over an endpoint in a VPLS instance

A static MAC address can be associated with the logical interface for an attachment circuit (AC) endpoint in a bridge domain.

You can configure a MAC address for a logical interface for an endpoint in a VPLS instance by completing the following task.

### NOTE

Pre-configuration for the static mac is supported. Pre-configured static mac is shown as inactive mac.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Create the logical-interface (LIF) entry associated to a physical or port-channel interface, associate the LIF entry to the VPLS instance and configure the static mac associated with the LIF entry.

```
device(config)# mac-address-table static 0011.2345.6789 forward logical-interface ethernet 1/2.200
```

3. Enter privileged EXEC mode.

```
device(config)# exit
```

4. (Optional) Verify the configuration using any of the following commands.

```
device# show mac-address-table
device# show mac-address-table static
device# show mac-address-table bridge-domain [bd-id]
```

## Displaying MAC address information for VPLS bridge domains

Various show commands can be used to display MAC address information for bridge domains.

- Enter the **show mac-address-table bridge-domain** command to display information about MAC addresses in VPLS bridge domains. The following example shows details of all MAC addresses learned on all bridge domains.

```
device# show mac-address-table bridge-domain all
```

| VlanId/BD-Id | Mac-address    | Type    | State    | Ports/LIF/peer-ip |
|--------------|----------------|---------|----------|-------------------|
| 629 (B)      | 0011.2222.5555 | Dynamic | Active   | eth 1/3.100       |
| 629 (B)      | 0011.2222.6666 | Dynamic | Inactive | eth 1/1.500       |
| 629 (B)      | 0011.2222.1122 | Dynamic | Active   | 10.12.12.12       |
| 629 (B)      | 0011.2222.3333 | static  | Inactive | po 5.700          |
| 629 (B)      | 0011.0101.5555 | Dynamic | Active   | eth 1/2.400       |

Total MAC addresses : 5

- Enter the **show mac-address-table bridge-domain** command specifying a bridge domain to display information about MAC addresses for a specific bridge domain.

```
device# show mac-address-table bridge-domain 1
```

| BD-Name | Mac-address    | Type    | State    | Ports/LIF/Peer-IP |
|---------|----------------|---------|----------|-------------------|
| 1       | 0011.2222.5555 | Dynamic | Active   | eth 1/3.200       |
| 1       | 0011.2222.6666 | Dynamic | Inactive | eth 2/2.500       |

Total MAC addresses : 2

## Configuring a VPLS instance

A virtual private LAN Service (VPLS) instance provides multipoint LAN services.

Prior to completing the following task, the underlying L3 configuration of MPLS tunnels must be completed. In addition, the logical interfaces to be attached the VPLS instance (bridge domain) should be configured. For information on configuring logical interfaces, refer to *Logical Interfaces*.

You can configure a VPLS instance by completing the following task.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Create a multipoint bridge domain.

```
device(config)# bridge-domain 5
```

By default, the bridge-domain service type is multipoint. In this example, bridge domain 5 is configured as a multipoint service.

3. Configure a virtual connection identifier for the bridge domain.

```
device(config-bridge-domain-5)# vc-id 8
```

4. **NOTE**

Logical interfaces representing bridge-domain endpoints must be created before they can be bound to a bridge domain.

Bind the logical interfaces for attachment circuit endpoints to the bridge domain.

```
device(config-bridge-domain-5)# logical-interface ethernet 1/6.400
```

In this example, Ethernet logical interface 1/6.400 is bound to bridge domain 5.

5. Repeat Step 4 to bind other logical interfaces for attachment circuit endpoints to the bridge domain.

```
device(config-bridge-domain-5)# logical-interface port-channel 2.200
```

In this example, port channel logical interface 2.200 is bound to bridge domain 5.

6. Configure peer IP addresses to create pseudowire (PW) endpoints.

```
device(config-bridge-domain-5)# peer 10.15.15.15 load-balance
```

In this example, a peer IP address of 10.15.15.15 is configured under bridge domain 5 and specifies load balancing.

7. Repeat Step 6 to configure more peer IP addresses to create PW endpoints.

```
device(config-bridge-domain-5)# peer 10.12.12.12 lsp lsp1 lsp2
```

In this example, a peer IP address of 10.12.12.12 under bridge domain 5 and specifies two label-switched paths (lsp1 and lsp2).

8. (Optional) Configure local switching for bridge domain 5.

```
device(config-bridge-domain-5)# local-switching
```

9. (Optional) Enable dropping L2 bridge protocol data units (BPDUs) for bridge domain 5.

```
device(config-bridge-domain-5)# bpdu-drop-enable
```

10. (Optional) Configure a PW profile under the bridge domain 5.

```
device(config-bridge-domain-5)# pw-profile 2
```

The following example creates bridge domain 5 and configures virtual connection identifier 8 for the bridge domain. It binds ethernet and port-channel logical interfaces to the bridge domain and configures peer IP addresses under the domain. It configures local switching, enables dropping of L2 BPDUs, and configures a PW profile for the domain.

```
device# configure terminal
device(config)# bridge-domain 5
device(config-bridge-domain-5)# vc-id 8
device(config-bridge-domain-5)# logical-interface ethernet 1/6.400
device(config-bridge-domain-5)# logical-interface port-channel 2.200
device(config-bridge-domain-5)# peer 10.15.15.15 load-balance
device(config-bridge-domain-5)# peer 10.12.12.12 lsp lsp1 lsp2
device(config-bridge-domain-5)# local-switching
device(config-bridge-domain-5)# bpdu-drop-enable
device(config-bridge-domain-5)# pw-profile 2
```

# Configuring a VLL instance

A virtual leased line (VLL) instance provides point-to-point (peer) LAN services.

Prior to completing the following task, the Ethernet logical interface and pseudowire profiles must be created. There is an example at the end of this task that shows all the steps in order.

You can configure a VLL instance by completing the following task.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Create a point-to-point bridge domain to use VLL services.

```
device(config)# bridge-domain 3 p2p
```

In this example, bridge domain 3 is created as a point-to-point service. By default, the bridge-domain service type is multipoint.

3. Configure a virtual connection identifier for the bridge domain.

```
device(config-bridge-domain-3)# vc-id 500
```

4. Bind the logical interfaces for attachment circuit endpoints to the bridge domain.

```
device(config-bridge-domain-3)# logical-interface ethernet 1/5.15
```

In this example, the Ethernet logical interface 1/5.15 is bound to bridge domain 3.

5. Configure peer IP addresses to create pseudowire (PW) endpoints.

```
device(config-bridge-domain-3)# peer 10.10.10.10
```

6. Configure a PW profile under the bridge domain.

```
device(config-bridge-domain-3)# pw-profile to-mpls-nw
```

The following example configures a PW profile 2 under bridge domain 3.

7. Repeat this configuration on the other peer device with appropriate parameters.
8. Enter Privileged EXEC mode.

```
device(config-bridge-domain-3)# end
```

## 9. (Optional) Display information about the configured VLL instance.

```

device# show bridge-domain 3

```

# Configuration example for VPLS with switching between ACs and network core

VPLS can be configured with switching between attachment circuits (ACs) and the network core. Because VPLS emulates LAN switching, it is considered to be a Layer 2 (L2) service that operates over Layer 3 (L3) clouds.

FIGURE 29 VPLS configuration with switching between attachment circuits (ACs) and network core

The topology in the preceding figure shows a L2 VPN that enables transport of L2 traffic between two or more native Ethernet networks through an underlying Multiprotocol Label Switching (MPLS) provider network. Customer edge (CE) is the last mile and provider edge (PE) is the first mile node for packets transported towards the provider network. The provider intermediary network is an emulated switch (LAN) or wire (LINE) to the CE. The AC represents the logical link between the CE and PE.

Pseudowire is a circuit emulation infrastructure that extends L2 connectivity from CE1 to CE2 by way of PE1 and PE2. The tunnel is typically a L3 tunnel on which a L2 circuit is emulated.

The following examples show how to configure the provider edge devices (PE1 and PE2) shown in this topology.

## PE1

```
device# configure terminal
device(config)# bridge-domain 500 p2mp
device(config-bridge-domain-500)# vc-id 501
device(config-bridge-domain-500)# peer 10.9.9.9 load-balance
device(config-bridge-domain-500)# logical-interface ethernet 1/5.1 ! AC1
device(config-bridge-domain-500)# exit

device(config)# pw-profile default
```

## PE2

```
device# configure terminal
device(config)# bridge-domain 300 p2mp
device(config-bridge-domain-300)# vc-id 501
```

```

device(config-bridge-domain-300)# peer 10.9.9.0 load-balance
device(config-bridge-domain-500)# logical-interface ethernet 1/2.5      ! AC2
device(config-bridge-domain-500)# exit

device(config)# pw-profile default

```

## VPLS MAC withdrawal

VPLS MAC address withdrawal removes MAC addresses that have been dynamically learned, thus providing faster convergence.

A MAC address withdrawal message is sent with a MAC list Type Length Value (TLV). 200 MAC addresses are bulked and sent in one Mac TLV message.

### NOTE

The MAC withdrawal support is only for explicit MAC addresses in MAC withdrawal TLV. Empty MAC list as well as sending MAC withdrawal TLV to specific subset of peers will not be supported.

The maximum number of MAC addresses supported is 5000 in a 5 second interval. The remaining MAC in the AC LIF are not sent. After the 5 second interval, another LIF down event triggers MAC withdrawal message for a new 5 second interval. MAC withdrawal is supported for both VPLS and MCT-VPLS. MPLS signals the MAC withdraw TLV to all the peers.

The **mac-address withdrawal** command enables MAC withdrawal on the bridge domain. The **no** form of the command disables MAC withdrawal.

Disabling MAC withdrawal on a bridge domain stops sending of MAC withdraw messages. MAC withdraw messages are received at the receiver end and MAC flush happens even when MAC address withdrawal is not enabled.

## Enabling VPLS MAC address withdrawal

VPLS MAC address withdrawal removes dynamically-learned MAC addresses.

Convergence is faster when VPLS MAC address withdrawal is enabled.

Perform the following task to enable VPLS MAC address withdrawal.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Enter bridge domain configuration mode. The following example shows how to enter configuration mode for bridge domain 1.

```
device(config)# bridge domain 1
```

3. Enable VPLS MAC address withdrawal.

```
device(config-bridge-domain-1)# mac-address withdrawal
```

After it is enabled, use the **no** form of the command to disable MAC address withdrawal.

4. Return to privileged EXEC mode.

```
device(config-bridge-domain-1)# end
```

## 5. Verify the configuration.

```

device# show bridge-domain
Bridge-domain 1
-----
Bridge-domain Type: MP , VC-ID: 0
Number of configured end-points: 0 , Number of Active end-points: 0
VE if-indx: 0, Local switching: TRUE, bpdu-drop-enable: TRUE
MAC Withdrawal: Enabled
PW-profile: default, mac-limit: 0
Total VPLS peers: 0 (0 Operational):
device#

```

The following example shows how to enable VPLS MAC address withdrawal and then verify the configuration for bridge domain 1.

```

device# configure terminal
device(config)# bridge domain 1
device(config-bridge-domain-1)# mac-address withdrawal
device(config-bridge-domain-1)# end
!
device# show bridge-domain
Bridge-domain 1
-----
Bridge-domain Type: MP , VC-ID: 0
Number of configured end-points: 0 , Number of Active end-points: 0
VE if-indx: 0, Local switching: TRUE, bpdu-drop-enable: TRUE
MAC Withdrawal: Enabled
PW-profile: default, mac-limit: 0
Total VPLS peers: 0 (0 Operational):
device#

```

## Routing over VPLS

Routing over VPLS is known as VEOVPLS and is enabled by configuring a Virtual Ethernet (VE) interface on a Virtual Private LAN Service (VPLS) instance.

### NOTE

VEOVPLS is not supported for high availability (HA) configurations.

A VPLS instance on which a VE interface is configured can participate in routing protocols (for example, OSPF and ISIS) and exchange routes with provider edge (PE) devices on remote customer sites.

In a VPLS configuration:

- Provider core devices are not aware of customer MAC addresses, VC labels, or VPLS instances
- Provider edge devices:
  - Learn the MAC addresses of locally connected customer devices (attachment circuit [AC] toward customer edge devices [CEs])
  - Flood broadcast and unknown unicast frames to other PE devices in the virtual private network (VPN)
  - Create associations between remote MAC addresses and remote PEs
  - Encapsulate or decapsulate Layer 2 packets with VC and MPLS labels, for sending packets through PWs or toward AC endpoints

By configuring a VE interface on a VPLS instance, VE routing packets can arrive on the VPLS endpoint or from an uplink port. VEOVPLS also routes packets between the VPLS VE interface and all other IP interfaces outside the VPLS domain that reside on the PE device including:

- Physical interfaces

- Other VLAN-based VE interfaces for both tagged and untagged ports
- VE interfaces that reside on other VPLS instances

Multiple VPLS instances may belong to the same VRF instance; for example, you may configure different VPLS instances to different sites while all sites are in the same routing area.

A unicast packet that is to be routed has the PE MAC address in the MAC destination address field and is subjected to Layer 3 processing.

Routing for VPLS packets is the same as routing for non-VPLS packets. The next-hop address obtained from the routing table may be a VLAN interface, a VPLS endpoint, or a VPLS uplink port.

The following types typify of packet routing on a VPLS instance:

- Packet from the local endpoint of a VPLS VE interface to:
  - A VPLS uplink port of the same VPLS instance or another VPLS instance
  - A local VPLS endpoint of the same VPLS instance or another VPLS instance
  - A VE over VLAN interface
  - A normal IP interface over a physical interface
  - An IPoMPLS interface
  - A GRE tunnel
  - A VXLAN tunnel
- Packet from the remote endpoint (uplink port) of a VPLS VE interface to:
  - A VPLS uplink port of another VPLS instance
  - A local endpoint of the same VPLS instance or another VPLS instance
  - A VE over VLAN interface
  - A normal IP interface over a physical interface
  - An IPoMPLS interface
- Packet from a non-VPLS (VE over VLAN, IPoMPLS or GRE tunnel) interface to a local endpoint on the VPLS instance
- Packet from a non-VPLS (VE over VLAN or IPoMPLS) interface to a remote endpoint on a VPLS instance

VE over VPLS:

- Operates with routing over GRE, VXLAN, MCT, L3 VPN, and VRRP
- Supports both IPv4 and IPv6 addressing
- Supports different platform types for VPLS PE nodes, including MLX Series platforms

The following table describes the operation of VEOVPLS components.

**TABLE 29** VEOVPLS component operation

| Component | Operation  |
|-----------|--|
| Routing   | <p>A virtual Ethernet (VE) interface supports most of the existing functionality of a legacy IP interface or a VE over VLAN interface:</p> <ul style="list-style-type: none"> <li>• When the VE interface is disabled, all packets routed to the interface are dropped.</li> <li>• When the VE interface is not configured over a VPLS instance, all the routed traffic to the interface is forwarded, at the Layer-2 level, by VPLS. This forwarding by VPLS, ensures that traffic to the interface does not break existing routing by way of loopback connections that may already be configured.</li> </ul> |
| Switching | The configuration of VE over VPLS has no impact on VPLS Layer 2 switching functionality.   |
| ARP       | <p>As with ARP, VEOVPLS ARP maintains the relationship between the Layer 2 MAC address and the IP address:</p> <ul style="list-style-type: none"> <li>• ARP entries associated with the VEOVPLS interface are resolved on one member of the VPLS instance; that is, either the local endpoint or remote endpoint (remote VPLS peer).</li> <li>• ARP broadcast goes out through each endpoint member of the VPLS instance.</li> </ul>   |

**TABLE 29** VEOVPLS component operation (continued)

| Component    | Operation   |
|--------------|---|
|              | <ul style="list-style-type: none"> <li>Static ARP is supported for VEOVPLS in the same way that it is supported for VE over VLAN</li> <li>Static MAC addresses for local endpoints are supported.</li> <li>Static MAC addresses for remote endpoints are not supported.</li> <li>ARP Guard is not supported.</li> </ul>   |
| ARP DAI      | Dynamic ARP inspection is not supported for VEOVPLS.  |
| ECMP         | When a VE interface is configured over a label-switched path (LSP) with a load-balanced-enabled VPLS interface and the next hop is the pseudowire (PW), ECMP is automatically handled; the Layer 3 FEC points to the PW FEC and interface traffic is load-balanced across multiple LSPs.  |
| RPF          | <ul style="list-style-type: none"> <li>Loose mode RPF is supported.</li> <li>Strict mode RPF is not supported when the packet is coming from the PW tunnel.</li> </ul>  |
| TTL handling | <p>When the next hop is the PW, TTL value handling for VEOVPLS is the same as MPLS TTL behavior; two TTL modes exist:</p> <ul style="list-style-type: none"> <li>pipe</li> <li>uniform (default value)</li> </ul> <p>In uniform mode, the TTL value of the IP packet is decremented and copied to the MPLS header. MPLS TTL is decremented at each hop. At the LER router, the TTL value is decremented and copied to the IP header before computing the IP checksum.</p> <p>In pipe mode, the TTL value of the IP packet is decremented and a constant TTL value of 255 is set in the MPLS header. The TTL value of the MPLS packet is decremented at each hop. In the LER router, the MPLS header TTL value is discarded and the inner IP packet TTL value is decremented again before computing the IP checksum.</p> <p>Traceroute ICMP packets work isimilarly to other IP packets; that is, when the TTL value is 0 or 1, the packets are sent, in order, to the CPU for sending the TTL Expiry ICMP packet to the source.</p> |
| VRF          | VEOVPLS is supported on all VRFs. Routing is supported between both remote and local endpoints of a VPLS VE instance and other non-VPLS IP interfaces. All IP interfaces must be in the same VRF. Inter-VRF routing is supported based on leaking routes between VRFs.  |

## OAR for VEOVPLS

One Armed Router (OAR) supports the configuration of multiple logical interfaces (Multi LIF) on a port.

By default, OAR is supported for VPLS AC endpoints.

When Multi LIF support is not required on AC endpoints in a VPLS instance, you can disable it by using the **disallow-oar-ac** command in router interface configuration mode. Disabling OAR on VPLS instances when it is not required helps system scaling of hardware resources.

## Enabling routing on a VPLS instance

A Virtual Private LAN Service (VPLS) instance can participate in routing protocols when a virtual Ethernet (VE) interface is enabled.

Before completing this task, configure the VPLS instance on which routing is to be enabled. An example is provided at the end of this task that shows all the configuration steps in order.

### NOTE

You cannot enable routing on a VPLS instance when the **vc-mode** option on the PW attached to the instance is set to **raw**.

Perform the following steps to enable routing on a VPLS instance.

1. From privileged EXEC mode, enter global configuration mode.

```
device# configure terminal
```

2. Enter configuration mode for the VPLS instance bridge domain.

```
device(config)# bridge-domain 5
```

A bridge domain created for a VPLS application is also known as a VPLS instance.

3. Bind a virtual router interface to the bridge domain and enter router interface configuration mode.

```
device(config-bridge-domain-5)# router-interface ve 10
```

Routing is enabled on the VPLS instance by binding a virtual router interface to the bridge domain that was created for the instance.

4. (Optional) Disallow multiple attachment circuit (AC) endpoints on the virtual router interface.

```
device(config-router-interface-10)# disallow-oar-ac
```

By default, multiple AC endpoints are allowed on a port. To help with system scaling of hardware resources when multiple endpoints are not required, you can disallow them.

5. Return to privileged EXEC mode.

```
device(config-router-interface-10)# end
```

6. Verify the configuration.

```
device# show running-config bridge-domain 5
```

```
bridge-domain 5 p2mp
  vc-id 8
  peer 10.2.2.1
  router-interface ve 10
  !
  logical-interface ethernet 0/38.99
  logical-interface ethernet 0/14.99
  pw-profile default
  bpdu-drop-enable
  local-switching
```

The following example first shows how to configure a VPLS instance (a bridge domain that is configured for a VPLS application), then shows how to enable routing on the instance (by binding a virtual router interface to the bridge domain), and finally shows how to disallow multiple AC endpoints on the virtual router interface.

```
device# configure terminal
device(config)# bridge-domain 5
device(config-bridge-domain-5)# vc-id 8
device(config-bridge-domain-5)# logical-interface ethernet 0/38.99
device(config-bridge-domain-5)# logical-interface ethernet 0/14.99
device(config-bridge-domain-5)# peer 10.2.2.1
device(config-bridge-domain-5)# local-switching
device(config-bridge-domain-5)# bpdu-drop-enable
device(config-bridge-domain-5)# pw-profile 2
!
device(config-bridge-domain-5)# router-interface ve 10
device(config-router-interface-10)# disallow-oar-ac
```

## Configuration example for enabling routing over VPLS

After creating a virtual Ethernet (VE) interface and configuring a Virtual Private LAN Service (VPLS) instance, the VE interface is bound to the VPLS instance to enable routing over VPLS.

### Configure a VE interface

```
device# configure terminal
device(config)# interface ve 99
device(config-if-ve-99)# ip proxy-arp
device(config-if-ve-99)# ip address 10.1.1.1/24
device(config-if-ve-99)# no shutdown
device(config-if-ve-99)# exit
```

### Configure a logical interface

```
device# configure terminal
device(config)# interface Ethernet 1/1
device(config-if-eth-1/1)# switchport
device(config-if-eth-1/1)# switchport mode trunk
device(config-if-eth-1/1)# switchport trunk allowed vlan add 100
device(config-if-eth-1/1)# switchport trunk tag native-vlan
device(config-if-eth-1/1)# no shutdown
device(config-if-eth-1/1)# logical-interface ethernet 1/1.99
device(config-if-eth-lif-1/1.99)# vlan 99
device(config-if-eth-lif-1/1.99)# end
```

### Configure a PW profile

```
device(config)# pw-profile test1
device(config-pw-test1)# vc-mode tag
device(config-pw-test1)# exit
```

### Configure a VPLS instance

```
device(config)# bridge-domain 99 p2mp
device(config-bridge-domain-99)# vc-id 10
device(config-bridge-domain-99)# router-interface ve 99
device(config-bridge-domain-99)# logical-interface ethernet 1/1.99
device(config-bridge-domain-99)# pw-profile test1
device(config-bridge-domain-99)# bpdu-drop-enable

Bridges are increasingly used in networks operated by multiple independent organizations, each with restricted management access to each other's equipment. CFM provides capabilities for detecting, verifying and isolating connectivity failures in such networks.

There are multiple organizations involved in a Metro Ethernet Service: Customers, Service Providers and Operators.

Customers purchase Ethernet Service from Service Providers. Service Providers may utilize their own networks, or the networks of other Operators to provide connectivity for the requested service. Customers themselves may be Service Providers, for example a Customer may be an Internet Service Provider which sells Internet connectivity.

FIGURE 30 OAM Ethernet tools

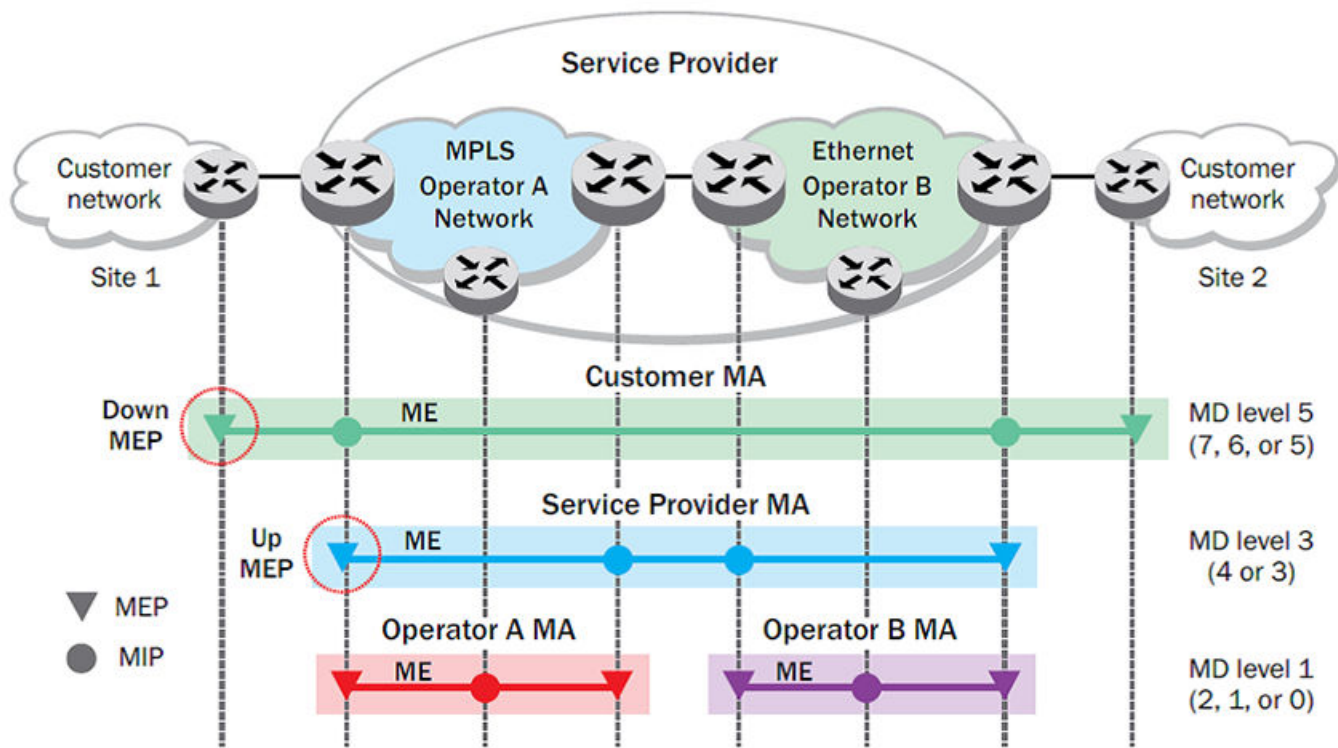

## Maintenance Domain (MD)

A Maintenance Domain is part of a network controlled by a single operator. In the following figure, a customer domain, provider domain and operator domain are described.

The Maintenance Domain (MD) levels are carried on all CFM frames to identify different domains. For example, in the following figure, some bridges belong to multiple domains. Each domain associates to an MD level.

- Customer Level: 5-7
- Provider Level: 3-4
- Operator Level: 0-2

FIGURE 31 CFM deployment

## Maintenance Association (MA)

Every MD can be further divided into smaller networks having multiple Maintenance End Points (MEP). Usually an MA is associated with a service instance (for example, a VLAN or a VPLS).

## Maintenance End Point (MEP)

An MEP is located on the edge of an MA and defines the endpoint of the MA. Each MEP has unique ID (MEPID) within the MA. The connectivity in a MA is defined as connectivity between MEPs. MEPs generate a Continuity Check Messages that are multicast to all other MEPs in same MA to verify the connectivity.

Each MEP has a direction, down or up. Down MEPs receive CFM PDUs from the LAN and sends CFM PDUs towards the LAN. Up MEPs receive CFM PDUs from a bridge relay entity and sends CFM PDUs towards the bridge relay entity on a bridge. End stations support down MEPs only, as they have no bridge relay entities.

## Maintenance Intermediate Point (MIP)

An MIP is located within a MA. It responds to Loopback and Linktrace messages for Fault isolation.

## CFM Hierarchy

MD levels create a hierarchy in which 802.1ag messages sent by customer, service provider, and operators are processed by MIPs and MEPs at the respective level of the message. A common practice is for the service provider to set up a MIP at the customer MD level at the edge of the network, as shown in the figure above, to allow the customer to check continuity of the Ethernet service to the edge of the network. Similarly, operators set up MIPs at the service provider level at the edge of their respective networks, as shown in the figure above, to allow service providers to check the continuity of the Ethernet service to the edge of the operators' networks. Inside an operator network, all MIPs are at the respective operator level, also shown in the figure above.

## Mechanisms of Ethernet IEEE 802.1ag OAM

Mechanisms supported by IEEE 802.1ag include Connectivity Check (CC), Loopback, and Link trace. Connectivity Fault Management allows for end-to-end fault management that is generally reactive (through Loopback and Link trace messages) and connectivity verification that is proactive (through Connectivity Check messages).

## Fault detection (continuity check message)

Each MEP transmits periodic multicast CCMs towards other MEPs. For each MEP, there is 1 transmission and n-1 receptions per time period. Each MEP has a remote MEP database. It records the MAC address of remote MEPs.

## Fault verification (Loopback messages)

A unicast Loopback Message is used for fault verification. A Loopback message helps a MEP identify the precise fault location along a given MA. A Loopback message is issued by a MEP to a given MIP along an MA. The appropriate MIP in front of the fault responds with a Loopback reply. The MIP behind the fault do not respond. For Loopback to work, the MEP must know the MAC address of the MIP to ping.

## Fault isolation (Linktrace messages)

Linktrace mechanism is used to isolate faults at Ethernet MAC layer. Linktrace can be used to isolate a fault associated with a given Virtual Bridge LAN Service. Note that fault isolation in a connectionless (multi-point) environment is more challenging than a connection oriented (point-to-point) environment. In case of Ethernet, fault isolation can be even more challenging since a MAC address can age out when a fault isolates the MAC address. Consequently a network-isolating fault results in erasure of information needed for locating the fault.

## Enabling or disabling CFM

To enable or disable the Connectivity Fault Management (CFM) protocol globally on the devices and enter into the CFM protocol configuration mode, enter the following command.

```
device# configure terminal
device(config)# protocol cfm
device(config-cfm) #
```

The **no** form of the command disables the CFM protocol.

## Creating a Maintenance Domain

A Maintenance Domain (MD) is the network or the part of the network for which faults in connectivity are to be managed. A Maintenance Domain consists of a set of Domain Service Access Points.

An MD is fully connected internally. A Domain Service Access Point associated with an MD has connectivity to every other Domain Service Access Point in the MD, in the absence of faults.

Each MD can be separately administered.

The **domain-name** command in Connectivity Fault Management (CFM) protocol configuration mode creates a maintenance domain with a specified level, name, and ID and enters the specific MD mode specified in the command argument.

```
device# configure terminal
device(config)# protocol cfm
device(config-cfm)# domain-name md1 id 1 level 4
device(config-cfm-md-md1)#
```

The **no** form of the command removes the specified domain from the CFM protocol configuration mode.

## Creating and configuring a Maintenance Association

Perform the following steps to create and configure a Maintenance Association (MA).

1. Create a MA within a specific domain, use the **ma-name** command.

```
device# configure terminal
device(config)# protocol cfm
device(config-cfm)# domain name md1 id 1 level 4
device(config-cfm-md-md1)# ma-name mal id 1 vlan-id 30 priority 4
device(config-cfm-md-ma-mal)#
```

This command changes the Maintenance Domain (MD) mode to the specific MA mode.

2. Set the time interval between two successive Continuity Check Messages (CCMs) that are sent by Maintenance End Points (MEP) in the specified MA, use the **ccm-interval** command.

```
device# configure terminal
device(config)# protocol cfm
device(config-cfm)# domain name md1 id 1 level 4
device(config-cfm-md-md1)# ma-name mal id 1 vlan-id 30 priority 3
device(config-cfm-md-ma-mal)# ccm-interval 10-second
device(config-cfm-md-ma-mal)#
```

The **id** field specifies the short MAID format that is carried in the CCM frame. The default time interval is 10 seconds.

3. Add local ports as MEP to a specific maintenance association using the **mep** command in MA mode.

```
device# configure terminal
device(config)# protocol cfm
device(config-cfm)# domain name md1 id 1 level 4
device(config-cfm-md-md1)# ma-name mal id 1 vlan-id 30 priority 3
device(config-cfm-md-ma-mal)# mep 1 down ethernet 1/2
device(config-cfm-md-ma-mep-1)#
```

To configure a CFM packet to a **Down MEP**, you must send it out on the port on which it was configured. To configure a Connectivity Fault Management (CFM) packet to an **Up MEP**, you must send it to the entire VLAN for multicast traffic and the unicast traffic must be sent to a particular port as per the MAC table.

4. Configure the remote MEPs using the **remote-mep** command.

```
device# configure terminal
device(config)# protocol cfm
device(config-cfm)# domain name mdl id 1 level 4
device(config-cfm-md-mdl)# ma-name mal id 1 vlan-id 30 priority 3
device(config-cfm-md-ma-mal)# mep 1 down ethernet 1/2
device(config-cfm-md-ma-mep-1)# remote-mep 2
device(config-cfm-md-ma-mep-1)#
```

If a remote MEP is not specified, the remote MEP database is built based on the CCM. If one remote MEP never sends CCM, the failure cannot be detected.

5. Configure the conditions to automatically create MIPs on ports using the **mip-policy** command, in Maintenance Association mode.

```
device# configure terminal
device(config)# protocol cfm
device(config-cfm)# domain name mdl id 1 level 4
device(config-cfm-md-mdl)#ma-name mal id 1 vlan-id 30 pri 7
device(config-cfm-md-ma-mal)#mip-policy explicit
device(config-cfm-md-ma-mal)#
```

A MIP can be created on a port and VLAN, only when explicit or default policy is defined for them. For a specific port and VLAN, a MIP is created at the lowest level. Additionally, the level created should be the immediate higher level than the MEP level defined for this port and VLAN.

## Displaying CFM configurations

The following commands are used to display the CFM configurations and connectivity status.

### show cfm

Use the **show cfm** command to display the Connectivity Fault Management (CFM) configuration.

```
device# show cfm
Domain: mdl
Index: 1
Level: 7
Maintenance association: ma5
MA Index: 5
CCM interval: 100 ms
Bridge-Domain ID: 50
Priority: 7
MAID Format: Short
MEP Direction MAC PORT VLAN INNER-VLAN PORT-STATUS-TLV
====
1 UP 609c.9f5f.700d Eth 1/9 50 -- N
```

#### NOTE

For the **show cfm** command to generate output, you must first enable CFM in protocol configuration mode.

### show cfm connectivity

Use the **show cfm connectivity** command to display the Connectivity Fault Management (CFM) configuration.

The following commands display the received port status tlv state at RMEP.

```
device# show cfm connectivity
Domain: md1
Index: 1
Level: 7
Maintenance association: ma5
MA Index: 5
CCM interval: 100 ms
Bridge-Domain ID: 50
Priority: 7
MAID Format: Short
MEP Id: 1
MEP Port: Eth 1/9
```

| RMEP  | MAC            | VLAN/PEER | INNER-VLAN | PORT  | STATE |
|-------|----------------|-----------|------------|-------|-------|
| ===== | =====          | =====     | =====      | ===== | ===== |
| 2     | 609c.9f5e.4809 | 19.1.1.1  | --         | --    | OK    |

#### NOTE

For the **show cfm** command to generate output, you must first enable CFM in protocol configuration mode.

## show cfm brief

Use the **show cfm brief** command to display the Connectivity Fault Management (CFM) brief output.

```
device# show cfm brief
Domain: md1
Index: 1
Level: 7 Num of MA: 1
Maintenance association: ma5
MA Index: 5
CCM interval: 100 ms
Bridge-Domain ID: 50
Priority: 7
MAID Format: Short
Num of MEP: 1 Num of RMEP: 1
rmepfail: 0 rmepok: 1
```

# 802.1d Spanning Tree Protocol

## Spanning Tree Protocol overview

The Spanning Tree Protocol (STP) prevents Layer 2 loops in a network by providing redundant links. If a primary link fails, the backup link is activated and network traffic is not affected. STP also ensures that the least cost path is taken when multiple paths exist between ports or VLANs.

The IEEE 802.1d Spanning Tree Protocol (STP) runs on bridges and switches that are 802.1d-compliant.

These variants are Rapid STP (RSTP), Multiple STP (MSTP), Per-VLAN Spanning Tree Plus (PVST+), and Rapid-PVST+ (R-PVST+)

When the spanning tree algorithm is run, the network switches transform the real network topology into a spanning tree topology. In an STP topology any LAN in the network can be reached from any other LAN through a unique path. The network switches recalculate a new spanning tree topology whenever there is a change to the network topology.

For each LAN, the switches that attach to the LAN select a designated switch that is the closest to the root switch. The designated switch forwards all traffic to and from the LAN. The port on the designated switch that connects to the LAN is called the designated port. The switches decide which of their ports is part of the spanning tree. A port is included in the spanning tree if it is a root port or a designated port.

STP runs one spanning tree instance (unaware of VLANs) and relies on long duration forward-delay timers for port state transition between disabled, blocking, listening, learning and forwarding states.

## Spanning Tree Protocol configuration notes

Enabling the Spanning Tree Protocol (STP) creates a loop-free topology of Ethernet LANs connected by bridge devices.

The Extreme device supports STP as described in the IEEE 802.1d-1998 specification.

The STP is disabled by default on the Extreme device. Thus, any new VLANs you configure on the Extreme device have STP disabled by default.

## Optional features

The following STP configuration features are optional:

- Root guard
- BPDU guard
- PortFast

## STP states

Each Layer 2 interface participating in a spanning tree is in one of five states.

A network topology of bridges typically contains redundant connections to provide alternate paths in case of link failures. The redundant connections create a potential for loops in the system. As there is no concept of time to live (TTL) in Ethernet frames, a situation may arise where there is a permanent circulation of frames when the network contains loops. To prevent this, a spanning tree connecting all the bridges is formed in real time.

Every Layer 2 interface running the STP is in one of these states:

| State      | Action or inaction   |
|------------|--|
| Blocking   | The interface does not forward frames. Redundant ports are put in a blocking state and enabled when required. This is a transitional state after initialization.                 |
| Listening  | The interface is identified by the spanning tree as one that should participate in frame forwarding. This is a transitional state after the blocking state for a legacy STP.     |
| Learning   | The interface prepares to participate in frame forwarding. This is a transitional state after the blocking state for a legacy STP.   |
| Forwarding | The interface forwards frames. This is a transitional state after the learning state.  |
| Disabled   | The interface is not participating in a spanning tree because of shutdown of a port or the port is not operationally up. Any of the other states may transition into this state. |

## BPDUs

To build a spanning tree for the bridge topology, the bridges must exchange control frames called Bridge Protocol data units (BPDUs).

To construct a spanning tree requires knowledge of all the participants. The bridges must determine the root bridge and compute the port roles (root, designated, or blocked) with only the information that they have. To ensure that each bridge has enough information, the bridges use BPDUs to exchange information about bridge IDs and root path costs.

A bridge sends a BPDU frame using the unique MAC address of the port itself as a source address, and a destination address of the STP multicast address 01:80:C2:00:00:00.

BPDUs are exchanged regularly (every 2 seconds by default) and enable switches to keep track of network changes and to start and stop forwarding through ports as required.

When a device is first attached to a switch port, it does not immediately forward data. It instead goes through a number of states while it processes inbound BPDUs and determines the topology of the network. When a host is attached, after a listening and learning delay of about 30 seconds, the port always goes into the forwarding state. The time spent in the listening and learning states is determined by the forward delay. However, if instead another switch is connected, the port may remain in blocking mode if it would cause a loop in the network.

There are four types of BPDUs in the original STP specification:

- Configuration BPDU (CBPDU) is used for spanning tree computation.
- Topology Change Notification (TCN) BPDU is used to announce changes in the network topology.
- RSTP BPDU is used for RSTP
- MSTP BPDU is used for MSTP

## TCN BPDUs

TCN BPDUs are used to inform other switches of port changes.

TCNs are injected into the network by a non-root switch and propagated to the root. Upon receipt of the TCN, the root switch will set a Topology Change flag in its normal BPDUs. This flag is propagated to all other switches to instruct them to rapidly age out their forwarding table entries.

Consider these configuration rules:

- TCN BPDUs are sent per VLAN.
- TCN BPDUs are sent only in those VLANs in which a topology change is detected.
- TCN BPDUs are sent only in those VLANs for which the bridge is not the root bridge.
- If a topology change is detected on a VLAN for which the bridge is the root bridge, the topology change flag is set in the configuration BPDU that is sent out.

For a given link, in conjunction with the configuration rules, a TCN BPDU is sent out as follows:

- On an access port, only a standard IEEE TCN BPDU is sent out. This TCN BPDU corresponds to a topology change in the access VLAN.
- On a trunk port, if VLAN 1 is allowed (either untagged or tagged), a standard IEEE TCN BPDU is sent for VLAN 1.
- On a trunk port, if the native VLAN is not 1, an untagged TCN BPDU is sent to Cisco or Extreme proprietary MAC address for that VLAN.
- On a trunk port, a tagged TCN BPDU is sent to Cisco or Extreme proprietary MAC address for a tagged VLAN.

As part of the response to TCN BPDUs, the Topology Change and Topology Change Acknowledgment flags are set in all configuration BPDUs corresponding to the VLAN for which the TCN was received.

When a topology change is detected on a trunk port, it is similar to detecting topology changes in each VLAN that is allowed on that trunk port. TCN BPDUs are sent for each VLAN as per the rules.

## STP configuration guidelines and restrictions

Follow these configuration guidelines and restrictions when configuring STP and STP variants:

- Only one form of a spanning tree protocol, such as STP or RSTP, can be enabled at a time. You must disable one form of xSTP before enabling another.
- When any form of STP is enabled globally, that form of STP is enabled by default on all switch ports.
- LAGs are treated as normal links for any form of STP.
- The STP is disabled by default on the SLX device. Thus, any new VLANs you configure on the SLX device have STP disabled by default.
- PVST/RPVST BPDUs are flooded only if PVST/RPVST is not enabled. STP/RSTP (IEEE) BPDUs are never flooded if STP/RSTP is not enabled.

## Understanding the default STP configuration

You should be familiar with STP defaults before you make configuration changes.

**TABLE 30** Default STP configuration

| Parameter          | Default setting                              |
|--------------------|--|
| Spanning-tree mode | By default, STP, RSTP, and MSTP are disabled |

**TABLE 30** Default STP configuration (continued)

| Parameter                      | Default setting |
|--------------------------------|-----------------|
| Bridge priority                | 32768           |
| Bridge forward delay           | 15 seconds      |
| Bridge maximum aging time      | 20 seconds      |
| Error disable timeout timer    | Disabled        |
| Error disable timeout interval | 300 seconds     |
| Port-channel path cost         | Standard        |
| Bridge hello time              | 2 seconds       |

The following table lists the switch defaults for the interface-specific configuration.

**TABLE 31** Default interface specific configuration

| Parameter                | Default setting          |
|--------------------------|--------------------------|
| Spanning tree            | Enabled on the interface |
| Automatic edge detection | Disabled                 |
| Path cost                | 2000                     |
| Edge port                | Disabled                 |
| Guard root               | Disabled                 |
| Hello time               | 2 seconds                |
| Link type                | Point-to-point           |
| Portfast                 | Disabled                 |
| Port priority            | 128                      |
| BPDU restriction         | Restriction is disabled. |

## STP features

The following sections discuss root guard, BPDU guard, and PortFast.

### Root guard

Root guard can be used to predetermine a root bridge location and prevent rogue or unwanted switches from becoming the root bridge.

At times it is necessary to protect the root bridge from malicious attack or even unintentional misconfigurations where a bridge device that is not intended to be the root bridge becomes the root bridge, causing severe bottlenecks in the data path. These types of mistakes or attacks can be avoided by configuring root guard on ports of the root bridge.

The root guard feature provides a way to enforce the root bridge placement in the network and allows STP and its variants to interoperate with user network bridges while still maintaining the bridged network topology that the administrator requires. Errors are triggered if any change from the root bridge placement is detected.

When root guard is enabled on a port, it keeps the port in designated FORWARDING state. If the port receives a superior BPDU, which is a root guard violation, it sets the port into a DISCARDING state and triggers a Syslog message and an SNMP trap. No further traffic will be forwarded on this port. This allows the bridge to prevent traffic from being forwarded on ports connected to rogue or wrongly configured STP or RSTP bridges.

Root guard should be configured on all ports where the root bridge should not appear. In this way, the core bridged network can be cut off from the user network by establishing a protective perimeter around it.

Once the port stops receiving superior BPDUs, root guard automatically sets the port back to a FORWARDING state after the timeout period has expired.

## BPDU guard

In an STP environment, switches, end stations, and other Layer 2 devices use BPDUs to exchange information that STP will use to determine the best path for data flow.

In a valid configuration, edge port-configured interfaces do not receive BPDUs. If an edge port-configured interface receives a BPDU, an invalid configuration exists, such as the connection of an unauthorized device. The BPDU Guard provides a secure response to invalid configurations because the administrator must manually put the interface back in service.

BPDU guard removes a node that reflects BPDUs back in the network. It enforces the STP domain borders and keeps the active topology predictable by not allowing any network devices behind a BPDU guard-enabled port to participate in STP.

In some instances, it is unnecessary for a connected device, such as an end station, to initiate or participate in an STP topology change. In this case, you can enable the STP BPDU guard feature on the Extreme device port to which the end station is connected. The STP BPDU guard shuts down the port and puts it into an "error disabled" state. This disables the connected device's ability to initiate or participate in an STP topology. A log message is then generated for a BPDU guard violation, and a message is displayed to warn the network administrator of an invalid configuration.

The BPDU Guard provides a secure response to invalid configurations because the administrator must manually put the interface back in service with the **no shutdown** command if error disable recovery is not enabled by enabling the **errdisable-timeout** command. The interface can also be automatically configured to be enabled after a timeout. However, if the offending BPDUs are still being received, the port is disabled again.

### *Expected behavior in an interface context*

When BPDU Guard is enabled on an interface, the device is expected to put the interface in Error Disabled state when BPDU is received on the port when edge-port and BPDU guard is enabled on the switch interface. When the port ceases to receive the BPDUs, it does not automatically switch to edge port mode, you must configure **error disable timeout** or **no shutdown** on the port to move the port back into edge port mode.

## Error disable recovery

A port is placed into an error-disabled state when:

- A BPDU guard violation or loop detection violation occurs
- The number of inError packets exceeds the configured threshold
- An EFM-OAM enabled interface receives a critical event from the remote device (functionally equivalent to a disable state)

Once in an error disable state, the port remains in that state until it is re-enabled automatically or manually.

In STP, RSTP, MSTP, PVST+, or R-PVST+ mode, you can specify the time in seconds it takes for an interface to time out. The range is from 10 through 1000000 seconds. The default is 300 seconds. By default, the timeout feature is disabled.

## PortFast

PortFast allows an interface to transition quickly to the forwarding state.

Consider the following when configuring PortFast:

- Do not enable PortFast on ports that connect to other devices.
- PortFast only needs to be enabled on ports that connect to workstations or PCs. Repeat this configuration for every port connected to workstations or PCs.
- Enabling PortFast on ports can cause temporary bridging loops, in both trunking and nontrunking mode.
- If BPDUs are received on a PortFast-enabled interface, the interface loses the edge port status unless it receives a **shutdown/no shutdown** command.
- PortFast immediately puts the interface into the forwarding state without having to wait for the standard forward time.

## STP parameters

The following section discusses bridge parameters.

### Bridge parameters

These parameters are set in STP, RSTP, MSTP, PVST+, and R-PVST+.

#### *Bridge priority*

Use this parameter to specify the priority of a device and to determine the root bridge.

Each device has a unique bridge identifier called the bridge ID. The bridge ID is an 8 byte value that is composed of two fields: a 2 B bridge priority field and the 6 B MAC address field. The value for the bridge priority ranges from 0 to 61440 in increments of 4096. The default value for the bridge priority is 32768. You use the **bridge-priority** command to set the appropriate values to designate a device as the root bridge or root device. A default bridge ID may appear as 32768.768e.f805.5800. If the bridge priorities are equal, the device with the lowest MAC address is elected the root.

After you decide what device to designate as the root, you set the appropriate device bridge priorities. The device with the lowest bridge priority becomes the root device. When a device has a bridge priority that is lower than that of all the other devices, it is automatically selected as the root.

The root device should be centrally located and not in a "disruptive" location. Backbone devices typically serve as the root because they usually do not connect to end stations. All other decisions in the network, such as which port to block and which port to put in forwarding mode, are made from the perspective of the root device.

You may also specify the bridge priority for a specific VLAN. If the VLAN parameter is not provided, the priority value is applied globally for all per-VLAN instances. However, for the VLANs that have been configured explicitly, the per-VLAN configuration takes precedence over the global configuration.

Bridge Protocol data units (BPDUs) carry information between devices. All the devices in the Layer 2 network, participating in any variety of STP, gather information on other devices in the network through an exchange of BPDUs. As the result of exchange of the BPDUs, the device with the lowest bridge ID is elected as the root bridge.

When setting the bridge forward delay, bridge maximum aging time, and the hello time parameters keep in mind that the following relationship should be kept:

$$(2 \times (\text{forward-delay} - 1)) \geq \text{max-age} \geq (2 \times (\text{hello-time} + 1))$$

## Bridge forward delay

The bridge forward delay parameter specifies how long an interface remains in the listening and learning states before the interface begins forwarding all spanning tree instances. The valid range is from 4 through 30 seconds. The default is 15 seconds.

Additionally, you may specify the forward delay for a specific VLAN. If the VLAN parameter is not provided, the bridge forward delay value is applied globally for all per-VLAN instances. However, for the VLANs that have been configured explicitly, the per-VLAN configuration takes precedence over the global configuration.

## Bridge maximum aging time

You can use this setting to configure the maximum length of time that passes before an interface saves its BPDU configuration information.

Keeping with the inequality shown above, when configuring the maximum aging time, you must set the value greater than the hello time. The range of values is 6 through 40 seconds while the default is 20 seconds.

You may specify the maximum aging for a specific VLAN. If the VLAN parameter is not provided, the priority value is applied globally for all per-VLAN instances. However, for the VLANs that have been configured explicitly, the per-VLAN configuration takes precedence over the global configuration.

## Bridge hello time

You can use this parameter to set how often the device interface broadcasts hello BPDUs to other devices.

Use the **hello-time** command to configure the bridge hello time. The range is from 1 through 10 seconds. The default is 2 seconds.

You may also specify the hello time for a specific VLAN. If the VLAN parameter is not provided, the priority value is applied globally for all per-VLAN instances. However, for the VLANs that have been configured explicitly, the per-VLAN configuration takes precedence over the global configuration.

## Error disable timeout parameter

Configure this parameter to enable a timer that brings a port out of the disabled state.

These parameters are set in STP, RSTP, MSTP, PVST+, and R-PVST+.

When the STP BPDU guard disables a port, the port remains in the disabled state unless the port is enabled manually. The parameter specifies the time in seconds it takes for an interface to time out. The range is from 10 through 1000000 seconds. The default is 300 seconds.

By default, the timeout feature is disabled.

## Port-channel path cost parameter

You configure this parameter to specify the port channel path cost.

This parameter can be set in STP, RSTP, MSTP, PVST+, and R-PVST+ mode.

There are two path cost options:

- Custom – Specifies that the path cost changes according to the port channel bandwidth.
- Standard – Specifies that the path cost does not change according to the port channel bandwidth.

The default port cost is standard.

# Configuring STP

The following section discusses configuring STP.

## Enabling and configuring STP globally

Follow these steps to enable or disable STP and configure STP parameters.

You can enable STP or STP with one or more parameters enabled.

The parameters can be configured individually by:

1. Entering the commands in steps 1 and 2
2. Running the relevant parameter command
3. Verifying the result
4. Saving the configuration

For detailed descriptions of the parameters and features, see the sections STP parameters and STP features.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enable STP globally.

```
device(config)# protocol spanning-tree stp
```

A spanning tree can be disabled by entering the **no protocol spanning-tree stp** command.

3. Describe or name the STP.

```
device(config-stp)# description stp1
```

A description is not required.

4. Specify the bridge priority.

```
device(config-stp)# bridge-priority 4096
```

The bridge with the lowest priority number (highest priority) is designated the root bridge. The range of values is 0 through 61440; values can be set only in increments of 4096. The default priority is 32678.

5. Specify the bridge forward delay.

```
device(config-stp)# forward-delay 20
```

The forward delay specifies how long an interface remains in the listening and learning states before it begins forwarding all spanning tree instances. The valid range is from 4 through 30 seconds. The default is 15 seconds.

6. Configure the maximum aging time.

```
device(config-stp)# max-age 25
```

This parameter controls the maximum length of time that passes before an interface saves its BPDU configuration information. You must set the maximum age to be greater than the hello time. The range is 6 through 40 seconds. The default is 20 seconds.

7. Configure the maximum hello time.

```
device(config-stp)# hello-time 8
```

The hello time determines how often the switch interface broadcasts hello BPDUs to other devices. The default is 2 seconds while the range is from 1 through 10 seconds.

8. Enable the error disable timeout timer.

```
device(config-stp)# error-disable-timeout enable
```

This parameter enables a timer that brings a port out of the disabled state. By default, the timeout feature is disabled.

9. Set the error disable timeout timer.

```
device(config-stp)# error-disable-timeout interval 60
```

When enabled the default is 300 seconds and the range is from 10 through 1000000 seconds.

10. Configure the port channel path cost.

```
device(config-stp)# port-channel path-cost custom
```

Specifying **custom** means the path cost changes according to the port channel's bandwidth.

11. Return to privileged EXEC mode.

```
device(config-stp)# end
```

12. Verify the configuration.

```
device# show spanning-tree brief

Spanning-tree Mode: Spanning Tree Protocol

      Root ID          Priority 4096
                Address 768e.f805.5800
                Hello Time 8, Max Age 25, Forward Delay 20

      Bridge ID        Priority 4096
                Address 768e.f805.5800
                Hello Time 8, Max Age 25, Forward Delay 20

Interface    Role   Sts   Cost           Prio  Link-type   Edge
-----
Eth 0/2      DES   FWD   2000           128   P2P         No
Eth 0/20     DIS   DIS   200000000     128   P2P         No
Eth 0/25     DIS   DIS   200000000     128   P2P         No
Eth 0/30     DIS   DIS   200000000     128   P2P         No
Eth 0/31     DIS   DIS   2000000       128   P2P         No
```

Observe that the settings comply with the formula set out in the STP parameter configuration section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

Or in this case  $38 \geq 25 \geq 18$ .

13. Save the configuration.

```
device# copy running-config startup-config
```

## STP configuration example

```
device# configure terminal
device(config)# protocol spanning-tree stp
device(config-stp)# description stpForInterface
device(config-stp)# bridge-priority 4096
device(config-stp)# forward-delay 20
device(config-stp)# max-age 25
device(config-stp)# hello-time 8
device(config-stp)# error-disable-timeout enable
device(config-stp)# error-disable-timeout interval 60
device(config-stp)# port-channel path-cost custom
device(config-stp)# end
device# show spanning-tree brief
device# copy running-config startup-config
```

## Enabling and configuring STP on an interface

Follow these steps to enable STP and STP features on an interface.

Globally enable STP and STP parameters.

The parameters can be configured individually by:

1. Entering the commands in steps 1-3
2. Running the relevant parameter command
3. Verifying the result
4. Saving the configuration

For detailed descriptions of the parameters and features, see the sections STP parameters and STP features.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enter interface configuration mode.

```
device(config)# interface ethernet 0/20
```

3. Enable the interface.

```
device(conf-if-eth-0/20)# no shutdown
```

4. Configure the path cost for spanning tree calculations on the interface.

```
device(conf-if-eth-0/20)# spanning-tree cost 10000
```

The lower the path cost means a greater chance that the interface becomes the root port. The range is 1 through 200000000. The default path cost is assigned as per the port speed.

5. Enable BPDU guard on the interface.

```
device(conf-if-eth-0/20)# spanning-tree port-fast bpdu-guard
```

BPDU guard removes a node that reflects BPDUs back in the network. It enforces the STP domain borders and keeps the active topology predictable by not allowing any network devices behind a BPDU guard-enabled port to participate in STP.

6. Configure Root Guard on the interface.

```
device(conf-if-eth-0/20)# spanning-tree guard root
```

Root Guard protects the root bridge from malicious attacks and unintentional misconfigurations where a bridge device that is not intended to be the root bridge becomes the root bridge.

7. Specify an interface link-type.

```
device(conf-if-eth-0/20)# spanning-tree link-type point-to-point
```

Specifying a point-to-point link enables rapid spanning tree transitions to the forwarding state. Specifying a shared link disables spanning tree rapid transitions. The default setting is point-to-point.

8. Specify port priority to influence the selection of root or designated ports.

```
device(conf-if-eth-0/20)# spanning-tree priority 64
```

The range is from 0 through 240 in increments of 16. The default value is 128.

9. Verify the configuration.

```
device# show spanning-tree brief

Spanning-tree Mode: Spanning Tree Protocol

      Root ID          Priority 4096
                        Address 768e.f805.5800
                        Hello Time 8, Max Age 25, Forward Delay 20

      Bridge ID         Priority 4096
                        Address 768e.f805.5800
                        Hello Time 8, Max Age 25, Forward Delay 20
```

| Interface | Role | Sts | Cost     | Prio | Link-type | Edge |
|-----------|------|-----|----------|------|-----------|------|
| Eth 0/2   | DES  | FWD | 2000     | 128  | P2P       | No   |
| Eth 0/20  | DES  | FWD | 1000     | 64   | P2P       | No   |
| Eth 0/25  | DIS  | DIS | 20000000 | 128  | P2P       | No   |
| Eth 0/30  | DIS  | DIS | 20000000 | 128  | P2P       | No   |
| Eth 0/31  | DIS  | DIS | 2000000  | 128  | P2P       | No   |

**NOTE**

Observe that the settings comply with the formula set out in the STP parameters section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case:  $38 \geq 25 \geq 18$

```
device# show running-config interface ethernet 0/20
interface ethernet 0/20
switchport
switchport mode access
switchport access val 1
spanning-tree cost 1000
spanning-tree guard root
spanning-tree link-type point-to-point
spanning-tree portfast bpdu-guard
spanning-tree priority 64
```

10. Save the settings by copying the running configuration to the startup configuration.

```
device# copy running-config startup-config
```

## STP on an interface configuration example

```
device# configure terminal
device(config)# interface ethernet 0/20
device(conf-if-eth-0/20)# no shutdown
device(conf-if-eth-0/20)# spanning-tree cost 10000
device(conf-if-eth-0/20)# spanning-tree port-fast bpdu-guard
device(conf-if-eth-0/20)# spanning-tree guard root
device(conf-if-eth-0/20)# spanning-tree link-type point-to-point
device(conf-if-eth-0/20)# spanning-tree priority 64
device(conf-if-eth-0/20)# end
device# show spanning-tree brief
device# copy running-config startup-config
```

## Configuring basic STP parameters

Follow this example to configure basic STP behavior.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enable STP globally

```
device(config)# protocol spanning-tree stp
```

3. Name the STP.

```
device(config-stp)# description stp1
```

4. Designate the root switch.

```
device(conf-stp)# bridge-priority 28672
```

The priority values can be set only in increments of 4096. The range is 0 through 61440.

5. Specify the bridge forward delay.

```
device(config-stp)# forward-delay 20
```

6. Configure the maximum aging time.

```
device(config-stp)# max-age 25
```

7. Configure the maximum hello time.

```
device(config-stp)# hello-time 8
```

8. Enable the error disable timeout timer.

```
device(config-stp)# error-disable-timeout enable
```

9. Set the error disable timeout timer interval.

```
device(config-stp)# error-disable-timeout interval 60
```

## 10. Enable port fast on switch ports.

- a) Configure port fast on Ethernet port 0/1.

```
device(config)# interface ethernet 0/1
device(conf-if-eth-0/1)# spanning-tree portfast
device(conf-if-eth-0/1)# exit
```

Spanning trees are automatically enabled on switch ports.

- b) Configure port fast on Ethernet port 0/2.

```
device(config)# interface ethernet 0/2
device(conf-if-eth-0/2)# spanning-tree portfast
device(conf-if-eth-0/2)# exit
```

- c) Repeat these commands for every port connected to workstations or PCs.

```
device(config)# interface ethernet ...
```

## 11. Specify port priorities to influence the selection of the root and designated ports.

```
device(config)# interface ethernet 0/1
device(conf-if-eth-0/1)# spanning-tree priority 1
device(conf-if-eth-0/1)# exit
```

## 12. Enable the guard root feature.

```
device(config)# interface ethernet 0/12
device(conf-if-eth-0/12)# no shutdown
device(conf-if-eth-0/12)# spanning-tree guard root
```

Root guard lets the device top participate in the STP but only when the device does not attempt to become the root.

## 13. Return to privileged exec mode.

```
device(conf-if-eth-0/12)# end
```

## 14. Verify the configuration.

```
device# show spanning-tree brief
Spanning-tree Mode: Spanning Tree Protocol
Root ID Priority 4096
Address 768e.f805.5800
Hello Time 8, Max Age 25, Forward Delay 20
Bridge ID Priority 4096
Address 768e.f805.5800
Hello Time 8, Max Age 25, Forward Delay 20
```

| Interface | Role | Sts | Cost | Prio | Link-type | Edge |
|-----------|------|-----|------|------|-----------|------|
| Eth 0/1   | DES  | FWD | 2000 | 128  | P2P       | No   |
| Eth 0/2   | DES  | FWD | 2000 | 128  | P2P       | No   |
| Eth 0/12  | DES  | FWD | 2000 | 128  | P2P       | No   |

Observe that the settings comply with the formula set out in the STP parameter configuration section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case  $38 \geq 25 \geq 18$ .

## 15. Save the configuration.

```
device# copy running-config startup-config
```

## Basic STP configuration example

```
device# configure terminal
device(config)# protocol spanning-tree stp
device(config-stp)# description stp1
device(config-stp)# bridge-priority 28672
device(config-stp)# forward-delay 20
device(config-stp)# max-age 25
device(config-stp)# hello-time 8
device(config-stp)# error-disable-timeout enable
device(config-stp)# error-disable-timeout interval 60
device(config)# interface ethernet 0/1
device(config-if-eth-0/1)# spanning-tree portfast
device(config-if-eth-0/1)# exit
device(config)# interface ethernet 0/2
device(config-if-eth-0/2)# spanning-tree portfast
device(config-if-eth-0/2)# exit
device(config)# interface ethernet 0/1
device(config-if-eth-0/1)# spanning-tree priority 1
device(config-if-eth-0/1)# exit
device(config)# interface ethernet 0/12
device(config-if-eth-0/12)# no shutdown
device(config-if-eth-0/12)# spanning-tree guard root
device(config-if-eth-0/12)# end
device# show spanning-tree brief
device# copy running-config startup-config
```

## Re-enabling an error-disabled port automatically

Enable a port to automatically recover from the error-disabled state after the expiration of an error recovery timer.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enter STP configuration mode.

```
device(config)# protocol spanning-tree stp
```

3. Enable the error-disable-timeout timer.

```
device(config-stp)# error-disable-timeout enable
```

4. Set an interval after which port shall be enabled.

```
device(config-stp)# error-disable-timeout interval 60
```

The interval range is from 0 to 1000000 seconds, the default is 300 seconds.

5. Return to privileged EXEC mode.

```
device(config-stp)# end
```

## 6. Verify the configuration.

```
device# show spanning-tree
Spanning-tree Mode: Spanning Tree Protocol

Root Id: 8000.768e.f805.5800 (self)
Bridge Id: 8000.768e.f805.5800

Root Bridge Forward Delay: 15; Hello Time: 2; Max Age: 20; Max-hops: 20
Configured Forward Delay: 15; Hello Time: 2; Max Age: 20; Max-hops: 20
Number of topology change(s): 0

Bpdu-guard errdisable timeout: enabled
Bpdu-guard errdisable timeout interval: 60 sec
```

## *Automatically re-enable an error-disabled port configuration example*

```
device# configure terminal
device(config)# protocol spanning-tree stp
device(config-stp)# error-disable-timeout enable
device(config-stp)# error-disable-timeout interval 60
device(config-stp)# end
device# show spanning-tree
```

## Clearing spanning tree counters

Follow these steps to clear spanning tree counters on all interfaces or on the specified interface.

1. Clear spanning tree counters on all interfaces.

```
device# clear spanning-tree counter
```

2. Clear spanning tree counters on a specified Ethernet interface.

```
device# clear spanning-tree counter interface ethernet 0/3
```

3. Clear spanning tree counters on a specified port channel interface.

```
device# clear spanning-tree counter interface port-channel 12
```

Port channel interface numbers range from 1 through 64.

## Clearing spanning tree-detected protocols

Follow these steps to restart the protocol migration process.

These commands force a spanning tree renegotiation with neighboring devices on either all interfaces or on a specified interface.

1. Restart the spanning tree migration process on all interfaces.

```
device# clear spanning-tree detected-protocols
```

2. Restart the spanning tree migration process on a specific Ethernet interface.

```
device# clear spanning-tree detected-protocols interface ethernet 0/3
```

3. Restart the spanning tree migration process on a specific port channel interface.

```
device# clear spanning-tree detected-protocols port-channel 12
```

Port channel interface numbers range from 1 through 64.

## Shutting down STP

Follow these steps to shut down STP either globally, on a specific interface, or a specific VLAN.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Shut down STP.

- Shut down STP globally and return to privileged EXEC mode.

```
device(config)# protocol spanning-tree stp
device(config-stp)# shutdown
device(config-stp)# end
```

- Shut down STP on a specific interface and return to privileged EXEC mode.

```
device(config)# interface ethernet 1/2
device(conf-if-eth-1/2)# spanning-tree shutdown
device(conf-if-eth-1/2)# end
```

- Shut down STP on a specific VLAN and return to privileged EXEC mode.

```
device(config)# vlan 10
device(config-vlan-10)# spanning-tree shutdown
device(config-vlan-10)# end
```

3. Verify the configuration.

```
device# show spanning-tree
device#
```

4. Save the running configuration to the startup configuration.

```
device# copy running-config startup-config
```

### Shut down STP configuration example

```
device# configure terminal
device(config)# vlan 10
device(config-vlan-10)# spanning-tree shutdown
device(config-stp)# end
device# show spanning-tree
device# copy running-config startup-config
```

#### NOTE

Shutting down STP on a VLAN is used in this example.

# 802.1w Rapid Spanning Tree Protocol

- [Rapid Spanning Tree Protocol overview](#) ..... 213
- [Configuring RSTP](#)..... 214

## Rapid Spanning Tree Protocol overview

The RSTP is a way to provide rapid traffic reconvergence for point-to-point links within a few milliseconds (< 500 milliseconds), following the failure of a bridge or bridge port.

The STP (802.1d) standard was designed at a time when recovering connectivity after an outage within a minute or so was considered adequate performance. With the advent of Layer 3 switching in LAN environments, bridging competes with routed solutions where protocols such as OSPF are able to provide an alternate path in less time.

The RSTP can be seen as evolution of STP standard. It provides rapid convergence of connectivity following the failure of bridge, a bridge port or a LAN. It provides rapid convergence of edge ports, new root ports and port connected through point-to-point links. The port, which qualifies for fast convergence, is derived from the duplex mode of a port. A port operating in full-duplex will be assumed to be point-to-point, while a half-duplex port will be considered as a shared port by default. This automatic setting can be overridden by explicit configuration.

RSTP is designed to be compatible and interoperate with the STP. However, the benefit of the RSTP fast convergence is lost when interacting with legacy STP (802.1d) bridges since the RSTP downgrades itself to the STP when it detects a connection to a legacy bridge.

The states for every Layer 2 interface running the RSTP are as follows:

| State      | Action   |
|------------|--|
| Learning   | The interface prepares to participate in frame forwarding.   |
| Forwarding | The interface forwards frames.   |
| Discarding | The interface discards frames. Ports in the discarding state do not take part in the active topology and do not learn MAC addresses. |

### NOTE

The STP disabled, blocking, and listening states are merged into the RSTP discarding state.

The RSTP port roles for the interface are also different. The RSTP differentiates explicitly between the state of the port and the role it plays in the topology. The RSTP uses the root port and designated port roles defined in the STP, but splits the blocked port role into backup port and alternate port roles:

|                |   |
|----------------|---|
| Backup port    | Provides a backup for the designated port and can only exist where two or more ports of the switch are connected to the same LAN; the LAN where the bridge serves as a designated switch. |
| Alternate port | Serves as an alternate port for the root port providing a redundant path towards the root bridge.   |

Only the root port and the designated ports are part of the active topology; the alternate and backup ports do not participate in it. When the network is stable, the root and the designated ports are in the forwarding state, while the alternate and backup ports are in the discarding state. When there is a topology change, the new RSTP port roles allow a faster transition of an alternate port into the forwarding state.

For more information about spanning trees, see the introductory sections in the [802.1d Spanning Tree Protocol](#) chapter.

## RSTP parameters

The parameters you would normally set when you configure STP are applicable to RSTP. Before you configure RSTP see the STP parameters sections for descriptions of the bridge parameters, the error disable timeout parameter and the port channel path cost parameter.

There is one parameter that can be configured in RSTP that is not available in STP; the transmit hold count. This parameter configures the BPDU burst size by specifying the maximum number of BPDUs transmitted per second for before pausing for 1 second. The range is 1 through 10 while the default is 6. See the section Enabling RSTP and configuring RSTP parameters for the procedure to configure this parameter.

The edge port and auto edge features can be enabled in RSTP as well. See the section Edge port and automatic edge detection and the section Configuring RSTP on an interface for descriptions of these features and how they are configured.

## Edge port and automatic edge detection

Configuring the edge port feature makes a port transition directly from initialization to the forwarding state, skipping the listening and learning states.

From an interface, you can configure a device to automatically identify the edge port. The port can become an edge port if no BPDU is received. By default, automatic edge detection is disabled.

Follow these guidelines to configure a port as an edge port:

- When edge port is enabled, the port still participates in a spanning tree.
- A port can become an edge port if no BPDU is received.
- When an edge port receives a BPDU, it becomes a normal spanning tree port and is no longer an edge port.
- Because ports that are directly connected to end stations cannot create bridging loops in the network, edge ports transition directly to the forwarding state and skip the listening and learning states.

### NOTE

If BPDUs are received on a port fast enabled interface, the interface loses the edge port status unless it receives a **shutdown** or **no shutdown** command.

# Configuring RSTP

## Enabling and configuring RSTP globally

Follow these steps to enable and configure RSTP.

See the section STP parameters for parameters applicable to all STP variants.

You can enable RSTP or RSTP with one or more parameters enabled. The parameters can be enabled or changed individually by entering the commands in steps 1 and 2, running the parameter command, verifying the result, and then saving the configuration.

1. Enter global configuration mode.

```
device# configure terminal
```

## 2. Enable RSTP.

```
device(config)# protocol spanning-tree rstp
```

You can shut down RSTP by entering the **shutdown** command.

## 3. Designate the root device.

```
device(conf-rstp)# bridge-priority 28582
```

The range is 0 through 61440 and the priority values can be set only in increments of 4096.

You can shut down RSTP by entering the **shutdown** command when in RSTP configuration mode.

## 4. Configure the bridge forward delay value.

```
device(conf-rstp)# forward-delay 15
```

## 5. Configure the bridge maximum aging time value.

```
device(conf-rstp)# max-age 20
```

## 6. Enable the error disable timeout timer.

## a) Enable the timer.

```
device(conf-rstp)# error-disable-timeout enable
```

## b) Configure the error disable timeout interval value.

```
device(conf-rstp)# error-disable-timeout interval 60
```

## 7. Configure the port-channel path cost.

```
device(conf-rstp)# port-channel path-cost custom
```

## 8. Configure the bridge hello-time value.

```
device(conf-rstp)# hello-time 2
```

## 9. Specify the transmit hold count.

```
device(config-rstp)# transmit-holdcount 5
```

This command configures the maximum number of BPDUs transmitted per second.

## 10. Return to privileged exec mode.

```
device(conf-rstp)# end
```

## 11. Verify the configuration

```

device# show spanning-tree

Spanning-tree Mode: Rapid Spanning Tree Protocol

Root Id: 8000.01e0.5200.0180 (self)
Bridge Id: 8000.01e0.5200.0180

Root Bridge Forward Delay: 15; Hello Time: 2; Max Age: 20; Max-hops: 20
Configured Forward Delay: 15; Hello Time: 2; Max Age: 20; Max-hops: 20
Number of topology change(s): 0

Bpdu-guard errdisable timeout: enabled
Bpdu-guard errdisable timeout interval: 60 sec

```

Observe that the settings comply with the formula set out in the STP parameters section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case:  $28 \geq 20 \geq 6$ .

## 12. Save the configuration.

```

device# copy running-config startup-config

```

*Enabling RSTP and configuring RSTP parameters example*

```

device# configure terminal
device(config)# protocol spanning-tree rstp
device(config-rstp)# bridge-priority 28582
device(config-rstp)# forward-delay 20
device(config-rstp)# max-age 25
device(config-rstp)# error-disable-timeout enable
device(config-rstp)# error-disable-timeout interval 60
device(config-rstp)# port-channel path-cost custom
device(config-rstp)# hello-time 5 forward-delay 16 max-age 21
device(config-rstp)# transmit-holdcount 5
device(config-rstp)# end
device# show spanning-tree
device# copy running-config startup-config

```

**Enabling and configuring RSTP on an interface**

Follow these steps to configure RSTP on an Ethernet interface.

You can configure the parameters individually on an interface by doing the following:

1. Entering the commands in Steps 1 through 3.
2. Specifying additional parameters, as appropriate.
3. Verifying the result.
4. Saving the configuration.

For detailed descriptions of the parameters and features, see the sections STP parameters and STP features.

1. Enter global configuration mode.

```

device# configure terminal

```

2. Enter interface subtype configuration mode.

```
device(config)# interface ethernet 0/10
```

3. Enable the interface.

```
device(conf-if-eth-0/10)# no shutdown
```

To disable the spanning tree on the interface you use the **spanning-tree shutdown** command.

4. Specify the port priority on the interface.

```
device(conf-if-eth-0/10)# spanning-tree priority 128
```

The range is from 0 through 240 in increments of 16. The default value is 128.

5. Specify the path cost on the interface.

```
device(conf-if-eth-0/10)# spanning-tree cost 20000000
```

The lower the path cost means a greater chance that the interface becomes the root port. The range is 1 through 200000000. The default path cost is assigned as per the port speed.

6. Enable edge port.

```
device(conf-if-eth-0/10)# spanning-tree edgeport
```

If BPDUs are received on a port fast enabled interface, the interface loses the edge port status unless it receives a **shutdown** or **no shutdown** command.

7. Enable BPDU guard on the interface.

```
device(conf-if-eth-0/10)# spanning-tree edgeport bpdu-guard
```

BPDU guard removes a node that reflects BPDUs back in the network. It enforces the STP domain borders and keeps the active topology predictable by not allowing any network devices behind a BPDU guard-enabled port to participate in STP.

8. Enable automatic edge detection on the interface.

```
device(conf-if-eth-0/10)# spanning-tree autoedge
```

You use this command to automatically identify the edge port. A port becomes an edge port if it receives no BPDUs. By default, automatic edge detection is disabled.

9. Enable root guard on the interface.

```
device(conf-if-eth-0/10)# spanning-tree guard root
```

Root guard protects the root bridge from malicious attacks and unintentional misconfigurations where a bridge device that is not intended to be the root bridge becomes the root bridge.

10. Specify a link type on the interface.

```
device(conf-if-eth-0/10)# spanning-tree link-type point-to-point
```

#### NOTE

The link type is explicitly configured as **point-to-point** rather than **shared**.

11. Return to privileged EXEC mode.

```
device(conf-if-eth-0/10)# end
```

## 12. Verify the configuration.

```

device# show spanning-tree

Spanning-tree Mode: Rapid Spanning Tree Protocol

Root Id: 8000.01e0.5200.0180 (self)

```

| Interface | Role | Sts | Cost     | Prio | Link-type | Edge |
|-----------|------|-----|----------|------|-----------|------|
| Eth 0/10  | DES  | FWD | 20000000 | 128  | P2P       | No   |

The **forward-delay**, **hello-time**, and **max-age** parameters are set globally, not on the interface.

Observe that the settings comply with the formula set out in the STP parameters section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case:  $28 \geq 20 \geq 6$ .

## 13. Save the configuration.

```
device# copy running-config startup-config
```

***RSTP on an interface configuration example***

```

device# configure terminal
device(config)# interface ethernet 0/10
device(conf-if-eth-0/10)# no spanning-tree shutdown
device(conf-if-eth-0/10)# spanning-tree priority 128
device(conf-if-eth-0/10)# spanning-tree cost 20000000
device(conf-if-eth-0/10)# spanning-tree edgeport
device(conf-if-eth-0/10)# spanning-tree edgeport bpdu-guard
device(conf-if-eth-0/10)# spanning-tree autoedge
device(conf-if-eth-0/10)# spanning-tree guard root
device(conf-if-eth-0/10)# spanning-tree link-type point-to-point
device(conf-if-eth-0/10)# end
device# show spanning-tree
device# copy running-config startup-config

```

## Configuring basic RSTP parameters

Follow these steps to configure basic RSTP parameters.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enable RSTP.

```
device(config)# protocol spanning-tree rstp
```

3. Designate the root device.

```
device(config-rstp)# bridge-priority 28582
```

4. Enable the error disable timeout timer value.

```
device(config-rstp)# error-disable-timeout enable
```

5. Configure the error-disable-timeout interval value.

```
device(config-rstp)# error-disable-timeout interval 60
```

6. Enable edge port on switch ports.

- a) Enter interface subtype configuration mode for the switchport.

```
device(config-rstp)# interface ethernet 0/10
```

- b) Enable edge port.

```
device(config-if-eth-0/10)# spanning-tree edge-port
```

- c) Return to global configuration mode.

```
device(config-if-eth-0/10)# exit
```

- d) Repeat the above steps for all ports that connect to a workstation or PC.

7. Specify port priorities.

- a) Enter interface subtype configuration mode.

```
device(config)# interface ethernet 0/11
```

- b) Configure the port priority.

```
device(config-if-eth-0/11)# spanning-tree priority 1
```

- c) Return to global configuration mode.

```
device(config-if-eth-0/11)# exit
```

## 8. Enable the guard root feature.

- a) Enter interface configuration mode.

```
device(config)# interface ethernet 0/1
```

- b) Configure the port priority.

```
device(config-if-eth-0/1)# spanning-tree guard root
```

- c) Return to privileged EXEC mode.

```
device(config-if-eth-0/1)# exit
```

## 9. Verify the configuration.

```
device# show spanning-tree
```

```
Spanning-tree Mode: Rapid Spanning Tree Protocol
```

```
Root Id: 4096.01e0.5200.0180 (self)
Bridge Id: 4096.01e0.5200.0180
Root Bridge Forward Delay: 15; Hello Time: 2; Max Age: 20; Max-hops: 20
Configured Forward Delay: 15; Hello Time: 2; Max Age: 20; Max-hops: 20
Number of topology change(s): 0
Bpdu-guard errdisable timeout: disabled
Bpdu-guard errdisable timeout interval: 300 sec
switch# show spanning-tree brief
Spanning-tree Mode: Rapid Spanning Tree Protocol
Root ID Priority 4096
Address 768e.f805.5800
Hello Time 2, Max Age 20, Forward Delay 15
Bridge ID Priority 4096
Address 768e.f805.5800
```

| Interface | Role | Sts | Cost | Prio | Link-type | Edge |
|-----------|------|-----|------|------|-----------|------|
| Eth 0/1   | DES  | FWD | 2000 | 128  | P2P       | No   |
| Eth 0/10  | DES  | FWD | 2000 | 128  | P2P       | No   |
| Eth 0/11  | DES  | FWD | 2000 | 128  | P2P       | No   |

Observe that the settings comply with the formula set out in the STP parameters section, as follows:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case:  $28 \geq 20 \geq 6$ .

## 10. Save the configuration.

```
device# copy running-config startup-config
```

## Basic RSTP configuration example

```
device# configure terminal
device(config)# protocol spanning-tree rstp
device(conf-rstp)# bridge-priority 28582
device(conf-rstp)# error-disable-timeout enable
device(conf-rstp)# error-disable-timeout interval 60
device(conf-rstp)# interface ethernet 0/10
device(conf-if-eth-0/10)# spanning-tree edge-port
device(conf-if-eth-0/10)# exit
device(config)# interface ethernet 0/11
device(conf-if-eth-0/11)# spanning-tree priority 1
device(conf-if-eth-0/11)# exit
device(config)# interface ethernet 0/1
device(conf-if-eth-0/1)# spanning-tree guard root
device(conf-if-eth-0/1)# exit
device# show spanning-tree
device# copy running-config startup-config
```

## Clearing spanning tree counters

Follow these steps to clear spanning tree counters on all interfaces or on the specified interface.

1. Clear spanning tree counters on all interfaces.

```
device# clear spanning-tree counter
```

2. Clear spanning tree counters on a specified Ethernet interface.

```
device# clear spanning-tree counter interface ethernet 0/3
```

3. Clear spanning tree counters on a specified port channel interface.

```
device# clear spanning-tree counter interface port-channel 12
```

Port channel interface numbers range from 1 through 64.

## Clearing spanning tree-detected protocols

Follow these steps to restart the protocol migration process.

These commands force a spanning tree renegotiation with neighboring devices on either all interfaces or on a specified interface.

1. Restart the spanning tree migration process on all interfaces.

```
device# clear spanning-tree detected-protocols
```

2. Restart the spanning tree migration process on a specific Ethernet interface.

```
device# clear spanning-tree detected-protocols interface ethernet 0/3
```

3. Restart the spanning tree migration process on a specific port channel interface.

```
device# clear spanning-tree detected-protocols port-channel 12
```

Port channel interface numbers range from 1 through 64.

## Shutting down RSTP

Follow these steps to shut down RSTP either globally or on a specific interface.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Shut down RSTP.

- Shut down STP globally and return to privileged EXEC mode.

```
device(config)# protocol spanning-tree rstp
device(config-rstp)# shutdown
device(config-rstp)# end
```

- Shut down RSTP on a specific interface and return to privileged EXEC mode.

```
device(config)# interface ethernet 0/2
device(config-if-eth-0/2)# spanning-tree shutdown
device(config-if-eth-0/2)# end
```

- Shut down RSTP on a specific VLAN and return to privileged EXEC mode.

```
device(config)# vlan 10
device(config-vlan-10)# spanning-tree shutdown
device(config-vlan-10)# end
```

3. Verify the configuration.

```
device# show spanning-tree
device#
```

4. Save the configuration.

```
device# copy running-config startup-config
```

# Per-VLAN Spanning Tree+ and Rapid Per-VLAN Spanning Tree+

- [PVST+ and R-PVST+ overview.....](#) 223
- [Configuring PVST+ and R-PVST+.....](#) 229

## PVST+ and R-PVST+ overview

The Per-VLAN Spanning Tree Plus (PVST+) protocol runs a spanning tree instance for each VLAN in the network. The version of PVST+ that uses the RSTP state machine is called Rapid-PVST Plus (R-PVST+). R-PVST+ has one instance of spanning tree for each VLAN on the device.

Both the STP and the RSTP build a single logical topology. A typical network has multiple VLANs. A single logical topology does not efficiently utilize the availability of redundant paths for multiple VLANs. A single logical topology does not efficiently utilize the availability of redundant paths for multiple VLANs. If a port is set to the blocked state or the discarding state for one VLAN (under the STP or the RSTP), it is the same for all other VLANs. PVST+ builds on the STP on each VLAN, and R-PVST+ builds on the RSTP on each VLAN.

PVST+ R-PVST+ provide interoperability with Cisco PVST and R-PVST and other vendor switches which implement Cisco PVST or R-PVST. the PVST+ and R-PVST+ implementations are extensions to PVST and R-PVST, which can interoperate with an STP topology, including MSTP (CIST), on Extreme and other vendor devices sending untagged IEEE BPDUs.

## PVST+ and R-PVST+ guidelines and restrictions

Consider the following when configuring PVST+ and R-PVST+:

- Extreme supports PVST+ and R-PVST+ only. The PVST and R-PVST protocols are proprietary to Cisco and are not supported.
- A port native VLAN is the native VLAN ID associated with a trunk port on an Extreme switch. This VLAN ID is associated with all untagged packets on the port. The default native VLAN ID for a trunk port is 1.
- IEEE compliant switches run just one instance of STP protocol shared by all VLANs, creating a Mono Spanning Tree (MST). A group of such switches running a single spanning tree forms an MST region.
- You can configure up to 128 PVST+ or R-PVST+ instances. If you have more than 128 VLANs configured on the switch and enable PVST then the first 128 VLANs are PVST/+ or R-PVST+ enabled.
- In PVST/+ or R-PVST+ mode, when you are connected to a Cisco or MLX switch, the Cisco proprietary MAC address to which the BPDUs are sent/processed must be explicitly configured on a per-port basis.
- In PVST/+ or R-PVST+ mode, when you connect to a Cisco switch using a trunk port, the Extreme switch must have a native VLAN configured on the trunk port (same configuration as on the other side).
- A Common Spanning Tree (CST) is the single spanning tree instance used by Extreme switches to interoperate with 802.1q bridges. This spanning tree instance stretches across the entire network domain (including PVST, PVST+ and 802.1q regions). It is associated with VLAN 1 on the Extreme switch.
- In order to interact with STP and IEEE 802.1q trunk, PVST evolved to PVST+ to interoperate with STP topology by STP BPDU on the native or default VLAN.
- A group of switches running PVST+ is called a PVST+ region.

For more information about spanning trees, see the introductory sections in the Spanning Tree Protocol chapter.

## PVST+ and R-PVST+ parameters

The parameters you would normally set when you configure STP are applicable to PVST+ and R-PVST+. Before you configure PVST+ or R-PVST+ parameters see the sections in the Standing Tree Protocol chapter explaining bridge parameters, the error disable timeout parameter and the port channel path cost parameter.

There is one parameter that can be configured in R-PVST+ that is not available in STP or PVST+; the transmit hold count. This parameter configures the BPDUs burst size by specifying the maximum number of BPDUs transmitted per second for before pausing for 1 second. The range is 1 through 10 while the default is 6. See the section Configuring R-PVST+ for the procedure to configure this parameter.

## Bridge protocol data units in different VLANs

PVST+ uses the spanning tree instance for VLAN 1 to join the CST in the network to build the CST, PVST+ processes and sends standard IEEE Bridge protocol data units (BPDUs) on all the ports in VLAN 1 (access/trunk).

Across IEEE 802.1q trunks, Extreme switches run PVST+. The goal is to interoperate with standard IEEE STP (or RSTP or MSTP), while transparently tunneling PVST+ instance BPDUs across the MST region to potentially connect to other Extreme switches across the MST region.

On trunk ports that allow VLAN 1, PVST+ also sends PVST+ BPDUs to a Cisco-proprietary multicast MAC address (0100.0ccc.cccd) or Extreme-proprietary multicast MAC address (0304.0800.0700) depending on the configuration. By default, the PVST+ BPDUs are sent to Extreme-proprietary multicast MAC address on Extreme switches. These BPDUs are tunneled across an MST region. The PVST+ BPDUs for VLAN 1 are only used for the purpose of consistency checks and that it is only the IEEE BPDUs that are used for building the VLAN 1 spanning tree. So in order to connect to the CST, it is necessary to allow VLAN 1 on all trunk ports.

For all other VLANs, PVST+ BPDUs are sent on a per-VLAN basis on the trunk ports. These BPDUs are tunneled across an MST region. Consequently, for all other VLANs, MST region appears as a logical hub. The spanning tree instances for each VLAN in one PVST+ region map directly to the corresponding instances in another PVST+ region and the spanning trees are calculated using the per-VLAN PVST+ BPDUs.

Similarly, when a PVST+ region connects to a MSTP region, from the point of view of MSTP region, the boundary bridge thinks it is connected to a standard IEEE compliant bridge sending STP BPDUs. So it joins the CIST of the MSTP region to the CST of the PVST+ region (corresponding to VLAN 1). The PVST+ BPDUs are tunneled transparently through the MSTP region. So from the Extreme bridge point of view, the MSTP region looks like a virtual hub for all VLANs except VLAN 1.

The PVST+ BPDUs are sent untagged for the native VLAN and tagged for all other VLANs on the trunk port.

On access ports, Extreme switches run classic version of IEEE STP/RSTP protocol, where the BPDUs are sent to the standard IEEE multicast address "0180.C200.0000". So if we connect a standard IEEE switch to an access port on the Extreme switch, the spanning tree instance (corresponding to the access VLAN on that port) of the Extreme switch is joined with the IEEE STP instance on the adjacent switch.

For introductory information about STP BPDUs, see the section [BPDUs](#) on page 198.

## BPDUs configuration notes

In order to build a spanning tree for the bridge topology, the bridges must exchange control frames. These frames are called Bridge Protocol data units (BPDU).

BPDU's are sent to a Cisco-proprietary multicast MAC address 0100.0ccc.cccd or Extreme-proprietary multicast MAC address 0304.0800.0700. By default, the PVST+ BPDUs are sent to Extreme-proprietary multicast MAC address on Extreme switches. These are called SSTP (Single Spanning Tree Protocol) BPDUs. The format of the SSTP BPDU is nearly identical to the 802.1d BPDU after the SNAP header, except that a type-length-value (TLV) field is added at the end of the BPDU. The TLV has 2 bytes for type (0x0), 2 bytes for length, and 2 bytes for the VLAN ID. See [Extreme BPDU PVST+ headers/fields](#) on page 225 and [BPDU R-PVST+ header and field comparisons](#) on page 225 for an outline of the BPDU header content.

Topology Change Notification (TCN) BPDUs are used to inform other switches of port changes. TCNs are injected into the network by a non-root switch and propagated to the root. Upon receipt of the TCN, the root switch will set a Topology Change flag in its normal BPDUs. This flag is propagated to all other switches to instruct them to rapidly age out their forwarding table entries.

In PVST+, three types of TCN BPDUs are sent out depending on the type of the link. See [Extreme PVST+ TCN BPDU headers/fields](#) on page 227 and [Cisco PVST TCN BPDU headers/fields](#) on page 228.

- Standard IEEE TCN BPDU.
- Untagged TCN BPDU sent to the Cisco/Extreme proprietary MAC address.
- Tagged TCN BPDU sent to the Cisco/Extreme proprietary MAC address.

### BPDU R-PVST+ header and field comparisons

These tables outline the differences between Extreme R-PVST+ BPDU and Cisco R-PVST+ BPDU header fields.

#### Extreme R-PVST+ BPDU headers/fields

### Sent BPDUs

On an 802.1q trunk, the PVST+ enabled switch sends the following BPDUs:

1. For all tagged VLANs on the port on which PVST+ is enabled, 802.1q tagged SSTP BPDUs are sent to the Cisco or Extreme MAC address. The 802.1q tag contains the VLAN ID. (VLAN 1 could be tagged on the port. In that case a tagged BPDU for VLAN 1 is sent). The IEEE compliant switches do not consider these BPDUs as a control packet. So they forward the frame as they would forward to any unknown multicast address on the specific VLAN.
2. If PVST+ is enabled on the untagged (native) VLAN of the port, an untagged SSTP BPDU is sent to the Extreme or Cisco MAC address on the native VLAN of the trunk. It is possible that the native VLAN on the Extreme or Cisco port is not VLAN 1. This BPDU is also forwarded on the native VLAN of the IEEE 802.1q switch just like any other frame sent to an unknown multicast address.
3. In addition to the above SSTP BPDUs, a standard IEEE BPDU (802.1d) is also sent, corresponding to the information of VLAN 1 on the Extreme or Cisco switch. This BPDU is not sent if VLAN 1 is explicitly disabled on the trunk port.

The following table lists the types of BPDUs sent in case of different port types. The numbers in the third column are the VLAN instance for which these BPDUs are sent/processed.

**TABLE 32** Types of BPDUs sent for different port types

| Port Configuration          | Extreme or Cisco - PVST(+)           | VLAN instance |
|-----------------------------|--------------------------------------|---------------|
| Access - VLAN 1             | Standard IEEE BPDU (64B)             | 1             |
| Access - VLAN 100           | Standard IEEE BPDU (64B)             | 100           |
| Trunk - Native VLAN 1       | Standard IEEE BPDU (64B)             | 1             |
| Allowed VLANs - 1, 100, 200 | Extreme or Cisco untagged BPDU (68B) | 1             |
|                             | Extreme or Cisco tagged BPDU (72B)   | 100           |
|                             | Extreme or Cisco tagged BPDU (72B)   | 200           |
| Trunk - Native VLAN 100     | Standard IEEE BPDU (64B)             | 1             |
| Allowed VLANs - 1, 100, 200 | Extreme or Cisco untagged BPDU (68B) | 100           |
|                             | Extreme or Cisco tagged BPDU (72B)   | 1             |
|                             | Extreme or Cisco tagged BPDU (72B)   | 200           |
| Trunk - Native VLAN 100     | Extreme or Cisco untagged BPDU (68B) | 100           |
| Allowed VLANs - 100         |                                      |               |
| Trunk - Native VLAN 100     | Extreme or Cisco untagged BPDU (68B) | 100           |
| Allowed VLANs - 100, 200    | Extreme or Cisco untagged BPDU (68B) | 100           |
|                             | Extreme or Cisco tagged BPDU (72B)   | 200           |

## TCN headers and fields

Since PVST+ is based on STP, and Rapid-PVST+ is based on RSTP, TCN BPDUs are sent only in PVST+ and not in Rapid-PVST+ mode.

For introductory information about STP BPDUs, see the section [TCN BPDUs](#) on page 199.

## Extreme PVST+ TCN BPDU headers/fields

| Header/field | Standard IEEE STP TCN BPDU<br>(64B with padding) | PVST+ untagged TCN BPDU<br>(64B with padding) | PVST+ tagged TCN BPDU<br>(68B with padding) |

## PortFast

PortFast allows an interface to transition quickly to the forwarding state.

Consider the following when configuring PortFast:

- Do not enable PortFast on ports that connect to other devices.
- PortFast only needs to be enabled on ports that connect to workstations or PCs. Repeat this configuration for every port connected to workstations or PCs.
- Enabling PortFast on ports can cause temporary bridging loops, in both trunking and nontrunking mode.
- If BPDUs are received on a PortFast- enabled interface, the interface loses the edge port status unless it receives a **shutdown/no shutdown** command.
- PortFast immediately puts the interface into the forwarding state without having to wait for the standard forward time.

## Edge port and automatic edge detection

Configuring the edge port feature makes a port transition directly from initialization to the forwarding state, skipping the listening and learning states.

From an interface, you can configure a device to automatically identify the edge port. The port can become an edge port if no BPDU is received. By default, automatic edge detection is disabled.

Follow these guidelines to configure a port as an edge port:

- When edge port is enabled, the port still participates in a spanning tree.
- A port can become an edge port if no BPDU is received.
- When an edge port receives a BPDU, it becomes a normal spanning tree port and is no longer an edge port.
- Because ports that are directly connected to end stations cannot create bridging loops in the network, edge ports transition directly to the forwarding state and skip the listening and learning states.

**NOTE**

If BPDUs are received on a port fast enabled interface, the interface loses the edge port status unless it receives a **shutdown** or **no shutdown** command.

# Configuring PVST+ and R-PVST+

## Enabling and configuring PVST+ globally

Use this procedure to enable and set parameters for PVST+.

You can enable PVST+ with one or more parameters configured. The parameters can be configured or changed individually by entering the commands in steps 1 and 2, running the parameter command, verifying the result, and then saving the configuration.

For more information about spanning trees and spanning tree parameters, see the introductory sections in the Spanning Tree Protocol chapter.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enable PVST+.

```
device(config)# protocol spanning-tree pvst
```

3. Configure the bridge priority for the common instance.

```
device(config-pvst)# bridge-priority 4096
```

Valid values range from 0 through 61440 in increments of 4096. Assigning a lower priority value indicates that the bridge might become root.

You can shut down PVST+ by entering the **shutdown** command when in PVST configuration mode.

4. Configure the forward delay parameter.

```
device(config-pvst)# forward-delay 11
```

5. Configure the hello time parameter.

```
device(config-pvst)# hello-time 2
```

6. Configure the maximum age parameter.

```
device(config-pvst)# max-age 7
```

7. Return to privileged exec mode.

```
device(config-pvst)# end
```

## 8. Verify the configuration.

```

device# show spanning-tree brief
VLAN 1

Spanning-tree Mode: PVST Protocol

    Root ID          Priority 4097
                    Address 01e0.5200.0180
                    Hello Time 2, Max Age 7, Forward Delay 11

    Bridge ID         Priority 4097
                    Address 01e0.5200.0180
                    Hello Time 2, Max Age 7, Forward Delay 11

Interface      Role  Sts  Cost        Prio  Link-type      Edge
-----
VLAN 100

Spanning-tree Mode: PVST Protocol

    Root ID          Priority 4196
                    Address 01e0.5200.0180
                    Hello Time 2, Max Age 7, Forward Delay 11

    Bridge ID         Priority 4196
                    Address 01e0.5200.0180
                    Hello Time 2, Max Age 7, Forward Delay 11

Interface      Role  Sts  Cost        Prio  Link-type      Edge
-----

```

Observe that the settings comply with the formula set out in the STP parameters section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case:  $20 \geq 7 \geq 6$ .

## 9. Save the configuration.

```
device# copy running-config startup-config
```

**PVST+ configuration example**

```

device# configure terminal
device(config)# protocol spanning-tree pvst
device(config-pvst)# bridge-priority 4096
device(config-pvst)# forward-delay 11
device(config-pvst)# hello-time 2
device(config-pvst)# max-age 7
device(config-pvst)# end
device# show spanning-tree brief
device# copy running-config startup-config

```

For more information about configuring PVST+ parameters, see [STP parameters](#) on page 202. PVST+, R-PVST+, and other types of spanning trees share many tasks with STP.

**Enabling and configuring PVST+ on an interface**

Follow these steps to enable and configure PVST+ on an interface.

The ports and parameters can be configured individually on a system by:

1. Entering the commands in steps 1, and 2

2. Running the relevant addition steps and parameter commands
3. Verifying the result
4. Saving the configuration

For detailed descriptions of the parameters and features, see the sections STP parameters and STP features.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enable PVST+.

```
device(config)# protocol spanning-tree pvst
```

3. Enter interface configuration mode.

```
device(config-pvst)# interface ethernet 0/3
```

4. Enable spanning tree on the interface.

```
device(conf-if-eth-0/3)# no spanning-tree shutdown
```

5. Configure the interface link type.

```
device(conf-if-eth-0/3)# spanning-tree link-type point-to-point
```

6. Specify the port priority to influence the selection of root or designated ports.

```
device(conf-if-eth-0/3)# spanning-tree priority 64
```

The range is from 0 through 240 in increments of 16. The default value is 128.

7. Configure the path cost for spanning tree calculations on the interface.

```
device(conf-if-eth-0/3)# spanning-tree cost 10000
```

The lower the path cost means a greater chance that the interface becomes the root port. The range is 1 through 200000000. The default path cost is assigned as per the port speed.

8. Configure the path cost for spanning tree calculations a specific VLAN.

```
device(conf-if-eth-0/3)# spanning-tree vlan 10 cost 10000
```

The lower the path cost means a greater chance that the interface becomes the root port. The range is 1 through 200000000. The default path cost is assigned as per the port speed.

9. Enable root guard on the interface.

```
device(conf-if-eth-0/3)# spanning-tree guard root
```

Root guard protects the root bridge from malicious attacks and unintentional misconfigurations where a bridge device that is not intended to be the root bridge becomes the root bridge.

10. Enable BPDU guard on the interface.

```
device(conf-if-eth-0/3)# spanning-tree port-fast bpdu-guard
```

BPDU guard removes a node that reflects BPDUs back in the network. It enforces the STP domain borders and keeps the active topology predictable by not allowing any network devices behind a BPDU guard-enabled port to participate in STP.

11. Enable BPDU filtering on the interface.

```
device(conf-if-eth-0/3)# spanning-tree port-fast bpdu-filter
```

BPDU filtering allows you to avoid transmitting BPDUs on ports that are connected to an end system.

12. Return to privileged EXEC mode.

```
device(conf-if-eth-0/3)# exit
```

13. Verify the configuration.

```
device# show spanning-tree brief
```

Spanning-tree Mode: PVST Protocol

|           |  |  |  |  |  |  |
|-----------|--|--|--|--|--|--|
| Root ID   | Priority 4096                              |  |  |  |  |  |
|           | Address 768e.f805.5800                     |  |  |  |  |  |
|           | Hello Time 8, Max Age 25, Forward Delay 20 |  |  |  |  |  |
| Bridge ID | Priority 4096                              |  |  |  |  |  |
|           | Address 768e.f805.5800                     |  |  |  |  |  |
|           | Hello Time 8, Max Age 25, Forward Delay 20 |  |  |  |  |  |

| Interface | Role | Sts | Cost   | Prio | Link-type | Edge |
|-----------|------|-----|--------|------|-----------|------|
| Eth 0/3   | DES  | FWD | 200000 | 64   | P2P       | No   |

Observe that the settings comply with the formula set out in the STP parameters section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case :38 ≥ 25 ≥ 18.

14. Save the configuration.

```
device# copy running-config startup-config
```

## PVST+ on an interface configuration example

```
device# configure terminal
device(config)# protocol spanning-tree pvst
device(conf-pvst)# interface ethernet 0/3
device(conf-if-eth-0/3)# no spanning-tree shutdown
device(conf-if-eth-0/3)# spanning-tree link-type point-to-point
device(conf-if-eth-0/3)# spanning-tree priority 64
device(conf-if-eth-0/3)# spanning-tree cost 10000
device(conf-if-eth-0/3)# spanning-tree vlan 10 cost 10000
device(conf-if-eth-0/3)# spanning-tree guard root
device(conf-if-eth-0/3)# spanning-tree port-fast bpdu-guard
device(conf-if-eth-0/3)# exit
device# show spanning-tree
device# copy running-config startup-config
```

## Enabling and configuring PVST+ on a system

Follow the steps to configure PVST+ on a system.

The ports and parameters can be configured individually on a system by:

1. Entering the commands in steps 1, and 2
2. Running the relevant addition steps and parameter commands

3. Verifying the result
4. Saving the configuration

For detailed descriptions of the parameters and features, see the sections STP parameters and STP features.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enable PVST+.

```
device(config)# protocol spanning-tree pvst
```

3. Configure the bridge priority for the common instance.

```
device(config-pvst)# bridge-priority 4096
```

Valid values range from 0 through 61440 in multiples of 4096. Assigning a lower priority value indicates that the bridge might become root.

4. Configure the forward delay parameter.

```
device(config-pvst)# forward-delay 15
```

5. Configure the hello time parameter.

```
device(config-pvst)# hello-time 2
```

6. Configure the maximum age parameter.

```
device(config-pvst)# max-age 20
```

7. Add VLANs.

- a) Configure VLAN 100 with a priority of 0.

```
device(config-pvst)# vlan 100 priority 0
```

The bridge priority is configured in multiples of 4096.

- b) Configure VLAN 201 with a priority of 12288.

```
device(config-pvst)# vlan 201 priority 12288
```

- c) Configure VLAN 301 with a priority of 20480.

```
device(config-pvst)# vlan 301 priority 20480
```

## 8. Set the switching characteristics for interface 0/3.

- a) Enter interface configuration mode.

```
device(config)# interface ethernet 0/3
```

- b) Set the switching characteristics of the interface.

```
device(conf-if-eth-0/3)# switchport
```

- c) Set the interface mode to trunk.

```
device(conf-if-eth-0/3)# switchport mode trunk
```

- d) Add VLAN 100 as a member VLAN.

```
device(conf-if-eth-0/3)# switchport trunk allowed vlan add 100
```

- e) Add VLAN 201 as a member VLAN.

```
device(conf-if-eth-0/3)# switchport trunk allowed vlan add 201
```

- f) Add VLAN 301 as a member VLAN.

```
device(conf-if-eth-0/3)# switchport trunk allowed vlan add 301
```

- g) Enable spanning tree on the interface.

```
device(conf-if-eth-0/3)# no spanning-tree shutdown
```

- h) Return to privileged EXEC mode.

```
device(conf-if-eth-0/3)# exit
```

9. Set the switching characteristics for interface 0/4.

- a) Enter interface configuration mode.

```
device(config)# interface ethernet 0/4
```

- b) Set the switching characteristics of the interface.

```
device(conf-if-eth-0/4)# switchport
```

- c) Set the interface mode to trunk.

```
device(conf-if-eth-0/4)# switchport mode trunk
```

- d) Add VLAN 100 as a member VLAN.

```
device(conf-if-eth-0/4)# switchport trunk allowed vlan add 100
```

- e) Add VLAN 201 as a member VLAN.

```
device(conf-if-eth-0/4)# switchport trunk allowed vlan add 201
```

- f) Add VLAN 301 as a member VLAN.

```
device(conf-if-eth-0/4)# switchport trunk allowed vlan add 301
```

- g) Enable spanning tree on the interface.

```
device(conf-if-eth-0/4)# no spanning-tree shutdown
```

- h) Return to privileged EXEC mode.

```
device(conf-if-eth-0/4)# exit
```

10. To interoperate with switches other than VDX switches in PVST+ mode, you must configure the interface that is connected to that switch.

- a) Enter interface configuration mode for the port that interoperates with a VDX device.

```
device(config)# interface ethernet 0/12
```

- b) Specify the MAC address for the device.

```
device(conf-if-eth-0/12)# spanning-tree bpdu-mac 0100.0ccc.cccd
```

- c) Enable spanning tree on the interface.

```
device(conf-if-eth-0/12)# no spanning-tree shutdown
```

- d) Return to privileged EXEC mode.

```
device(conf-if-eth-0/12)# end
```

## 11. Verify the configuration.

```

device# show spanning-tree

VLAN 1

Spanning-tree Mode: PVST Protocol

  Configured Path Cost: 20000000
  Designated Port Id: 0; Port Priority: 128
  Designated Bridge: 0000.0000.0000.0000
  Number of forward-transitions: 0
  Version: Per-VLAN Spanning Tree Protocol - Received None - Sent STP
  Portfast: off
  Configured Root guard: off; Operational Root guard: off
  Bpdu-guard: off
  Link-type: point-to-point
  Received BPDUs: 0; Sent BPDUs: 0

```

Observe that the settings comply with the formula set out in the STP parameters section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case:  $28 \geq 20 \geq 6$ .

## 12. Save the configuration.

```
device# copy running-config startup-config
```

## Enable PVST+ on a system configuration example

```

device# configure terminal
device(config)# protocol spanning-tree pvst
device(config-pvst)# bridge-priority 4096
device(config-pvst)# forward-delay 15
device(config-pvst)# hello-time 2
device(config-pvst)# max-age 20
device(config-pvst)# vlan 100 priority 0
device(config-pvst)# vlan 201 priority 12288
device(config-pvst)# vlan 301 priority 20480
device(config-pvst)# interface ethernet 0/3
device(conf-if-eth-0/3)# switchport
device(conf-if-eth-0/3)# switchport mode trunk
device(conf-if-eth-0/3)# switchport trunk allowed vlan add 100
device(conf-if-eth-0/3)# switchport trunk allowed vlan add 201
device(conf-if-eth-0/3)# switchport trunk allowed vlan add 301
device(conf-if-eth-0/3)# no spanning-tree shutdown
device(conf-if-eth-0/3)# exit
device(config)# interface ethernet 0/4
device(conf-if-eth-0/4)# switchport
device(conf-if-eth-0/4)# switchport mode trunk
device(conf-if-eth-0/4)# switchport trunk allowed vlan add 100
device(conf-if-eth-0/4)# switchport trunk allowed vlan add 201
device(conf-if-eth-0/4)# switchport trunk allowed vlan add 301
device(conf-if-eth-0/4)# no spanning-tree shutdown
device(conf-if-eth-0/4)# end
device# show spanning-tree
device# copy running-config startup-config

```

## Enabling and configuring R-PVST+ globally

Use this procedure to enable the Rapid Per-VLAN Spanning Tree Protocol Plus (R-PVST+).

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enable R-PVST+.

```
device(config)# protocol spanning-tree rpvst
```

3. Configure the bridge priority for the common instance.

```
device(config-rpvst)# bridge-priority 4096
```

Valid priority values range from 0 through 61440 in multiples of 4096. Assigning a lower priority value indicates that the bridge might become root.

4. Configure the forward delay parameter.

```
device(config-rpvst)# forward-delay 20
```

5. Configure the hello time parameter.

```
device(config-rpvst)# hello-time 22
```

6. Configure the maximum age parameter.

```
device(config-rpvst)# max-age 8
```

7. Set the transmit hold count for the bridge.

```
device(config-rpvst)# transmit-holdcount 9
```

This command configures the maximum number of BPDUs transmitted per second before pausing for 1 second. The range is 1 through 10. The default is 6.

8. Return to privileged exec mode.

```
device(config-rpvst)# end
```

## 9. Verify the configuration.

```

device# show spanning-tree brief
VLAN 1

Spanning-tree Mode: Rapid PVST Protocol

    Root ID          Priority 4096
                  Address 01e0.5200.0180
                  Hello Time 2, Max Age 7, Forward Delay 11

    Bridge ID        Priority 32769
                  Address 01e0.5200.0180
                  Hello Time 8, Max Age 22, Forward Delay 20, Tx-HoldCount 9
                  Migrate Time 3 sec

Interface      Role  Sts  Cost      Prio  Link-type      Edge
-----

```

Observe that the settings comply with the formula set out in the STP parameters section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case:  $20 \geq 7 \geq 6$ .

## 10. Save the configuration.

```
device# copy running-config startup-config
```

***R-PVST+ configuration example***

```

device# configure terminal
device(config)# protocol spanning-tree rpvst
device(config-rpvst)# bridge-priority 4096
device(config-rpvst)# forward-delay 20
device(config-rpvst)# hello-time 22
device(config-rpvst)# max-age 8
device(config-rpvst)# transmit-holdcount 9
device(config-rpvst)# end
device# show spanning-tree brief
device# copy running-config startup-config

```

For more information about configuring parameters, see the section STP parameter configuration.

**Enabling and configuring R-PVST+ on an interface**

Follow these steps to enable and configure R-PVST+ on an interface.

The ports and parameters can be configured individually on a system by:

1. Entering the commands in steps 1-3
2. Running the relevant addition steps and parameter commands
3. Verifying the result
4. Saving the configuration

For detailed descriptions of the parameters and features, see the sections STP parameters and STP features.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enable R-PVST+.

```
device(config)# protocol spanning-tree rpvt
```

3. Enter interface configuration mode.

```
device(config-rpvst)# interface ethernet 0/3
```

4. Enable the spanning tree on the interface.

```
device(conf-if-eth-0/3)# no spanning-tree shutdown
```

5. Configure the interface link type.

```
device(conf-if-eth-0/3)# spanning-tree link-type point-to-point
```

6. Specify the port priority to influence the selection of root or designated ports.

```
device(conf-if-eth-0/3)# spanning-tree priority 64
```

The range of priority values is from 0 through 240 in multiples of 16. The default value is 128.

7. Configure the path cost for spanning tree calculations on the interface.

```
device(conf-if-eth-0/3)# spanning-tree cost 200000
```

The lower the path cost means a greater chance that the interface becomes the root port. The range is 1 through 200000000. The default path cost is assigned as per the port speed.

8. Configure the path cost for spanning tree calculations a specific VLAN.

```
device(conf-if-eth-0/3)# spanning-tree vlan 10 cost 10000
```

The lower the path cost means a greater chance that the interface becomes the root port. The range is 1 through 200000000. The default path cost is assigned as per the port speed.

9. Enable automatic edge detection on the interface.

```
device(conf-if-eth-0/3)# spanning-tree autoedge
```

You use this command to automatically identify the edge port. A port becomes an edge port if it receives no BPDUs. By default, automatic edge detection is disabled.

10. Enable root guard on the interface.

```
device(conf-if-eth-0/3)# spanning-tree guard root
```

Root guard protects the root bridge from malicious attacks and unintentional misconfigurations where a bridge device that is not intended to be the root bridge becomes the root bridge.

11. Enable the spanning tree on the edge port.

```
device(conf-if-eth-0/3)# spanning-tree edgeport
```

If BPDUs are received on a port fast enabled interface, the interface loses the edge port status unless it receives a **shutdown** or **no shutdown** command.

12. Enable BPDU guard on the interface.

```
device(conf-if-eth-0/3)# spanning-tree edgeport bpdu-guard
```

BPDU guard removes a node that reflects BPDUs back in the network. It enforces the STP domain borders and keeps the active topology predictable by not allowing any network devices behind a BPDU guard-enabled port to participate in STP.

13. Return to privileged EXEC mode.

```
device(conf-if-eth-0/3)# exit
```

14. Verify the configuration.

```
device# show spanning-tree brief

Spanning-tree Mode: Rapid PVST Protocol

      Root ID            Priority 4096
              Address 768e.f805.5800
              Hello Time 8, Max Age 25, Forward Delay 20

      Bridge ID          Priority 4096
              Address 768e.f805.5800
              Hello Time 8, Max Age 25, Forward Delay 20
```

| Interface | Role | Sts | Cost   | Prio | Link-type | Edge |
|-----------|------|-----|--------|------|-----------|------|
| Eth 0/3   | DES  | FWD | 200000 | 128  | P2P       | No   |

Observe that the settings comply with the formula set out in the STP parameters section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case:  $38 \geq 25 \geq 18$ .

15. Save the configuration.

```
device# copy running-config startup-config
```

## *R-PVST+ on an interface configuration example*

```
device# configure terminal
device(config)# protocol spanning-tree rpvst
device(config-rpvst)# interface ethernet 0/3
device(conf-if-eth-0/3)# no spanning-tree shutdown
device(conf-if-eth-0/3)# spanning-tree link-type point-to-point
device(conf-if-eth-0/3)# spanning-tree priority 64
device(conf-if-eth-0/3)# spanning-tree cost 200000
device(conf-if-eth-0/3)# spanning-tree vlan 10 cost 10000
device(conf-if-eth-0/3)# spanning-tree autoedge
device(conf-if-eth-0/3)# spanning-tree guard root
device(conf-if-eth-0/3)# spanning-tree edgeport
device(conf-if-eth-0/3)# spanning-tree edgeport bpdu-guard
device(conf-if-eth-0/3)# exit
device# show spanning-tree
device# copy running-config startup-config
```

## Enabling and configuring R-PVST+ on a system

Follow the steps to configure R-PVST+ on a system.

The ports and parameters can be configured individually by:

1. Entering the commands in steps 1 and 2
2. Running the relevant addition steps and parameter commands
3. Verifying the result
4. Saving the configuration

For detailed descriptions of the parameters and features, see the sections STP parameters and STP features.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enable R-PVST+.

```
device(config)# protocol spanning-tree rpvst
```

You can shut down R-PVST+ by entering the **shutdown** command when in `rpvst` configuration mode.

3. Configure the bridge priority for the common instance.

```
device(config-rpvst)# bridge-priority 4096
```

Valid values range from 0 through 61440 in increments of 4096. Assigning a lower priority value indicates that the bridge might become root.

4. Configure the forward delay parameter.

```
device(config-rpvst)# forward-delay 20
```

5. Configure the hello time parameter.

```
device(config-rpvst)# hello-time 8
```

6. Configure the maximum age parameter.

```
device(config-rpvst)# max-age 22
```

7. Specify the transmit hold count.

```
device(config-rpvst)# transmit-holdcount 5
```

This command configures the maximum number of BPDUs transmitted per second. The range of values is 1 through 10.

8. Configure VLANs.

- a) Configure VLAN 100 with a priority of 0.

```
device(config-rpvst)# vlan 100 priority 0
```

Valid priority values range from 0 through 61440 in multiples of 4096.

- b) Configure VLAN 201 with a priority of 12288.

```
device(config-rpvst)# vlan 201 priority 12288
```

- c) Configure VLAN 301 with a priority of 20480.

```
device(config-rpvst)# vlan 301 priority 20480
```

## 9. Set the switching characteristics for interface 0/3.

- a) Enter interface configuration mode.

```
device(config-rpvst)# interface ethernet 0/3
```

- b) Set the switching characteristics of the interface.

```
device(conf-if-eth-0/3)# switchport
```

- c) Set the interface mode to trunk.

```
device(conf-if-eth-0/3)# switchport mode trunk
```

- d) Add VLAN 100 as a member VLAN.

```
device(conf-if-eth-0/3)# switchport trunk allowed vlan add 100
```

- e) Add VLAN 201 as a member VLAN.

```
device(conf-if-eth-0/3)# switchport trunk allowed vlan add 201
```

- f) Add VLAN 301 as a member VLAN.

```
device(conf-if-eth-0/3)# switchport trunk allowed vlan add 301
```

- g) Enable spanning tree on the interface.

```
device(conf-if-eth-0/3)# no spanning-tree shutdown
```

- h) Return to privileged EXEC mode.

```
device(conf-if-eth-0/3)# exit
```

## 10. Set the switching characteristics for interface 0/4.

- a) Enter interface configuration mode.

```
device(config-rpvst)# interface ethernet 0/4
```

- b) Set the switching characteristics of the interface.

```
device(conf-if-eth-0/4)# switchport
```

- c) Set the interface mode to trunk.

```
device(conf-if-eth-0/4)# switchport mode trunk
```

- d) Add VLAN 100 as a member VLAN.

```
device(conf-if-eth-0/4)# switchport trunk allowed vlan add 100
```

- e) Add VLAN 201 as a member VLAN.

```
device(conf-if-eth-0/4)# switchport trunk allowed vlan add 201
```

- f) Add VLAN 301 as a member VLAN.

```
device(conf-if-eth-0/4)# switchport trunk allowed vlan add 301
```

- g) Enable spanning tree on the interface.

```
device(conf-if-eth-0/4)# no spanning-tree shutdown
```

- h) Return to privileged EXEC mode.

```
device(conf-if-eth-0/4)# exit
```

## 11. To interoperate with switches other than VDX switches in R-PVST+ mode, you must configure the interface that is connected to that switch.

- a) Enter interface configuration mode for the port that interoperates with a VDX switch.

```
device(config)# interface ethernet 0/12
```

- b) Specify the MAC address for the device.

```
device(conf-if-eth-0/12)# spanning-tree bpdu-mac 0100.0ccc.cccd
```

- c) Enable spanning tree on the interface.

```
device(conf-if-eth-0/12)# no spanning-tree shutdown
```

- d) Return to privileged EXEC mode.

```
device(conf-if-eth-0/12)# end
```

## 12. Verify the configuration.

```

device# show spanning-tree

VLAN 1

Spanning-tree Mode: Rapid PVST Protocol

Root Id: 0001.01e0.5200.0180 (self)
Bridge Id: 0001.01e0.5200.0180

Root Bridge Forward Delay: 15; Hello Time: 2; Max Age: 20; Max-hops: 20
Configured Forward Delay: 20; Hello Time: 8; Max Age: 22; Max-hops: 20
Tx-HoldCount 5
Number of topology change(s): 0

Bpdu-guard errdisable timeout: disabled
Bpdu-guard errdisable timeout interval: 300 sec

Port Et 0/3 enabled
  Ifindex: 201351168; Id: 8001; Role: Disabled; State: Disabled
  Designated Path Cost: 0
  Configured Path Cost: 20000000
  Designated Port Id: 0; Port Priority: 128

```

Observe that the settings comply with the formula set out in the STP parameters section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case:  $28 \geq 20 \geq 6$ .

### 13. Save the configuration.

```
device# copy running-config startup-config
```

## Enable R-PVST+ on a system configuration example

```

device# configure terminal
device(config)# protocol spanning-tree rpvst
device(config-rpvst)# bridge-priority 4096
device(config-rpvst)# forward-delay 20
device(config-rpvst)# hello-time 8
device(config-rpvst)# max-age 22
device(config-rpvst)# transmit-holdcount 5
device(config-rpvst)# vlan 100 priority 0
device(config-rpvst)# vlan 201 priority 12288
device(config-rpvst)# vlan 301 priority 20480
device(config-rpvst)# interface ethernet 0/3
device(conf-if-eth-0/3)# switchport
device(conf-if-eth-0/3)# switchport mode trunk
device(conf-if-eth-0/3)# switchport trunk allowed vlan add 100
device(conf-if-eth-0/3)# switchport trunk allowed vlan add 201
device(conf-if-eth-0/3)# switchport trunk allowed vlan add 301
device(conf-if-eth-0/3)# no spanning-tree shutdown
device(conf-if-eth-0/3)# exit
device(config)# interface ethernet 0/4
device(conf-if-eth-0/4)# switchport
device(conf-if-eth-0/4)# switchport mode trunk
device(conf-if-eth-0/4)# switchport trunk allowed vlan add 100
device(conf-if-eth-0/4)# switchport trunk allowed vlan add 201
device(conf-if-eth-0/4)# switchport trunk allowed vlan add 301
device(conf-if-eth-0/4)# no spanning-tree shutdown
device(conf-if-eth-0/4)# end
device# show spanning-tree
device# copy running-config startup-config

```

## Clearing spanning tree counters

Follow these steps to clear spanning tree counters on all interfaces or on the specified interface.

1. Clear spanning tree counters on all interfaces.

```
device# clear spanning-tree counter
```

2. Clear spanning tree counters on a specified Ethernet interface.

```
device# clear spanning-tree counter interface ethernet 0/3
```

3. Clear spanning tree counters on a specified port channel interface.

```
device# clear spanning-tree counter interface port-channel 12
```

Port channel interface numbers range from 1 through 64.

## Clearing spanning tree-detected protocols

Follow these steps to restart the protocol migration process.

These commands force a spanning tree renegotiation with neighboring devices on either all interfaces or on a specified interface.

1. Restart the spanning tree migration process on all interfaces.

```
device# clear spanning-tree detected-protocols
```

2. Restart the spanning tree migration process on a specific Ethernet interface.

```
device# clear spanning-tree detected-protocols interface ethernet 0/3
```

- Restart the spanning tree migration process on a specific port channel interface.

```
device# clear spanning-tree detected-protocols port-channel 12
```

Port channel interface numbers range from 1 through 64.

## Shutting down PVST+ or R-PVST+

Follow these steps to shut down PVST+, or R-PVST+ either globally, on a specific interface, or a specific VLAN.

- Enter global configuration mode.

```
device# configure terminal
```

- Shut down PVST+ or R-PVST+.

- Shut down PVST+ or R-PVST+ globally and return to privileged EXEC mode.

```
device(config)# protocol spanning-tree pvst
device(config-pvst)# shutdown
device(config-pvst)# end
```

- Shut down PVST+ or R-PVST+ on a specific interface and return to privileged EXEC mode.

```
device(config)# interface ethernet 0/2
device(conf-if-eth-0/2)# spanning-tree shutdown
device(conf-if-eth-0/2)# end
```

- Shut down PVST+ or R-PVST+ on a specific VLAN, and return to privileged EXEC mode.

```
device(config)# vlan 10
device(config-vlan-10)# spanning-tree shutdown
device(config-vlan-10)# end
```

- Verify the configuration.

```
device# show spanning-tree
device#
```

- Save the running configuration to the startup configuration.

```
device# copy running-config startup-config
```

### Shut down PVST+ or R-PVST+ configuration example

```
device# configure terminal
device(config)# vlan 10
device(config-vlan-10)# spanning-tree shutdown
device(config-vlan-10)# end
device# show spanning-tree
device# copy running-config startup-config
```

#### NOTE

Shutting down PVST+ on a VLAN is used in this example.

# 802.1s Multiple Spanning Tree Protocol

---

|  |     |

| • MSTP overview.....                   | 251 |
| • MSTP global level parameters.....    | 253 |
| • MSTP interface level parameters..... | 254 |
| • Configuring MSTP.....                | 255 |

## MSTP overview

IEEE 802.1s Multiple STP (MSTP) helps create multiple loop-free active topologies on a single physical topology.

MSTP uses RSTP to group VLANs into separate spanning-tree instance. Each instance has its own spanning-tree topology independent of other spanning tree instances, which allows multiple forwarding paths, permits load balancing, and facilitates the movement of data traffic. A failure in one instance does not affect other instances. By enabling the MSTP, you are able to more effectively utilize the physical resources present in the network and achieve better load balancing of VLAN traffic.

The MSTP evolved as a compromise between the two extremes of the RSTP and R-PVST+, it was standardized as IEEE 802.1s and later incorporated into the IEEE 802.1Q-2003 standard. The MSTP configures a meshed topology into a loop-free, tree-like topology. When the link on a bridge port goes up, an MSTP calculation occurs on that port. The result of the calculation is the transition of the port into either a forwarding or blocking state. The result depends on the position of the port in the network and the MSTP parameters. All the data frames are forwarded over the spanning tree topology calculated by the protocol.

### NOTE

Multiple switches must be configured consistently with the same MSTP configuration to participate in multiple spanning tree instances. A group of interconnected switches that have the same MSTP configuration is called an MSTP region. MSTP is backward compatible with the STP and the RSTP.

## Common Spanning Tree (CST)

The single Spanning Tree instance used by the Extreme device, and other vendor devices to interoperate with MSTP bridges. This spanning tree instance stretches across the entire network domain (including PVST, PVST+ and MSTP regions). It is associated with VLAN 1 on the Extreme device.

## Internal Spanning Tree (IST)

An MSTP bridge must handle at least these two instances: one IST and one or more MSTIs (Multiple Spanning Tree Instances). Within each MST region, the MSTP maintains multiple spanning-tree instances. Instance 0 is a special instance known as IST, which extends CST inside the MST region. IST always exists if the device runs MSTP. Besides IST, this implementation supports up to 31 MSTIs.

## Common Internal Spanning Tree (CIST)

The single spanning tree calculated by STP (including PVST+) and RSTP (including R-PVST+) and the logical continuation of that connectivity through MSTP bridges and regions, calculated by MSTP to ensure that all LANs in the bridged LAN are simply and fully connected

## Multiple Spanning Tree Instance (MSTI)

One of a number of spanning trees calculated by the MSTP within an MST Region, to provide a simply and fully connected active topology for frames classified as belonging to a VLAN that is mapped to the MSTI by the MST configuration table used by the MST bridges of that MST region.

The Extreme implementation supports up to 32 spanning tree instances in an MSTP enabled bridge that can support up to 32 different Layer 2 topologies. The spanning tree algorithm used by the MSTP is the RSTP, which provides quick convergence.

By default all configured VLANs including the default VLAN are assigned to and derive port states from CIST until explicitly assigned to MSTIs.

## MST regions

MST regions are clusters of bridges that run multiple instances of the MSTP protocol. Multiple bridges detect that they are in the same region by exchanging their configuration (instance to VLAN mapping), name, and revision-level. Therefore, if you need to have two bridges in the same region, the two bridges must have identical configurations, names, and revision-levels. Also, one or more VLANs can be mapped to one MST instance (IST or MSTI) but a VLAN cannot be mapped to multiple MSTP instances

## MSTP regions

MSTP introduces a hierarchical way of managing device domains using regions. Devices that share common MSTP configuration attributes belong to a region. The MSTP configuration determines the MSTP region where each device resides. The common MSTP configuration attributes are as follows:

- Alphanumeric configuration name (32 bytes)
- Configuration revision number (2 bytes)
- 4096-element table that maps each of the VLANs to an MSTP instance

Region boundaries are determined by the above attributes. An MSTI is an RSTP instance that operates inside an MSTP region and determines the active topology for the set of VLANs mapping to that instance. Every region has a CIST that forms a single spanning tree instance which includes all the devices in the region. The difference between the CIST instance and the MSTP instance is that the CIST instance operates across the MSTP region and forms a loop-free topology across regions, while the MSTP instance operates only within a region. The CIST instance can operate using the RSTP only if all the devices across the regions support the RSTP. However, if any of the devices operate using the STP, the CIST instance reverts to the STP.

Each region is viewed logically as a single STP or a single RSTP bridge to other regions.

### NOTE

Extreme supports 32 MSTP instances and one MSTP region.

For more information about spanning trees, see the introductory sections in the Spanning Tree Protocol chapter.

## MSTP guidelines and restrictions

Follow these restrictions and guidelines when configuring the MSTP:

- Create VLANs before mapping them to the MSTP instances.
- The Extreme implementation of the MSTP supports up to 32 MSTP instances and one MSTP region.
- The MSTP **force-version** option is not supported.
- You must create VLANs before mapping them to the MSTP instances.

- For two or more switches to be in the same the MSTP region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same region name.
- MSTP is backward compatible with the STP and the RSTP.
- Only one MSTP region can be configured on a bridge.
- A maximum of 4090 VLANs can be configured across the 32 MSTP instances.
- MSTP and topology groups cannot be configured together.
- MSTP configured over MCT VLANs is not supported.

## Default MSTP configuration

As well as the defaults listed in the section [Understanding the default STP configuration](#) on page 199 there are defaults that apply only to MSTP configurations.

| Parameter   | Default setting |
|---|-----------------|
| Cisco interoperability                                    | Disabled        |
| Device priority (when mapping a VLAN to an MSTP instance) | 32768           |
| Maximum hops  | 20 hops         |
| Revision number   | 0               |

## Interoperability with PVST+ and R-PVST+

Since Extreme or other vendor devices enabled with PVST+ and R-PVST+ send IEEE STP BPDUs in addition to the PVST and R-PVST BPDUs, the VLAN 1 spanning tree joins the Common Spanning Tree (CST) of the network and thus interoperates with MSTP. The IEEE compliant devices treat the BPDUs addressed to the Extreme proprietary multicast MAC address as an unknown multicast address and flood them over the active topology for the particular VLAN.

# MSTP global level parameters

To configure a switch for MSTP, first you set the region name and the revision on each switch that is being configured for MSTP. You must then create an MSTP Instance and assign an ID. VLANs are then assigned to MSTP instances. These instances must be configured on all switches that interoperate with the same VLAN assignments.

Each of the steps used to configure and operate MSTP are described in the following:

### NOTE

The MSTP Region and Revision global parameters are enabled for interface level parameters as described below.

- Set the MSTP region name — Each switch that is running MSTP is configured with a name. It applies to the switch which can have many different VLANs that can belong to many different MSTP regions. The default MSTP name is "NULL".
- Set the MSTP revision number — Each switch that is running MSTP is configured with a revision number. It applies to the switch, which can have many different VLANs that can belong to many different MSTP regions.
- Enabling and disabling Cisco interoperability — While in MSTP mode, use the **cisco-interoperability** command to enable or disable the ability to interoperate with certain legacy Cisco switches. If Cisco interoperability is required on any switch in the network, then all switches in the network must be compatible, and therefore enabled by means of this command. By default the Cisco interoperability is disabled.

- The parameters you would normally set when you configure STP are applicable to MSTP. Before you configure MSTP parameters see the sections explaining bridge parameters, the error disable timeout parameter and the port-channel path cost parameter in the STP section of this guide.

## MSTP interface level parameters

### Edge port and automatic edge detection

Configuring the edge port feature makes a port transition directly from initialization to the forwarding state, skipping the listening and learning states.

From an interface, you can configure a device to automatically identify the edge port. The port can become an edge port if no BPDU is received. By default, automatic edge detection is disabled.

Follow these guidelines to configure a port as an edge port:

- When edge port is enabled, the port still participates in a spanning tree.
- A port can become an edge port if no BPDU is received.
- When an edge port receives a BPDU, it becomes a normal spanning tree port and is no longer an edge port.
- Because ports that are directly connected to end stations cannot create bridging loops in the network, edge ports transition directly to the forwarding state and skip the listening and learning states.

#### NOTE

If BPDUs are received on a port fast enabled interface, the interface loses the edge port status unless it receives a **shutdown** or **no shutdown** command.

### BPDU guard

In an STP environment, switches, end stations, and other Layer 2 devices use BPDUs to exchange information that STP will use to determine the best path for data flow.

In a valid configuration, edge port-configured interfaces do not receive BPDUs. If an edge port-configured interface receives a BPDU, an invalid configuration exists, such as the connection of an unauthorized device. The BPDU Guard provides a secure response to invalid configurations because the administrator must manually put the interface back in service.

BPDU guard removes a node that reflects BPDUs back in the network. It enforces the STP domain borders and keeps the active topology predictable by not allowing any network devices behind a BPDU guard-enabled port to participate in STP.

In some instances, it is unnecessary for a connected device, such as an end station, to initiate or participate in an STP topology change. In this case, you can enable the STP BPDU guard feature on the Extreme device port to which the end station is connected. The STP BPDU guard shuts down the port and puts it into an "error disabled" state. This disables the connected device's ability to initiate or participate in an STP topology. A log message is then generated for a BPDU guard violation, and a message is displayed to warn the network administrator of an invalid configuration.

The BPDU Guard provides a secure response to invalid configurations because the administrator must manually put the interface back in service with the **no shutdown** command if error disable recovery is not enabled by enabling the **errdisable-timeout** command. The interface can also be automatically configured to be enabled after a timeout. However, if the offending BPDUs are still being received, the port is disabled again.

### *Expected behavior in an interface context*

When BPDU Guard is enabled on an interface, the device is expected to put the interface in Error Disabled state when BPDU is received on the port when edge-port and BPDU guard is enabled on the switch interface. When the port ceases to receive the BPDUs, it does not automatically switch to edge port mode, you must configure **error disable timeout** or **no shutdown** on the port to move the port back into edge port mode.

## Restricted role

Configuring restricted role on a port causes the port not to be selected as root port for the CIST or any MSTI, even if it has the best spanning tree priority vector.

Restricted role ports are selected as an alternate port after the root port has been selected. It is configured by a network administrator to prevent bridges external to a core region of the network influencing the spanning tree active topology, possibly because those bridges are not under the full control of the administrator. It will protect the root bridge from malicious attack or even unintentional misconfigurations where a bridge device which is not intended to be root bridge, becomes root bridge causing severe bottlenecks in data path. These types of mistakes or attacks can be avoided by configuring 'restricted-role' feature on ports of the root bridge. This feature is similar to the "root-guard" feature which is proprietary implementation of Cisco for STP and RSTP but had been adapted in the 802.1Q standard as "restricted-role". The "restricted-role" feature if configured on an incorrect port can cause lack of spanning tree connectivity.

### *Expected behavior in an interface context*

When this feature is enabled on an interface the device is expected to prevent a port configured with restricted-role feature from assuming the role of a Root port. Such a port is expected to assume the role of an Alternate port instead, once Root port is selected.

## Restricted TCN

TCN BPDUs are used to inform other switches of port changes.

Configuring "restricted TCN" on a port causes the port not to propagate received topology change notifications and topology changes originated from a bridge external to the core network to other ports. It is configured by a network administrator to prevent bridges external to a core region of the network from causing MAC address flushing in that region, possibly because those bridges are not under the full control of the administrator for the attached LANs. If configured on an incorrect port it can cause temporary loss of connectivity after changes in a spanning trees active topology as a result of persistent incorrectly learned station location information.

### *Expected behavior in an interface context*

When this feature is enabled on an interface, the device is expected to prevent propagation of topology change notifications from a port configured with the Restricted TCN feature to other ports. In this manner, the device prevents TCN propagation from causing MAC flushes in the entire core network.

# Configuring MSTP

## Enabling and configuring MSTP globally

Follow this procedure to configure the Multiple Spanning Tree Protocol.

1. Enter global configuration mode.

```
device# configure terminal
```

2. Enable MSTP.

```
device(config)# protocol spanning-tree mstp
```

This command creates a context for MSTP. MSTP is automatically enabled. All MSTP specific CLI commands can be issued only from this context. Entering **no protocol spanning-tree mstp** deletes the context and all the configurations defined within the context.

3. Specify the region name.

```
device(config-mstp)# region kerry
```

4. Specify the revision number.

```
device(config-mstp)# revision 1
```

5. Configure an optional description of the MSTP instance.

```
device(config-mstp)# description kerry switches
```

6. Specify the maximum hops for a BPDU to prevent the messages from looping indefinitely on the interface.

```
device(config-mstp)# max-hops 25
```

Setting this parameter prevents messages from looping indefinitely on the interface. The range is 1 through 40 hops while the default is 20.

7. Map VLANs to MSTP instances and set the instance priority.

- a) Map VLANs 7 and 8 to instance 1.

```
device(config-mstp)# instance 1 vlan 7,8
```

- b) Map VLANs 21, 22, and 23 to instance 2.

```
device(config-mstp)# instance 2 vlan 21-23
```

- c) Set the priority of instance 1.

```
device(config-mstp)# instance 1 priority 4096
```

This command can be used only after the VLAN is created. VLAN instance mapping is removed from the configuration if the underlying VLANs are deleted.

8. Configure a bridge priority for the CIST bridge.

```
device(config-mstp)# bridge-priority 4096
```

The range is 0 through 61440 in increments of 4096. The default is 32768.

## 9. Set the error disable parameters.

- a) Enable the timer to bring the port out of error disable state.

```
device(config-mstp)# error-disable-timeout enable
```

- b) Specify the time in seconds it takes for an interface to time out..

```
device(config-mstp)# error-disable-timeout interval 60
```

The range is from 10 to 1000000 seconds with a default of 300 seconds.

## 10. Configure forward delay.

- a) Specify the bridge forward delay.

```
device(config-mstp)# forward-delay 15
```

This command allows you to specify how long an interface remains in the listening and learning states before it begins forwarding. This command affects all MSTP instances. The range of values is from 4 to 30 seconds with a default of 15 seconds.

## 11. Configure hello time.

```
device(config-mstp)# hello-time 2
```

The hello time determines how often the switch interface broadcasts hello BPDUs to other devices. The range is from 1 through 10 seconds with a default of 2 seconds.

## 12. Configure the maximum age.

```
device(config-mstp)# max-age 20
```

You must set the **max-age** so that it is greater than the **hello-time**. The range is 6 through 40 seconds with a default of 20 seconds.

## 13. Specify the port-channel path cost.

```
device(config-mstp)# port-channel path-cost custom
```

This command allows you to control the path cost of a port channel according to bandwidth.

## 14. Specify the transmit hold count.

```
device(config-mstp)# transmit-holdcount 5
```

The transmit hold count is used to limit the maximum number of MSTP BPDUs that the bridge can transmit on a port before pausing for 1 second. The range is from 1 to 10 seconds with a default of 6 seconds.

## 15. Configure Cisco interoperability.

```
device(config-mstp)# cisco-interoperability enable
```

This command enables the ability to interoperate with certain legacy Cisco switches. The default is Cisco interoperability is disabled.

## 16. Return to privileged exec mode.

```
device(config-mstp)# end
```

17. Verify the configuration. The following is an example configuration.

```
device# show spanning-tree mst-config

Spanning-tree Mode: Multiple Spanning Tree Protocol

CIST Root Id: 8000.001b.ed9f.1700
CIST Bridge Id: 8000.768e.f80a.6800
CIST Reg Root Id: 8000.001b.ed9f.1700

CIST Root Path Cost: 0; CIST Root Port: Eth 1/2
CIST Root Forward Delay: 15; Hello Time: 2; Max Age: 20; Max-hops: 19
Configured Forward Delay: 15; Hello Time: 2; Max Age: 20; Max-hops: 20;
Tx-HoldCount: 6
Number of topology change(s): 139; Last change occurred 00:03:36 ago on Eth 1/2

Bpdu-guard errdisable timeout: disabled
Bpdu-guard errdisable timeout interval: 300 sec
Migrate Time: 3 sec

Name          : kerry
Revision Level : 1
Digest        : 0x9357EBB7A8D74DD5FEF4F2BAB50531AA

Instance      VLAN
-----
0:            1
1:            7,8
2:            21-23
```

Observe that the settings comply with the formula set out in the STP parameters section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case:  $28 \geq 20 \geq 6$ .

18. Save the configuration.

```
device# copy running-config startup-config
```

## MSTP configuration example

```
device# configure terminal
device(config)# protocol spanning-tree mstp
device(config-mstp)# region kerry
device(config-mstp)# revision 1
device(config-mstp)# description kerry switches
device(config-mstp)# max-hops 20
device(config-mstp)# instance 1 vlan 7,8
device(config-mstp)# instance 2 vlan 21-23
device(config-mstp)# instance 1 priority 4096
device(config-mstp)# bridge-priority 4096
device(config-mstp)# error-disable-timeout enable
device(config-mstp)# error-disable-timeout interval 60
device(config-mstp)# forward-delay 16
device(config-mstp)# hello-time 5
device(config-mstp)# max-age 16
device(config-mstp)# port-channel path-cost custom
device(config-mstp)# transmit-holdcount 5
device(config-mstp)# cisco-interoperability enable
device(config-mstp)# end
device# show spanning-tree mst
device# copy running-config startup-config
```

## Enabling and configuring MSTP on an interface

Follow these steps to configure and enable MSTP on an Ethernet interface.

The parameters can be configured individually on an interface by:

1. Entering the commands in Steps 1 through Step 3 for the target interface
2. Running the relevant parameter command
3. Verifying the result
4. Saving the configuration

For detailed descriptions of the parameters and features, see the sections STP parameters and STP features.

1. Enter configuration mode.

```
device# configure terminal
```

2. Enable MSTP.

```
device(config)# protocol spanning-tree mstp
```

3. Enter interface configuration mode.

```
device(config-mstp)# interface ethernet 0/5
```

4. Enable the interface.

```
device(conf-if-eth-0/5)# no shutdown
```

5. Configure the restricted role feature for the port.

```
device(conf-if-eth-0/5)# spanning-tree restricted-role
```

This command keeps a port from becoming a root.

6. Restrict topology change notifications (TCN) BPDUs for an MSTP instance.

```
device(conf-if-eth-0/5)# spanning-tree instance 5 restricted-tcn
```

This prevents the port from propagating received TCNs and topology changes originating from a bridge, external to the core network, to other ports.

7. Enable auto detection of an MSTP edge port.

```
device(conf-if-eth-0/5)# spanning-tree autoedge
```

Enabling this feature allows the system to automatically identify the edge port. The port can become an edge port if no BPDU is received. By default, automatic edge detection is disabled.

8. 

```
device(conf-if-eth-0/5)# spanning-tree edgeport
```

Enabling edge port allows the port to quickly transition to the forwarding state. By default, automatic edge detection is disabled.

9. Enable BPDU guard on the port

```
device(conf-if-eth-0/5)# spanning-tree edgeport bpdu-guard
```

BPDU guard removes a node that reflects BPDUs back in the network. It enforces the STP domain borders and keeps the active topology predictable by not allowing any network devices behind a BPDU guard-enabled port to participate in STP.

## 10. Set the path cost of a port.

```
device(conf-if-eth-0/5)# spanning-tree cost 200000
```

The path cost range is from 1 to 2000000000. Leaving the default adjusts path cost relative to changes in the bandwidth. A lower path cost indicates greater likelihood of becoming root port.

## 11. Configure the link type.

```
device(conf-if-eth-0/5)# spanning-tree link-type point-to-point
```

The options are point-to-point or shared.

## 12. Enable port priority.

```
device(conf-if-eth-0/5)# spanning-tree priority 128
```

The range is from 0 to 240 in increments of 16 with a default of 32. A lower priority indicates greater likelihood of becoming root port.

## 13. Return to privileged exec mode.

```
device(conf-if-eth-0/5)# end
```

## 14. Verify the configuration.

```
device# show spanning-tree interface ethernet 0/5

Spanning-tree Mode: Multiple Spanning Tree Protocol

Root Id: 8000.001b.ed9f.1700
Bridge Id: 8000.01e0.5200.011d

Port Eth 0/5 enabled
Ifindex: 411271175; Id: 8002; Role: Designated; State: Forwarding
Designated External Path Cost: 0; Internal Path Cost: 20000000
Configured Path Cost: 200000
Designated Port Id: 8002; Port Priority: 128
Designated Bridge: 8000.01e0.5200.011d
Number of forward-transitions: 1
Version: Multiple Spanning Tree Protocol - Received MSTP - Sent MSTP
Edgeport: yes; AutoEdge: yes; AdminEdge: no; EdgeDelay: 3 sec
Restricted-role is enabled
Restricted-tcn is enabled
Boundary: no
Bpdu-guard: on
Link-type: point-to-point
Received BPDUs: 86; Sent BPDUs: 1654
```

## 15. Save the configuration.

```
device# copy running-config startup-config
```

## Enable MSTP on an interface configuration example

```
device# configure terminal
device(config)# protocol spanning-tree mstp
device(config-mstp)# interface ethernet 0/5
device(config-if-eth-0/5)# no shutdown
device(config-if-eth-0/5)# spanning-tree restricted-role
device(config-if-eth-0/5)# spanning-tree instance 5 restricted-tcn
device(config-if-eth-0/5)# spanning-tree autoedge
device(config-if-eth-0/5)# spanning-tree edgeport
device(config-if-eth-0/5)# spanning-tree edgeport bpdu-guard
device(config-if-eth-0/5)# spanning-tree cost 200000
device(config-if-eth-0/5)# spanning-tree link-type point-to-point
device(config-if-eth-0/5)# spanning-tree priority 128
device(config-if-eth-0/5)# end
device# show spanning-tree interface ethernet 0/5
device# copy running-config startup-config
```

## Enabling MSTP on a VLAN

1. Enter configuration mode.
2. Enter the protocol command to enable MSTP configuration.

```
device# configure terminal
```

2. Enter the protocol command to enable MSTP configuration.

```
device(config)# protocol spanning-tree mstp
```

3. Map a VLAN to an MSTP instance.

```
device(config-mstp)# instance 5 vlan 300
```

4. Return to privileged EXEC mode.

```
device(config-mstp)# end
```

## 5. Verify the configuration.

```

device# show spanning-tree mst

Spanning-tree Mode: Multiple Spanning Tree Protocol

CIST Root Id: 8000.609c.9f5d.4800 (self)
CIST Bridge Id: 8000.609c.9f5d.4800
CIST Reg Root Id: 8000.609c.9f5d.4800 (self)

CIST Root Forward Delay: 15; Hello Time: 2; Max Age: 20; Max-hops: 20
Configured Forward Delay: 15; Hello Time: 2; Max Age: 20; Max-hops: 20;
Tx-HoldCount: 6
Number of topology change(s): 0

Bpdu-guard errdisable timeout: disabled
Bpdu-guard errdisable timeout interval: 300 sec
Migrate Time: 3 sec

Name          : NULL
Revision Level : 0
Digest        : 0xD5FF4C3F6C18E2F27AF3A8300297ABAA

Instance      VLAN
-----
0:            1
5:            100

```

Observe that the settings comply with the formula set out in the STP parameters section, as:

$$(2 \times (\text{forward delay} - 1)) \geq \text{maximum age} \geq (2 \times (\text{hello time} + 1))$$

or in this case:  $28 \geq 20 \geq 6$ .

## 6. Save the configuration.

```
device# copy running-config startup-config
```

## Enable spanning tree on a VLAN configuration example

```

device# configure terminal
device(config)# protocol spanning-tree mstp
device(config-mstp)# instance 5 vlan 300
device(config-mstp)# end
device# show spanning-tree mst
device# copy running-config startup-config

```

## Configuring basic MSTP parameters

Follow these steps to configure basic MSTP parameters.

## 1. Enter global configuration mode.

```
device# configure terminal
```

## 2. Enable MSTP.

```
device(config)# protocol spanning-tree mstp
```

## 3. Specify the region name.

```
device(config-mstp)# region connemara
```

4. Specify the revision number.

```
device(config-mstp)# revision 1
```

5. Map MSTP instances to VLANs.

- a) Map instance 1 to VLANs 2 and 3.

```
device(config-mstp)# instance 1 vlan 2,3
```

- b) Map instance 2 to VLANs 4, 5, and 6.

```
device(config-mstp)# instance 2 vlan 4-6
```

6. Set a priority for an instance.

```
device(conf-Mstp)# instance 1 priority 28672
```

The priority ranges from 0 through 61440 and the value must be in multiples of 4096.

7. Specify the maximum hops for a BPDU.

```
device(conf-Mstp)# max-hops 25
```

This prevents the messages from looping indefinitely on an interface

8. Return to privileged EXEC mode.

```
device(conf-Mstp)# end
```

## 9. Verify the configuration.

```

device# show spanning-tree mst

Spanning-tree Mode: Multiple Spanning Tree Protocol

CIST Root Id: 8000.609c.9f5d.4800 (self)

instance 1 vlan 2,3
instance 1 priority 28672
instance 2 vlan 4-6
region connemars
revision 1
max-hops 25
!
...

```

## 10. Save the configuration

```
device# copy running-config startup-config
```

**Basic MSTP configuration example**

```

device# configure terminal
device(config)# protocol spanning-tree mstp
device(config-mstp)# region connemara
device(config-mstp)# revision 1
device(config-mstp)# instance 1 vlan 2,3
device(config-mstp)# instance 2 vlan 4-6
device(conf-Mstp)# instance 1 priority 28582
device(conf-Mstp)# max-hops 25
device(conf-Mstp)# end
device# show spanning-tree mst
device# copy running-config startup-config

```

## Clearing spanning tree counters

Follow these steps to clear spanning tree counters on all interfaces or on the specified interface.

1. Clear spanning tree counters on all interfaces.

```
device# clear spanning-tree counter
```

2. Clear spanning tree counters on a specified Ethernet interface.

```
device# clear spanning-tree counter interface ethernet 0/3
```

3. Clear spanning tree counters on a specified port channel interface.

```
device# clear spanning-tree counter interface port-channel 12
```

Port channel interface numbers range from 1 through 64.

## Clearing spanning tree-detected protocols

Follow these steps to restart the protocol migration process.

These commands force a spanning tree renegotiation with neighboring devices on either all interfaces or on a specified interface.

1. Restart the spanning tree migration process on all interfaces.

```
device# clear spanning-tree detected-protocols
```

2. Restart the spanning tree migration process on a specific Ethernet interface.

```
device# clear spanning-tree detected-protocols interface ethernet 0/3
```

3. Restart the spanning tree migration process on a specific port channel interface.

```
device# clear spanning-tree detected-protocols port-channel 12
```

Port channel interface numbers range from 1 through 64.

## Shutting down MSTP

Follow these steps to shut down MSTP either globally, on a specific interface, or a specific VLAN.

1. Enter global configuration mode.

```
device# configure terminal
```

## 2. Shut down MSTP.

- Shut down MSTP globally and return to privileged EXEC mode.

```
device(config)# protocol spanning-tree mstp
device(config-mstp)# shutdown
device(config-mstp)# end
```

- Shut down MSTP on a specific interface and return to privileged EXEC mode.

```
device(config)# interface ethernet 0/2
device(config-if-eth-0/2)# spanning-tree shutdown
device(config-if-eth-0/2)# end
```

- Shut down MSTP on a specific VLAN and return to privileged EXEC mode.

```
device(config)# vlan 10
device(config-vlan-10)# spanning-tree shutdown
device(config-vlan-10)# end
```

## 3. Verify the configuration.

```
device# show spanning-tree
device#
```

## 4. Save the running configuration to the startup configuration.

```
device# copy running-config startup-config
```

*Shut down MSTP configuration example*

```
device# configure terminal
device(config)# vlan 10
device(config-vlan-10)# spanning-tree shutdown
device(config-stp)# end
device# show spanning-tree
device# copy running-config startup-config
```

**NOTE**

Shutting down MSTP on a VLAN is used in this example.

# Topology Groups

---

|  |     |
|--|-----|
| • Topology Groups.....                               | 267 |
| • Master VLAN, member VLANs, and bridge-domains..... | 267 |
| • Control ports and free ports.....                  | 268 |
| • Configuration considerations.....                  | 268 |
| • Configuring a topology group.....                  | 268 |
| • Displaying topology group information.....         | 271 |

## Topology Groups

A topology group is a named set of VLANs and bridge-domains that share a Layer 2 control protocol. Topology groups simplify configuration and enhance scalability of Layer 2 protocols by allowing you to run a single instance of a Layer 2 protocol on multiple VLANs and bridge-domains. One instance of the Layer 2 protocol controls all the VLANs and bridge-domains.

You can use topology groups with the following Layer 2 protocols:

- Per VLAN Spanning Tree (PVST+)
- Rapid per VLAN Spanning tree (R-PVST+)

## Master VLAN, member VLANs, and bridge-domains

Each topology group contains a master VLAN and can contain one or more member VLANs and bridge-domains. A definition for each of these VLAN types follows:

- Master VLAN—The master VLAN contains the configuration information for the Layer 2 protocol. For example, if you plan to use the topology group for Rapid per VLAN Spanning tree (R-PVST), the topology group's master VLAN contains the R-PVST configuration information.
- Member VLANs—The member VLANs are additional VLANs that share ports with the master VLAN. The Layer 2 protocol settings for the ports in the master VLAN apply to the same ports in the member VLANs. A change to the master VLAN's Layer 2 protocol configuration or Layer 2 topology affects all the member VLANs. Member VLANs do not independently run a Layer 2 protocol.
- Member bridge domains—The member bridge domains are similar to VLANs that share ports with the master VLAN. The Layer 2 protocol settings for the ports in the master VLAN apply to the same ports in the bridge domains. A change to the master VLAN's Layer 2 protocol configuration or Layer 2 topology affects all the bridge domains. Bridge domains do not independently run a Layer 2 protocol. In a bridge domain, a single port can have multiple logical interfaces. In this scenario, all the logical interfaces on that port (and bridge domain) will follow the state of master VLAN port.

When a Layer 2 topology change occurs, resulting in a change of port state in the master VLAN, the same port state is applied to all the member VLANs and bridge-domains belonging to the topology group on that port. For example, if you configure a topology group whose master VLAN contains ports 1/1 and 1/2, a Layer 2 state change on port 1/1 applies to port 1/1 in all the member VLANs and bridge-domains that contain that port. However, the state change does not affect port 1/1 in VLANs that are not members of the topology group.

## Control ports and free ports

A port in a topology group can be a control port or a free port:

- A **control port** is a port in the master VLAN and, therefore, is controlled by the Layer 2 protocol configured in the master VLAN. The same port in all the member VLANs and bridge-domains is controlled by the master VLAN's Layer 2 protocol. Each member VLAN and bridge-domain must contain all of the control ports. All other ports in the member VLAN and bridge-domain are "free ports."
- **Free ports** are not controlled by the master VLAN's Layer 2 protocol. The master VLAN can contain free ports. (In this case, the Layer 2 protocol is disabled on those ports.) In addition, any ports in the member VLANs and bridge-domains that are not also in the master VLAN are free ports.

### NOTE

Because free ports are not controlled by the master port's Layer 2 protocol, they are always in the forwarding state.

## Configuration considerations

The configuration considerations are as follows:

- You can configure up to 128 topology groups. A VLAN or bridge-domain cannot be controlled by more than one topology group. You can configure up to 4K VLANs or bridge-domains as members of a topology group.
- The topology group must contain a master VLAN. The group can also contain individual member VLANs and/or member bridge-domains. You must configure the member VLANs or member bridge-domains before adding them to the topology group. Bridge-domains cannot be configured as a master VLAN.
- You cannot delete a master VLAN from the topology group when the member VLANs or bridge-domains are in the topology group.
- The control port membership must match the master VLAN when adding a member VLAN or member bridge-domain.
- If a VLAN enabled with the PVST+ or R-PVST+ protocol is added as a member VLAN of a topology group, the protocol is disabled. The member VLAN is added to the topology group. If the VLAN is removed from the topology group, the protocol is disabled, and you must enable the protocol if required.
- Enabling STP on an interface is only allowed if both master VLAN and member VLAN or bridge-domains are configured on the interface across all topology groups.
- You cannot remove the master VLAN or member VLAN or bridge-domains from an STP-enabled interface.
- Topology group configuration is allowed only with PVST+ and R-PVST+ spanning tree configurations.

## Configuring a topology group

Follow this procedure to configure a topology group. Extreme SLX devices support creating 128 topology groups in a system.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
device(config)#
```

2. Enter the **topology-group** command to create a topology group at the global configuration level.

```
device(config)# topology-group 1
device(conf-topo-group-1)#
```

#### NOTE

The **no topology-group** command deletes an existing topology group.

## Configuring a master VLAN

Follow this procedure to configure a master VLAN in a topology group.

Before configuring a master VLAN, you should have configured a topology group.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
device(config)#
```

2. Enter the **topology-group** command to create a topology group at the global configuration level.

```
device(config)# topology-group 1
device(conf-topo-group-1)#
```

3. Enter the **master-vlan** command to configure a master VLAN in the topology group.

```
device(conf-topo-group-1)# master-vlan 100
```

#### NOTE

The **no master-vlan** command removes an existing master VLAN from the topology group.

## Adding member VLANs

Follow this procedure to add member VLANs to a topology group. Member VLANs follow the master VLAN protocol states and also no L2 protocol will be running on the member VLANs.

Before adding a member VLAN, you should have created a topology group and configured the master VLAN for that group. The VLAN should not be part of any other topology group. All control ports of master VLAN must also be configured for the member VLAN.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
device(config)#
```

2. Enter the **topology-group** command to create a topology group at the global configuration level.

```
device(config)# topology-group 1
device(conf-topo-group-1)#
```

3. Enter the **master-vlan** command to configure a master VLAN in the topology group.

```
device(conf-topo-group-1)# master-vlan 100
```

4. Enter the **member-vlan** command to add member VLANs to the topology group.

```
device(conf-topo-group-1)# member-vlan add 200-201
```

#### NOTE

The **member-vlan remove** command removes an existing member VLAN from the topology group.

```
device(conf-topo-group-1)# member-vlan remove 200
```

## Adding member bridge-domains

Follow this procedure to add member bridge domains to a topology group. Member bridge domains follow the master VLAN protocol states and also no L2 protocol will be running on the bridge domains.

Before adding a bridge domain, you should have created a topology group and configured the master VLAN for that group. The bridge-domain should not be part of any other topology group. All control ports of master VLAN must also be configured for the member bridge-domain.

1. Enter the **configure terminal** command to access global configuration mode.

```
device# configure terminal
device(config)#
```

2. Enter the **topology-group** command to create a topology group at the global configuration level.

```
device(config)# topology-group 1
device(conf-topo-group-1)#
```

3. Enter the **master-vlan** command to configure a master VLAN in the topology group.

```
device(conf-topo-group-1)# master-vlan 100
```

4. Enter the **member-bridge-domain** command to add member bridge-domains to the topology group.

```
device(conf-topo-group-1)# member-bridge-domain add 300
```

#### NOTE

The **member-bridge-domain remove** command removes an existing member bridge-domain from the topology group.

```
device(conf-topo-group-1)# member-bridge-domain remove 1
```

The example adds 300 as member bridge-domain to the topology group.

```
device# configure terminal
device(config)# topology-group 1
device(conf-topo-group-1)# master-vlan 100
device(conf-topo-group-1)# member-bridge-domain add 300
```

## Replacing a master VLAN

For replacing the existing master VLAN of a topology group, use the **master-vlan** command with the new master VLAN.

To avoid temporary loops when the master VLAN is replaced by another VLAN, the following recommendation is made:

- Control ports for both the old and the new master VLAN must match.
- The new master VLAN and the old master VLAN must have same ports in the blocking state to avoid the possibility of temporary loops.

If the recommendation is not followed, and a new master VLAN is configured with a different convergence, the configuration is still accepted.

#### NOTE

The master VLAN replacement is accepted if both the old and the new master VLANs are spanning-tree disabled.

## Displaying topology group information

Follow the procedure to display topology group information for a specified group.

Before displaying the topology group information, you should have configured a topology group and defined the master VLAN.

Enter the **show topology-group** command to display the group information.

```
device# show topology-group 1
Topology Group 1
=====
Master VLAN : 100
L2 Protocol: R-PVST
Member VLANs : 200 300
Member Bridge-domains: 10
Control Ports : eth 2/1, eth 2/2, po10
Free Ports : VLAN: 200 -eth 2/3, po11
Bridge-domain: 10 -eth 2/3.20, po11.10
```

The example displays information about topology group 1.

The **show running-config** command displays topology group configurations.

```
device# show running-config
topology-group 1
  master-vlan 100
  member-vlan add 200 300
  member-bridge-domain add 10
```

# Loop Detection

- LD protocol overview.....273
- LD use cases.....278
- Configuring LD protocol.....280
- Loop detection for VLAN.....283

## LD protocol overview

The loop detection (LD) protocol is an Extreme proprietary protocol used to detect and break Layer 2 loops caused by misconfigurations, thereby preventing packet storms.

Layer 2 networks rely on learning and flooding to build their forwarding databases. Because of the flooding nature of these networks, any loops can be disastrous as they cause broadcast storms.

**ATTENTION**  
The LD feature should be used only as a tool to detect loops in the network. It should not be used to replace other Layer 2 protocols such as STP.

This feature provides support for the following:

- Strict and loose modes
- Multi-Chassis Trunk (MCT)
- Breakout ports
- EPVN VLAN tunnels

LD protocol data units (PDUs) are initiated and received on the native device. Loop detection and action on the port state is also done on the same native device. Intermediate devices in the network must be capable of flooding unknown Layer 2 unicast PDUs on the VLAN through which they are received.

### Strict mode

In what is referred to as *strict mode*, LD is configured on an interface. If the LD PDU is sent on an interface and received on the same interface, that port is shut down by LD. Strict mode overcomes specific hardware issues that cause packets to be echoed back to the input port. The following figure illustrates strict mode.

FIGURE 32 Strict mode

If the user provides a VLAN, then the PDUs are tagged accordingly. Otherwise PDUs are sent untagged. With a LAG, PDUs are sent out on the port-channel interface. If Device A has a loop (for example, a LAG is not configured), then the PDU is flooded back to SLX-OS, which detects the loop. In case of a loop, the port-channel interface is shut down. The following figure illustrates LD on a LAG.

FIGURE 33 LD on a LAG

LD supports 256 instances of strict mode.

## Loose mode

In what is referred to as *loose mode*, LD is configured on a VLAN. If a VLAN in the device receives an LD PDU that originated from the same device on that VLAN, this is considered to be a loop and the receiving port is shut down. In loose mode, LD works at the VLAN level and takes action at the logical interface (LIF) level. The following figure illustrates loose mode, with LD on a VLAN.

FIGURE 34 Loose mode: LD on a VLAN

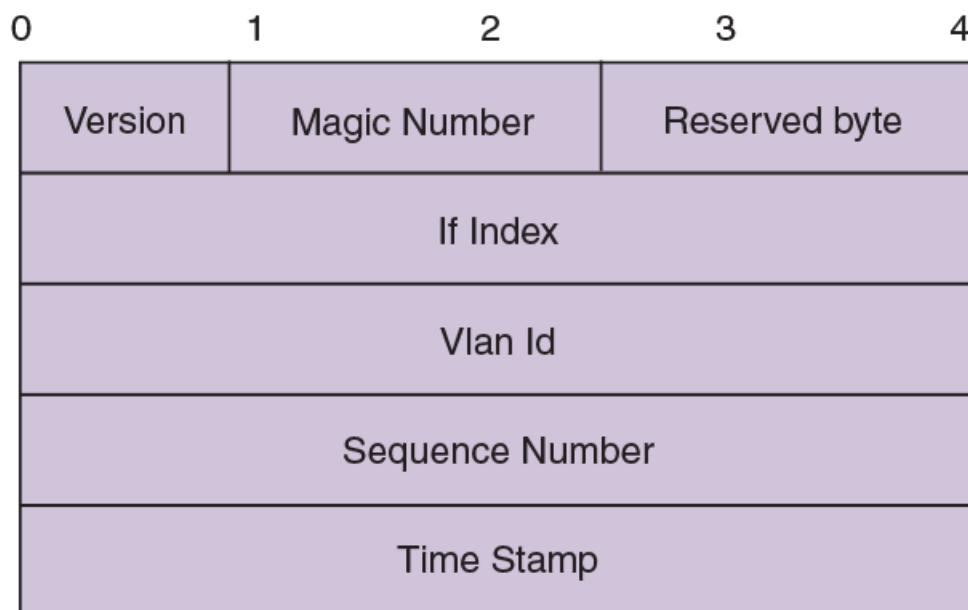

SLX-OS generates the LD PDUs on the VLAN. If Device A has a loop, PDUs are flooded back to SLX-OS, which detects the loop. SLX-OS then shuts down the receiving LIF of the port on the VLAN.

LD supports 256 instances of loose mode, which means that it can be enabled on 256 VLANs.

## LD PDU format

The following figure illustrates the format of the LD PDU in bytes.

**FIGURE 35** LD PDU format in bytes

| Parameter       | Definition   |
|-----------------|--|
| Version         | LD protocol version (1 by default)   |
| Magic Number    | 0x13EF; used to differentiate between LD multicast PDUs and other multicast PDUs |
| Reserved byte   | For future use   |
| If Index        | Index of the source port; populated only in strict mode                          |
| Vlan Id         | VLAN ID  |
| Sequence Number | Reserved for future enhancements   |
| Time Stamp      | Reserved for future enhancements   |

## LD PDU transmission

Each LD-enabled interface or VLAN on a device continually transmits Layer 2 LD PDUs at a 1-second default hello-timer interval, with the destination MAC address as the multicast address. The multicast MAC address is derived from the system MAC address of the device with the multicast bit (8) and the local bit (7) set.

For example, if the MAC address is 00E0.5200.1800, then the multicast MAC address is 03E0.5200.1800. In the case of a LAG port-channel, LD PDUs are sent out one of the ports of the LAG as chosen by hardware.

## LD PDU reception

When the LD PDU is received and is generated by the same device, the PDU is processed. If the PDU is generated by another device, then the PDU is flooded.

If a port is already blocked by any other Layer 2 protocol such as STP, then the LD PDUs are neither sent for LD processing nor flooded on that port.

## LD parameters

This section discusses the various global protocol-level, interface level, and VLAN-level parameters that are used to control and process LD PDUs.

### Protocol level

#### hello-interval

**hello-interval** is the rate at which the LD PDUs are transmitted by an LD-enabled interface or VLAN, which is 1000 milliseconds by default. Lowering the hello-interval below the default increases the PDU transmission rate, providing faster loop detection and also removing transient loops that last less than one second. On the other hand, increasing the interval above the default (for example, to 100 milliseconds) can increase the steady-state CPU load.

#### shutdown-time

**shutdown-time** is the duration after which an interface that is shut down by LD is automatically reenabled. The range is from 0 through 1440 minutes. The default is 0 minutes, which means that the interface is not automatically reenabled.

#### ATTENTION

Changing this value can cause repeated interface flapping when a loop is persistent in the network.

#### raslog-duration

**raslog-duration** is the interval between RASLog messages when a port is shut down by LD to prevent flooding of these messages. The range is from 10 through 1440 minutes. The default is 10.

### Interface level

In strict mode, the parameters in this section are configurable at the interface level, and the configuration is specific to an interface. The following figure illustrates strict mode configuration.

FIGURE 36 Strict mode configuration

#### shutdown-disable

By default, the device shuts down the interface if a loop is detected. Configuring **shutdown-disable** means that the interface shutdown is disabled and LD never brings down such interface. If a loop is already detected by LD and the port is in shutdown state, then configuring **shutdown-disable** is not effective until the port is back up.

#### vlan-association

Although user can enable LD on an interface without specifying a VLAN, the **vlan-association** keyword is used to specify a VLAN associated with the interface.

### VLAN level

In loose mode, the user can configure LD under a VLAN. In this case, LD PDUs are flooded on the VLAN. The following figure illustrates loose mode configuration.

FIGURE 37 Loose mode configuration

## LD PDU processing

As long as LD PDUs are not received, there is no loop. If an LD PDU is received, then there is a loop that is present in the network.

If the if-index field in the received LD PDU is valid, then it is considered to be operating in strict mode. If the port on which the LD PDU was received is same as one encoded in the PDU (with a match for VLAN ID if a VLAN is associated), the port is shut down. For an MCT, if a strict mode LD PDU is received on an ICL interface, and the PDU is originated by another interface, then the ICL interface is not shut down. Instead, the sender interface is shut down. In addition, for strict mode the required interfaces should be configured with LD, or else the PDUs will not get processed.

If the if-index field in the received LD PDU is invalid, then it is considered to be operating in loose mode. Based on VLAN ID information present in the received LD PDU, the receiving LIF is shut down. If the receiving interface is an MCT ICL interface, the LD PDU is dropped.

In the case of an LD-enabled LAG (port-channel) interface, if the sent LD PDU is received on the port-channel, then the port-channel interface is shut down.

If the **shutdown-disable** option is configured for the particular interface, then the port drops the received PDU without processing it.

The re-enablement of the LD shut down port depends on the **shutdown-time** configuration. For manual recovery, either flap the interface, by means of the **shutdown** and **no shutdown** commands, or clear the loop by means of the **clear loop-detection** command.

## Support for EPVN VLAN tunnels

LD loose mode is used to support a shutdown at the attachment circuit (AC) logical interface (LIF) level instead of at the physical port level. See [Loop detection for VLAN](#) on page 283 and configuration examples.

## Configuration considerations

On an external switch that is unaware of LD or where LD is not configured, there may be some ACL rules applied to interfaces to permit traffic from known MAC addresses, and at the last of these rules there is an ACL deny-any rule to block all unknown MAC addresses. If this interface is part of a loop, LD enabled on SLX-OS will not be able to detect and break the loop.

## LD use cases

In an MCT configuration, LD runs independently on both nodes. With loose mode the user must enable loop detection for the same VLANs on both nodes in the MCT cluster. MCT strict mode and loose mode use cases are detailed below.

### MCT strict mode

The following figure illustrates a use case for MCT strict mode, followed by a sequence of events.

Strict mode LD is enabled on the MCT 1 cluster client edge port (CCEP) interface that connects to the Client.

**FIGURE 38** MCT strict mode

1. MCT 1 generates LD PDUs.
2. If the Client has the LAG interface configured to support LD, the Client drops the PDUs and there is no loop.
3. If there is a misconfiguration, the Client floods the PDUs, reaching MCT 2.
4. MCT 1 then identifies the interface information encoded in the PDUs, shutting down the interface on which the packets were generated.

## MCT loose mode

The following figures illustrates two use cases for MCT loose mode, followed by a sequence of events.

**FIGURE 39** MCT loose mode: Use case 1

**Use case 1:** LD enabled on VLAN x on MCT 1

1. MCT 1 sends LD PDUs on VLAN x on all the interfaces that are part of the CCEP, client edge port (CEP), and ICL interface.
2. If the Client has LD configured on the LAG interface, then it drops the PDUs and no loop exists. If there is a misconfiguration, the Client floods the PDUs and they reach MCT 2.
3. MCT 2 floods the PDUs back to MCT 1, where the loop is detected. With loose mode no information about the interface that transmitted the PDU is encoded in the PDU, so normally the receiving interface is shut down. Because in this case the PDU is received on the ICL interface, that interface is not shut down.
4. MCT 1 receives the loop detection PDUs on the CCEP interface as well, as the packets were flooded in the VLAN in the following sequence: MCT 1 > MCT 2 > Client > MCT 1. In this case the receiving CCEP is shut down to break the loop. For MCT 2 to forward the PDUs in this case it must be the designated forwarder (DF) for that VLAN.

FIGURE 40 MCT loose mode: Use case 2

**Use case 2:** LD enabled on VLAN x on MCT 1 and MCT 2

- Both MCT 1 and MCT 2 will flood the PDUs in VLAN x on all the interfaces that are part of the CCEP, CEP, and ICL interface.
- Assuming PDUs from MCT 1 take the path MCT 1 > MCT 2 > Node > Client > MCT 1, then the receiving CCEP interface is shut down. For MCT 2 to forward the PDUs in this case, it must be the DF for that VLAN.
- Assuming PDUs from MCT 2 take the path MCT 2 > MCT 1 > Client > Node > MCT 2, then the receiving CEP interface is shut down.
- If PDUs from MCT 2 take the path MCT 2 > Node > Client > MCT 2, then the receiving CCEP interface is shut down.
- Multiple interfaces can be shut down in this case, depending on the sequence in which loops are detected.
- In addition, to avoid CCEP interfaces from being shut down over a CEP interface, the user can configure a CCEP port not to be shut down.

## Configuring LD protocol

Follow these steps to configure loop detection (LD) protocol globally and at the interface and VLAN level.

- Enter global configuration mode.
- Enter the **protocol loop-detection** command to enable loop detection, enter Protocol Loop Detect configuration mode, and configure a variety of global options.

```
device# configure terminal
```

```
device(config)# protocol loop-detection
```

- (Optional) Enter the **hello-interval** command to change the hello interval from the default.

```
device(config-loop-detect)# hello-interval 2000
```

4. (Optional) Enter the **shutdown-time** command to change from the default the interval after which an interface that is shut down by loop detection (LD) protocol is automatically reenabled.

```
device(config-loop-detect)# shutdown-time 20
```

5. (Optional) Enter the **raslog-duration** command to change from default the interval between RASLog messages that are sent when a port is disabled by the loop detection (LD) protocol.

```
device(config-loop-detect)# raslog-duration 20
```

6. Enable LD at the interface level.

- a) In global configuration mode, specify an interface (either an Ethernet interface or a port-channel interface).

```
device(config)# interface ethernet 2/6
```

- b) In interface subtype configuration mode, enter the **loop-detection** command.

```
device(conf-if-eth-2/6)# loop-detection
```

7. Enable LD at the VLAN level.

- a) In global configuration mode, create a VLAN.

```
device(config)# vlan 5
```

- b) In VLAN configuration mode, enter the **loop-detection** command.

```
device(config-vlan-5)# loop-detection
```

8. Associate the VLAN with an interface.

- a) In global configuration mode, specify an interface (either an Ethernet interface or a port-channel interface).

```
device(config)# interface ethernet 2/6
```

- b) In interface subtype configuration mode, enter the **loop-detection vlan** command and specify a VLAN. (The VLAN must already be created.)

```
device(conf-if-eth-2/6)# loop-detection vlan 5
```

9. (Optional) Disable the shutting down of an interface (Ethernet or port-channel) as a result of the loop detection (LD) protocol.

- a) In global configuration mode, specify an interface (either an Ethernet interface or a port-channel interface).

```
device(config)# interface ethernet 2/6
```

- b) In interface subtype configuration mode, enter the **loop-detection shutdown-disable** command.

```
device(conf-if-eth-2/6)# loop-detection shutdown-disable
```

10. (Optional) Disable the shutting down of an interface (Ethernet or port-channel) as a result of the loop detection (LD) protocol.

- a) In global configuration mode, specify an interface (either an Ethernet interface or a port-channel interface).

```
device(config)# interface ethernet 2/6
```

- b) In interface subtype configuration mode, enter the **loop-detection shutdown-disable** command.

```
device(conf-if-eth-2/6)# loop-detection shutdown-disable
```

11. Confirm the LD configuration, using the **show loop-detection** command with a variety of options.

- a) To display LD information at the system level, enter the **show loop-detection** command as in the following example.

```
device# show loop-detection
Strict Mode:
-----

Number of loop-detection instances enabled: 1

Interface: eth 2/6
  Enabled on VLANs: 100
  Shutdown Disable: No
  Interface status: UP
  Auto enable in: Never

Packet Statistics:
vlan      sent      rcvd      disable-count
100       100        0         0

Loose Mode:
-----

Number of LD instances: 2
Disabled Ports:          2/7

Packet Statistics:
vlan      sent      rcvd      disable-count
100       100        0         0
```

- b) To display ports disabled by LD, enter the **show loop-detection disabled-ports** command as in the following example.

```
device# show loop-detection disabled-ports
Ports disabled by loop detection
-----
port      age(min)      disable cause
2/6       5              Disabled by Self
```

- c) To display global LD configuration values, enter the **show loop-detection globals** command.

```
device# show loop-detection globals
Loop Detection:          Disabled
Shutdown-time (minutes): 0
Hello-time (msec):       1000
Raslog-duration (minutes): 10
```

12. Use the **clear loop-detection** command in privileged EXEC mode with a variety of options to reenabling ports that were disabled by LD and clear the LD statistics.

- a) To enable LD-disabled ports and clear LD statistics on all interfaces, enter the **clear loop-detection** command.

```
device# clear loop-detection
```

- b) To enable LD-disabled ports and clear LD statistics on an Ethernet interface, enter the **clear loop-detection interface ethernet** command.

```
device# clear loop-detection interface ethernet 2/6
```

- c) To enable LD-disabled ports and clear LD statistics on a port-channel interface, enter the **clear loop-detection interface port-channel** command.

```
device# clear loop-detection interface port-channel 20
```

- d) To enable LD-disabled ports and clear LD statistics on a VLAN, enter the **clear loop-detection interface vlan** command.

```
device# clear loop-detection interface vlan 10
```

## Loop detection for VLAN

LD loose mode is used to support a shutdown at the attachment circuit (AC) logical interface (LIF) level instead of at the physical port level.

### NOTE

Loop detection is not supported for bridge domains (BDs).

When a loop is detected on a VLAN and port, only the LIF of the VLAN on the port is shut down, but the physical port still remains up and other VLANs on the port are not affected.

The existing LD loose mode configuration commands support loop detection for VLAN tunnels. In LD loose mode, if the VLAN is mapped to VLAN tunnels and LD is enabled, VLAN tunnels loop detection is supported. Up to 256 LD loose mode instances can be configured.

If a loop is detected from a VLAN tunnel, the following actions can take place:

- A RASLog is sent and the tunnel VNI LIFs on which the loop is detected is shut down.
- A RASLog is sent but the tunnel LIF is not shut down.

## Configuring loop detection for VLAN

This section presents a variety of examples that configure Layer 2 loop detection for VLAN.

The following example enables loop detection on a VLAN and enters Protocol Loop Detection configuration mode.

```
device# configure terminal
device(config)# vlan 5
device(config-vlan-5)# loop-detection
device(config-loop-detect)#
```

The following example enables ports associated with VLAN 8 and clears LD statistics for that VLAN.

```
device# clear loop-detection vlan 8
```

The following example displays LD configuration values, including logical interfaces (LIFs), for a VLAN tunnel.

```
device# show loop-detection vlan 20
Number of LD instances: 1
LIF (Logical Interface) Disabled on Ports: eth2/2

Packet Statistics:
vlan      sent      rcvd
20        119        1
```

The following example displays LD configuration values for a VLAN tunnel if LD shutdown is disabled.

```
device# show loop-detection vlan 20
Number of LD instances: 1
LIF (Logical Interface) ShutDown is disabled for VLAN 20

Packet Statistics:
vlan      sent      rcvd
20        10        10
```

The following example disables the shutdown of a VLAN VLAN tunnel.

```
device# configure terminal
device(config)# vlan 20
device(config-vlan-20)# loop-detection-shutdown-disable
```

You can control the auto-enable behavior of an LD-disabled logical interface (LIF), by using the **shutdown-time** command in Protocol Loopback Detection configuration mode. The following example specifies a shutdown time of 1 minute.

```
device# configure terminal
device(config)# loop-detection
device(config-loop-detect)# shutdown-time 1
2017/10/20-16:04:48, [ELD-1005], 3749, M2 | Active | DCE, INFO, SLX, Loop is detected on Ethernet 2/2 VLAN 20,
the LIF (logical interface) is shutdown.
2017/10/20-16:05:46, [ELD-1007], 3750, M2 | Active | DCE, INFO, SLX, Loop detection disabled LIF (Logical
interface) on Ethernet 2/2 VLAN 20 is auto-enabled.
```

By default the shutdown time is 0, which means that an LD-disabled LIF is never auto-enabled. If the shutdown time is configured with a nonzero value, the LD-disabled LIF is auto-enabled following the specified shutdown time.

To enable LD-disabled ports and clear LD statistics on all interfaces, use the **clear loop-detection** command as in the following example.

```
device# clear loop-detection
```
